Fast furfural formation from xylose using solid acid catalysts assisted by a microwave reactor

Gerardo Gómez Millán*[a,b], Zouhair El Assal[c], Kaarlo Nieminen[a], Sanna Hellsten[a], Jordi Llorca[b], Herbert Sixta*[a]

Abstract: The production of furfural (FUR) from xylose was carried out using sulfated zirconia (SZ) on cordierite, alumina on cordierite and commercially-available polymeric solid catalysts (Amberlyst DT and Nafion NR40) to provide insights into the reaction pathways and kinetics for the dehydration of xylose in aqueous phase. Experiments conducted at three temperatures were investigated (170, 190 and 210 °C) in a stirred microwave-assisted batch reactor, which established the optimal conditions to obtain the highest FUR yield as well as extensive and fast xylose conversion. The maximum FUR yields obtained from xylose were 41 mol% when using SZ on cordierite in 2 min (at 210 °C), 43 mol% when using alumina on cordierite in 30 min (at 210 °C) and 48 mol% for an auto-catalyzed system in 60 min (at 210 °C). Based on the experimental results, a reaction mechanism was proposed considering the formation of an intermediate from xylose when solid acid catalysts were added. After five reusability cycles using SZ on cordierite, this catalyst can be regenerated with a similar performance and similar FUR yield on the 6th cycle.

Keywords: alumina; Amberlyst DT; furfural; Nafion NR40; sulfated zirconia; xylose
1. Introduction

Furfural (furan-2-carbaldehyde, FUR) is the dehydration product of xylose and other pentoses, C_5-sugars typically found in hemicellulose in lignocellulosic biomass. A wide range of FUR derivatives with high potential for applications has been identified. FUR is considered a selective solvent for organic compounds and serves as a building block for its hydrogenation to furfuryl alcohol, for components of P-series fuels or liquid alkanes, and in the manufacture of foundry resins [1-3]. Tetrahydrofuran and tetrahydrofurfuryl alcohol are the other two main chemicals obtained from FUR that have wide applications in the chemical industry. The rest of the FUR is employed in oil refining, pharmaceutical, plastics and agrochemical industries (as fungicide and nematicide) [4]. Although xylan and xylose have not yet been fully utilized in the paper industry, a significant amount of xylose, from the hydrolysis of woody biomass, is mixed with lignin-derived compounds and burned to provide process heat [5]. Therefore, valorization of these compounds offers a new economic approach for new ideas and new markets.

The commercial process for the production of FUR involves several environmental issues, such as toxic effluents derived from mineral acids (sulfuric or phosphoric acid) at temperatures of approximately 200 °C and the consumption of high stripping-steam to FUR ratios, especially related to important energy and environmental concerns regarding the fuel employed to generate the steam. Homogeneous acids (in the form of dilute aqueous solutions) achieve a one-step hemicellulose deconstruction and xylose dehydration in the same reactor. However, the utilization of these corrosive homogeneous mineral acids leads to challenges in product separation, equipment corrosion, mineral acid loss, high amounts of acidic and toxic waste, as well as a significant amount of side reactions that limit FUR yields to ca. 50% [6]. New methodologies based on the use of easily-separable solid catalysts including zeolites [7-14], aluminosilicates supported with metals [15], modified silica [16-23], alumina [12], zirconia [12,24] solid acids like layered zeolite Nu-6 [25], sulfonated graphenes [26], heteropolyacids [27-29], coated activated carbon [30] and resins [20,31,32] to yield xylose dehydration are currently being explored to improve FUR yields in a much more environmentally friendly and efficient industrial process.
Previous published literature has described the high catalytic activity of metal oxides in the dehydration of xylose into FUR. However, the hydrothermal stability of these materials has not been properly addressed. Furthermore, the reaction times to reach the highest FUR yields usually require from two [12] up to twenty hours [21,23,27-29,33]. Dias et al [29] studied various sulfated zirconias in the formation of FUR from xylose in an aqueous-toluene system at 160 °C in 4 h. They are able to identify a correlation of the catalytic activity with the sulfur content of the sulfated zirconia. Nevertheless, a significant amount of sulfur leaching is observed in the reusability tests. Zhang et al [34] used a SO$_4^{2-}$/ZrO$_2$-TiO$_2$ catalyst in a sugar mixture employing an aqueous-n-butanol biphasic system. The maximum FUR yield (48 mol%) was reached at 170 °C in 2 h. Even though the authors performed a reusability test, two cycles might not be enough to observe hydrothermal stability of the catalyst. Li et al [24] employed a SO$_4^{2-}$/TiO$_2$-ZrO$_2$/La$^{3+}$ catalyst in a biphasic system to form FUR from xylose. The highest FUR yield reported (3563 μmol of FUR/g of xylose) was reached in 12 h at 180 °C. However, the article lacks hydrothermal stability studies and the reusability potential of the metal oxide catalyst.

The ongoing discussion of the proper reaction mechanisms of FUR formation has generated proposals for different formation pathways under homogeneous and heterogeneous catalysis. O’Neill and co-workers claim that xylose could be isomerized to lyxose via adsorption onto the acidic active sites of ZSM-5 zeolite [8]. These steps would occur through the formation of the linear open chain of xylose molecules caused by the acid-catalyzed hydrolysis. On the other hand, Verma et al [35] proposed a mechanism via the formation of 2,5-anhydroxylose furanose cyclic intermediate using a sulfonated graphitic carbon nitride. Xylulose, a xylose isomer, has been under discussion as possible intermediate on FUR formation [36,37]. However, there is no conclusive information on either pathway.

In this work, we aimed to employ solid acid catalysts for the dehydration of xylose to produce FUR in short times (<2 h). In addition, the kinetic model for this reaction was further investigated and a reaction mechanism is proposed for heterogeneously catalyzed systems. The hydrothermal stability of the solid catalysts is also addressed in the present paper. Due to their high acid site density [38,39], solid acid catalysts were developed (Al$_2$O$_3$ and ZrO$_2$(SO$_4^{2-}$) on cordierite) and compared to commercially available polymeric resins (Amberlyst DT and Nafion NR40). Their textural properties and acid site density were analyzed.
2. Materials and Methods

D-Xylose powder (99%, Sigma Aldrich) was used in the experiments without further purification. Formic acid (98%), levulinic acid (99%) and acetic acid (99%) were purchased from Sigma Aldrich and used for the preparation of calibration standards for HPLC analysis. Millipore grade water was used for preparing the solutions. Cordierite was obtained from Corning (Germany) and Disperal from Sasol Germany GmbH (Hamburg, Germany). Amberlyst DT was purchased from Rohm and Haas (France). Nafion NR40 beads were purchased from Ion Power GmbH (Germany).

2.1. Catalyst preparation

Pieces of cordierite (1-4 mm) were used as support. Sulfated zirconia (SZ, ZrO$_2$(SO$_4^{2-}$)) and Al$_2$O$_3$ were prepared by impregnation of ZrOCl$_2$·8H$_2$O and boehmite suspensions as precursors over cordierite following the method of Ledesma et al [40]. The notation for SZ over cordierite is SZ$_{cord}$ and for Al$_2$O$_3$ over cordierite is Al$_2$O$_3$$_{cord}$. The resulting samples were dried at 105 °C and then calcined in air for 2-5 h to obtain the corresponding active oxides (SZ$_{cord}$ at 500 °C; Al$_2$O$_3$$_{3cord}$ at 450 °C). Saez et al [38] found that cordierite presented no appreciable reactivity. The inclusion of cordierite in the catalyst preparation is to provide the catalyst a physical support for practical application. Reaction tests were conducted over Nafion NR40 and Amberlyst DT for the sake of comparison. Nafion NR40 was purified by treatment with hot hydrogen peroxide (5%) to remove organic impurities and soaked in 5 wt% hot hydrochloric acid to remove cations and exchange them by protons. It was dried overnight at 105 °C. Amberlyst DT was also dried overnight at 105 °C prior experimental tests.

2.2. Catalytic activity tests

Single component solution of D-xylose (186 mmol l$^{-1}$) were freshly prepared before the experiments. This specific xylose concentration was found to be in the prehydrolysate liquor from birch wood [41]. The first set of experiments was performed in the absence of solid acid catalysts. The second set of experiments was performed using 50 mg of Al$_2$O$_3$$_{3cord}$, SZ$_{cord}$, Amberlyst DT or Nafion NR40 as a catalyst. In a typical experiment, the glass reactor was loaded with 3 ml of the xylose solution and heated using a borosilicate glass reactor (V = 10 cm$^3$) with magnetic stirring (600 min$^{-1}$) and microwave-assisted heating (Monowave 300, Anton Paar GmbH, Graz, Austria). After the reaction, the reactor was rapidly cooled to room temperature by utilizing compressed air. The highest temperature and the
longest reaction time studied at the present work were 210 °C and 180 min, respectively. After reaction, the solutions were tested for FUR yield, selectivity and xylose conversion at the reaction temperatures of 170, 190 and 210 °C with different reaction times in the range of 2-180 min.

In a typical experiment with solid acid catalyst, the glass reactor was loaded with 3 ml of an aqueous solution of 28 g l⁻¹ xylose and 50 mg of the catalyst. The reactor was placed in the microwave, heated to the set reaction temperature with an irradiation power of ≤ 850 W for maximum 1.5 min and kept at the reaction temperature for the set time. After the reaction, the reactor was rapidly cooled to room temperature by utilizing compressed air. For the reusability experiments, SZcord was collected after each use. It was washed with deionized water several times at room temperature and dried at 105 °C prior to reuse. All catalytic activity tests were performed in duplicate with a standard deviation below 10% (except for Nafion NR40, which its standard deviation is up to 33%).

2.3. Reaction mechanism

The kinetic modeling of xylose dehydration and FUR formation were based on the obtained experimental results following three possible reaction mechanisms. These reaction mechanisms were screened in order to find the optimal kinetic model explaining the xylose dehydration and FUR formation. Even though the reaction mechanism of FUR formation has been under discussion, these reaction mechanisms consider a pathway of FUR formation via an intermediate or xylose itself, a reaction mechanism did not consider a pathway solely via an intermediate. Using the xylose conversion data only in the modeling resulted in multiple equally well-fitting models with different mechanistic assumptions. The tested reaction mechanism considering the intermediate formation from xylose is as follows:
In the reaction model presented in scheme 1, xylose can be converted to FUR directly ($k_1$). In scheme 2, FUR can be formed from xylose either stepwise with an intermediate product ($k_4+k_5$), or via a direct or pseudo-direct reaction pathway ($k_3$). In the reaction model presented in scheme 3, FUR is formed stepwise via an intermediate ($k_4+k_5$) [41] or via a direct or pseudo-direct reaction pathway ($k_3$). The latter scheme proposes a parallel reaction model from the intermediate. The produced FUR further forms degradation products (DP). DP 2 is formed in the auto-catalyzed reaction and DP 4 formation is promoted by solid acid catalysts. Simultaneously, some fraction of xylose and intermediates (isomers or epimers of xylose) form also degradation products (DP 1 and DP 3). The HPLC analysis did not identify any significant amount from products originating from side reactions between xylose and FUR, as well as the isomerization of the intermediate back to xylose.

Previous kinetic studies have used either scheme 1 [42] or 2 [41,43,44] using homogeneous catalysts. Different formation pathways include isomerization of xylose to other pentoses such as lyxose and xylulose. Dias et al [29]
proposed a similar reaction mechanism for sulfated zirconia as scheme 2 shown in the present study, however there was no kinetic studies reported on the pathway of FUR formation from the intermediate.

3. Results and Discussion

3.1. Auto-catalyzed dehydration of xylose

Kinetic studies for auto-catalyzed xylose dehydration were performed at various reaction times at temperatures of 170, 190 and 210 °C. Figure 1 shows the FUR yield, xylose conversion and selectivity to FUR under these reaction conditions. The experimental tests can be considered as auto-catalyzed, since water is self-ionized to H⁺ and OH⁻ ions that act as acid or base catalysts at the given temperature [45]. Later on, the carboxylic acids (formic, levulinic and acetic acid) or intermediates formed during the reaction, may have a catalytic effect [32,41,46]. The influence of the reaction temperature on the FUR yield and xylose conversion has been observed previously in similar work [37,47]. As Figure 1a displays, the FUR yield increased with reaction temperature up to 4 times from 170 to 190 °C after the first 60 min. When the reaction temperature was further increased from 190 to 210 °C, a 2-fold increase can be seen. It was observed that at the highest temperature investigated in the present study (210 °C) the FUR yield firstly increases and thereafter decreases, as the reaction time prolongs. The decrease of FUR yield in prolonged reaction time occurs due to decomposition and polymerization with humins production [48,49]. Under the present experimental conditions, the maximum FUR yield (48-49%) was reached after the first 60 min at 210 °C, which corresponds to a xylose conversion of 94% (Figure 1b) and a FUR selectivity of 52% (Figure 1c).

At reaction temperatures of 170 and 190 °C, no distinct FUR yield culmination point, with subsequent rapid decrease was perceived during the reaction time range investigated. However, a yield decrease similar to that observed at 210 °C could be possibly observed at lower reaction temperatures (170 and 190 °C) during prolonged reaction times. Nevertheless, the maximum yield unmistakably shifts to a longer reaction time with a decline of the reaction temperature. Furthermore, the FUR yield (and thus also the selectivity) decreases with decreasing the reaction temperature, this is in agreement with literature [50]. It is worth noting that the maximum selectivity to FUR observed in the auto-catalyzed conversion of xylose was 56-58% in the present studied range of reaction temperatures. These results agree with previously published papers [37].
**3.2. Catalyzed dehydration of xylose by solid acids**

Figures 2a, 2b and 2c show the FUR yield, xylose conversion and selectivity to FUR at various reaction times at 170, 190 and 210 °C when Al₂O₃cord is present in the dehydration of xylose. For SZcord-catalyzed conversion of xylose Figures 2d, 2e and 2f show the FUR yield, xylose conversion and selectivity to FUR, respectively. Similarly to the auto-catalyzed process, the FUR yield and the xylose conversion are visibly influenced by the reaction temperature. When using Al₂O₃cord, the maximum FUR yield is clearly influenced by the reaction temperature: at 170 °C starts
from 26%, it increases furthermore up to 43% at 210 °C (Figure 2a). This is similar to the effect observed when adding SZ$_{\text{cord}}$, the maximum FUR yield increases from 36 to 41% when the reaction temperature is increased from 170 °C to 210 °C (Figure 2d). After the maximum FUR yield has been reached, selectivity decreases because the FUR formed reacts further, via condensation and resinification [12]. Hence, humin formation was observed. These FUR yield losses were observed at reaction temperatures of 190 and 210 °C.

Similarly as in the auto-catalyzed process, conversion of xylose to FUR needs relatively high temperatures (Figure 2b and 2e). When using Al$_2$O$_3$$_{\text{cord}}$ in the dehydration reaction of xylose, the maximum FUR yield (43%, Figure 2a) was reached in 30 min at 210 °C, corresponding to a xylose conversion of 91% (Figure 2b) and a FUR selectivity of 48% (Figure 2c). The maximum FUR yield (41%) was reached after 2 min at 210 °C during the SZ$_{\text{cord}}$-catalyzed reaction, corresponding to a xylose conversion of 96% (Figure 2e) and a FUR selectivity of 43% (Figure 2f). During the SZ$_{\text{cord}}$-catalyzed reaction, the maximum selectivity to FUR was 43% (at 210 °C in 2 min) in contrast to 57% (at 210 °C in 30 min) obtained in the auto-catalyzed reaction system. When comparing the present results with the catalyzed system using H$_2$SO$_4$ [37] and a xylose concentration of 196 mmol l$^{-1}$, the highest selectivity to FUR is 68% (at 180 °C in 5 min) and 65% (at 200 °C in 1 min, and at 220 °C in 2 min).
Figure 2. FUR yield (a,d), xylose conversion (b,e) and selectivity to FUR (c,f) at various reaction times during conversion of xylose 186 mmol l\(^{-1}\) using Al\(_2\)O\(_{3}\)cord (a,b,c) and SZ\(_{cord}\) (d,e,f), respectively (purple square – 170 °C, blue circle – 190 °C, green triangle – 210 °C, lines are to guide the eye).

The FUR yield, xylose conversion and selectivity to FUR at various reaction times at 170 °C during conversion of xylose conducted with Amberlyst DT are shown in Figure S1. Amberlyst DT was only tested at 170 °C (maximum operational temperature) due to its limited hydrothermal stability as stated by the manufacturer. The maximum FUR yield (30%) was reached in 60 min at 170 °C with a xylose conversion of 70%.

The FUR yield, xylose conversion and selectivity to FUR at 170, 190 and 210 °C at various reaction times during xylose conversion conducted with Nafion NR40 are shown in Figure S2. In the same way that reaction temperature strongly influences FUR yield and xylose conversion in the auto-catalyzed process, the effect can be also observed
when adding Nafion NR40. When adding Nafion NR40 pellets to the aqueous system, the maximum FUR yield is determined by the reaction temperature: at 170 °C starts from 33%, furthermore it increases up to 41% at 210 °C. (Figure S2a). Due to the nature of the catalysts, the standard deviation increased at high reaction times and at high temperatures (>190 °C), even though the manufacturer guarantees its stability from 220 to 240 °C in aqueous systems. The catalysts clogged into each other making a barrier in the middle of the reactor. Therefore, the FUR and xylose concentration do not follow a smooth tendency. Nevertheless, xylose conversion behaves similarly to the auto-catalyzed system, since it requires longer reaction times to convert the same amount of xylose at a lower reaction temperature (Figure S2b). In the case of Nafion NR40, the maximum FUR yield (41%, Figure S2a) was reached in 8 min at 210 °C, resulting on a xylose conversion of 70% (Figure S2b) and a FUR selectivity of 60% (Figure S2c). During the Nafion NR40-catalyzed reaction, the maximum selectivity to FUR was 67% (at 210 °C in 2 min) in contrast to 43% (at 210 °C in 2 min) obtained in the SZcord-catalyzed reaction system, and 52% (at 210 °C in 60 min) in the auto-catalyzed reaction system.

Control experiments for cordierite were performed at 170 °C and 210 °C for 60 min. Xylose conversion, FUR yield and pH values can be considered comparable for systems in the presence of cordierite and in the auto-catalyzed system. In contrast, experiments employing 0.1 mol l⁻¹ H₂SO₄ were performed in earlier work [37]. These experiments show that the highest FUR yield (65%) is reached at 220 °C in 2 min. At 200 °C, the highest FUR yield (59%) is reached in 5 min. At 180 °C the highest FUR yield (55%) is reached in 25 min.

The xylulose formation, a possible key intermediate [36,51,52], was monitored by means of HPLC utilizing a pure xylulose solution as a reference. No detectable amounts of xylulose were observed in the initial xylose solutions. Under auto-catalyzed conditions at temperature reactions of 170-210 °C, xylulose formation was not detectable. This is in accordance with the low amount of xylulose yield (< 3 mol%) reported by Ershova et al [37] when employing a 196 mmol l⁻¹ xylose solution at reactions temperatures of 180, 200 and 220 °C.

Fig. S3a shows that the highest amount of xylulose (18 mol%) was formed when employing alumina as catalyst in the dehydration of xylose at 170 °C in 120 min. At this temperature, some amount of xylulose was still present even
after 3 h of treatment. When adding $SZ_{cord}$ (Fig. S3b), 46 mol% was the highest amount of xylulose formed at 170 °C in 6 min. When the reaction temperature increased to 190 °C, the amount of yielded xylulose decreased (27 %). At 210 °C, 2% of xylulose was yielded in 2 min. The extent of xylulose formation was highest at the lowest reaction temperature (170 °C) used in the present paper.

Xylulose was not identified at any experimental temperature employed in the present paper when polymeric resins (Amberlyst DT and Nafion NR40) were added into the system.

### 3.3. Mathematical modeling

Assuming a sequence of predominantly pseudo-first order reactions, the reactions of the model are assumed to follow the rate equations for similar elementary reactions. When the reactions are carried out in a batch reactor, the component mass balance for scheme 1 (assuming that the $k_3$ rate constant describes that the reaction consumes equal amount of moles of xylose and FUR) are: equations 7 and 8;

$$
\frac{d[Xylose]}{dt} = -(k_1 + k_2)[Xylose] - (k_4)[Xylose][FUR] \quad (7)
$$

$$
\frac{d[FUR]}{dt} = k_1[Xylose] - ((k_3)[FUR] + (k_4)[Xylose][FUR]) \quad (8)
$$

for scheme 2 the component mass balance are shown in equations 9, 10 and 11;

$$
\frac{d[Xylose]}{dt} = -(k_1 + k_2 + k_4)[Xylose] + k_{-4}[Intermediate] \quad (9)
$$

$$
\frac{d[Intermediate]}{dt} = k_4[Xylose] - (k_{-4} + k_5 + k_6)[Intermediate] \quad (10)
$$

$$
\frac{d[FUR]}{dt} = k_5[Intermediate] + k_1[Xylose] - k_3[FUR] \quad (11)
$$

For scheme 3 for the auto-catalyzed system equations 12 and 13 show the component mass balance:

$$
\frac{d[Xylose]}{dt} = -(k_1 + k_6)[Xylose] \quad (12)
$$

$$
\frac{d[FUR]}{dt} = k_1[Xylose] - k_3[FUR] \quad (13)
$$
And for the solid acid-catalyzed system equations 14, 15 and 16:

\[
\frac{d[\text{Xylose}]}{dt} = -(k_1 + k_2 + k_4)[\text{Xylose}] 
\]

(14)

\[
\frac{d[\text{Intermediate}]}{dt} = k_4[\text{Xylose}] - (k_5 + k_6)[\text{Intermediate}] 
\]

(15)

\[
\frac{d[\text{FUR}]}{dt} = k_1[\text{Xylose}] + k_5[\text{Intermediate}] - (k_3 + k_7)[\text{FUR}] 
\]

(16)

where \(k_1, k_2, k_3, k_4, k_5, k_6, k_7\) are rate constants and \([\text{Xylose}], [\text{Intermediate}], [\text{FUR}]\) are concentrations (in mol l\(^{-1}\)) for xylose, intermediate and FUR, respectively.

The fittings of the kinetic models of the experimental results with pure xylose solution and solid acid catalysts corresponding to scheme 3 are shown in figures 3-5. The fittings show that the chemical intermediate concentration is strongly influenced by the reaction temperature and the presence of the solid acid catalysts. As it can be seen in figures 4 and 5, the concentration of the intermediate decreases when the reaction temperature increases. In the case of the Al\(_2\)O\(_3\)cord (Figure 5), the concentration of the chemical intermediate reaches up to 32 mmol l\(^{-1}\) at 170 °C. When adding SZcord, this concentration increases up to 86 mmol l\(^{-1}\) (Figure 4) also at 170 °C.

It has been reported previously that SZcord possesses Brønsted acid (BA) sites, while Al\(_2\)O\(_3\)cord presents a combination of BA and Lewis acid (LA) sites. BA are linked to direct pentose dehydration into FUR, and LA tend to isomerize pentoses into chemical intermediates, such as xylulose [12,20,36,53-55]. However, the discussion on the co-existence of BA and LA sites on the surface of SZcord and how to properly measure it still continues [56-58]. Furthermore, the discussion on the relationship between LA and BA sites effect on the dehydration mechanism is largely unclear [59]. The extent of sulfation on the SZcord was low (Table 5), which might favor the presence of LA [56], thus promoting reaction pathways with chemical intermediates, such as xylulose. For both systems employing solid acid catalysts (SZcord and Al\(_2\)O\(_3\)cord), the highest concentration of xylulose is reached at the lowest temperature (170 °C). This is in agreement with previous studies [36,37], which highlighted that the reaction of xylulose to FUR is favored at low temperatures in the presence of LA over the reaction of xylose to FUR. In contrast, at high temperatures LA catalysts lose the pathway via xylulose, due to gradual transformation of LA into BA, which can be
seen in Figure 4 and 5 where xylulose disappears as temperature increases. Their presence also involves the formation of degradation products such as carboxylic acids (formic, acetic and levulinic acid). These compounds were identified but not quantified. The figures corresponding to the models following scheme 1 and scheme 2 are displayed on Figures S4-S11.

3.4. Model fitting

The Figures 3-5 show that Scheme 3 predicts xylose and FUR concentrations properly. The models fit all the xylose conversion experimental data as well as FUR formation. The main difference between the three models is that scheme 3 includes a parallel reaction when the solid acid catalyst is added, thus describing the formation of an intermediate (xylulose). The best fitting of the model to experimental data was obtained considering a parallel pathway via an intermediate compound leading to the formation of FUR when using solid acid catalysts (Scheme 3) and a direct formation of FUR from xylose in the auto-catalyzed system.

In order to be able to elucidate relative contributions of individual steps (Table 1), the pre-exponential factor and the activation energy values were evaluated by fitting the models to the data. The rate constants were then calculated from the pre-exponential factor and the activation energy according to the Arrhenius equation. When SZcord and Al₂O₃cord are added the temperature dependence of $k_i$ is more pronounced, indicating that the reaction rates in the presence of solid acid catalyst are subtler to the reaction temperature. Tables 1-3 display the obtained kinetic parameters and the activation energy for each reaction step.
As Table 1 reveals, the rate constants for the xylose dehydration into FUR ($k_2$) increase as the temperature increases in the auto-catalyzed system. Similar to this, the rate constants for the decomposition of xylose ($k_2$) and FUR ($k_3$) also increase as the reaction temperature increases. The addition of $SZ_{cord}$ and $Al_2O_{3cord}$ as solid acid catalysts adds a reaction for the xylose isomerization ($k_4$), its dehydration to FUR ($k_5$) and the further decomposition products from the chemical intermediate ($k_6$) and from FUR ($k_7$). This observation is supported by the fact that sugar isomerization reactions are catalyzed by the presence of LA sites [36,37,53,59,60]. The addition of $SZ_{cord}$ and $Al_2O_{3cord}$ increases the xylose decomposition ($k_2$). These results are in agreement with You et al [61], which confirms that LA sites are involved in the formation of humin from xylose dehydration. The rate constant for the decomposition of FUR ($k_3, k_7$) in the auto-catalyzed and catalyzed systems with $SZ_{cord}$ and $Al_2O_{3cord}$ are negligible. At the studied conditions when $SZ_{cord}$ and $Al_2O_{3cord}$ are added to the system, the formation of decomposition products is found to decrease in the order $k_6>k_2>k_7>k_3$. This could be due to the introduction of BA sites, which increase the decomposition rate of pentoses [38].

**Table 1.** Kinetic rate constants $k_i$ (min$^{-1}$) at each experimental temperature for auto-catalyzed and acid-catalyzed systems following Scheme 3.

This is in line with the activation energy values presented in Table 3. The ratio of the reaction rate $k_4/k_2$ indicates that the dehydration of xylose is faster than the formation of decomposition products (Table 2). At the same time, the high ratio of $k_4/k_3$ shows that the reaction to FUR from xylose is much faster than the decomposition of FUR. When adding SZ$_{cord}$, the low ratio values of $k_5/k_6$ indicate that the intermediate decomposes faster than FUR is formed from it. This could be due to the introduction of LA sites, which are known to promote humin formation and decomposition into C$_1$-C$_3$ products [36,61]. Nevertheless, in the case of Al$_2$O$_{3cord}$, the opposite is true except at high temperatures (210 °C). This could be explained by the presence of LA sites that at high temperatures are transformed into BA sites [10,57]. Furthermore, the ratio $k_4/k_4$ demonstrates that the addition of solid acid catalysts, which present LA sites isomerize xylose into other pentoses (xylulose) as other authors have previously reported [12,20,36,55,60,62]. Furthermore, when SZ$_{cord}$ is added to the reaction the ratio $k_3/k_7$ decreases as temperature increases. However, in the case of Al$_2$O$_{3cord}$, the rate of decomposition products forming from FUR in the auto-catalyzed system is faster than in the solid acid-catalyzed system. Nevertheless, $k_3$ and $k_7$ values are negligible as Table 1 shows.

**Table 2.** Ratio of selected kinetic rate constants at each experimental temperature for auto-catalyzed and solid acid-catalyzed systems following Scheme 3.

The frequency factors and activation energy values for each reaction step are shown in Table 3. For comparison reasons, some published data related to similar reaction steps are also shown in Table S1. To the authors’ knowledge, the frequency factors and activation energy values of xylose isomerization to the intermediate, to FUR and degradation products formation from the intermediate following scheme 3 have not been previously reported in literature for neither auto-catalyzed nor catalyzed reactions with solid acid catalysts present. In comparison to the auto-catalyzed system, when using SZ\textsubscript{cord} and Al\textsubscript{2}O\textsubscript{3cord} in the system the activation energy values increased. The activation energy calculated when employing SZ\textsubscript{cord} and Al\textsubscript{2}O\textsubscript{3cord} in the present study are higher than those published before the present study. These divergences between data could be possibly explained by either implementation of simplified reaction mechanism [2,53,63-66] or utilization of subcritical and supercritical reaction condition in earlier studies [67].

**Table 3.** Frequency factors (A\textsubscript{ref,i} min\textsuperscript{-1}) and activation energy values (E\textsubscript{ai}, kJ mol\textsuperscript{-1}) for the kinetic model proposed in scheme 3; auto-catalyzed system, SZ\textsubscript{cord} and Al\textsubscript{2}O\textsubscript{3cord}-catalyzed system.
Confidence intervals for the kinetic parameters in Table 3 are shown in Table S2 in the Supplementary Information. As expected, the ranges of the intervals are significant; the frequency factors vary with several orders of magnitude, which is in agreement with the exponential nature of the quantity. For reaction (7) it was not possible to calculate the confidence interval for the activation energy in the case of Al\textsubscript{2}O\textsubscript{3cord} due to the proximity of zero.

Reaction rate constants, frequency factors and activation energy values when using Nafion NR40 can be seen in Tables S3, S4 and S5. Frequency factors and activation energy values for the kinetic models (scheme 1 and 2); in the auto-catalyzed system and when using SZ\textsubscript{cord} and Al\textsubscript{2}O\textsubscript{3cord} can be seen in Table S7. Due to the absence of xylulose when the polymeric resins were employed, scheme S1 shows the model use to fit the experimental data when using the resins in the present system.
3.5. Catalyst characterization

Solid acid catalysts before and after hydrothermal reaction were characterized based on the highest FUR yield reached at the three selected temperatures (170, 190 and 210 °C). The notation for $SZ_{\text{cord}}$ and Al$_2$O$_3$$_{\text{cord}}$ after hydrothermal reaction at 170 °C includes a hyphen, e.g., $SZ_{\text{cord}}$-170 (where the highest FUR yield was reached).

3.5.1. Morphology of the solid acid catalysts

Fig. 6 shows, as an example, the scanning electron micrographs of Al$_2$O$_3$$_{\text{cord}}$-fresh and Al$_2$O$_3$$_{\text{cord}}$-210 catalyst samples. On the Al$_2$O$_3$$_{\text{cord}}$-fresh sample, Fig. 6(a), the alumina plates can be seen on the surface. Fig. 6(c) corresponds to Al$_2$O$_3$$_{\text{cord}}$-210 on cordierite sample (210 °C after 30 min). Fig. 6(b,d) correspond to Al$_2$O$_3$$_{\text{cord}}$-fresh and Al$_2$O$_3$$_{\text{cord}}$-210 on cordierite sample at a higher magnification. It can be seen on Fig. 6(c,d) humin formation on the surface of the metal oxide catalyst samples (see spheres marked with arrows).

![Figure 6. SEM images of (a,b) Al$_2$O$_3$$_{\text{cord}}$, (c,d) Al$_2$O$_3$$_{\text{cord}}$-210.](image)

$SZ_{\text{cord}}$ can be seen on Fig. 7(a,b), the SEM images show similitude of the $SZ_{\text{cord}}$ characteristically cylindrical-like structure as reported by Al-Hazmi and Apblett [68]. $SZ_{\text{cord}}$-210 on cordierite catalyst sample is shown on Fig. 7(c,d) after the hydrothermal reaction at 210 °C for 2 min. On the surface of the spent samples appeared spheres (marked by arrows in Fig. 7(c,d)), which are humins formed in the hydrothermal reaction.
Figure 7. SEM images of (a,b) $SZ_{\text{cord}}$, (c,d) $SZ_{\text{cord-210}}$.

SEM images of Nafion NR40$_{\text{fresh}}$ and Nafion NR40$_{\text{210}}$, Amberlyst DT$_{\text{fresh}}$ and Amberlyst DT$_{\text{170}}$, as well as $SZ_{\text{cord-170}}$, $SZ_{\text{cord-190}}$ and $SZ_{\text{cord-reused}}$ can be seen in Figures S12, S13 and S14, respectively. The structure of these spherical particles 2-3 $\mu$m in size agree with the findings of Van Zandvoort et al [48], who studied humin formation from acid-catalyzed dehydration of xylose under standard reaction conditions of 180 °C, 1 M solution of sugar and 0.01 M $\text{H}_2\text{SO}_4$. These insoluble polymeric structures are formed by aqueous acidic media of most lignocellulosic biomass valorization processes [2,59,69]. The formation of carbonaceous deposits is detrimental to the reaction as can be seen in Figures 1 and 2.

### 3.5.2. $\text{N}_2$-sorption

The BET (Brunauer-Emmett-Teller) specific surface areas and pore volumes obtained by the nitrogen physisorption are compiled in Table 4. Both polymeric resins (Amberlyst DT and Nafion NR40) show low BET specific surface area (0.2 m$^2$ g$^{-1}$), but $\text{Al}_2\text{O}_3_{\text{cord}}$ sample exhibits a higher surface area (11.8 m$^2$ g$^{-1}$). $SZ_{\text{cord}}$ sample also shows a low BET of 0.8 m$^2$ g$^{-1}$ (as reported by Casanovas et al [70] the $A_{\text{BET}}$ of the support (cordierite) is 0.1 m$^2$ g$^{-1}$). The pore width distributions shown in Figure S15 reveal a narrow pore width of approximately 45 Å in $\text{Al}_2\text{O}_3_{\text{cord}}$. These pores occupy a large part of the total pore volume in $\text{Al}_2\text{O}_3_{\text{cord}}$. There are three other broader pore widths at 115, 153 and 311 Å with high pore volumes. There can be seen two similar pore width distributions in $SZ_{\text{cord}}$ at 193 and 310 Å with high
pore volumes. The pore volume for both commercial polymeric resins is below $4 \times 10^{-5}$ cm$^3$ g$^{-1}$. The pore width distributions of Amberlyst DT reveal a broad pore width of approximately 604 Å. Nafion NR40 shows a small pore width at 513 Å.

**Table 4.** Textural properties of solid acid catalysts (i.e., BET ($A_{\text{BET}}$), Pore volume ($V_p$) and Pore diameter ($d_p$)).

<table>

</tbody>
</table>

As reported by other researchers [59,71], a large surface area is preferable to ease accessibility of xylose (for adsorption and further dehydration purposes). The effect of a higher $A_{\text{BET}}$, hence a higher amount of active sites available in the reaction to dehydrate xylose, in the case of $\text{Al}_2\text{O}_3\text{cord}$ could be observed in Figure 2 with a higher selectivity (48%) in comparison to $\text{SZ}_{\text{cord}}$ (43%). The pore widths of solid acid catalysts used in the present study are larger than optimal pore widths reported previously to provide accessibility for xylose and FUR molecules [71].

### 3.6. Catalyst stability

#### 3.6.1. NH$_3$-TPD

To obtain insight into the catalytic activity tendency, Table 5 shows the total density of acid sites determined by temperature-programmed desorption profile of NH$_3$ (NH$_3$-TPD). Even though there are continuing discussions about the acidity of SZ [72,73] and $\text{Al}_2\text{O}_3$, clearly, the acidity of $\text{Al}_2\text{O}_3\text{cord}$ ($137.2$ μmol of NH$_3$ g$^{-1}$) was much higher than that of $\text{SZ}_{\text{cord}}$ ($38.4$ μmol of NH$_3$ g$^{-1}$). This comparison agrees with that reported by Saez et al [38], which confirms that $\text{Al}_2\text{O}_3\text{cord}$ have higher total acid sites than $\text{SZ}_{\text{cord}}$. This is in contrast with the acid site density of SZ and $\text{Al}_2\text{O}_3$ reported by other researchers [2,12,74], the reported values could be due to the synthesis method employed.
After hydrothermal reaction at 210 °C in 30 min, $\text{Al}_2\text{O}_3$ cord lost more than half of its total acid sites ($41.9 \, \mu\text{mol} \, \text{of} \, \text{NH}_3 \, \text{g}^{-1}$), as well as $\text{SZ}_{\text{cord}}$ after hydrothermal reaction at 190 °C in 10 min ($27.8 \, \mu\text{mol} \, \text{of} \, \text{NH}_3 \, \text{g}^{-1}$). It is assumed that the loss of acid sites under experimental conditions is due to high pressure (>12 bar) and hydrothermal conditions in the reactor.

**Table 5.** Total acid site density of calcined catalysts determined by temperature-programmed desorption (TPD) of NH$_3$ from 100 °C to 600 °C.

</tbody>
</table>

The ion exchange capacities of the polymeric resins were verified by back-titration following the method reported by Goertzen et al [75]. Table S6 shows that Amberlyst DT (a macroreticular, sulfonic acid polymeric catalyst) has three times more acid sites (3.1 meq g$^{-1}$) than Nafion NR40 in bead form (1.0 meq g$^{-1}$). According to the manufacturer, Nafion NR40 in bead-form has an ion exchange capacity of 1.0 meq g$^{-1}$. Amberlyst DT (a macroreticular, sulfonic acid polymeric catalyst) has a concentration of acid sites of ≥3.1 meq g$^{-1}$.

3.6.2. XPS

Apart from the thorough microstructural analysis of the above samples, a detailed XPS analysis was performed to get a deeper insight about the surface composition of the materials. In Table 6 the binding energy values and surface atomic composition of metal oxides before and after hydrothermal reaction are shown.
Table 6. XPS data of $SZ_{\text{cord}}$ and $Al_2O_{3\text{cord}}$ on cordierite before and after the hydrothermal reaction at different temperatures.

</table>
The amount of sulphur at the surface in the sample SZ\textsubscript{fresh} is 15%, and the amount of sulphur in the samples SZ\textsubscript{170}, SZ\textsubscript{190} and SZ\textsubscript{210}, is 0.1, 0.7 and 0.7, respectively. For the sample SZ\textsubscript{reused} there was no measurable sulphur traces. It is inferred from Tables 5 and 6 that there is leaching of the acid sites of both Al\textsubscript{2}O\textsubscript{3cord} and SZ\textsubscript{cord}. This means that the acid sites found in the fresh sample have leached out into the aqueous solution under the reaction conditions presented in this paper. It is also shown that the atomic concentration of C is lower on the surface of the fresh sample (29%) than the atomic concentration of C on the spent samples SZ\textsubscript{cord-170} (76%), SZ\textsubscript{cord-190} (67%), SZ\textsubscript{cord-210} (61%) and SZ\textsubscript{cord-reused} (49%). This means that there is carbon deposition on the surface of the catalyst after hydrothermal reaction, in accordance to the humins imaged by SEM (Figures 7c and 7d).
The amount of aluminum at the surface in the sample Al$_2$O$_3$-fresh is 19.5%, and the amount of aluminum in the sample Al$_2$O$_3$-210 is 1.8%. This shows the leaching of the acid sites found in the fresh sample have also leached out from the catalyst into the aqueous solution. The sample of Al$_2$O$_3$-fresh contains a lower C amount (24%) than the sample Al$_2$O$_3$-210 after hydrothermal reaction (59%). This also evidences the formation of carbon deposits on the surface (Figures 6c and 6d) of the catalyst after hydrothermal reaction.

Table S7 shows the binding energy and the atomic concentration percentages of Nafion NR40 before and after hydrothermal reaction at 210 °C, and Amberlyst DT before and after hydrothermal reaction at 170 °C. Under those conditions, both catalysts suffer a sulphur loss. In addition, Amberlyst DT loses Cl and Nafion NR 40 loses F. Hence, leaching of acid sites under these conditions was seen from all solid acid catalysts tested.

Figures S16 and S17 show the X-ray photoelectron spectra of SZ$_{cord}$ and Al$_2$O$_3$-$_{3cord}$ respectively, before and after hydrothermal reactions at different temperatures. Figures S18 and S19 show the X-ray photoelectron spectra of Amberlyst DT and Nafion NR40, respectively, before and after hydrothermal treatment. Figures S20 and S21 show the TCD of SZ$_{cord}$ and Al$_2$O$_3$-$_{3cord}$ before and after hydrothermal reaction.

In the dehydration of xylose, the degradation of acid concentration, the leaching of S and the accumulation of by-products are the main factors that cause the deactivation of the catalyst. The results shown in Tables 5 and 6 from samples SZ$_{cord}$ and Al$_2$O$_3$-$_{3cord}$ before and after hydrothermal reaction correlate with the catalytic activity tests in Figure 1 and 2 and the models shown in Figures 3-5. Under the above-mentioned experimental conditions FUR, once it is formed, it decomposes as well as the xylose. The decomposition products evolve forming humins on the surface of the catalysts (Figure 6 and 7), which is obviously detrimental to the reaction.

Besides, the proposed kinetic model (Scheme 3) was applied also to a purely homogeneous catalyzed dehydration reaction (employing H$_2$SO$_4$) in order to exclude the effect of leaching acidic species on the reaction mechanism of SZ$_{cord}$ (this information can be found in the Supplementary Information). The proposed kinetic model simulates heterogeneous- and homogeneous-catalyzed systems very well (Figure S22 and S23, Table S1 and S2). Furthermore,
the acid content in the sulfuric acid-catalyzed reaction (Figure S24) was almost one order of magnitude higher, both xylose concentration and FUR formation can be simulated with the same kinetic model (Figure S4).

3.7. Reusability

The stability of the \( \text{SZ}_{\text{cord}} \) under reaction conditions was investigated by employing this catalyst in a series of xylose dehydration reactions. Prior to each cycle, the \( \text{SZ}_{\text{cord}} \) was washed with deionized water and dried at 105 °C. Figure 8 shows five consecutive reaction runs of \( \text{SZ}_{\text{cord}} \) at 190 °C in 9 min. After this, the catalyst was washed, dried at 105 °C, calcined and impregnated again with 1 M H\(_2\)SO\(_4\) (cycle 6).

After 5 cycles, the catalytic activity of the reused catalyst decreased from 38% to 7%, as well as the conversion of xylose (from 97% to 37%). At the same time, the activity of the catalyst can be recovered by calcination and a FUR yield of 39% is obtained again. These results are in accordance with the XPS results, since the catalytic activity of the reused catalysts decreased in each cycle without regeneration. This result indicates that the observed progressive catalyst deactivation might be related to the accumulation of insoluble organic matter, which could be blocking the surface of the catalyst, hence leading to disabled acid sites. The catalyst deactivation includes also leaching of the active sites (Table 6).
4. Conclusions

A kinetic model for the auto-catalyzed and solid acid-catalyzed decomposition of xylose using \( \text{SZ}_{\text{cord}} \), \( \text{Al}_2\text{O}_{3\text{cord}} \) on cordierite and Nafion NR40 at temperatures from 170 to 210 °C in aqueous phase was developed. Reaction rate constants for xylose and FUR decomposition were also determined in the temperature range of 170 to 210 °C. The major product of auto-catalyzed and solid acid-catalyzed xylose dehydration was FUR, the maximum mole fraction yield of which was 49% in 60 min at 210 °C. When using \( \text{SZ}_{\text{cord}} \), the fastest time to reach the maximum mole fraction yield (41%) was in 2 min (at 210 °C). When adding \( \text{Al}_2\text{O}_{3\text{cord}} \), the fastest time to reach the maximum mole fraction yield (43%) was in 30 min (at 210 °C). When adding Nafion NR40 and Amberlyst DT, the maximum mole fraction yield of FUR was 41% in 8 min at 210 °C and 30% in 60 min at 170 °C, respectively. Under the experimental conditions used, leaching of S, F, Cl was evidenced from \( \text{SZ}_{\text{cord}} \), Nafion NR40 and Amberlyst DT, respectively. Besides, the acid site density of spent samples shows lower values than those of fresh catalysts. It was also seen deposition of C on
the surface of samples after hydrothermal reaction, which means that humins were formed on the solid acid catalysts, affecting the solid acid catalysts’ performance.

There was no xylulose formation detected under auto-catalyzed conditions, xylulose was only formed when adding SZ$_{cord}$ and Al$_2$O$_{3cord}$. This could be due to the presence of Lewis acid sites contained in the solid acid catalysts.

Overall, hydrothermal stability should be further improved in future work, as well as their acid site density. In addition, it is crucial to avoid the decomposition of FUR once it is formed, either by a secondary process such as nitrogen-stripping or on-site extraction systems such as organic solvents included in a bi-phasic set-up.
