ABSTRACT: Cancer is ranked as the second leading cause of death globally. Traditional cancer therapies including chemotherapy are flawed, with off-target and on-target toxicities on the normal cells, requiring newer strategies to improve cell selective targeting. The application of nanomaterial has been extensively studied and explored as chemical biology tools in cancer theranostics. It shows greater applications toward stability, biocompatibility, and increased cell permeability, resulting in precise targeting, and mitigating the shortcomings of traditional cancer therapies. The nanoplatform offers an exciting opportunity to gain targeting strategies and multifunctionality. The advent of nanotechnology, in particular the development of smart nanomaterials, has transformed cancer diagnosis and treatment. The large surface area of nanoparticles is enough to encapsulate many molecules and the ability to functionalize with various biosubstrates such as DNA, RNA, aptamers, and antibodies, which helps in theranostic action. Comparatively, biologically derived nanomaterials perceive advantages over the nanomaterials produced by conventional methods in terms of economy, ease of production,

and reduced toxicity. The present review summarizes various techniques in cancer theranostics and emphasizes the applications of smart nanomaterials (such as organic nanoparticles (NPs), inorganic NPs, and carbon-based NPs). We also critically discussed the advantages and challenges impeding their translation in cancer treatment and diagnostic applications. This review concludes that the use of smart nanomaterials could signifcantly improve cancer theranostics and will facilitate new dimensions for tumor detection and therapy.

1. INTRODUCTION

The alarming increase in new cancer cases worldwide concerns people's lives and physical well-being. Despite advancements in science and technology and drug discovery methods, cancer is still the second leading cause of death worldwide after cardiovascular diseases.^{[1](#page-21-0)} The global survey, including the individual medical data of 37.5 million cancer patients diagnosed between 2000 and 2014, shows that overall cancer survival rates are improving, including those for cancers with high malignancies.^{[2](#page-21-0)} Cancer is responsible for about one in six deaths worldwide. Global Cancer Statistics 2020 estimates that 19.3 million new cancer cases will be responsible for approximately 10 million deaths. 3 It turns out that low- and middle-income countries account for over 70% of cancerrelated fatalities globally. Five main dietary and lifestyle disorders, including tobacco use, high body mass index, inadequate intake of fruits and vegetables, inactivity, and high alcohol consumption, are responsible for one-third of cancer-related fatalities.^{[4](#page-21-0)} The complex, multifaceted origin makes cancer treatment more difficult. Additionally, many cancer treatments fail because of the development of multidrug resistant cells. Consequently, a single line of treatment cannot apply to all patients. Recurrence is frequently possible because

cancer may become resistant to therapies that formerly cured it successfully.^{[5](#page-21-0)}

Chemotherapy, radiotherapy, and surgical intervention are the first-line cancer treatments,⁶ and they have continued to be the most efective methods for cancer treatment for the last several decades. Still, they have not been able to cure the disease entirely and have important limitations including low tumor selectivity, systemic toxicity, off-target toxicity, multi-drug resistance, and serious adverse effects on human health.^{[7](#page-22-0),[8](#page-22-0)} In particular, if a prompt diagnosis is not carried out, the probability of treatment failure or tumor recurrence and metastasis increases. Efective and personalized treatment plans incorporating cancer diagnostic and therapeutic approaches are required to achieve excellent clinical results. Afterward, monoclonal antibody based therapy has been explored by utilizing tumor-specifc antigens (TSAs) and tumor-associated

antigens (TAAs)[.9](#page-22-0) Antibody−drug conjugates (ADCs) are biopharmaceutical drugs designed for targeted cancer therapy and sparing healthy cells. This approach has also paved the way from the bench side to the bedside in a majestic way.^{[10](#page-22-0)} Despite the substantial progress of these techniques, the aforementioned techniques have their own advantages and disadvantages. To address this, researchers and scientists have worked on several methods and techniques, including organic chemistry, supramolecular chemistry, nanotechnology, oncol-ogy, and pharmacology.^{[11](#page-22-0)} Nanotheranostics harnesses the capabilities of nanotechnology; due to their small size and leaky tumor vascularization, nanosystems can preferentially aggregate in tumor cells and exhibit enhanced therapeutic efficacy and diagnostic capability. Additionally, these nanoparticles (NPs) can be redirected and reoriented in a variety of ways while carrying the medicines on them.^{12,[13](#page-22-0)} The emerging area of nanotechnology brings the concept of nanotherapeutics, and this technique has proved very promising in cancer treatment. Nanotechnology has been considered as the engineering of the molecule at the nanoscale level, which endows high drug loading capabilities due to high external surface area.^{[14](#page-22-0)} Moreover, owing to the small size which is comparable with the biological system, nanomaterials actively interact with cellular components of the cell and show promising application in both *in vivo* and *in vitro* biomedical applications.

The fusion of biology with nanotechnology has been hailed as a revolutionary technological advance with numerous applications, including diagnostic devices, biosensing, drug delivery systems, and specialized therapeutic treatments.^{[15,16](#page-22-0)} As a result of the recent advancements in the nanotechnology feld, researchers are developing NP-based transport systems for the simultaneous delivery of diagnostic and therapeutic medications. The ability to codeliver a variety of therapeutic medicines and imaging agents is made possible by the small size of nanomaterials, which endows them with high surface areas and high drug-loading capacities.^{[17](#page-22-0)} NPs can passively collect in tumors due to their well-known increased permeability and retention efects because dysfunctional arteries in tumor tissues cause aberrant molecular and fuid transport dynamics.[18](#page-22-0) Advance research focuses on discovering ground-breaking innovations in nanostructured medical devices with creative capabilities in diagnostic and preventative health. $\frac{19,20}{2}$ $\frac{19,20}{2}$ $\frac{19,20}{2}$ $\frac{19,20}{2}$ $\frac{19,20}{2}$

Drug resistance and tumor heterogeneity remain signifcant obstacles to efective therapy for cancer. Early and precise cancer detection is essential for the most potent therapeutic benefit after intervention.^{[21](#page-22-0)} These critical aspects of the disease should be addressed by efective cancer treatment. A treatment that combines focused therapy based on precise diagnostic test results is known as theranostics, an emerging discipline of medicine.²² Hence, strategies combining simultaneous diagnosis and treatment are known as theranostics, enabling simultaneous target detection, drug distribution tracking, and therapeutic response evaluation to produce personalized medicine.²³ As per Warner,^{[24](#page-22-0)} theranostics is diagnosis along with therapy, which means it is an integrated approach that provides therapy, diagnosis, and monitoring through imaging.

The feld of theranostic nanosystems is promising and extensive, and it warrants further research for the discovery of efective theranostic NPs, which enable a more personalized approach to nanomedicine. To this, NPs can be coated with hydrophilic materials such as folate, polyethylene glycol

(PEG), hyaluronic acid, transferrin, aptamers, and antibodies that make NPs hydrophilic, which in turn increases the period of drugs, targeting efficiency by specific recognition, and enhances their penetration and accumulation in tumors.²⁵ Numerous NPs also act as imaging agents due to the unique physicochemical properties of nanomaterials, along with improved transport. Hence, they need not be loaded with an additional imaging agent. $26,27$ $26,27$ $26,27$ For instance, the use of iron oxide in magnetic resonance imaging (MRI) allows diagnosis and therapy to be carried out concurrently rather than before or after therapy.²⁸ The unique properties of noble metal Au and Ag nanoparticles show unique tunable optical properties because of their surface plasmon resonance (SPR) and have a strong penetrating ability, which makes them appropriate for theranostic applications.^{[29,30](#page-22-0)} Thus, as theranostic agents, nanomaterials provide a unique advantage, including passive or active accumulation in tumor tissues and monitoring all activities within one formulation, ultimately reducing the patient's inconvenience and potential adverse efects on the human body. The challenge associated with nanomaterials is their toxic properties, which should be addressed before their administration in clinical applications.

This review describes the documented literature on the recent progress of nanotechnology-based theranostic systems that have been extensively employed to support numerous clinical and preclinical cancer treatments. This provides an overview of nanomaterials used for cancer theranostics platforms along with a brief introduction to nanomaterial synthesis and its types, and attempts were also made to summarize the comprehensive novel nanotheranostic systems that have the potential for simultaneous cancer diagnosis and treatment in clinical translations followed by future perspectives and challenges. We conclude this review with a retrospective outlook of this important feld and identify potential implications of this feld's paradigm in healthcare. With continued innovation and serious attention to the key challenges, it is expected that this important feld will play a pivotal role in cancer diagnosis and treatment in clinical translations. We believe the summary of recent developments for the use of nanomaterials in cancer theranostics will provide a comprehensive understanding of the applications of NPs in biomedical research investigations and clinical uses.

2. RECENT PROGRESS AND PERSPECTIVES OF SMART NANOMATERIALS BASED THERANOSTICS

Theranostics is a unique concept that integrates therapy and diagnosis in a single system to achieve an accurate cancer diagnosis. It has been recognized as a potential breakthrough in resolving the problems with conventional oncotherapy.

Nanoparticles are ideal candidates as carriers for theranostic agents due to their exceptional physicochemical characteristics, such as nanoscale sizes, functional properties, active or passive tumor targeting, specifc cellular uptake, and excellent optical properties that perfectly meet the needs of phototherapy and imaging at the same time. Metals and biological materials have signifcantly advanced cancer therapy and personalized medicine with the advancement of nanotechnology and medical technology. Theranostics has advanced signifcantly with the advancement of nanotechnology and is currently in the "bench to bedside" transition phase. In this review, we summarize recent progress on nanotechnology-based theranostics, i.e., nanotheranostics, that has signifcantly surpassed conventional therapies and has provided new therapeutic

Figure 1. Nanotheranostic platform for simultaneous therapy and diagnosis. Comprehensive smart nanoplatforms from organic, inorganic, and carbon-based nanoparticles for cancer theranostics. PET, positron emission tomography; CT, computer tomography; MRI, magnetic resonance imaging.

strategies, as well as "cocktail" theranostics (mixing various treatment modalities), as shown in Figure 1.

2.1. Applications of Nanomedicines and Targeted Nanotheranostics in Cancer Therapy. Chemotherapeutic medications sufer from several problems, including signifcant side effects and poor therapeutic efficacy. 31 Nanomedicines help to improve the biodistribution and target accumulation of chemotherapy drugs, which allows them to better balance the effectiveness and toxicity of the treatment.^{[32](#page-22-0)} Many nanomedicines have been investigated throughout the years, including liposomes, polymer−drug conjugates, and polymeric assemblies, to enhance tumor-targeted drug delivery.^{[33,34](#page-22-0)} These nanomedicines use passive targeting, active targeting, and triggered release techniques. Recently, nanoscale biomaterial based technologies have resolved several complicated and challenging issues in science and technology.

Nevertheless, they also opened a new window in biomedical research focusing on personalized medicine. Nanoparticles are one of the greatest scientifc breakthroughs because they have unique properties, including a high specifc surface area and physicochemical features like optical, magnetic, electronic, catalytic, and antibacterial qualities. 35 To combat the negative efects of cancer treatment, it is crucial to transport therapeutic medication molecules to the targeted tumor site. To enable site-specific cancer therapy, numerous efforts have been made over the past 20 years to develop drug delivery systems based on nanomaterials.^{[36](#page-22-0)} Theranostics integrates therapy and diagnostics in one system which helps in developing an improved understanding of the treatment for its side efects and benefts and captures an image while dispensing therapeutic medications at a precise dosage. 37

An overview of recent advancements in targeted nanobased cancer treatments is provided in this review article, along with a variety of diagnostic probes and therapeutic medications. Moreover, syntheses and applications of inorganic nanoparticles, carbon nanoparticles, micelles, protein conjugates,

linear and branching polymers, and dendrimers in theranostics are also covered. The use of theranostics in imaging methods like computed tomography, magnetic resonance imaging, single-photon emission computed tomography, and fuorescence/optical imaging for *in vivo* imaging was also highlighted. About a dozen nanomedicines based on polymeric micelles are currently undergoing clinical trials for various cancers. The latter is desirable for delivering chemotherapeutic drugs with low water solubility.^{[38](#page-22-0)} Integrating therapy with noninvasive imaging is extremely valuable for understanding the *in vivo* fate, pharmacokinetics, target site accumulation, and therapeutic efficacy of nanomedicines.^{[39](#page-22-0)} By selecting patients in advance who are most likely to respond to nanotherapy, this information can be utilized to evaluate the suitability of nanotherapeutic treatments based on nanomedicine.^{[40](#page-22-0)} The fundamental ideas of nanoparticle-based tumor targeting and clinical and preclinical cancer treatments from chemotherapy, to radiotherapy and to photodynamic therapy, and from photothermal therapy to gene therapy, are outlined in this paper, along with the advantages of utilizing imaging to preselect patients and tailor nanomedicine therapies.

Being heterogeneous by nature, cancer is a complicated disease.⁴¹ Despite notable advancements in the development of new drugs and conventional treatment modalities, still the success rate of cancer survival remains undermined. 42 Drug resistance and cancer heterogeneity are the main obstacles that reduce a drug's efficacy. A patient-centric or individualized approach is required for a poor medication response for a better therapeutic result.⁴³ Nanotheranostics has become a promising way to handle such complex problems which amalgamates therapy and diagnosis.

These advanced nanocarriers are capable for drug targeting while enabling diagnostic attributes like imaging.⁴⁴ Recent studies indicate that the cancer nanotheranostics platform provides improved pharmacology of the drugs leading to low toxicity compared to conventional approaches.^{[45](#page-22-0)} Passive or

Figure 2. Synthesis of nanomaterials: top-down and bottom-up approaches.

active, the targeting of drugs by nanoparticle-based drug delivery systems (NDDSs) achieves a better distribution of the drug to the tumor sites, which shows a great advantage in cancer therapy.^{[46](#page-22-0)} A nanoparticle-based theranostic agent is rendered more attractive for personalized therapy because it integrates the three perspectives-diagnosis, drug delivery, and treatment response monitoring-in a single platform. Nanotheranostics, in combination with the targeted drug, could provide great potential for an individualized therapeutic paradigm for cancer. In addition, NDDSs could also combine distinct therapeutic modalities into a single feasible platform to ofer synergistic efects and also to reverse the development of drug resistance.^{[47](#page-22-0)} Lipid-based nanoparticles, polymers, dendrimer-based nanoparticles, metal nanoparticles (noble metals such as gold and silver), semiconductor nanoparticles, carbon nanotubes, metal oxide nanoparticles, metal−organic frameworks (MOFs), and up-converting nanoparticles (UCNPs) are NDDSs which are available for cancer therapy.^{[48](#page-23-0)−[52](#page-23-0)} Cancer nanotheranostics aims to utilize nanotechnology to combine cancer therapy and imaging. Engineering nanomaterials can greatly enhance the efectiveness and specifcity of therapy for cancers to interact with cancer cells at the molecular level. 1 The greatest therapeutic challenge for targeted therapy is posed by metastasis, drug-resistant cancers, and cancer stem cells.[53](#page-23-0) Nanoparticles, adult stem cells, or T-cells in immunotherapy can appropriately be developed as drug delivery systems to achieve a targeted therapy.⁵

3. SYNTHESIS OF NANOMATERIALS

The various techniques used to synthesize the nanomaterials can be broadly categorized as bottom-up and top-down, as shown in Figure 2.

3.1. Bottom-Up Approach. This method is called a constructive approach for synthesizing nanomaterials. Common bottom-up approaches are sol−gel, spinning, chemical vapor deposition (CVD), pyrolysis, and biosynthesis.

3.1.1. Chemical Vapor Deposition Technique (CVD). In the chemical vapor deposition method, a thin flm is deposited onto a substrate via the chemical reaction of the gaseous substrate. This reaction is generally carried out at ambient temperature. A thin flm is formed by the chemical reaction which occurs when a heated substrate comes into contact with the precursor gas. This method can obtain a uniform, pure, rigid, and robust flm with good reproducibility. One of the major disadvantages of this technique is the requirement of special equipment and gaseous byproducts, which are sometimes highly toxic. $¹$ </sup>

3.1.2. Solvothermal and Hydrothermal Methods. Solvothermal and hydrothermal methods are popular conventional approaches for synthesizing nanomaterials such as nanowires, nanorods, nanosheets, and nanospheres. In the solvothermal process, the reaction is carried out in a closed sealed vessel whose pressure should be greater than the solvent's boiling point. In the hydrothermal process, instead of solvent, water is used. The microwave-assisted hydrothermal approach combines the merit of microwave and hydrothermal methods. In this approach, temperature afects the morphology of the nanomaterials.

3.1.3. Sol−*Gel Method.* The sol−gel method is one of the most widely used wet chemical approaches for synthesizing nanomaterials owing to its simplicity, economical viability, and environmental benignity. As the name suggests, in this method, there is the dissolution of precursor in a solvent system which is transformed into the sol, and the sol is fnally converted into gel through the process of condensation, hydrolysis, gel aging, etc. Metal oxides and chlorides are the conventional precursors for this method. During the condensation process, hydroxo (M−OH−M) or oxo (M−O−M) bridges synthesize metal− hydroxo or metal−oxo clusters in solution. The material's structure, characteristics, and porosity change due to ongoing polycondensation. Aging results in a reduction in porosity and an increase in the spacing between colloidal particles and formation of a gel. After the aging process, the gel is dried, which removes water and organic solvents from it, followed by calcination to get nanoparticles.

3.1.4. Pyrolysis. In industry, pyrolysis is a well-used technology for the large-scale synthesis of nanomaterials. Herein, the precursor is fed into the furnace at high pressure through a small orifce and burned in the fame at a high temperature involving the thermal decomposition of materials in an inert atmosphere. This method is simple, efficient, and economically viable with a high yield.

3.1.5. Biosynthesis. This is the greener approach for synthesizing nontoxic and biodegradable nanoparticles. Instead of using conventional chemicals for bioreduction and capping, the biosynthesis method produces NPs using bacteria, plant extracts, fungi, and other microorganisms together with the precursors. Because of their distinctive and improved features, biosynthesized NPs are used in various applications, including drug carriers for targeted delivery, cancer treatment, gene therapy, DNA analysis, antibacterial agents, biosensors, separation science, and magnetic resonance imaging (MRI).

3.1.6. Reverse Micelle Method. The reverse micelle method is an intriguing wet chemical method that can be used to synthesize nanomaterials with the desired shape and size. In this process, reverse micelles are formed from at least three components; two are immiscible and the third is a surfactant with amphiphilic properties. Aqueous systems with nanometer

Figure 3. Organic nanoparticles: (a) dendrimer and (b) liposome.

dimensions are used to carry out specifc reactions in order to develop materials with controlled size and shape. For controlling the size of the nanomaterial, the reverse micelles' size plays a crucial role. In this method, the reverse micelle acts as a nanoreactor, leading to an enhanced reaction rate and uniform distribution of NPs. The advantage of this approach over other approaches lies in improved control of particle size, shapes, uniformity, and dispersibility.

3.2. Top-Down Method. In contrast to bottom-up approaches, top-down approaches reduce bulk materials to nanoscale particles. As a result, this method is also known as a destructive method for nanoparticle synthesis. Some of the common synthetic methods for this approach include lithography, mechanical milling, laser ablation, sputtering, and thermal decomposition.

3.2.1. Lithography. A focused electron beam is used to synthesize nanomaterials. This approach is broadly classifed into two main categories: masked lithography and maskless lithography. Generally, lithography is used in microfabrication to pattern part of a thin flm using the bulk substrate.

3.2.2. Mechanical Milling. Among the various top-down approaches, mechanical milling is a physical method for synthesizing various nanoparticles. Milling aims to reduce the particle size and blend the particle in an inert atmosphere. Plastic deformation determines the particle shape and fracture and reduces particle size, and cold welding, which increases particle size, is the infuencing factor in mechanical milling. This method is simple, is low cost, and can produce various nanoparticle sizes.

3.2.3. Laser Ablation. This is a common method for fabricating a wide range of nanomaterials, including semiconductors, metal NPs, nanowires, composites, ceramic carbon nanotubes, etc., from various solvents. In this approach, a laser beam is irradiated on a metal solution. Due to the high laser energy, the precursor vaporizes, followed by nucleation and growth of a plasma plume, which leads to the synthesis of nanoparticles. This technique is considered a green process as it obviates the need to stabilize and reduce agents for the NP synthesis.

3.2.4. Sputtering. In this process, high-energy particles bombard the solid surface, which leads to the production of NPs. It is a very efective technique for producing a thin flm. Sputtering is usually a deposition of a thin layer of materials onto a particular surface by ejecting atoms from that material and condensing ejected atoms onto the surface when a high

vacuum environment is applied. 55 Sputtering can be carried out in a number of ways, including radio frequency diodes, magnetrons, and DC diodes. Sputtering is often carried out in an evacuated chamber that is then flled with sputtering gas. Free electrons collide with the gas due to a high voltage supplied to the cathode target, creating gas ions. Atoms are ejected off the cathode target's surface due to the positively charged ions' rapid acceleration in the electric feld as they approach the target.⁵⁶ The thickness of the layer, temperature, duration of annealing, substrate type, etc., determine the shape and size of the synthesized film over the substrate.^{[57](#page-23-0)}

4. CLASSIFICATION OF NANOMATERIALS

Nanoparticles can be classifed according to their physical and chemical properties. Generally, NPs can be classifed into organic, inorganic, and carbon-origin nanoparticles.^{[58](#page-23-0)}

4.1. Organic Nanoparticles. Organic nanoparticles are synthesized utilizing natural or synthetic organic molecule templates, as shown in Figure 3. There are many diferent types of organic NPs in nature, including protein aggregates, lipid bodies, milk emulsions, and more complex structures like viruses, to mention a few.^{[59](#page-23-0)} Common names for organic nanoparticles or polymers include dendrimers, micelles, chitosan, silk fbroin, liposomes, and ferritin. These nanoparticles are biodegradable and nontoxic, and some are like micelles and liposomes, which have hollow centers, so they are also called "nanocapsules". The high stability of organic NPs in biological fuids and during storage makes them an ideal choice for stimuli-responsive materials triggered by electromagnetic radiation like heat and light.^{[59](#page-23-0)} Biopolymer nanoparticles offer several advantages, including the ease of their preparation, higher colloidal stability, improved dispersibility, and surface reactivity, making them a perfect candidate for drug administration.^{[60](#page-23-0)}

4.2. Inorganic Nanoparticles. Inorganic nanoparticles are biocompatible, hydrophilic toxic, and highly stable. Some common examples of inorganic nanoparticles include quantum dots and metal and metal oxide nanoparticles. These inorganic NPs are highly efficient for diagnosis and imaging due to their unique electrical, chemical, and magnetic properties.^{[61](#page-23-0)–6}

4.2.1. Metal-Based NPs. Metal nanoparticles are currently being used for biological applications. This covers a broad range of substances, including elemental metals such as cadmium (Cd), cobalt (Co), aluminum (Al), iron (Fe), copper (Cu), gold (Au), silver (Ag), lead (Pb), and zinc (Zn),

as well as metal oxides and metal salts. $63,64$ Silver nanoparticles (AgNPs) and gold nanoparticles (AuNPs) show optical plasmonic behavior that leads to enhancement in the electromagnetic feld due to collective oscillation of the electrons and accordingly enhances the radiative properties for cancer theranostics applications.^{[65](#page-23-0),[66](#page-23-0)} Moreover, iron nanoparticles are exclusively used for magnetic resonance imaging (MRI) applications.^{[67](#page-23-0)}

4.2.2. Metal Oxide NPs. Metal oxide NPs are well-known for their anticancer activity and enhanced radiosensitization ability. In order to modify the properties of their respective metal-based nanoparticles, metal oxide nanoparticles are synthesized. For example, in the presence of oxygen at room temperature, iron (Fe) nanoparticles instantly oxidize to iron oxide $(Fe₂O₃)$, increasing their reactivity compared to iron NPs. It has also been proven that ZnO NPs are most efective in targeting certain cancer cells. The genotoxic ZnO NPs ofer a promising platform for designing more potent anticancer agents for therapeutic use. The surface modifcation of metal oxides can be performed with carboxylate, oleic acid, and polyethylene glycol to deliver various therapeutic agents. Surface modifcations of these NPs make them more biocompatible, reactive, and biodegradable by improving properties such as cytotoxicity, hydrophilicity, large pore volume, high surface area, and pore size. These modifcations lead to an enhancement in therapeutic efficacy. Metal oxides such as aluminum oxide (AI_2O_3) , iron oxide (Fe_2O_3) , cerium oxide $(CeO₂)$, and zinc oxide (ZnO) are attracting particular interest due to their enormous potential in anticancer therapy.⁶⁸ Particularly $CeO₂$, by virtue of its redox-modulatory enzyme-like activities, is envisaged as a promising candidate in nanomedicine[.68](#page-23-0)[−][70](#page-23-0) The ability of cerium nanoparticles to mimic various redox activities, allowing them to scavenge reactive oxygen species, such as catalase, superoxide dismutase, peroxidase, phosphotriesterase, phosphatase, and oxidase, make it a potential candidate for cancer theranostics.

4.3. Carbon-Based NPs. Carbon-based nanomaterials are extensively used in biomedical applications, particularly for cancer theranostics, thanks to their unique physicochemical properties and inert nature, which enhances their ability to deliver drugs to the cell without any adverse efects. The feasibility of surface functionalization with organic and biological molecules makes them some of the most promising materials capable of targeted drug delivery. Carbon nanomaterials show strong absorption in the near-infrared region (NIR), which is helpful for photothermal tumor ablation. Furthermore, these materials are capable of releasing heat in a radio frequency feld, which can be utilized to kill cancer cells by heating them. As a result, they can be applied to photodynamic and photothermal therapies. Carbon-based nanomaterials can be classifed into activated carbon, fullerenes, graphene, carbon nanotubes (CNTs), carbon nanofbers, carbon black, etc. as shown in Figure 4.

4.3.1. Activated Carbon. Activated carbon (AC) is an amorphous form of carbon and is produced from a range of carbonaceous sources, such as bamboo, wood, coconut shells, and coal, by the process of carbonization and activation. AC is economically viable and biofriendly, making it an ideal candidate as a carrier for tumor therapeutic agents.

4.3.2. Graphene. Graphene is a carbon allotrope and comes under two-dimensional materials. Graphene possesses extraordinary physicochemical properties, including ultrahigh carrier mobility, excellent electrical conductivity, superior

Figure 4. Diferent types of nanoparticles for cancer theranostics.

thermal conductivity, large specifc surface area, high optical transmittance, and good biocompatibility. Due to the above properties, graphene has been widely used as an excellent drug delivery system, in fuorescence imaging, and in cancer theranostics.

4.3.3. Carbon Nanotubes. Carbon nanotubes (CNTs) are novel-type synthetic nanomaterials a few nanometers in diameter with distinct hollow and cylindrical structures. CNTs are formed by rolling graphene sheets. CNTs possess extraordinary chemical, electronic, mechanical, and optical properties. The functionalization of CNTs with other biological systems makes them ideal for biocompatible drug delivery strategies for targeting and eliminating specifc tumor cells.

4.3.4. Fullerene. A fullerene is also an allotrope of carbon. In a fullerene, carbon atoms are held together by $sp²$ hybridization and belong to the carbon nanomaterials family. The distinct cagelike structure and electron-defcient nature impart fascinating properties, making fullerenes a promising focus of various research areas, including cancer theranostics.

4.3.5. Carbon Nanodots. Carbon nanodots (CNDs) are zero-dimensional nanoparticles having a size of less than 10 nm. CNDs are fuorescent materials and exhibit unique characteristics such as high water solubility, chemical inertness, low toxicity, ease of functionalization, and good biocompatibility. CNDs are fascinating carbon-based materials and have received much attention in bioimaging, optical sensing, anticancer, photocatalysis, lasers, drug delivery, and optoelectronics.

5. RECENT TRENDS OF NANOMATERIALS IN CANCER THERANOSTICS

Due to their low cost, simple synthesis, and minimal toxicity, bioinspired nanoparticles surpass traditionally synthesized nanoparticles by mimicking nature. This review article provides a comprehensive overview of cancer theranostics using a variety of bioinspired materials, which include lipid nano-

Figure 5. Recent trends in cancer theranostics: identifcation, drug delivery, real-time treatment, and imaging.

particles, protein-based nanoparticles, liposomes, inorganic nanoparticles, viral nanoparticles chitosan, and silk fbroin.[71](#page-23-0)[−][75](#page-23-0) Because of their dimensions in the range 1−100 nm, nanocarriers possess greater and more efective interactions with cancerous cells and are greatly explored for biomedical applications.^{[76](#page-23-0)}

Due to their distinct physicochemical characteristics, bionanoparticles have received a lot of attention recently. Viral NPs, protein NPs, apoferritin, aptamers, solid-lipid NPs, etc.^{[21](#page-22-0)[,77](#page-23-0)−[80](#page-23-0)} appear to be the most promising members of the cauldron. Recent trends in cancer theranostics are displayed in Figure 5.

However, it has been shown that biosynthesized multifunctional nanoparticles encapsulating therapeutic and imaging agents possess theranostic activity.^{[81](#page-23-0)} The following approaches can synthesize a bioinspired theranostic agent: (i) screening of plant extracts; (ii) standardizing a variety of physicochemical parameters for biosynthesis; (iii) inclusion of therapeutic and imaging agents; (iv) characterization of nanocarriers to determine their properties.^{[82](#page-23-0),[83](#page-23-0)}

The hybridization of gold NPs with quantum dots (QDs) can produce multifunctional nanohybrids with superior imaging and anticancer properties. Chen et al. created ZnO QDs conjugated to gold nanoparticles containing the anticancer drug camptothecin.^{[84](#page-23-0)} AuNPs convert absorbed light energy into localized heat responsible for tumor cells' destruction via photothermal therapy. Nanocarriers, with and without drug loading, exhibited similar cytotoxicity toward HeLa cells. On the contrary, hybridization of the paramagnetic Gd ion and CuInS/ZnS QDs could enable dual fuorescence/ magnetic resonance mediated imaging.^{[85](#page-23-0)}

Yang et al. synthesized Gd-doped ZnS QDs without Cd in lipid vesicles with enhanced fuorescence and improved

colloidal stability. Similarly, to avoid fuorescence quenching of QDs, superparamagnetic $Fe₃O₄$ was separated from fluorescent graphene–CdTe QDs by a SiO_2 shell.^{[86](#page-23-0)} 5-Fluorouracil could be loaded into this bifunctional cytocompatible model, which would be efective against hepatoma cells. Overall, the hybridization of QDs with diferent types of inorganic NPs enables their use in multimodal imaging, such as fuorescence, magnetic, and ultrasound imaging. By combining magnetic hyperthermia, photothermal therapy, and photodynamic therapy, synergistic cancer therapy could also be achieved.^{[33](#page-22-0)}

5.1. Organic Nanoparticles in Cancer Theranostics. In the past decade, there have been signifcant increases in the application of nanotechnology to detect and treat numerous diseases, including cancer.^{[87](#page-24-0)} Nanotechnology helps to improve the biodistribution and target accumulation of chemotherapy drugs, allowing them to balance better the efficacy and toxicity of the treatment.[88](#page-24-0) In response to the various limitations in conventional therapeutic strategies and to improve tumortargeted drug delivery, various nanomedicines including liposomal nanoparticles, nonmetallic nanoparticles, viral nanoparticles, protein nanoparticles, and lipid nanoparticles have been studied.^{89,[90](#page-24-0)} It is important to note that nanoparticles ofer small size and enhanced drug loading capacity, ease of functionalization, simple penetration capabilities, and improved retention inside the targeted tissue which have signifcantly improved the diagnostics and therapeutics of various cancers. These nanomedicines use passive targeting, active targeting, and triggered release techniques. In the recent era, nanotechnology has resolved several complicated issues in the fields of science and technology. ^{[91](#page-24-0),[92](#page-24-0)} It may also open a new window in the biomedical realm focusing on personalized medicine. To combat the negative effects of cancer treatment,

it is crucial to transport therapeutic medication molecules to the targeted tumor site. Numerous efforts have been made over the past 20 years to enable site-specifc cancer therapy to develop drug delivery systems based on nanomaterials.⁹³ Theranostics is a recently developed nanotechnology that describes a method of combining medicinal, diagnostic, and imaging methods into a single unit. Doxil is the frst nanomedicine approved by the U.S. Food and Drug Administration $(FDA).⁹⁴$ $(FDA).⁹⁴$ $(FDA).⁹⁴$ About a dozen nanomedicines based on polymeric micelles are currently undergoing clinical trials for various cancers. The latter is particularly attractive for delivering chemotherapeutic drugs with low water solubility.⁹⁵ Integrating therapy with noninvasive imaging is extremely valuable for better understanding the *in vivo* fate of nanomedicines, pharmacokinetics, target-site accumulation, and therapeutic efficacy.^{[39](#page-22-0)} Furthermore, these nanomaterials' outstanding biocompatibility, biodegradability, and multifunctional uses for biosensing, bioimaging, diagnostics, and therapies have expanded their applications in a vast range of biomedical applications.^{[96](#page-24-0)} Following are the details of the organic cancer theranostics platform:

5.1.1. Liposome Nanoparticles in Cancer Theranostics. Liposomes, a type of biomimetic nanoparticle, are undoubtedly the most well-known and adaptable lipid-based nanoweapon for cancer theranostics. These are generally made of concentric lipid bilayers that self-assemble around an aqueous core domain. They have proved to be efective nanocarriers for the delivery of a variety of drugs by encasing hydrophilic ones inside the liposomal aqueous core domain (or on the bilayer membrane surface) and hydrophobic ones inside the liposomal bilayer.^{[97](#page-24-0)} These carriers offer many advantages, including biocompatibility, biodegradability, ease of synthesis, sustained release of the therapeutics, low toxicity, and the ability to incorporate both hydrophilic and hydrophobic chemother-apeutic compounds.^{[98,99](#page-24-0)} Additionally, the liposome surfaces can be tailored for targeted cancer therapy.^{[100](#page-24-0)} Liposomes can accumulate in cancerous tissues passively through the enhanced permeability and retention (EPR) effect and actively by specifcally targeting a cancer cell or an angiogenic marker.¹⁰¹ Liposomal therapeutic agents with multimodality imaging make it highly impressive for individual monitoring of *in vivo* cancer and pharmacokinetics of therapeutic drugs. This platform also predicts the therapeutic efficacies of the drugs in combination with the useful information collected by imaging techniques.¹⁰² Numerous liposomal medications are now used in clinical trials or have received clinical approval due to their numerous benefits.^{[35](#page-22-0)[,103](#page-24-0),[104](#page-24-0)} Liposomes can transport small and large molecules and have also been investigated for the delivery of various diagnostic agents, such as ${}^{64}Cu^{105}$ ${}^{64}Cu^{105}$ ${}^{64}Cu^{105}$ and ${}^{14}C$ isotopes, 106 106 106 quantum dots $\rm (QDs)_\nu^{107}$ $\rm (QDs)_\nu^{107}$ $\rm (QDs)_\nu^{107}$ gadolinium (Gd)-based contrast agents, 103 etc. It is expected that liposomes as a theranostic tool for cancer patients will soon be applied in clinical trials.

5.1.2. Lipid Nanoparticles in Cancer Therapy. Lipid nanoparticles (LNPs) remain one of the most promising platforms for cancer theranostics because of their biocompatibility and scalability.[108](#page-24-0) Lipidic nanocarriers have unique benefits that set them apart from other nanoformulations.^{[108](#page-24-0)} Recent investigations have shown that lipidic theranostic nanomedicines are a promising and prospective strategy for increasing the efficacy of cancer treatment to a benchmark
level.^{[42](#page-22-0)[,109](#page-24-0)−[111](#page-24-0)} LNPs can penetrate the vascular endothelial gaps of tumors and deliver chemotherapy drugs to tumor

tissue. In one of the studies, it has been found that DiR $(DiIC_{18}(7); 1,1'-dioctadecyl-3,3,3',3'-tetramethylindotricarbo$ cyanine iodide) dyes have the ability of enhanced tissue penetration owing to an elongated absorption wavelength for superior antitumor activity. 54 The size of the nanocarrier strongly depends on the targeted organ and type of imaging. For the purpose of sensitive and specifc tumor detection, Zhang et al .^{112} developed a fluorinated nanoemulsion. These nanoemulsions showed dramatically improved fuorescence imaging signals. Their theranostic method was extremely efective at identifying a particular type of tumor tracking the possible *in vivo* fate of the nanoemulsion and providing highly efective photodynamic therapy. Zheng et al. developed a nanoemulsion with a porphyrin shell that allows the encapsulation and stabilization of the oil core, resulting in a monodisperse nanostructure for imaging and phototherapy.^{[113](#page-24-0)} A noninvasive and real-time monitoring of drug delivery for an orthopedic prostate tumor model was presented by Lin et al. by utilizing LNPs loaded with dye and siRNA.^{[114](#page-24-0)} Liang et al. developed a theranostic nanoplatform based on a relatively smaller (<20 nm) iron oxide loaded with porphyrin-grafted lipid nanoparticles (Fe₃O₄@PGLNPs), demonstrating an excellent photodynamic efect against HT-29 cancer cells *in* vitro.^{[115](#page-24-0)} LNPs are exclusively used in cancer theranostics agents for curing diferent types of tumors due to their negligible toxicity, multifunctional potential, and functionalization fexibility which helps them to cross diferent physiological barriers.[51](#page-23-0),[116](#page-24-0)−[118](#page-24-0)

5.1.3. Protein Nanoparticles in Cancer Theranostics. Scientists extensively explored protein NPs because of their natural availability and compatibility with physiology. Proteins belong to the biological molecules with distinctive properties and perspectives, making them amenable to biomedicine and materials science. 119 Due to the amphiphilicity nature of a protein, it interacts favorably with the drug and solvent, making it an ideal choice for NP preparation. The natural origin of a protein makes it biodegradable, metabolizable, and readily susceptible to changing surfaces to facilitate drug attachment and targeted ligand attachment. Albumin has been recognized as a potential carrier for delivering imaging/anticancer medicines to tumor microenvironments after the FDA's clinical approval of Abraxane (paclitaxel bound to albumin).^{[120](#page-24-0)} Patients had a better response rate with Abraxane than with conventional paclitaxel (Taxol), which increased progressionfree survival with the least amount of side efects. Eventually, albumin was developed into a fexible delivery system for medications with poor water solubility, such as rapamycin (water solubility is 2.50 mg/mL).^{[121](#page-24-0)} A clinical trial involving albumin-bound rapamycin (ABI-009) was conducted to treat nonhematologic cancers. There are many albumin-based NPs currently undergoing clinical studies.^{[122](#page-25-0)} Human serum albumin (HSA) caps are among other intriguing possibilities since the human liver supplies a plentiful amount of the same (35−50 mg/mL)[.123](#page-25-0) To build efective theranostics, HSA has been investigated as a natural transporter of superparamagnetic iron oxide, organic/inorganic oxides, IR780, IR825, and chlorin e6 $(Ce6).¹²⁴$ $(Ce6).¹²⁴$ $(Ce6).¹²⁴$ NIR probes like IR825, indocyanine green (ICG), and IR780 are becoming more popular because of their ability to penetrate relatively deep tissue and their low autofuorescence interference. A recent publication noted that IR825 and gadolinium (Gd) were encapsulated in HSA to produce HAS-Gd-IR825 complexes for dual imaging-guided photothermal treatment (PTT) to prevent lymphatic metastases after surgery.^{[36](#page-22-0)} Yu et al. developed gemcitabine and pheophorbide-a (P@) loaded human serum albumin (HSA) (P@-Gem-HSA) to create multifunctional nanoparticles for the treatment of lymphatic PDAC metastases.¹

5.1.4. Metal−*Organic Frameworks in Cancer Theranostics.* Metal−organic frameworks (MOFs), a fascinating and intriguing class of porous hybrid coordination polymers with metal ions or ion clusters serving as nodes and organic ligands serving as linkers, have been synthesized and utilized for a variety of applications, including gas storage, catalysis, sensing, biomedical applications, and cancer theranostics addressing the drawbacks of conventional cancer treatment or the inability of therapeutic drugs to target the tumor sites without damage to healthy tissues and organs. In order to synthesize structurally diverse MOFs (specifc physical and chemical properties), metal (such as d- and f-block elements) and organic linkers (such as carboxylates and nitrogen heterocycles) can be varied, which leads to the synthesis of thousands of MOFs with distinctive characteristics.^{[126](#page-25-0)} The development of nanoscale MOFs (nMOFs) presented potential applications in photodynamic therapy (PDT), drug delivery, and imaging and has led to considerable contemplation of their potential as therapeutic platforms in oncology and other felds of medicine, as shown in Figure 6. Their remarkable characteristics, which

Figure 6. Schematic illustration of MOFs showing diferent applications for cancer diagnosis and treatment.

include easy surface functionalization, structural diversity, high surface area, enormous porosity, tunable energy gap, tailored synthesis, excellent biocompatibility, and a variety of physicochemical properties, make MOFs suitable candidates
for cancer theranostics.^{[127](#page-25-0)−[129](#page-25-0)} A major reason for the failure of conventional cancer treatment is the inability of therapeutic drugs to reach the target tumor sites without damaging healthy tissues and organs. Due to their exceptional qualities, MOFs not only enhance the outcomes of conventional therapies like radiation therapy (RT) and chemotherapy but also beneft the recently developed phototherapy methods.^{[130](#page-25-0)−13}

Moreover, MOFs are suitable materials for imaging-guided cancer theranostics, as they can codeliver various bioactive

substances, including medications, enzymes, genes, and gases.^{[133](#page-25-0)} Zn-based MOFs have also been reported as nanocarriers. Wang et al. developed a chiral Zn-based MOF using zinc ions and achiral 5.5^{\prime} , $5^{\prime\prime}$ - $(1.3,5$ -triazine-2,4,6-triyl)tris(azanediyl)triisophthalate (TATAT) ligands for the delivery of the anticancer medication 5-fuorouracil (5-FU). The experimental results indicated the high drug loading capacity and slow release of the loaded drug, with a complete delivery time of about 1 week.^{[134](#page-25-0)} Gao et al. reported a multifunctional tumor targeting MOF nanocomposite with fuorescence (FL) imaging, MRI, and controlled drug release for cancer therapy. The targeting group folic acid (FA) and 5-fuorouracil agent were decorated on the surface of 5-FU-loaded Fe-MIL-53-NH₂ as an outer layer through an amidation reaction to give Fe- $MIL-53-NH₂-FA-5-FAM/5-FU.¹³⁵$ $MIL-53-NH₂-FA-5-FAM/5-FU.¹³⁵$ $MIL-53-NH₂-FA-5-FAM/5-FU.¹³⁵$ In this approach, Fe-MIL- $53-NH₂$ was utilized to encapsulate the drug and magnetic resonance imaging feature.

Liu and co-workers^{[136](#page-25-0)} have synthesized UiO-66-NH₂ with controlled particle sizes of 20−200 nm. Later the MOF was modifed with FA and the fuorescence imaging agent 5 carboxyfluorescein (5-FAM) known as $UiO-66-NH_2-FA-5-$ FAM/5-FU, a multifunctional theranostic nanoplatform with FL imaging. The *in vivo* studies indicated that UiO-66-NH₂-FA-5-FAM/5-FU could be accumulated in the tumor and display more vital antitumor efficiency due to the long-term drug release. In one study, Cherkasov et al. synthesized an MOF through antibodies to selectively absorb HER2/neu-positive cancer cells.^{[137](#page-25-0)} A biomimetic MOF, Hf-DBP-Fe, was synthesized for efective cancer therapy utilizing a synergistic combination of radiation and an immune checkpoint block-ade.^{[138](#page-25-0)} Chen et al. synthesized folic acid modified hafniumbased manganoporphyrin metal−organic framework nanoparticles (MnTCPP-Hf-FA MOF NPs) to enhance radio-therapy and prevent postoperative recurrence.^{[139](#page-25-0)} [Table 1](#page-10-0) shows some representative MOFs for cancer therapy.

5.2. Carbon-Based Nanomaterials in Cancer Theranostics. One of the most promising felds of biomedical sciences with the fastest growth is nanotechnology, which has been cleverly applied to unravel various biological challenges.³⁵ In recent years, carbon-based nanomaterials have signifcantly increased the detection and treatment of cancer and neuro-degenerative diseases.^{[152,153](#page-25-0)} Various research groups have concentrated on the development of carbon-based nanomaterials such as fullerene, carbon nanotubes, graphene, and derivatives for biomedical applications, which has opened the way for their application in the emerging feld of cancer theranostics.[154](#page-25-0)[,155](#page-26-0) The carbon-based nanomaterials exhibit several extraordinary properties, such as high surface area, tunable pore structure, and nonreactive and easy surface functionalization, making them suitable for their biological application, in particular, for cancer diagnosis, which in turns opens up a new avenue for improved therapeutic strat-egies.^{[156](#page-26-0)−[158](#page-26-0)} In addition to this, these nanomaterials possess outstanding biocompatibility, biodegradability, and multifunctional uses for biosensing, bioimaging, diagnostics, and therapies which have boosted their potential for biomedical applications.^{[159](#page-26-0)}

5.2.1. Carbon Nanotubes. In one of the studies, carbon nanotubes (CNTs) have been shown to be a promising material for drug delivery. In this study, CNTs are loaded with ginsenoside Rg3 and fabricated Rg3-CNT, and the efect was studied on triple-negative breast cancer (TNBC). This study has established that Rg3-CNT is a potential therapeutic

Table 1. Some Common MOFs for Cancer Therapy

strategy for the immunotherapy of TNBC.^{[162](#page-26-0)} M13 phage functionalized CNT (M13-CNT) was explored for the fuorescence imaging of targeted tumors even at low concentrations.[163](#page-26-0) In another work, a targeted M13 virus stabilized CNT probe was utilized for the detection of the human ovarian tumor by Ghosh et al. with a high signal-tonoise ratio. Results were compared with those with visible and NIR dyes, and it was found that the M13 virus stabilized CNT probe can detect a tumor in the submillimeter range.^{[164](#page-26-0)} A fuorescence imaging system for ovarian cancer was developed by Ceppi et al. utilizing single-walled carbon nanotubes (SWCNTs) conjugated to M13 bacteriophage, which carries a peptide-specific protein.^{[165](#page-26-0)} The developed system helps in intraoperative tumor debulking in real time. There was an improved survival rate in animals when treated with CNT fuorescence image surgery compared to conventional surgery. Lee and colleagues developed CNTs coupled with a plateletderived aptamer, and the result showed a signifcant change in NIR fluorescence due to conformal aptamer change.^{[166](#page-26-0)} Zhang et al. synthesized a nanocomposite comprising CNTs and CDs for dual-modal imaging of cancer cells.^{[167](#page-26-0)} It was observed that

the drug loading capabilities of CNTs depend on several factors, including the material's nature, the medium's pH, the free sites of the material, and the nature of the drug. Due to their substantial surface areas, SWCNTs have demonstrated a higher drug-loading capacity than MWCNTs.¹⁶⁸ Peptides having aromatic content showed high binding affinity toward CNTs due to $\pi-\pi$ interaction.¹⁶⁹ Yang et al. proved that the functionalized SWCNTs as DOX carriers are useful for treating MCF-7 cells. Results demonstrated that, when compared to CNT-COOH and CNT-PEG, SWCNT-PEG-PEI had the most substantial antitumor impact and drug delivery capacity. Fluorescence-based research and flow cytometry investigations show that SWCNT-PEG-PEI is internalized more readily, promoting the apoptosis that leads to tumor cell death due to increased dispersibility and a stronger affinity for cancer cells.[170](#page-26-0) CNTs are exclusively used for the pH-responsive release of cancer drugs as they are very susceptible to the acidic environment, making them a promising candidate for drug therapy.^{[171](#page-26-0)} Lu et al. functionalized CNTs with poly(acrylic acid) and used them for the FA for DOX drug loading. It has been found that DOX-loaded CNTs showed higher efficiency

when compared to free DOX; this could be due to hydrogen bonding and *π*−*π* stacking. The developed platform serves as an efficient tool for cancer theranostics.¹

5.2.2. Carbon Dots. Owing to their small sizes, carbon dots (CDs) are particularly promising since they can target cancerous tumors with an increased permeability and retention (EPR) impact. The urinary system can readily eliminate CDs to reduce *in vivo* toxicity. Additionally, CDs have shown to be a unique platform for delivering diferent therapeutic agents. CDs are widely used for various applications such as chemotherapy, photodynamic therapy (PDT), photothermal therapy (PTT), gene therapy, and radiation therapy.^{[173](#page-26-0)−17}

The quantitative cellular accumulation of free CDs and CDs with targeting ligands on cancerous (MDAMB and A-549) and healthy (MDCK) cells showed that diseased cells were more efectively treated than healthy cells. The ligand-attached CDs that ingested cancer cells demonstrated target-selective endocytosis via receptor-mediated therapy. Additionally, the tumor's uptake of nanosized CDs may be signifcantly infuenced by the enhanced permeability and retention effect.^{[178](#page-26-0)−[180](#page-26-0)} Photosensitizing properties of CDs have been extensively explored for NIR light triggered photodynamic therapy alone or in combination with photosensitizing agents such as photoporphyrin, zinc phthalocyanine, etc., which are responsible for the production of reactive oxygen species (ROS) for the treatment of cancer cells. $181-185$ $181-185$ $181-185$

The targeted cancer cells can be hyperthermally killed by NIR-responsive photothermal treatments, like PDT. Numerous carbon-based nanomaterials tend to absorb NIR light from the electromagnetic spectrum and transform it into heat, which thermally kills cancerous cells.[186](#page-26-0)−[188](#page-26-0) For example, under various excitation wavelengths, carbonized polydopamine has shown multiple fuorescence emissions along with NIRresponsive photothermal conversion and heat, which is responsible for the destruction of cancerous cells. CD-based hybrid systems are extensively explored for PDT, PTT, and pH- or NIR-responsive drug release all at once. Synergistic cancer therapy is made possible by such a multipurpose intelligent delivery system.^{[189](#page-26-0)} For instance, CD nanogels with integrated PEG−chitosan have demonstrated PTT against tumor cells and dual pH- and NIR-light-responsive drug release.¹⁸⁵ Mauro et al. developed an efficient protocol for onepot synthesis of N, S doped CDs having a high NIR photothermal conversion efficiency and efficient ROS production in the cancer cell.[190](#page-26-0) S-CD triggers more ROS generation in cancer cells when compared to a healthy cell. The NIR laser is responsible to enhance the oxidative stress in cancer cells at a moderate power density and open up a range of possibilities for real biomedical applications. In another work,^{[191](#page-27-0)} NIR-responsive core−shell hybrid nanocomposite as a smart theranostic platform based on hyaluronic acid−PLA and hydrophobic carbon dots (HA-*g*-PLA/HCDs) was designed to selectively recognize cancer cells overexpressing CD44 receptors and NIR-triggered chemo-phototherapy of solid tumors.

Moreover, combining the anticancer drug with NIRtriggered photothermal treatment may utilize the potential benefts of carbon dots, which may be overcome with specifc resistance to apoptosis eliciting alternative RCD routes such as necroptosis. Nicosia et al. developed a hybrid material CD bearing biotin and a high amount of irinotecan (CDs-PEG-BT/IT) for controlled release and imaging of MDA-MB231 and MCF-7 cancer cells and killing them by photothermal and

chemotherapeutic means.^{[192](#page-27-0)} The results indicate that CDs-PEG-BT/IT is a safe and potentially effective candidate as a theranostic agent in IG-PTT of breast cancer. Geng et al. have synthesized nitrogen and oxygen codoped CDs with an excellent optical response to NIR lasers.¹⁹³ These synthesized doped CDs showed excellent therapeutic efficacy and bioimaging ability with 100% tumor destruction without afecting the healthy cell.

CDs were also explored for the bioimaging and tracking of stem cells through endocytosis. Due to the nanosize, physicochemical properties, and surface charge of the nanoparticles, CDs can penetrate stem cells. They do not afect cell diferentiation and expression of the specifc marker. The rational design of CDs is anticipated to supplement the currently used fuorescence probes for biomedical applications. 194

5.2.3. Graphene. Graphene and its derivatives have been explored for biological and biomedical applications owing to their high surface areas, easy functionalization, and biocompatibility which render them for high drug loading capability and make them potential candidates as drug carriers, in imaging, and in drug delivery systems.^{[195,196](#page-27-0)}

Chen et al. have synthesized an rGO/PEG/ICG nanosystem, which is made up of the functionalization of reduced graphene oxide (rGO) with polyethylene glycol (PEG) and Indocyanine Green (ICG) and later used as a dual-modality contrast agent.¹⁹⁷ It was observed that the rGO/PEG/ICG nanosystem was sustained for a longer time in *in vivo* and was capable of targeting tumors. Mirrahimi et al. used GO for anchoring superparamagnetic iron oxides (SPIOs) and AuNPs adapted with phase-change material (PCM) for stimulus-based drug release.^{[198](#page-27-0)} The study also reveals that the synergistic efect of all, like NIR absorbance of GO, MRI contrast of SPIOs, AuNPs for X-ray attenuation, and PCM for thermosensitive features, make this platform ideally suited for synergistic thermo-chemotherapy in a controllable drug release.^{[198](#page-27-0)} Graphene has the potential for use in PET, imaging, and dual-modality MRI/fluorescence imaging.^{[199](#page-27-0)–[201](#page-27-0)} A novel platform consisting of GO with PEGylated and oxidized sodium alginate was used to load the anticancer drug paclitaxel to get a synergistic chemotherapy/PTT/PDT effect.^{[202](#page-27-0)} Yang et al. bound a molecular beacon (MB) on the surface of GO, which resulted in the enhanced fuorescence quenching of cy5 when compared to the self-quenching effect.²⁰³ The nanocomplex bound to miRNA-21, and the fuorescence response of cy5 was restored. With this technique, the fuorescence intensity was enhanced while the imaging's fuorescence background was diminished. The synthesized nanocomplexes showed excellent imaging capability for numerous tumor cells, as shown by *in vitro* and *in vivo* studies, suggesting that GObased nanomaterials had promising potential in cancer diagnostics. Graphene was also explored for breast tumor PTT and photoacoustic imaging (PAI). In this context, polydopamine (PDA) was bound to rGO, and then the diagnostic reagent ICG was loaded for PTT.^{[204](#page-27-0)} It was found that PDA improved the nanosystem's water solubility and biocompatibility, which in turn quenched rGO's fuorescence and improved the efectiveness of PAI. The ICG-PDA-rGO was processed with higher sensitivity and PAI ability than other control groups, according to *in vivo* imaging investigations. The endogenous contrast agent hemoglobin also allowed for the clear observation of the vascular tissue in tumor tissue. The aforementioned fndings suggested that rGO-based nanoma-

terials could be employed in PAI for tumor diagnostics as well as PTT to increase the efectiveness of cancer treatment. Graphene quantum dots (GQDs) show strong absorption in the NIR-II region. Liu et al. reported 9T-GQDs as a breast, cervical, and lung cancer imaging tool utilizing phenol as a precursor.^{[205](#page-27-0)} The photoluminescence (PL) quantum yield of the 9T-GQDs was 16.67%, almost 1.8 times more than that of ordinary GQDs. The synthesized 9T-GQDs are able to reach the cytoplasm of the 4T1 cancer cell by penetration of the cell membrane to induce continuous fuorescence.

5.2.4. Fullerene. A fullerene is a third allotrope of carbon with fused rings of five to seven carbon atoms joined by single and double bonds to form a closed or partially closed mesh.^{[206](#page-27-0)} Fullerene exhibits a unique physicochemical characteristic, making it a promising candidate for several industrial and medical applications. 2^{07} Pristine fullerenes are insoluble in water, limiting their use in biological applications. The surface modifcation of fullerenes has opened up a new horizon for pharmaceutical and biomedical applications due to their water solubility after modification.²⁰⁸ Furthermore, fullerenes have drawn much interest in biomedical applications due to their small diameters, large specifc surface areas, and high reactivity.²⁰⁸ Many water-soluble fullerene derivatives $(C_{70}$, C_{80} , C_{94}) with various carbon atoms have also been studied to utilize their small sizes, shapes, and molecular topologies for various biological applications.^{[209](#page-27-0)−[211](#page-27-0)} For the cancer theranostics application, fullerenes can be functionalized to make them with distinct physicochemical characteristics such as biocompatibility and water solubility. Additionally, the fullerene cage functions as a unique 3D scafold and may be utilized to attach a variety of drugs to it covalently.^{[212](#page-27-0)−21}

Fullerene is a promising nanomaterial for cancer imaging, PDT, and photo/thermoacoustic-assisted theranostics due to its intrinsic optical and thermodynamic qualities. Due to their distinctive physical−chemical characteristics, fullerenes have attracted a lot of attention in the field of cancer theranostics.^{[215](#page-27-0)} Notably, fullerene can act as a potent antineoplastic agent due to its anticancer action and sensitization efect on cancer cells.^{[216](#page-27-0)} Fullerene also acts as a free radical scavenger and can be employed as an antioxidant.^{[216](#page-27-0)} It is interesting to note that metal atoms can also be added to fullerene to create metallofullerene, which inherits the combined properties of the carbon cages and internal metal and has promising potential for use as contrasts in magnetic resonance imaging (MRI), X-ray, radiotracers, and anticancer agents.²¹⁷ Though with chemical modifcation the fullerene can be tailored for specifc applications for cancer, there are some intrinsic challenges associated with fullerenes such as intrinsic toxicity and solubility in water. In this context, various research groups tried numerous approaches such as modifcation of fullerene with water-soluble functional groups (hydroxyl, carboxyl, and amino groups)/polymers or grafting of the biocompatible molecule through covalent bonding.^{[216](#page-27-0)} Hence, owing to the unique advantages of biocompatible fullerene, it has been extensively explored as a potential platform for targeted drug delivery.²¹⁸ To cure pancreatic cancer, Serda et al. created Sweet- C_{60} (highly water-soluble hexakis-glucosamine fullerene derivative), a novel targeted anticancer drug that mostly accumulated in the nucleus of pancreatic stellate cells $(PSCs).²¹⁹$ $(PSCs).²¹⁹$ $(PSCs).²¹⁹$ It was observed that a glycoconjugate of fullerene could improve the cancer-targeting characteristics since the proliferation of tumors required the energy associated with glucose metabolism.

Wang et al. synthesized an amphiphilic fullerene derivative $(C_{60}$ -Dex-NH₂) to deliver siRNA into cancerous cells to address the lysosomal degradation of RNAi.^{[220](#page-27-0)} The results showed that the synthesized fullerene derivative promoted the lysosomal entrapment and caused the destruction of the lysosomal membrane by triggering controllable ROS under visible light irradiation. Through binding to the MYH9 protein, Zhou et al. created a class of C_{70} fullerene derivatives $(C_{70}$ EDA) modifed with multiple ethylenediamine (EDA) moieties that might prevent cancer cell migration, alter intracellular MYH9 distribution, and prevent EMT.^{221} EMT.^{221} EMT.^{221} C₇₀-EDA treatment inhibited cancer cell migration and reversed the EMT process in A549 cells *in vitro*. Li et al. modifed gadofullerene with *β*-alanine (GF-Ala) to develop a strategy against tumor immunity. 222 This study revealed that immunosuppressive TME (ITM) is crucial for successful immunotherapy. This strategy could induce macrophages to exert an inhibitory tumor growth to convert to tumorsupportive M1 type from M2 type. From the above discussion, it can be concluded that judicial modifcation of fullerene is required to explore the excellent biocompatibility and signifcant antitumor activity, which can open up the horizon of materials for the broad application prospects in cancer therapy.

[Table 2](#page-13-0) summarizes the use of graphene and its derivatives for cancer imaging and theranostic applications.

5.3. Engineered Inorganic Nanoparticles in Cancer Theranostics. Due to their unique physicochemical characteristics, inorganic nanoparticles such as platinum, gold, silica, palladium, silver, iron oxides, zinc oxide, and rare earth oxides have been widely used for a number of biomedical applications including cancer theranostics, nucleic acid delivery, bioimaging, drug administration, and biosensing. $61,248,249$ $61,248,249$

Green chemistry is a promising approach that can be used for the natural design of metallic or nonmetallic nano-particles.^{[250](#page-28-0)} Many advantages are associated with this technique, including their eco-friendly setups, which ignore harmful chemicals, simplicity, robustness, time savings, and use of safe solvents, especially water.^{[251](#page-28-0)} This green approach uses bioreducing agents comprising plant extracts, bacteria, algae, etc., in place of hazardous chemical catalysts. Because of these benefts, such safe, natural nanoparticles are highly desirable for cancer theranostics.²⁵²

In many parts of the world, various research teams are utilizing nanoparticles of silver and gold synthesized by a biological process that can work as one of the ideal candidates for cancer theranostics applications. AuNPs and AgNPs produced through biosynthesis have the potential to be used in the *in vitro* and *in vivo* delivery of anticancer medications.^{[253](#page-28-0)} Mukherjee et al. demonstrated the transport of doxorubicin (DOX) to an *in vitro* and *in vivo* mouse melanoma tumor model utilizing biosynthesized gold nanoparticles (b-AuNPs) made from the aqueous leaf extract of *Peltophorum pterocarpum* popularly known as "yellow flame tree".^{[254](#page-28-0)} Outstandingly, these b-AuNPs were shown to be exceptionally biologically attuned when C57BL6/J mice were cured with b-AuNPs as compared to mice cured with (chemically designed) AuNPs subsequent to successive intraperitoneal injections of 10 mg/ kg of body weight. In addition, melanoma tumor development in mice was signifcantly inhibited by b-AuNP conjugated DOX treatment compared to pristine DOX. In another study by Ganeshkumar et al., the anticancer medication 5 fuorouracil was administered to breast cancer cells in a

Table 2. continued

targeted way utilizing folic acid linked b-AuNPs (made using Punica granatum fruit peel extract).^{[44](#page-22-0)} These b-NPs were used as anticancer medicines because the bioresources that adhere to the nanosurface during the manufacturing process contain therapeutically active phytochemicals (isofavone, favonoids, polyphenols, taxol, etc.). As a result, b-NPs showed a distinct advantage over NPs created chemically. Mukherjee et al. 255 demonstrated the 4-in-1 theranostic uses of biosynthesized silver nanoparticles employing a methanolic extract of *Olax scandens* leaves (biocompatible, anticancer, cell imaging, and antibacterial). Mukherjee et al. 256 showed that b-AuNPs made from *Lantana montevidensis* leaf extract have antitumor action. The anticancer phytochemicals cirsilineol, apigenin, eupatorine, hispidulin, eupafolin, and *β*-caryophyllene are responsible for their therapeutic efficacy in *L. montevidensis* leaf extract. Fazal et al. 257 exhibited the photothermal ablation capabilities of anisotropic b-AuNPs produced using cacao seed extract toward epidermoid carcinoma A431 cells grown *in vitro*. Wang et al.[258](#page-29-0) demonstrated fuorescence-based bioimaging of *in situ* b-AuNPs for identifying malignancies in cancer cells. Chloroauric acid $(HAuCl₄)$ was incubated with human leukemia cells (K562) and human hepatocarcinoma cells (HepG2), which produced green fuorescence. Noncancerous L02 (human embryo liver cell strand) cells did not have any fluorescence after incubating with $HAuCl₄$, demonstrating the specifcity of b-AuNP synthesis to cancerous cells. Following subcutaneous injection of $HAuCl₄$ solution (10 mmol/L), the scientists further demonstrated the applicability of *in vivo* bioimaging to an *in vivo* xenograft tumor model of HepG2 or K562 cancer cells in BALB/c mice. The *in vivo* fuorescence showed high fuorescence surrounding the tumor even 72 h after $HAuCl₄$ injection, showing the persistent fluorescence of *in vivo* biosynthesized b-AuNPs, which can be used for tumor diagnosis. AuNPs are extensively used in targeted drug delivery along with X-ray imaging, NIR imaging, fuorescence imaging and photoacoustic imaging as they have a tendency to accumulate in the tumor at the cellular level.^{[259](#page-29-0)} Kotcherlakota et al.[260](#page-29-0) synthesized greener AuNPs using *Zinnia elegans* (ZE) plants. The synthesized AuNPs were tested for biocompatibility with the cancer cell lines using an MTT assay and were found to be biocompatible. This study has proven that AuZE NPs can be used in diagnostic imaging as these NPs are homogeneously distributed in the brain of mice without the ligand and exhibit strong fuorescence in the NIR region. AuNPs have great potential for diagnostic and theranostic tools due to their optical and chemical characteristics.^{[261](#page-29-0)} The surface functionalization of these NPs makes them a potential nanovehicle for cancer treatments.^{[262](#page-29-0)}

Silver nanoparticles (AgNPs) are one of the most important and fascinating nanomaterials and have been employed as an antibacterial agent since ancient times. The use of AgNPs was also witnessed in World War I to treat bacterial infections. Owing to unique physiochemical and biological properties, AgNPs have attracted signifcant attention in cancer theranostics. AgNPs exhibit optical properties of surface plasmon resonance and can be tuned to the visible spectrum for lower detection limits. Austin et al. have captured the image of cancer cells (phagocytic activity) using light-scattering darkfeld microscopy where AgNPs were incubated with oral squamous cell carcinoma (HSC-3).[263](#page-29-0) *Moringa oleifera* aqueous stem bark extract and *Styrax benzoin* gum powder materials were explored for the greener synthesis of AgNPs and later used for the apoptosis of HeLa cells due to ROS

production by AgNPs.^{[264](#page-29-0),[265](#page-29-0)} In another study, Gurunathan et al. reported the preparation of AgNPs by using leaf extract of *Artemisia princeps*, which was used as a bioreductant, and AgNPs were found to be killing A549 lung carcinomas without any adverse effect on normal lung cell. 26

Padinjarathil et al. have utilized a surfactant-free environmentally friendly technique for the synthesis of AgNPs, and it provides a potential theranostic platform with synergistic anticancer and immunomodulatory potential in the same platform. 267 The AgNPs were synthesized from galactomannan with an average size of around 30 nm and a negative surface charge of 35.2 mV. In a work by Oves et al., AgNPs were synthesized using root extract of *Phoenix dactylifera*. [268](#page-29-0) FTIR, XRD, and UV−vis characterization studies were carried out to see the nature of synthesized NPs. The developed AgNPs were tested for antimicrobial and anticancer potential and destroyed cancer cells by arresting the cell cycle at sub-G1 and S phases. Biogenic silver nanoparticles (2−50 nm) were synthesized utilizing an extract of the latex of *Calotropis gigantean.* The results showed that the NPs are toxic to breast cancer cells, lymphoblastic leukemia (Jurkat cell lines), and ascites tumor cells (EAC cell lines) without producing cytotoxicity in mice and human lymphocytes.^{[269](#page-29-0)} The results reveal that AgNPs could be a potential chemotherapeutic formulation for cancer therapy. AgNPs produce ROS that lead to damage to DNA, triggering apoptosis, and damage to the cancerous cells. 270 This study also revealed that AgNPs afected the cells' respiration and the vascular endothelial growth factor activity, which is responsible for angiogenesis. Dinparvar et al. 271 used seed extract of *Cuminum cyminum* to synthesize bio-AgNPs, and efficacy was checked against the human breast cancer cell line MCF-7 and cancer cell line AU565. This study observed that chemically synthesized AgNPs exhibit toxicity while biologically synthesized AgNPs were far less cytotoxic and exhibited strong inhibitory efects against human breast cancer cells. Kumar et al. 272 synthesized AgNPs using Andean mora leaf. Their efficacy was checked against Hep-G2 human liver cancer cells, and it was found that the synthesized AgNPs are useful for anticancer therapy and drug delivery.

Copper-based nanoparticles $(Cu_2O, CuO, Cu_2S, CuS,$ $Cu₂Se, CuSe, etc.)$ have attracted the scientific community's attention because of their biocompatibility and unique physicochemical properties.[273](#page-29-0) The synthesis of CuNPs mainly includes solvothermal/hydrothermal methods, colloidal synthesis, thermal decomposition methods, microwave-assisted synthesis, cationic exchange methods, and template-oriented synthesis methods. $274,275$ Zhao et al. have synthesized Ag2[−]*x*Cu*x*S quantum dots and characterized all-in-one theranostic nanomedicine photothermal therapy. 276 The resultant materials show high photothermal conversion efficiency, and PTT can be performed under a low-power laser of 635 nm and demonstrates no long-term toxicity.

CuS nanocrystals (NCs) were grafted onto the surface of gelatin nanoparticles. These transformable nanoparticles, CuS@GNPs, were later used for the thermal ablation of human MDA-MB-23 tumors.^{[277](#page-29-0)} The spatiotemporal multistage delivery behavior of CuS@GNPs within tumor tissue was observed *in vivo* and in real time by photoacoustic imaging. The multistage behavior of CuS@GNPs enhances photothermal ablation. The result indicated that the developed method may undergo enzyme-induced multistage administration for increased penetration and accumulation at the tumor site. Wang et al. have developed iron−copper codoped

polyaniline (Fe−Cu@PANI) NPs for simultaneous imaging and photothermal therapy.²⁷⁸ In this work, glutathione (GSH) was explored for diagnosis and tumor microenvironment activated therapy. GSH is responsible for the reduction of Cu^{2+} ions and produces protonated PANI. This redox reaction induces a red shift from 615 to 815 nm. This study paves the way for numerous potential application prospects in the detection and treatment of cancer. For PDT, copper doped carbon dots (Cu-CDs) were prepared and utilized for cervical cancer and neuroblastoma. Cu-CDs generated ROS with a quantum yield of 0.36 after irradiating with LED light. The prepared Cu-CDs exhibited an efective tumor suppression efect on HeLa cells and SH-SY5Y 3D multicellular spheroids (MCs). Deng et al. have synthesized a series of copper nanoparticles with tunable acid dissociation constant (p*K*a) values from 5.2 to 6.2 for H_2O_2 self-supplying CDT.^{[279](#page-29-0)} This study implies that lower pK_a value NPs exhibited better retention when compared to higher value ones. The catalytic ion produced by NPs converted self-supplied H_2O_2 into hydroxide free radical by the Fenton reaction, which permeates the lysosomal membrane and thus employs lysosome-mediated cell death to eliminate tumor cells.²⁷

5.3.1. Quantum Dots in Cancer Theranostics. Over the past few decades, researchers have paid signifcant attention to multimodal medication delivery systems. Due to their distinct physiochemical properties, quantum dots (QDs) are among the most efective tools utilized in theranostic applications for diagnosis and therapy[.280](#page-29-0) QDs are semiconductor crystals in the 2−10 nm nanoscale range and show emission from visible to near-infrared wavelengths along with outstanding light stability[.281,282](#page-29-0) The best QDs for cell labeling and cancer biomarker detection are those with intense photoluminescence and high molar extinction coefficient values. Symmetrical broad-absorption spectra and narrow-emission spectra distinguish QDs.[283](#page-29-0),[284](#page-29-0) However, due to the release of Cd ions and the production of reactive oxygen species, some concerns have been raised about the toxicity of QDs, particularly QDs containing Cd.^{[285](#page-29-0)} In order to provide effective tumor targeting and prevent their escape into the systemic circulation, techniques have been devised to minimize their toxicity and improve their biocompatibility through hybridization with other moieties such as proteins, lipids, polymers, and polysaccharides.[286](#page-29-0)[−][289](#page-29-0)

High-stability protein−QD nanohybrids in biological fuids are essential for bioimaging applications. QDs can combine with proteins by either physical trapping or chemical interaction.[290](#page-29-0) For instance, gemcitabine-loaded human serum albumin nanoparticles have successfully had graphene QDs attached to their surfaces (NPs).^{[291](#page-30-0)} Nigam et al. reported hyaluronic acid and graphene QDs functionalized human serum albumin nanoparticles for bioimaging and targeted delivery of gemcitabine to pancreatic cancer.²⁵¹ In a different work, spray-dried single bovine serum albumin (BSA) nanospheres were used to physically encapsulate several CdTe/CdS QDs of various sizes to create multifuorescent nanospheres, 292 which can be achieved by altering the QDs' size. When the QD-BSA nanospheres comprised a high molar ratio of QD:BSA, the fuorescence emission was reduced by 4% after being continuously irradiated (at 365 nm) for 1 h.^{[292](#page-30-0)} These fndings demonstrated the potential of QD-BSA nanospheres for long-term fuorescence observation in biomedical research felds. Song et al. synthesized a nanocomposite of phosphorus QDs with Bi@RP-PEG-DOX and

Table 3. Representative Theranostic Nanomaterials and Their Applications Table 3. Representative Theranostic Nanomaterials and Their Applications

bismuthene, which showed an efective platform for photothermal and photodynamic efects and controlled release of the drug in the presence of NIR-II irradiation.^{[293](#page-30-0)} Zein−ZnS QD nanohybrids could be used to deliver drugs like 5 fuorouracil.[294](#page-30-0) Girija Aswathy et al. examined the impact of these nanohybrids on the viability of L929 and MCF-7 cancer cells to ascertain their biocompatibility.^{[294](#page-30-0)} For zein-QDs and ordinary zein nanoparticles, the cell viability was found to be above 90 and 80%, respectively, which showed that they were compatible. Cell viability was considerably decreased when the cells were exposed to 5-FU-loaded zein-QDs. Furthermore, the zein−ZnS QD NPs' fuorescence emission demonstrated that they had successfully entered the cells. Shao et al. synthesized biodegradable titanium nitride quantum dots $(Ti₂N QDs)$, which showed excellent photothermal conversion efficiency under NIR.^{[295](#page-30-0)} The prepared material showed excellent biocompatibility, photoacoustic effect, and efficiency of photothermal therapy (PTT). Another study indicated multistage QD nanocarriers by joining silica-coated QDs to the surface of gelatin NPs to create 100 nm nanohybrids, among other intriguing methods to improve tumor penetration.²⁹⁶ In the tumor microenvironment the increased matrix of metalloproteinases dissolved the gelatin core after extravasations into the tumor tissue, producing incredibly tiny 10 nm QDs that efectively penetrated the tumor parenchyma. In general, utilizing proteins to hybridize QDs can be a viable method to extend their time in the body, boost their physical stability, improve their capacity to target tumors, and lessen their toxicity.

To enable nontoxic imaging, various polysaccharide types can be used to increase the safety and biocompatibility of QDs. Chitosan toxicity can be decreased by adding Mn-doped ZnS QDs (Mn:ZnS QDs), making folic acid functionalization possible.^{[297](#page-30-0)} Bwatanglang et al. integrated the targeted drug delivery properties of folic acid (FA) with the imaging properties of Mn:ZnS QDs into a unifed nanodelivery system.^{[297](#page-30-0)} In order to create an FACS-Mn:ZnS nanocomposite, FA−chitosan conjugate (FACS) was frst synthesized and electrostatically complexed with Mn:ZnS QDs. After 24 h, neither bare Mn:ZnS QDs nor FACS−Mn:ZnS (7−500 g/mL) displayed toxicity to cancer models of breast cells (MCF-7 and MDA-MB-231) or a healthy model of breast cells (MCF-10). Only a minor decrease in viability was seen in FACS−Mn:ZnS treated cells as compared to treatment with Mn:ZnS QDs when the QD concentration was increased from 62 to 500 g/mL. This marginal decrease in cell survival for the cells treated with FACS−Mn:ZnS may be attributed to the enhanced binding of the FA-coupled QDs to the cancer cell that expresses the folate receptor. Also, upon binding to the folate receptors expressed on the cancer cells, the FAconjugated QDs increased the intensity of the cellular fuorescence.

Hyaluronic acid and QD pairing have been discovered to be an intriguing strategy for improved intracellular transport into liver cells, mediated by contact with CD44 receptors, permitting *in vivo* real-time observation.^{[298,299](#page-30-0)} In another work, CdTe QD theranostic nanocapsules were coated with chondroitin sulfate followed by loading with rapamycin and celecoxib for cancer applications.^{[300](#page-30-0)} To prevent chondroitin sulfate nanocapsules from being absorbed by healthy cells unintentionally, an exterior coating of cationic gelatin-coupled QDs was applied to them. Gelatin was degraded by matrix metalloproteinases at tumor locations, releasing both medi-

cation nanocapsules and quantum dots (QDs) into cancer cells for imaging.^{[301](#page-30-0)} In a related experiment, lactoferrin, an ironbinding cationic protein, was used in place of gelatin to produce an on-off effect, where the fluorescence of QDs was frst quenched by energy transfer and subsequently recovered upon bond cleavage in tumor cells.[301](#page-30-0) As a result, QD fuorescence was used to show how nanocapsules were localized both *in vitro* and *in vivo* within breast cancers. On the basis of the studies mentioned above, it is clear that combining QDs with polysaccharides can enhance their ability to target tumors by interacting with their receptors, which cancer cells tend to overexpress.^{[302](#page-30-0)} This leads to an increase in the amount of QDs that accumulate at the tumor site. [Table 3](#page-16-0) summarizes the application of various nanomaterials in targeted cancer therapy and imaging.

6. CURRENT TECHNOLOGICAL CHALLENGES AND LIMITATIONS OF EFFECTIVE THERANOSTICS

Smart nanomaterials offer a robust platform for effective cancer theranostics as they can be triggered in response to specifc external or endogenous stimuli like pH, temperature, enzymes, or a particular biological molecule. Compared to traditional cancer theranostic approaches, smart nanomaterials based approaches exhibit improved selectivity and sensitivity with fewer adverse efects. Furthermore, an additional beneft of using a theranostic device is the noninvasive, rapid, and precise identifcation of early chemotherapeutic responses. Overall, using theranostic platforms based on nanotechnology gives chemotherapy unmatched advantages for overcoming its long-accompanied disadvantages.^{[338](#page-31-0)} Early cancer detection, tailored medication delivery, drug discovery, and efective anticancer therapy are all possible with nanotechnology-based techniques and nanomaterials in oncology.^{[339](#page-31-0)} Gold nanoparticles (AuNPs) have been widely used in treating breast and prostate cancers as drug delivery systems. AuNPs are considered because of their dependable qualities, such as their ability to scatter light, absorb light, and convert optical energy into heat.^{[340](#page-31-0)} Though the nanomaterials have proven their anticancer activities. One of the most challenging problems in the feld of nanotheranostics is system complexity, having numerous functionalities in a single nanometer particle size. Industrial scale-up production and its clinical translation are also two of the main obstacles in the feld of NPs. Scientists and engineers should adopt an interdisciplinary approach to successfully absorb this feld in cancer theranostic nanomedicine. With many of their intrinsic molecular properties and multifunctionality, diferent nanomaterials have recently become an exciting tool in cancer theranostic applications, assisting in successful therapy, diagnosis, and imaging. 341 However, several obstacles prevent their clinical translation, including systemic toxicity of nanomaterials within the body, nontargeted distribution, complex synthesis, high cost, reduced biocompatibility, stability and reduced photostability.^{[319](#page-30-0),[342](#page-31-0)} Another major obstacle to the use of nanomaterials in cancer theranostics is the selection of models as most of the research is in and around cell and animal models that may not be the right models to assess the anticancer efficacy of both diagnostic and therapeutic agents, as these models sufer from various degrees of diferent chemical and physical stresses and might not be representative of those of whole human organs. In the complex human system, it is difficult to replicate a reaction using just one model.

Table 4. Some Cancer Theranostics Agents and Their Characteristics and Indications

A single model may not mimic the complex human system; however, the possibility to link several of these models which are capable of recapitulating the *in vivo* interaction, extracellular matrix, intercellular signaling, and *in vivo* growth may provide a system that more closely resembles and can harness a better understanding of *in vivo* events. Biomimetic organ/tumor-on-a-chip tools and organoid model systems are possible solutions to imitate *in vivo* conditions of nanocarriers used in cancer patients.[343](#page-31-0)−[345](#page-31-0) First and foremost, developing a low-cost synthesis method and an easy purifcation procedure is vitally necessary to enable the mass production of nanomaterials. The focus on engineered nanomaterials with high hydrophilicities will open the door to anticancer drug carriers with enhanced tumor therapy efficacy and drug delivery. Last, but not least, the focus should be directed toward delivering genetic material to the cancer cell for efective cancer theranostics. So far, the full potential of nanomaterials in cancer is not fully utilized, as nanotoxicity and bioaccumulation of NPs constrain their broader applicability.

QDs have generated a great deal of attention in various biological domains due to their several signifcant benefts over conventional dyes in bioimaging. However, these applications face numerous difficulties, including cellular toxicity brought by producing reactive oxygen species and cadmium leakage, which might threaten the patient after the treatment. For example, graphene QDs have been demonstrated to be safe and nontoxic to normal cells. However, extensive *in vivo* toxicity studies are required prior to its administration^{[346](#page-31-0)} in cancer theranostics. Despite QDs' efectiveness in cancer theranostics, one of the biggest problems is the possibility of

nonspecifc reticuloendothelial absorption, which lowers the likelihood and efectiveness of these theranostic agents binding to the targeted cancer site. 347 In this article, we covered the development of many multifunctional platforms for cancer therapy and diagnosis, as well as diverse methods utilized to reduce the toxicity of nanomaterials through the process of hybridization with diferent biocompatible lipids, proteins, polymers, or nanoparticles. Table 4 summarizes some cancer theranostic agent characteristics, biocompatibility, and translation stages.

7. GLOBAL OPPORTUNITIES OF SMART NANOMATERIALS IN NEXT GENERATION CANCER THERANOSTICS

The use of nanomaterials has shown a paradigm shift in cancer theranostics when compared to conventional approaches. Nanotechnology has revolutionized the cancer theranostics feld as the sizes of biomolecules such as DNA, hemoglobin, proteins, and enzymes are in accordance with the size of NPs, which leads to enhanced biomedical application owing to their efective interactions. Owing to the unique properties of nanomaterials, a high surface-to-volume ratio lead to a broader surface area for interactions with biological molecules, resulting in increased sensitivity, enhanced selectivity, and shorter reaction times. Quantum dots (QDs), liposomes, micelles, metallic nanoparticles, dendrimers, and polymeric nanoparticles have recently been utilized for cancer therapy and imaging.^{[355](#page-31-0)} Contrarily, the traditional approaches to treating cancer are ineffective and lack selectivity.^{[356](#page-31-0)} As these traditional procedures afect healthy and cancerous cells,

opponents of health also dispute their selectivity.[357](#page-31-0),[358](#page-31-0) The most signifcant beneft of smart nanomaterials is their ability to overcome these constraints. Nanomedicine advancements have infuenced better outcomes for cancer detection and treatment and have opened new avenues for cancer treatment. Nanomaterials have shown improved pharmacokinetics, biocompatibility, tumor targeting, and stability compared to conventional methods. However, numerous uses of nanomaterials are still challenging because of certain restraints such as nonspecifc delivery, multistep synthesis, poor bioafnity, reduced light immovability, and toxicity of nanomaterials inside the living system.^{[359](#page-31-0)} Therefore, enhanced nanomaterial moieties with well-ordered physicochemical and biological characteristics are strongly considered for cancer theranostics. 360

Recent advancements in smart nanomaterials based cancer theranostic methodologies have been cultivated, and they are exposing recovering sensitivity and selectivity by condensed negative efects in contrast to traditional methods. In cancer treatment, the smart nanomaterials system reacts to the tumor microenvironment (TME) and leftovers in the neutralized form in standard cells, decreasing the side efects and overall toxicities.[361](#page-31-0) Nanomaterials expand drug efectiveness by enhanced sensitivity, light absorbing capacity, drug half-life lengthening, and drug solubility enhancement with long-standing confirming drug discharge.^{[362,363](#page-31-0)} Additionally, smart nanomaterials can also be applied to intensify the healing, drug loading capability, and organized continuous discharge of drugs, and specifc and selective biodissemination by engineering their conformation, designing methodologies, morphology, size, and surface chemistry.³⁶⁴ Unlike traditional materials, engineered smart nanomaterials can pierce transversely biological obstacles and empower pH, light, and heat based pursuit of malicious cells.^{[361](#page-31-0)} Manufacturing procedures may be fne-tuned to normalize the functionality and specifcity of nanomaterials by transforming the chemical confguration, shape (morphology), and size. For cancer-dealing approaches, nanomaterials can overwhelm the stability and solubility of anticancer drugs.^{[93](#page-24-0),[365](#page-31-0)} Nanomaterials also help in the treatment of persistent tissue by pointing to the cancer spots, delivery of various drugs, and falling drug conflict. 366 Additionally, to overwhelm the cytotoxic infuence of nanomaterials, novel methodologies have been projected to cultivate biocompatible nanomaterials resembling surface reformation with diverse biodegradable fragments. Extensive research studies need to be carried out for engineered hybrid NPs better suited for cancer treatment with specifc binding. The size, shape, composition, and surface of the NPs impact the immune system. Though the nanomaterial approaches are more effective than traditional approaches, the clinical efficacy of this therapy is still inadequate, and further research into the safety and tolerance of these novel techniques is required. Exploiting nanomaterial characteristics to improve the target specificity can achieve significant therapeutic efficacy. Though many research studies were carried out for the uses of nanomaterials in cancer theranostics, only a handful of nanomaterials have successfully translated to clinical applications. Extensive research needs to be carried out for the successful implementation of nanomaterials in clinical applications amid tumor heterogeneity, which poses one of the greatest technological challenges to theranostics.

8. CONCLUSIONS

The quick expansion of theranostics based on nanotechnology has impressively endorsed the uprising of diagnosis methodologies and cancer oncotherapy. The present review discusses the most relevant advancements in smart nanomaterials, from organic, inorganic, and carbon-based nanoparticles for cancer theranostic applications. The review article's fndings are incredibly inspiring and strongly urge the exploration of nanomaterials as nanocarriers, and their physicochemical attributes can be harnessed to improve *in vivo* performances in cancer theranostics. This review also detailed the limitation and global opportunities for the successful implementation of nanomaterials-based cancer theranostics, which can be translated into clinical applications. One can expect that, by giving attention to the key challenges mentioned above, the nanomaterials-based cancer theranostic platform will bring many exciting opportunities for therapy and diagnosis to achieve accurate cancer diagnoses and address the challenges of conventional oncotherapy. Nanotechnology has demonstrated a new dimension for cancer theranostics by delivering tiny molecules for cancer detection, diagnosis, and therapy. Many diferent types of cancer are treated using cancer medicines that are based on the exceptional qualities of NPs. With advancement in this vital feld, nanomaterials in their diferent forms have proved to possess enhanced drug delivery efectiveness for cancer. Perfect nanotheranostic arrangements are projected to be (1) harmless and biologically tuned, (2) greatly unwavering and efectual for drug stufng, (3) simple to modify and prepare, and (4) targeting malignant cells and active for endocytosis.

Furthermore, the groundwork and superiority mechanism of nanoparticles are still complex. Last, the equilibrium between the reliability and efficiency of nanotheranostic settings would be refected, though the overview of numerous agents in one theranostic stage may fetch various purposes. It is anticipated that, with the advancement in proteomics research on the mechanism of cancer origin, cancer heterogeneity, and multidrug resistance behavior, a large number of NP-based drugs can be exploited. Though extensive research was carried out on NPs, only a few NP-based medications are presently in use, a smaller number are in clinical trials, and the majority are still in the infancy stage. An interdisciplinary approach is required to realize nanomaterials in cancer therapy. Though the application of nanomaterials is in the midst of development, this can be proved to be a new and promising platform that can bring new hope not only for the diagnosis of cancer but also for imaging, treating, and preventing cancer owing to their small sizes, their functionalization potentiality, and the ability to introduce multiple therapeutic agents on their surfaces. This will be a paradigm shift in the way that we treat cancer. Nevertheless, the nanosystems could be too intricate for bulk-scale engineering. Since present research and development efforts have placed a cumulative effect on these nanosystems, innovation in materials science integrated with biological material may accomplish more real-world presentations of nanotheranostic platforms in cancer diagnostics.

In conclusion, the rapid advancement in theranostics based on nanotechnology has signifcantly acelerated the revolution in cancer oncotherapy and diagnosis. The best nanotheranostic systems should be (1) nontoxic and biocompatible, (2) very stable and efective in drug loading, (3) easy to prepare and modify, and (4) capable of tumor targeting and endocytosis.

Although the majority of the nanoparticles listed above do not appear to have obvious cytotoxicity, additional experiments are required to ensure safety in clinical translations. Moreover, nanoparticle preparation and quality assurance are still challenging tasks. Notably, the synthesis of organic nanomaterials is frequently laborious with low yields. Last, but not least, although combining several agents in a single theranostic platform may bring about a variety of activities, it is important to balance the efficiency and dependability of nanotheranostic systems. However, the nanosystem could be too complicated for large-scale synthesis. We presuppose that the revolution in clinical translation for NP-based cancer therapy with rational approaches dealing with synthetic strategies, toxicity, and cellular and physiological factors will be accomplished with nanotechnology and cancer therapy development. Laboratories are coming up with nanomedicine-based drug delivery systems with a strong emphasis on cutting-edge technological and scientifc advancements that succeed on a small scale. These laboratories often are familiar with the technical problems that occur in the industry for the commercializing processes. A strong collaboration among pharmaceutical companies and academic laboratory groups must be established to bridge this gap. Nevertheless, current investigators are emphasizing these difficulties, and several initiatives are being taken to achieve more practical applications of nanotheranostic platforms in the treatment of cancer.

NMOF = nanovesicular metal−organic framework

TBP = $5,10,15,20$ -tetra(*p*-benzoato)porphyrin

 $ZnP = zinc$ phthalocyanine

TBB = 5,10,15,20-tetra(*p*-benzoato)bacteriochlorin

 $QC = 2'', 3'$ -dinitro- $[1, 1': 4', 1'', 1'''$ -quaterphenyl]-4,4‴dicarboxylate

MOF-199 = Cu(II) carboxylate based metal−organic framework

MTT = 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-2*H*-tetrazolium bromide
