Abstract: The goal of the review series on the H2 economy is to highlight the current status, major issues, and opportunities associated with H2 production, storage, transportation, distribution and usage in various energy sectors. In particular, Part I discussed the various H2 (grey and green) production methods including the futuristic ones such as photoelectrochemical for small, medium, and large-scale applications. Part II of the H2 economy review identifies the developments and challenges in the areas of H2 storage, transportation and distribution with national and international initiatives in the field, all of which suggest a pathway for establishing greener H2 society in the near future. Currently, various methods, comprising physical and chemical routes are being explored with a focus on improving the H2 storage density, capacity, and reducing the cost. H2 transportation methods by road, through pipelines, and via ocean are pursued actively in expanding the market for large scale applications around the world. As of now, compressed H2 and its transportation by road is the most realistic option for the transportation sector.

Senior Associate Editor
International Journal of H2 Energy
Purdue University
West Lafayette, IN 47907-2021, USA

Dear Prof. John,

We are pleased to submit a series of three Manuscripts on “Is the H₂ Economy realizable in the foreseeable future?” to the International Journal of H₂ Energy. Part I is on “H₂ production methods” is in Press now. In continuation of this series, we are submitting Part II (H₂ storage, Transportation and Distribution) and Part III (H₂ Usage Technologies, Application, and Challenges and Opportunities) will be submitted in due course.

This review in three Parts brings out the capability of H₂ for enabling an energy revolution through much-needed flexibility in renewable energy resources. The review identifies the developments and challenges within the H₂ generation, storage, transportation, distribution, and usage - as well as applications along with national and international initiatives in the field, all of which suggest a pathway for a greener H₂ society. The review also highlights the opportunities and challenges in major energy sectors for H₂ technologies. Part II of the series focuses on H₂ storage technologies along with various methods in transporting and distributing H₂ to the end users.

Best regards,

Professor A.M. Kannan

Highlights:

- H₂ storage in compressed form is the commercially viable technology at present.
- Critical cost factors in H₂ storage, transportation and distribution are provided.
- Logistic flow of H₂ from storage points to various mobility applications is presented.
- H₂ transportation by road, through pipeline and via ocean is reviewed for large-scale applications.
- Transportation of compressed H₂ by road is the most realistic option for the automotive sector.

1. Introduction

Large-scale energy generation from renewable resources will be required for a transition towards a net zero-carbon footprint society. H₂ is known to be a key component to enable the integration of large-scale renewables, and also to become a major energy carrier able to transport and distribute the energy throughout sectors and regions as well as acting as a buffer to improve the resilience of the energy systems. Part I of this series [1] is focused on H₂ production methods that will be available for massive and clean productions in the future energy scenario featuring H₂ as an energy vector in the residential, industrial, transportation, and commercial sectors [2]. For making the H₂ economy commercially viable, H₂ should be stored, transported, and distributed for power and/or heat generation on-demand for various applications [3]. A very recent publication highlights outlook on the future prospects and recent research on H₂-based Energy Storage through the H₂ Technology Collaboration Program of the International Energy Agency [4]. Various studies have been conducted on the integration of renewable energy systems with H₂ storage as well; to achieve the net-zero-emission energy systems [5,6] and sustainable development goal [7]. With the H₂ utilization technologies (fuel cells) becoming more affordable, energy storage in batteries can be replaced through electrolyzers/H₂ storage due to higher efficiency, reliability and performance. Hence, integration of the H₂ storage in the H₂ value chain along with renewable energy sources such as solar, and wind is the most promising approach [8]. Currently, the cost of the H₂ system is higher compared to battery system but the recent research activities on the H₂ value chain for various applications are expected to make them competitive by 2030 [5,9]. In Part II of the series, H₂ storage, transportation, and distribution are reviewed in detail with a major focus on the technological and commercial point of view towards the H₂
economy. In addition, the review provides the insight of intercontinental large scale H₂ transportation.

In fact, H₂ could be distributed by blending (up to 15%) it with natural gas and using the existing infrastructure, with required modifications to the online monitoring for ensuring safety. Higher H₂ concentrations will require retrofitting or replacement of the existing infrastructure. The economic feasibility of a progressive H₂ deployment will become clear only if large-scale H₂ production, distribution, and transportation are adopted for various applications [10]. In this context, it is very critical for the energy industries, local and federal agencies, educational institutions and non-profit H₂ advocates/organizations to work together in establishing a robust storage and distribution systems for the seamless transition towards the H₂ economy.
Figure 1. Schematic representation of the H\textsubscript{2} storage, transportation, distribution and delivery showing the scope of the Part II of the review.

The scope of Part II of the H\textsubscript{2} economy review series can be visualized through the schematic representation in Figure 1. Once H\textsubscript{2} is produced in either small or large scales, the industrial and transportation applications depend on the storage and transportation/distribution capability. H\textsubscript{2} can either be compressed or liquefied and stored for small and medium scale applications or transported through pipelines (or by truck or ship tankers) for large-scale applications.

2. H\textsubscript{2} Storage Methods

H\textsubscript{2} can be stored either in compressed (350 - 700 bar) or liquefied (-253 °C) or solid forms for enhancing the gravimetric density [11]. This section also discusses the advantages and specific
issues about the H₂ storage options, the constraints related to materials, the important technological gaps, and the priorities and recommendations for further development.

Figure 2. Classification of H₂ storage methods and materials.

As seen in Figure 2, H₂ storage methods can be broadly classified into two, such as physical storage and material storage. While the physical storage system is based on the principle of compression and liquefaction, the material storage systems are many and offer a variety of utilization modes based on the service conditions.

2.1 Physical Storage methods

Physical methods of H₂ storage are based on either compression or liquefaction or the combination of both.
2.1.1 Compressed

The most common and simple method of H\(_2\) storage is in its natural form. Worldwide, the prevalent refueling stations adopt the gaseous storage under high pressure, which finds application in stationary, vehicular and bulk transportation [12]. Storing H\(_2\) as high-pressure gas has the advantage of fast filling and high release rate, whereas the large space requirement and safety concerns are the main drawbacks of H\(_2\) storage in high-pressure tanks. The compressed form in carbon fiber composite pressure vessels at pressures ranging from 20 to 100 MPa is used when lightweight capacity is needed, and in metal pressure vessels if high capacity is required [13,14]. Underground H\(_2\) storage could also be a potential method and is discussed briefly in Section 3.1.

2.1.2 Liquefied and Cryo-compressed

Storing liquid H\(_2\) achieves higher energy density per unit volume than compressed storage but the energy consumption is higher for liquefaction. Also, loss of H\(_2\) due to the boil-off phenomenon in vehicular applications needs to be minimized by insulating the container without any reduction in both the gravimetric and volumetric energy densities [15]. Cryogenic vessels are generally used for storing and transporting H\(_2\) for medical as well as industrial applications. Liquefaction of H\(_2\) at -253 °C is energy-intensive (40 % of H\(_2\) energy) compared to compressed H\(_2\) systems (10-15 % of H\(_2\) energy) [16]. Storage at -253 °C is achieved by vacuum insulated inner pressure vessel with an external casing. Cryo-compressed storage offers a synergy of both compressed gaseous H\(_2\) and liquefied H\(_2\) storage systems. While compressed H\(_2\) is stored at near-ambient temperatures, "cold" and "cryogenic" compressed H\(_2\) storage is carried out at a low temperature for realizing higher H\(_2\) densities. With a lower boil-off loss in liquefied H\(_2\) storage, storage density 80 g L\(^{-1}\) can be attained [17]. The performance of liquid H\(_2\) in terms of weight, volume, and cost are 2.0 kWh·kg\(^{-1}\)
1, 1.6 kWh·L\(^{-1}\), and $6 respectively, while those of various other storage technologies are given in Table 1 [18–22].

#### 2.2. Material Based Storage

H\(_2\) storage through chemical systems is one of the ways in effectively meeting various transportation applications. However, there is no single chemical compound meeting all the required properties. The anticipated storage solutions require a breakthrough in material properties. This can be achieved by innovation in basic research which is essential for technological advancement. The challenges demand commercially viable, higher H\(_2\) storage capability, cyclic stability of the chemical systems that can be achieved by various smart nanoscale materials [23]. In order to increase the volumetric H\(_2\) storage, solid-state organic hydrides have huge potential through physisorption and chemisorption. Alloy or complex-type materials are also expected to demonstrate high H\(_2\) storage capability. Carbonaceous materials are applicable, as they possess large surface areas to adsorb H\(_2\), and their performance enhancement can be done by techniques such as Kubas interaction, spillover effect, functionalization, and with
alloying and incorporating additives [23]. Materials such as ammonia or methylcyclohexane containing multiple H atoms can also serve as potential H₂ storage carriers. In addition, social acceptance as well as safety will be inexorable for commercializing the H₂ economy [24,25] with concurrent development of H₂ carrier materials and large scale storage technologies.

2.2.1. Physisorption

Physisorption is the physical bonding of H₂ molecules on the surface of an adsorbent by the weak van der Waals forces (binding energy: 10 to 100 meV) [26]. Physisorption happens quickly at low operating temperatures and does not encompass any chemical reaction. Large surface area and porous materials such as activated carbon (AC), graphene, carbon nanotubes, C60 buckyballs, zeolites, and metal-organic frameworks are alternatives for physisorption.

Activated carbon is formed from carbonaceous source or biomass and it possesses an astonishingly large surface area (up to ~3000 m²g⁻¹) and a network of submicroscopic pores. Graphene is a monolayer containing sp² hybridized atoms of carbon with a thickness of ∼0.34 nm and covalently bonded to three other carbon atoms in a honeycomb framework. The unique structure of graphene offers excellent physicochemical properties such as high specific surface area, superior mechanical strength, unparalleled thermal and electronic conductivities, and remarkable optical properties [27–29]. Morse et al. reported H₂ storage capacity of 3.2 wt. % using hydrogenated graphene for demonstrating fuel cell operation [30]. Fullerene is the third allotropic form of carbon material after graphite and diamond. The most common fullerene molecule is C60, containing exactly 60 carbon atoms.

Zeolites are crystalline, porous aluminosilicates in which the primary building blocks are TO₄ tetrahedron, where T indicates Si⁴⁺ or Al³⁺ cation. If there is silicon in the tetrahedron framework,
the overall structure becomes electrically neutral. In the zeolite structure, \( \text{Al}^{3+} \) cations replace part of the \( \text{Si}^{4+} \), leading to positive charge deficiency \([31,32]\). The large surface area of zeolite enables the adsorption of gases, which is used in the case of \( \text{H}_2 \) storage.

Metal organic framework (MOF) is a family of synthetic porous materials with metal ions or clusters linked to various organic ligands, for forming 1, 2 or 3D structures. They possess exceptionally high surface area and porosity that make MOFs more promising than zeolites or carbon nanostructures. When guest molecules are removed by heating under vacuum during the solvent exchange process, the MOFs porous structure can be obtained without the framework destabilization \([33,34]\). As a result, the \( \text{H}_2 \) molecules could adsorb by physisorption on the pore surface. In general, pore size, surface area, ligand structure, catenation, etc. are the major factors in determining the \( \text{H}_2 \) uptake by MOFs.

2.2.2. Chemisorption

In chemisorption, the adsorbate or vapor molecules split into atoms or radicals to form a chemical bond by sharing electrons with the adsorption site. Unlike physisorption, chemisorption involves a much stronger interaction and is difficult to reverse (Examples: metal, complex, and chemical hydrides) \([35]\).

2.2.2.1. Chemical Hydrides

In chemical hydrides, compounds of \( \text{H}_2 \) and non-metals, the bonds are formed by electron pairs sharing by atoms with comparable electronegativity. In the volatile non-metal hydrides, van der Waals forces hold together in the condensed state (Examples: \( \text{B}_2\text{H}_6 \), \( \text{NH}_3\text{BH}_3 \), \( \text{NH}_3 \)) \([36]\). Chemical hydrides are gases or liquids with relatively lower freezing and boiling points. Boron forms an extensive series of covalent hydrides. Borohydrides or tetrahydroborates are ionic
compounds \((\text{M(BH}_4)_n)\) with \(\text{M}^{n+}\) metal cations and \(\text{BH}_4^-\) borohydride anions in a tetrahedral geometry. The borohydride ion is bound to the metal cation by bridging \(\text{H}_2\) atoms in three different ways, namely mono-, bi-, and tri-dentates with one, two, and three \(\text{H}_2\) bridges, respectively. Several metal hydrides such as magnesium hydride, magnesium nickel hydride, sodium aluminum hydride, and compounds such as borohydrates and alanates, are investigated for cyclic uptake and release of \(\text{H}_2\) [8]. Unfavorable thermodynamics and kinetic barrier of these metal hydrides needs to be further improved for their commercialization [37]. Polymeric materials and micro-glass globules are also attempted for the storage of \(\text{H}_2\) [38]. Alanates are complex metal hydrides \((\text{M(AlH}_4)_x)\) with \(\text{M}^{n+}\) metal cations (\(\text{Li}^+\), \(\text{Na}^+\), \(\text{K}^+\), \(\text{Mg}^{2+}\), and \(\text{Ca}^{2+}\)) and \(\text{AlH}_4^-\) anions, bonded ionically. Table 2 summarizes the demonstrations of materials-based \(\text{H}_2\) storage systems [39], along with the \(\text{H}_2\) amount (without the system weight).

2.2.2.2 Intermetallic Hydrides

H₂ can be chemisorbed on metals and intermetallic alloys with varying degrees of storage capacity. Alloys of the type A₂B, AB, AB₂, and AB₅ are promising candidates, where A and B are metals. In the metal hydrides (MH), the bonds (metals to hydrogen) are covalent but some hydrides are formed with ionic bonds. There are H₂ filling stations using MHs with low-pressure H₂ (absorption capacity: ~ 3 wt. %) [40]. The automotive industry is not trying for MH based systems and decided to proceed with high-pressure H₂ tank (70 MPa). However, the MH systems for vehicles can solve the issues such as safety, development of cost effective refueling infrastructure and other operational hurdles [41]. Table 3 provides H₂ storage capability (number of hydrogen atom per formula unit), equilibrium pressure, and enthalpy of formation for various metal hydride systems studies in the literature [12,42–48]. Among various systems, the La based AB₅ intermetallic compounds have the highest H₂ storage capability, offering safety and reliability for portable applications, in-house and in-board storage.

### 2.2.2.3. Complex Metal Hydrides

In complex metal hydrides, $	ext{M}^{n+}$ metal ion forms ionic bonding with molecular hydride anion and the hydrogen and the second metal or metalloid atoms $	ext{M}'$ are bonded covalently [49]. The complex metal hydrides (MₓM’yHₙ) have alkali or alkaline metal M (Ca, Na, K, etc) and M’ (Al, Li, Na, etc) is a metal in the hydride anions ((AlH₄)²⁻, (LiAlH₆)²⁻, (NaAlH₆)²⁻ etc). Several, binary or pseudo-binary intermetallic compounds based hydrides in H₂-storage containers have been studied for various applications including heat pumps, high-performance Ni-MH batteries, etc [50], with facile absorption/desorption characteristics. Among various intermetallic compounds, Ti-based systems operate effectively for H₂ storage under moderate conditions [51]. The H₂ absorption/desorption leads to interstitial hydride formation through the following reaction pathways. Initially, the H₂ molecule is adsorbed on the metal (or alloy) surface and gets dissociated to form two atoms. Then, the hydrogen atoms diffuse to the bulk to occupy the metal (or alloy) sub-lattice’s interstitial sites, leading to a 20-30 % expansion of the sub-lattice. A self-trap mechanism of hydrogen occupying the interstitial sites has been proposed, based on the elastic energy of the lattice and the enthalpy of hydride formation [52].

### 2.2.2.4. Multicomponent

Multicomponent H₂ storage systems are also known as reactive hydride composites consisting of more than one phase in the H₂ loaded state, which may be simple physical mixtures or a composite where one phase represents a host matrix. During dehydrogenation, both phases react
leading to often the dehydrogenated products consisting of more than one phase. The design of novel multicomponent mixtures for H\textsubscript{2} storage focuses on the mixtures of materials from two distinct classes such as reversible and irreversible. High capacity multicomponent hydrides consist of complex hydrides (borohydrides, alanates or amides), metal hydrides (LiBH\textsubscript{4}–MgH\textsubscript{2} or LiAlH\textsubscript{4}–LiNH\textsubscript{2}), and other chemical hydrides (LiNH\textsubscript{2}+NH\textsubscript{3}BH\textsubscript{3}) phases [53].

2.2.2.5. Liquid Organic

Liquid organic H\textsubscript{2} carriers (LOHC) are the unsaturated organic compounds (cycloalkanes, N-heterocyclanes, formic acid, etc) for storing a large amount of liquid H\textsubscript{2} indirectly. The LOHC research is limited to cycloalkanes (6-8 wt. % H\textsubscript{2}) [54], heterocyclic aromatic compounds or N-Heterocycles (N-Ethylcarbazole [55,56], dibenzyl toluene (6.2 wt. % H\textsubscript{2}) [57], etc,) with various compounds as a semantic candidates for storage and possessing a higher overall energy efficiency compared to chemical storage options [58,59]. Formic acid is also one of the most promising H\textsubscript{2} storage candidates with 4.4 wt. % H\textsubscript{2} capacity [60]. In general, the dehydrogenation of cycloalkanes (catalysts: Ni, Mo, and Pt; 300 to 400 °C) is extremely endothermic (63-69 kJ.mol\textsuperscript{-1}) compared to other LOHCs [44,45,46]. The gravimetric and volumetric H\textsubscript{2} storage densities are 6.1 wt. % H\textsubscript{2} and 43 kg H\textsubscript{2} per m\textsuperscript{3}, respectively. Replacing some of the carbon atoms of hydrocarbons by heteroatoms (N, O, etc) lead to improved reversibility and reduced the temperature requirement for dehydrogenation/hydrogenation [62]. Dodecahedron-N-ethyl carbazole has been reported to store a large amount of H\textsubscript{2} (5.8 wt. %) [63]. The catalysts based on Ru and Rh improve the hydrogenation selectivity to 97 % at 7 MPa and ~140 °C. Formic acid was reported to be the H\textsubscript{2} storage material in 2006 by Swiss researchers, generating CO free H\textsubscript{2} in a very wide pressure range (0.1-60 MPa) [64]. Formic acid stores 4.3 wt. % H\textsubscript{2} at ambient temperature and pressure, nevertheless various important parameters such as the toxicity are
limiting factors. Therefore, there is intense need for the development of environmentally benign, cost effective, easy to transport, convenient and reversible hydrogen storage systems. In this regard, Zou et al. reported ethylene glycol based LOHC system with a proven H\textsubscript{2} storage capability of 6.5 wt. % and further development is in progress considering various key practical aspects [65]. LOHC could be one of the suitable candidates for terrestrial transportation and aviation industry [66], since it is economically advantageous as the existing infrastructure can also be employed for its transportation and delivery [67]. Currently, the major research and development focuses on the development of organic systems, which can generate H\textsubscript{2} at relatively higher pressure at ambient temperature using less expensive catalysts with a reversibility of >97 %.

2.3. H\textsubscript{2} Storage Challenges

The US-DOE has established the targets for an on-board H\textsubscript{2} storage system in terms of gravimetric/volumetric capacity, material cost, operating temperature, desorption temperature, and reusability of H\textsubscript{2} storage medium for automotive applications and are shown in Table 4 [68]. A large variety of H\textsubscript{2} storage materials such as borohydrides, chemical hydrides, metal hydrides, complex hydrides, zeolites, MOFs, etc. have been investigated for their applicability and efficiency as potential H\textsubscript{2} storage materials. The ultimate aim is to develop a lightweight and compact H\textsubscript{2} storage medium for meeting the DOE targets.

The R&D gaps for H$_2$ storage (liquid, solid, and gaseous forms) with respect to the technological status, best options that have to be addressed are given in Table 6. Evidently, the energy required to store H$_2$ is a major challenge in all three modes (gas, liquid and solid), even though commercial systems are available for targeted applications.

3. H$_2$ Storage, Transportation and Distribution
H₂ production can take place in large and centralized plants from various energy resources [1]. However, transferring the H₂ from the production site to the delivery site is challenging, especially when the energy source is in a remote area. Further, H₂ production and user demand will vary with time. Therefore, the seasonal storage of H₂ in large quantities at production and the closest H₂ delivery sites will help to regulate the consumption and production processes.

**Figure 3.** H₂ storage and transportation – a logistic flow along with cost targets, for mobility applications [68].

In general, the H₂ supply chain includes three main stages: (i) production and bulk/seasonal storage at the production site, (ii) transport, and (iii) bulk storage/seasonal storage at the delivery
site and delivery to the end-user. Figure 3 provides the logistic flow of transportation by tank and tube trailers of liquid and compressed H$_2$ to the delivery sites [68,70]. The H$_2$ pressure handled at each stage is different and hence the supporting technologies such as gaseous compressors, pumps, and pressure-reduction stations are required in each stage. Since H$_2$ tends to cause embrittlement of metals (H$_2$-assisted fracture), especially at higher pressures, more attention needs to be paid to the materials' compatibility. H$_2$ has very low ignition energy of around 0.02 mJ to start the combustion reaction with 4-75 vol. % H$_2$ in the air and even lower in the oxygen. Due to a higher diffusion coefficient of H$_2$ in air, 0.61 cm$^2$/s (0.05 cm$^2$/s for gasoline and 0.16 cm$^2$/s for methane), proper safety measurements should be implemented in each stage of the H$_2$ supply chain for ensuring safety. Today, the industry is already handling H$_2$ for many purposes on a large-scale including refineries or ammonia production. However, when it comes to handling H$_2$ at a broader scale, important points to consider are how H$_2$ can be transported efficiently, on time and safely. In addition, optimization models are important for infrastructure development, using the H$_2$ supply and demand, and evolution of the H$_2$ supply chain network in the near term, midterm and long terms [71]. As H$_2$ distribution is new to the energy companies and existing infrastructure, it will be necessary for them to find good solutions for handling large quantities of H$_2$ in order to be competitive in the future energy market. Since the market transformation is one of the main challenges therefore, enormous interdisciplinary opportunities and jobs emerge on the horizon for the associated community towards realizing H$_2$ economy [72].

3.1 Seasonal storage at production and delivery sites

As discussed in earlier sections, H$_2$ could be stored in different states (gaseous, solid, liquid, and dissolved in the organic solvent). Among them, storing H$_2$ in a gaseous form is simplest in terms of infrastructure required and it is also the best-developed method at present [73]. The only
equipment required for gaseous H\textsubscript{2} storage is a compressor and a pressure vessel [74,75]. For smaller quantities, the H\textsubscript{2} gas is compressed (20 MPa) and stored in 50 L cylinders with end domes, similar to those used for any process gases [73]. The cylinders can be stored at environmental temperatures between -50 to 60 °C. Usually, the cylinders are made of steel which is cheap, and they can withstand H\textsubscript{2} pressures up to 200 bar, holding 0.9 kg of H\textsubscript{2}. This type of cylinder is useful in small scale applications where low amounts of H\textsubscript{2} are required. For storage of larger amounts, H\textsubscript{2} can be compressed at 165 bar and stored in spherical vessels with a capacity of about 2000 m\textsuperscript{3} holding 29700 kg of H\textsubscript{2}. This is equivalent to the electrical energy of 989 MWh (41 MW for 24 h) with an energy density of 33.33 kWh·kg\textsuperscript{-1} H\textsubscript{2}. The power required for a city with a population of 1M is 1500 MW for countries such as the Nordics, USA, and Australia.

Therefore, the equivalent need is around 37 spherical vessels of 2000 m\textsuperscript{3} capacity, whereas a storage vessel with the same capacity of 2000 m\textsuperscript{3} can hold up to 142000 kg H\textsubscript{2} in liquid form at -253 °C and 1.013 bar. This is 4.8 times more than for compressed H\textsubscript{2} gas at 165 bar. The largest liquid H\textsubscript{2} tank is spherical (diameter: 20 m; volume: 3800 m\textsuperscript{3}) for storing ~230000 kg, for space shuttle application in the USA [73]. This tank could provide electrical energy of around 319 MWh. A small percentage of stored liquid H\textsubscript{2} will be lost (2-3 % in smaller and ~0.2 % in larger and smaller containers per day, respectively) due to evaporation (boil-off) [73]. Furthermore, there is an increased risk of vessel failure since the materials become brittle at low temperatures. Besides challenges in maintaining the liquid vessels, it is also very costly to install, along with other concerns such as lack of technical manpower for commissioning and maintenance. Consequently, the energy price will be high and not suitable for commercial applications.
Another possibility to store H\textsubscript{2} in larger volumes at a reduced price is storing underground such as in salt caverns, aquifer, salt domes, and human-made cavities [76]. The optimal seasonal storage pressure in a cavern is generally 175-200 bar, whereas the capacity is in the range of million m\textsuperscript{3}. This is a much more efficient, low-cost, and flexible system than installing many small storage vessels. H\textsubscript{2} produced continuously from wind/solar energy can be stored underground in huge quantities. The stored H\textsubscript{2} can later be transported whenever there is demand in the market facilitating the demand and supply process continuously. This is safer than working in smaller batches where there is a risk of running out of H\textsubscript{2} in the storage. Caglayan et al. [77] estimated the potential of H\textsubscript{2} storage in salt caverns for Europe to be 84.8 PWh\textsubscript{H2}, with Germany having ~40%.

Pure H\textsubscript{2} gas has been stored in three caverns in Teesside, UK, since 1972 operated by Sabic Petroleum [78]. The volume of each cavern is about 70000 m\textsuperscript{3} at 24 bar. The possible working gas capacity is 0.83 million kg, which is equivalent to ~ 1.3 GWh. There are also two caverns for storing H\textsubscript{2} in the USA at Clemens and Moss bluff with volumes of 580000 and 566000 m\textsuperscript{3}, pressure 70-135 bar, and 55-152 bar operated by Conoco Phillips and Praxair, respectively [78]. These caverns can store 2.56 and 3.72 million kg H\textsubscript{2} with the energy equivalent of 3555 and 5166 MWh, respectively. This is enough for powering a city with one million people in the USA. However, storing H\textsubscript{2} underground is demographically limited, as it is difficult to find suitable underground storage places near utility sites.

### 3.2 Transport

H\textsubscript{2} can be transported in gas, liquid, or metal hydrides form via road, pipeline or ocean. Compressed H\textsubscript{2} gas can be transported from site to site in small quantities and short distances [79]. For long distances and a large amount of H\textsubscript{2}, using pipelines could be a better method.
Liquid H$_2$ can largely be transported over long distances via road or ocean, while Low-pressure H$_2$ stored in metal hydrides can only be transported in a small quantity over a short distance.

3.2.1 Road transport

3.2.1.1 Truck

Trailers that are customized to carry stacked long gas cylinders as shown in Figure 4a are called tube-trailers [70]. The storage pressure range for each cylinder is from 200 to 300 bar and is currently limited to a maximum 250 bar by the Department of Transportation, USA [80]. Trucks hauling these tube-trailers are currently used by industrial gas companies to transport compressed H$_2$ gas over short distances (200-300 km), and a trailer can carry from 2000-6200 m$^3$ H$_2$ [70].

Figure 4. (a) Compressed H$_2$ in Tube-Trailers, (b) Metal hydrides H$_2$ storage, (c) Liquid H$_2$ storage, (d and e) H$_2$ transportation via pipeline, and (f and g) LH$_2$ or LOHC transportation via ocean.
amount of H\textsubscript{2} carried is thus in the range of 180 - 540 kg, depending on the number of tubes. This represents 1-2 \% of the total mass of a truck of ~40 tons. Current trailers utilize Type 1 cylinders with ~1 wt. \% H\textsubscript{2} storage capability due to the heavier steel. Composite materials based vessels can store ~550 kg of H\textsubscript{2} at 250 bar, thus up to 720 kg of H\textsubscript{2} can be transported per trailer [80].

Metal hydrides based containers can be used for transporting H\textsubscript{2} by directly loading onto a truck or railcar (Figure 4b) to the customer/end-user sites, where it can be exchanged with the empty hydride containers [75,81,82]. The advantage of this transportation method is that the existing logistics infrastructure can be used where there is no need for using pressure for transportation and storage. Further, the hydrides require heat to release H\textsubscript{2}, and the chance of accidental H\textsubscript{2} release is therefore minor. Thus, H\textsubscript{2} stored in metal hydrides is less hazardous to transport compared to compressed H\textsubscript{2} or LH\textsubscript{2} transportation. However, the H\textsubscript{2} stored in this system has low gravimetric densities (1 to 7 wt. \%), and it will, therefore, be very expensive to transport.

As described above, the LOHC technology enables H\textsubscript{2} storage under ambient conditions and hence high pressure or highly-insulated tanks are not required [83]. In this context, the LOHC can use the currently existing transportation mode for fossil fuels such as road oil tankers, tank trucks, pipelines, rail trucks, tanker ships, etc [84]. However, the storage density of H\textsubscript{2} in LOHC is 6 - 8 wt. \%, therefore, the net storage capacity is still a major controlling factor. Furthermore, unlike a gasoline tanker, the LOHC trailer has to be returned to the chemical plants for catalytic hydrogenation [84].
3.2.1.2 Liquid H\textsubscript{2} tankers

Currently, trailers customized to carry a single long cylinder, otherwise called tankers (Figure 4c) are used to transport the LH\textsubscript{2}. The trucks hauling the tankers with LH\textsubscript{2} are referred to as cryogenic tanker trucks or liquid tanker trucks. Liquid tanker trucks operating at atmospheric pressure have volumetric capacities of about 50000 - 60000 L and can transport up to 4000 kg H\textsubscript{2} with a truck mass of \~40 tons, which represents \~10 wt. % of the total mass of the truck [70]. The particulars of road H\textsubscript{2} delivery are given in Table 7 [85] and shows that LH\textsubscript{2} tanker trucks can transport 10 times more H\textsubscript{2} in terms of weight capacity than the tube-trailers with compressed H\textsubscript{2}. This transport mode is thus more economical than transporting H\textsubscript{2} in gaseous form. H\textsubscript{2} storage capital costs and operating costs are given in Table 8 [85]. Transporting H\textsubscript{2} in liquid form requires a liquefaction plant; which is capital-intensive, in addition to the liquefaction process being costly. Furthermore, the liquefaction process, the transport time and the utilization time (end-use or delivery time) must be timely scheduled to avoid excessive H\textsubscript{2} boil-off. The H\textsubscript{2} evaporation rate depends on the container size/shape/insulation and time of storage and is typically of the order of 0.2 % per day for a 100 m\textsuperscript{3} container [70]. However, the H\textsubscript{2} boil-off may not be an issue if the storage time is not longer than a week or two.

Kawasaki has demonstrated the performance of LH₂ containers at various stages, and the first public road test took place in January 2005 in Amagasaki-Tokyo Public Road [87]. A container carrying approximately 6000 L of liquid H₂, only half of the container's capacity, was transported along a 600 km route from the H₂ liquefaction site in Amagasaki City, Hyogo Prefecture, to the H₂ fuelling station in Koto-ku, Tokyo. The amount of liquid H₂ lost due to evaporation was limited to only 0.7 % per day. Kawasaki is currently developing containers for LH₂ transportation with the ultimate goal of lighter weight, higher insulation efficiency, and lower cost.

3.2.2 Pipeline

Pipelines (Figure 4d-e) are the most effective ones for transporting and distributing gaseous H₂ in a large scale continuously (tens of thousands of m³ per hour). A number of commercial H₂ pipelines are currently used in refining and chemical industries with large amounts of H₂ requirements for chemical processing. The length of the pipelines ranges from less than a km to several hundreds of km [70]. Typical operating pressures are 10-30 bar with flow rates of 310-8900 kg/h [75,88,89]. The first H₂ pipeline reported to be in operation was opened in 1939 in Germany and was 210 km long, carrying 8900 kg/h of H₂ through a 250 mm pipeline operating at 20 bar [88]. The longest H₂ pipeline owned by Air Liquide is 250 miles, from France to Belgium [88]. The USA has a total of > 1500 miles of H₂ pipelines, mostly in the Gulf Coast and the Great Lakes areas [75,88,90].
The total H\textsubscript{2} network in the world is estimated at around 16000 km and mostly situated in the USA, Canada, and Europe. Overall, the H\textsubscript{2} pipeline lengths are tiny when compared to the worldwide natural gas transport pipeline system, which exceeds 2000000 km [70]. A way to expand the H\textsubscript{2} network would, therefore, be to employ the available natural gas pipeline network. Currently, there is a project called H21 for the conversion of UK gas networks to carry 100% H\textsubscript{2}. The gas distributor Northern Gas Network launched the H21 Leeds City Gate report in July 2016 and proposed that it is techno-economical to convert the natural gas network of Leeds, UK to carry 100% H\textsubscript{2}. Currently, 83% of domestic homes in Leeds use natural gas for heating and cooking. The design incorporates a 1025 MW H\textsubscript{2} production facility via steam methane reformers located at Teesside, a 700000 MWh inter-seasonal storage in salt caverns in the Humber region and around 4000 MWh intraday storage in salt caverns in Teesside [91]. The total cost proposed for Leeds including H\textsubscript{2} production and storage, all associated infrastructure and appliance conversions in the region is £ 2 billion [91]. Cerniauskas et al. [92] evaluated the reassignment option of natural gas pipeline network for H\textsubscript{2} delivery in Germany, which will reduce the H\textsubscript{2} delivery cost by 60%. The pipelines for natural gas are constructed of steel and can withstand a maximum of 30 bar for H\textsubscript{2}. However, it is not clear whether the components (gaskets, fittings, etc) used for natural gas pipelines can withstand H\textsubscript{2} diffusion [92,93].

3.2.3 Ocean transport

Renewable energy and fossil resources are limited in countries like Japan to produce H\textsubscript{2} in larger quantities. Instead, intercontinental transport of H\textsubscript{2} in liquid form can be performed using ships similar to the ones used for natural gas. In 2014, Kawasaki along with Iwatani and J-power initiated a project to establish a supply chain model for marine transportation of LH\textsubscript{2} (Figure 4f) [94]. The idea is to transport H\textsubscript{2} from Australia produced by gasification of brown coal using a
LH$_2$ tanker (Figure 5) with the specifications given in Table 9 [94,95]. The main challenge for this supply chain model is keeping the LH$_2$ below its boiling point of -253 °C. A double-shell tank was designed with a vacuum maintained in the space between the inner and outer shells. However, the conventional "suspension structure" to support the double-shell tank did not provide sufficient strength to withstand the pitching and rolling on the ocean. In addition, the heat insulation of the tank was initially too low. New tank support methods and materials satisfying both strength and heat conduction requirements have been proposed by the “CO$_2$ -free H$_2$ Energy Supply-chain Technology Research Association (HySTRA) in Japan and demonstrated that construction of a liquid H$_2$ tanker is technically feasible. Indeed, the world’s first liquid H$_2$ tanker was finished in 2019 in Japan [95].

Moss Maritime, a design and engineering services company, has developed a design for a liquefied H₂ tanker vessel along with Equinor (Wilhelmsen and DNV GL group) (Figure 4g) [96]. The LH₂ tanker vessel has ~9000 m³ storage capacity incorporating a cargo containment system for minimizing boil-off along with stringent safety gadgets, for merchant ships and ocean transport. This is an important milestone for ocean transport of LH₂.

Once the market for H₂ grows, the number of developments, demonstration projects and feasibility studies initiated by big energy companies will also increase. Along with specialized ships with appropriate tanks, port facilities should be planned and built, or the existing facilities and infrastructure should be modified for storing and handling LH₂. As an alternative, the ocean transport and supply chain by means of LOHC has also been proposed, where demonstration plants (50 Nm³/h H₂) have been operated by Chiyoda Corporation using toluene and methylcyclohexane. Once the trade-in H₂ is established for large scale operation, these ideas can be realized.
3.3 Distribution

The H\textsubscript{2} delivery sites will have different designs depending on how the H\textsubscript{2} is delivered (mode of transport and physical state of the H\textsubscript{2}), H\textsubscript{2} demand, where the station is located and the end-users [97]. For example, the design of H\textsubscript{2} refueling stations (HRS) for FCVs varies depending on the mode of H\textsubscript{2} delivery. If the delivery mode is gaseous H\textsubscript{2} by tube trailer or cylinder racks, the HRS involves components such as seasonal H\textsubscript{2} storage, intraday H\textsubscript{2} storage tanks (tube trailer/tank/cylinder racks), compressors, refrigerators, and dispensers as shown in Figure 6. In addition, the HRS has diverse operational parameters that will vary for each application. The refueling station pressure depends on the type of vehicle; cars refuel at 700 bar, while heavy-duty vehicles (buses and trucks) and light-duty vehicles (forklifts) refuel at 350 bar. Therefore, a compression unit will be part of the HRS site to increase the pressure from 200/300 to 450 and finally to 850 bar. H\textsubscript{2} from high-pressure tanks will then be delivered to 350 or 700 bar dispensers through refrigerator units to provide enough cooling. The dispensable capacity of today’s H\textsubscript{2} stations is typically just under 200 kg per day, which is sufficient to fill approximately 50 light-duty vehicles [98]. Such an amount of H\textsubscript{2} can be stored in a parked trailer or tank with a capacity of 2000 - 6000 m\textsuperscript{3}.

*Figure 6. The process of low pressure to high pressure H\textsubscript{2} dispenser.*
If the demand for H$_2$ increases, it is also possible to deliver H$_2$ by pipeline. The Torrance Shell H$_2$ station in California, USA is one of a few stations in the world connected to an existing underground H$_2$ pipeline [99,100]. Air Products operates the H$_2$ gas pipeline in Wilmington and Carson. The H$_2$ gas is cleaned by palladium purifiers before transferring to high-pressure H$_2$ storage tanks. Pipeline stations are expected to be economically attractive for delivery to residential use and industries.

If the delivery mode is liquid H$_2$ by tanker trucks, special safety measures should be given during the withdrawal of LH$_2$ from the tanker. This would require safety relief devices in a closed system, for eliminating the possibility of flammable atmosphere or an explosive liquid air and LH$_2$ mixture [101]. He gas can be used for purging as LH$_2$ can solidify if N$_2$ is used, causing plugging and possible rupture of the transfer line/storage container [101]. Today’s LH$_2$ stations typically have the ability to dispense around 350 kg/day which is equal to about 90 light-duty vehicles per day [98].

4. Conclusion

Part II of the series on H$_2$ economy review examined various H$_2$ storage and distribution methods available in the market and their choice from the perspective of economic viability and safety. Storage and distribution are key components in a future H$_2$ economy, once green H$_2$ production methods are well developed (covered in Part I of the review series). Both the energy density (volumetric and gravimetric) and operating cost for H$_2$ storage and transportation play a critical role in distribution to the end-users. In the current scenario, H$_2$ in compressed form and transportation by road is the most realistic option for the early-stage transportation sector. Once the number of end-users increase, both on the residential as well as industrial, centralized storage, and distribution methods such as underground storage and continuous supply through the pipeline
will take effect. For realizing the H2 economy, mathematical modeling for techno-commercial aspects, technological development of components and systems, advanced manufacturing, large scale adoption of demonstration projects, and energy management with cybersecurity need to be pursued in parallel. Usage and application of H2 based technologies will be reviewed in Part III of the H2 Economy review series in decarbonizing various markets.
