Abstract. The interest towards monitoring and guiding the development of healthcare information systems on a national level is increasing. In this paper, we report results from the three cross-sectional surveys on physicians’ experiences on usability of their electronic health record (EHR) systems in Finland. The research question was: How have physicians’ experiences on usability of their EHR systems evolved between 2010 and 2017? The data consists of responses to six usability statements from Finnish physicians working in public healthcare centres and hospitals. Among physicians working in healthcare centres, results between 2010 and 2017 show change for the worse. Among their colleagues in hospitals, results indicate slight improvement only in the domain of ease of use of the systems. In general, contrary to general expectations, the results do not show improvements between the years 2010, 2014 and 2017. In the future, we will continue the monitoring work in Finland on a national level from the viewpoint of physicians and other professional groups.

Keywords. usability, physician, satisfaction, electronic health record, survey

1. Introduction

For several years, usability of electronic health record (EHR) systems has remained a timely topic of research [e.g. 1-5]. Factors of EHR usage, such as technical problems associated with time pressure, separated statistical documentation and difficulties in reading of nursing record, affect physicians’ work well-being [2]. Recent surveys have found that physicians experience overall dissatisfaction with their EHRs [1,6]. In addition, literature calls for purposeful and thoughtful design of the systems in order to capitalize on the powerful potential of the EHR systems towards better patient care [7].

In Finnish public healthcare, EHR coverage reached 100% in 2010 [8,9]. Efforts to improve usability of the currently used EHR systems are considered important and are even mentioned in the national Information Strategy for Social and Health Care 2020 [10]. National surveys on e-health implementation and use, EHR usability as well as experienced benefits and challenges from the physicians and nurses viewpoints’ have been carried out to monitor and guide the development of healthcare information systems.
The first survey on physicians’ experiences on EHR usability in Finland was conducted in 2010 [12,13]. Next cross-sectional surveys were conducted in 2014 and 2017 [1,14]. In 2017, a similar study with nurses took place [15].

In this paper, we report results from the three cross-sectional surveys for physicians. The research question is: How have physicians' experiences on usability of their EHR systems evolved between 2010 and 2017? Six usability statements, which have been identical in all surveys, were selected for the analysis. The focus of the presented analysis is on public healthcare hospitals and healthcare centres. In 2016, there were 20,970 working-age (<65 years) physicians living in Finland; 70% were working in the public sector [16].

2. Related Research

EHR systems with good usability have been reported to decrease the number of errors, help to improve patient safety, support efficient work and thereby allow the clinicians more time with their patients [17]. Typical EHR usability problems related to interface design include violation of natural dialog, control consistency, effective use of language, effective information presentation, customization principles, lack of error prevention, minimization of cognitive load and feedback [18]. Designing EHR user interfaces is particularly challenging because of a wide range of complex information needs in different healthcare contexts, user requirements arising from over 50 physician specialties as well as needs and requirements from other user groups including nurses, pharmacists and therapists [19].

The number of usability studies is increasing. According to a recent review, the most frequent evaluation method is survey; many studies have a summative study objective and are performed late in the EHR system design cycle [20]. Follow-up or long-term monitoring studies on development of EHR systems’ usability, however, seem to be scarce [1]. Our earlier study on Finnish physicians’ experiences on EHR usability has shown, that between 2014 and 2010 the overall satisfaction [1] had not improved considerably. On a scale 1-7 the average of the ratings varied from 3.2 to 4.4.

3. Materials and Methods

In this study we utilized the usability-focused questionnaire designed in 2010 [12,13] to gather follow-up data and to find out to what extent the situation regarding usability from the physicians’ viewpoint has changed between years 2010 and 2017. The procedure of the study was similar in years 2010, 2014 and 2017: The data was gathered from February to March [14] and the invitation to the web-based survey was e-mailed to all working-age physicians in Finland. Table 1 describes the study population.

For the analyses, we selected the respondents from public hospitals and healthcare centres. User responses to the six usability related statements identical in all three surveys were selected for this study. The themes of the statements were related to (1) Technical quality - responsiveness of the system, errors in use and their reflections on patient safety (2) Ease-of-use - success of user interface design and system support for routine tasks and (3) Benefits (Table 2). The five-point Likert scale answers ‘Fully agree’ and ‘Somewhat agree’ were combined to form the category ‘Agree’. Similarly, the answers ‘Fully disagree’ and ‘Somewhat disagree’ were combined to form the category
‘Disagree’. The means were calculated from the 5-point Likert-scale answers. Analysis of variance (ANOVA) and Bonferroni’s post-hoc tests were used to compare results between 2010, 2014 and 2017. All statistical analyses were carried out with SPSS software version 22.0 (SPSS Inc., Armonk, NY).

*In 2014 and 2017 the sample (N) contains all members of the Finnish Medical Association with valid e-mail address (N). The register did not contain information on who is in clinical work. Though targeted to clinicians, the response was calculated from all physicians, including those not in clinical work.

**In 2010 the sample (N) contained those Finnish Medical Association members, who reported being in clinical work and who had a valid e-mail address. The response rate was calculated from physicians in clinical work.

4. Results

The results on physician’s experiences on usability of their EHR systems in years 2010, 2014 and 2017 are presented in three parts:

- Summary of ‘Agree’ responses to six usability statements from physicians working in healthcare centres (Figure 1)
- Summary of ‘Agree’ responses to six usability statements from physicians working in hospitals (Figure 2)
- Mean opinion scores on a scale from 1 (or ‘Fully disagree’) to 5 (or ‘Fully agree’) and comparison of the scores between healthcare centres and hospitals (Table 3).
Figure 1. Summary of ‘Agree’ responses to six usability statements from physicians working in healthcare centres: Changes between 2010, 2014 and 2017.

Figure 2. Summary of ‘Agree’ responses to six usability statements from physicians working in hospitals: Changes between 2010, 2014 and 2017.

Table 3. Comparison of physician’s mean opinion scores with scale from 1 (or ‘Fully disagree’) or 5 (or ‘Fully agree’) for six usability statements between healthcare centres and hospitals in 2010, 2014 and 2017.

5. Discussion and Conclusions

In this paper, we report Finnish physicians’ experiences with the usability of currently used EHR systems and changes in their perceptions between 2010 and 2017 based on their responses to six usability statements. Overall, the results indicate that the situation has not improved. Among physicians working in healthcare centres, the mean opinion scores for nearly all statements between 2010 and 2017 showed change for the worse. However, in the responses of physicians working in hospitals ease of use had slightly improved: usability of the use interfaces (Q3 and Q4) concerning the arrangement of the fields and functions on screen as well as terminology, and system support for routine tasks (Q5). In general, the results indicate that the physicians working both in hospitals and in healthcare centres experience that the systems inadequately support their everyday work: both the portion of agree responses and the given mean opinion scores can be considered as low. Contrary to general expectations, the results do not indicate improvements between the years 2010, 2014 and 2017.

Our results suggest that the implementation of National Health Information Services (Kanta) i.e. national centralized patient data repository and electronic prescription since 2014 has not yet met its goals: enhancing continuity of care, patient safety and health care productivity. The six measures on technical quality, ease of use and benefits show no improvement during the follow-up period - in fact, there has been a slight decrease in technical quality and ease-of-use. The Kanta-service integration with the EHR-systems has been a complex technical operation, generating new operating procedures and screens, and also impacted overall speed and benefits of use. Another explanation for the lack of improvements between the years of study may be the EHR system vendors constantly lagging behind in configuring and developing their systems to support the constantly increasing requirements of physicians’ daily work.

For the purposes of monitoring of the development of EHR systems and eHealth in a national level, survey is a suitable tool for gathering self-reported data from a large group of participants, benchmarking systems and pinpointing problems and successes. Other usability evaluation methods are needed for detailing usability problems and design improvements [21].

This article is part of a larger research project, which started in 2009 when we developed the first version of the national usability-focused questionnaire for physicians. The project has grown to cover nurses and has become part of eHealth strategy implementation in Finland [10]. Currently, we are developing a similar questionnaire for social care workers. The monitoring of development of healthcare IT systems in Finland from the viewpoint of different professional groups continues, as will international research collaboration to work towards comparable results between countries.
