WELCOME

This book contains the contributions accepted for presentation at the 50th SEFI 2022 Annual Conference, which was held in Barcelona on 19-22 September 2022.

We are moving fast towards new scenarios in engineering education. Not only is technology strongly influencing education, human and social factors are also at the core of essential ways of shaping a new future for universities.

How can we shape the future of learning and teaching?

We can have a say, as we have comprehensive experience in all relevant elements that influence learning. We share our passion for education. We have the will to accompany teachers and new academics on the road to engineering education. We have all the SEFI Special Interest Groups working hard on key topics.

Let us share our vision for the future and the new scenarios that open up and bring together the transformative capacity of universities and teachers.

The focus of the proceedings also explore the new scenarios that European alliances of tech universities open up for the future of engineering education.

The organizers would like to thank all authors for submitting their contributions, as well as the supporting organizations for their help in making SEFI 2022 possible.

Furthermore, we are delighted to announce that in addition to ISBN, we will include a Digital Object Identifier (DOI) for each accepted paper at this year's conference. We hope that you appreciate this important step forward, we believe having a DOI is an excellent advantage for researchers

The UPC and its Institute of Education Sciences have just celebrated 50 years in teaching and education. The SEFI and the UPC are thankful for everyone's participation in this project.

Imma Ribas *(Vicerectora UPC)*

Santiago Silvestre *(Co-Chair SEFI Conference 2022)*

Ariadna Llorens *(co-Chair SEFI Conference amb Director of ICE UPC*

Universitat Politècnica de Catalunya- Barcelona Tech (UPC)

SEFI – EUROPEAN SOCIETY FOR ENGINEERING EDUCATION

SEFI is the largest network of higher engineering education institutions (HEIs) and educators in Europe. Created in 1973, SEFI is an international non-profit organisation aiming to support, promote and improve European higher engineering education, enhancing the status of both engineering education and engineering in society.

SEFI is an international forum composed of higher engineering education institutions, academic staff and teachers, students, related associations and companies present in 48 countries. Through its membership and network, SEFI reaches approximately 160.000 academics and 1.000.000 students. SEFI represents more than 4 decades of passion, dedication and high expertise in engineering education through actions undertaken according to its values: engagement and responsibility, respect of diversity and different cultures, institutional inclusiveness, multidisciplinary and openness, transparency, sustainability, creativity and professionalism.

SEFI formulates ideas and positions on engineering education issues, influences engineering education in Europe, acts as a link between its members and European and worldwide bodies, contributes to the recruitment of good students whilst always promoting an international dimension in engineering curricula.

Our activities: Annual scientific conferences, annual conventions for engineering deans, ad hoc seminars/workshops organised by our working groups and special committees, scientific publications (incl. the bi-monthly European Journal of Engineering Education), European projects under ERASMUS + and Horizon2020, position papers, European debates, cooperation with other major European and international bodies.

The cooperation with partner and sister engineering organisations in Europe and in the world is also one of our priorities.

TOWARDS A NEW FUTURE IN ENGINEERING,

NEW SCENARIOS THAT EUROPEAN ALLIANCES OF TECH UNIVERSITIES OPEN UP

We are moving fast towards new scenarios in engineering education. Not only is technology strongly influencing education, human and social factors are also at the core of essential ways of shaping a new future for universities.

How can we shape the future of learning and teaching?

We can have a say, as we have comprehensive experience in all relevant elements that influence learning. We share our passion for education. We have the will to accompany teachers and new academics on the road to engineering education. We have all the SEFI Special Interest Groups working hard on key topics.

Let us share our vision for the future and the new scenarios that open up and bring together the transformative capacity of universities and teachers.

The focus of the conference also explores the new scenarios that European alliances of tech universities open up for the future of engineering education.

The UPC and its Institute of Education Sciences have just celebrated 50 years in teaching and education. Therefore, at this 50th SEFI annual conference, the SEFI and the UPC are pleased to invite everyone to participate.

Theme of SEFI 2022

"Towards a new future in engineering education", new scenarios that European alliances of tech universities open up.

- Conference Tracks

1. Entrepreneurship Education.
2. Artificial Intelligence in Education.
3. Student Engagement. Building Communities and Coordination.
4. Industry and Companies liaison. Regional Involvement and Innovation.
5. Mentorship and Tutorship.
6. Fostering Engineering Education Research.
7. Sustainability. Sustainable Development Goals.
8. Ethics in Engineering Education. Social and Service Learning, Cooperation for Development.
9. Virtual and Remote Labs.
10. Navigating Open Learning Environments (Moodle and others).
11. Mathematics at the heart of Engineering.
12. Physics and Engineering Education.
13. Architecture Education.
14. Challenges of new European Universities (Joint Programmes, Flexible Study Pathways, Student Mobility, Metacampus, Co-teaching, Co-creation with students, ...).
15. Attractiveness of Engineering, Gender and Diversity.
16. Curriculum Development, Engineering Skills, Lifelong Learning. (Including skills and competences, transition to labour market, self-awareness, management of self, creativity and innovation, management competences, employability, competitiveness, professional development, career planning, principles and values).

Contributions on any other topic on Engineering Education are also welcome.

KEYNOTE SPEAKERS

Monday 19 September 2022

New scenarios that European alliances of tech universities open up

Lourdes Reig Puig

Vice-rector for International Policy

Universitat Politècnica de Catalunya (UPC), Spain

Lourdes Reig Puig has a degree in Biological Sciences from the Universitat Autònoma de Barcelona, a doctoral degree in Marine Sciences from the Universitat Politècnica de Catalunya and a master's degree in Scientific, Medical and Environmental Communication from the Universitat Pompeu Fabra. She has been an associate professor attached to the Department of Agri-Food Engineering and Biotechnology and affiliated with the Barcelona School of Agri-Food and Biosystems Engineering (EEABB) since 2003.As a researcher she is part of the Centre for Agrifood Economics and Development (CREDA-UPC-IRTA). Her research field is aquaculture, in which, as the technical director of an aquaculture facility for eight years, she focused on production before starting her activity at the UPC. She has spent mobility periods at the University of Washington (Seattle, USA) and the Lower Saxony Fish Health Control Centre (Hanover, Germany). She was a visiting professor at the University of California (Davis, USA) and the Technical University of Denmark (Copenhagen). She is the author or co-author of more than 30 publications in indexed and non-indexed journals and around 100 conference papers. She has participated in numerous national and European competitive research projects and technology transfer contracts. She is currently the director of the Maritime Network of Catalonia (BlueNetCat).In the area of management, she was the academic secretary (2005-2007), the assistant director of Promotion and International Relations (2008-2010) and the director (2011-2015) of the Barcelona School of Agricultural Engineering (ESAB, now EEABB). She coordinated the interuniversity master's degree in Aquaculture (2006-2010) and was the vice-rector for International Relations (2015-2017).

Wednesday 21 September 2022

Gender mainstreaming in Engineering Education

Alicia García-Holgado

Assistant Professor

Computer Science Department

University of Salamanca, Spain.

Alicia García-Holgado received the degree in Computer Sciences (2011), a M.Sc. in Intelligent Systems (2013) and a Ph.D. (Cum Laude) (2018) from the University of Salamanca, Spain. She is Assistant Professor at the Computer Science Department since September 2021 and member of the GRIAL Research Group of the University of Salamanca since 2009, where she currently leads the research line "Social Responsibility and Inclusion". She is a Researcher of International Impact at the Universidad Nacional San Agustín, Arequipa (Peru). She is also a member of the Women in Computing Committee of the Spanish Computing Scientific Society and sub-coordinator of the CLEI (Latin American Centre for Computer Science Studies) Community for Latin American women in computing. Her research is related to the development of technological ecosystems for knowledge and learning processes management in heterogeneous contexts, and the promotion of diversity and inclusion in STEM, with a particular focus on engineering and technology. She has participated as technological support and coordinator in a large number of regional, national and international research projects. She is currently part of the coordinating team in the W-STEM project, a capacity building project funding by the European Union (https://wstemproject.eu), and researcher in the CreaSTEAM project, both focused on creating inclusive spaces in education and reducing the gender gap in STEM.

The Future of Engineering Education in a Post-pandemic World

Arnold Pears

Professor and Department Head

Department of Learning in Engineering Sciences

KTH Royal Institute of Technology, Sweden

Arnold Pears BSc(Hons) 1986, PhD 1994, La Trobe University, Melbourne, Australia. Appointed to Professorial Chair, Department of Learning in Engineering Sciences, KTH Royal Institute of Technology, Stockholm, Sweden, 2018. Uppsala Served in the University Academic Senate, Programme Director for the IT Engineering programme, and served multiple terms as elected member of the educational advisory board of the Faculty of Technology and Natural Sciences. Currently supervises 4 PhD students and leads the KTH participation in projects funded by the EU and NordPlus. He coordinates KTH participation in 2 Swedish Reseach Council funded graduate schools. He has published more than 40 journal articles and more than 150 refereed conference papers. Citations: 1861, H-index: 19, Google Scholar 14/12/2020

COMMITTEES

INTERNATIONAL ORGANISING COMMITTEE (IOC)

- Imma Ribas (President of the Conference, UPC Vice-rector)
- Ariadna Llorens (Conference Co-Chair)
- Hannu-Matti Järvinen (SEFI President)
- Luis Manuel Sanchez Ruiz (SEFI Vice-president)
- Balázs Nagy (SEFI Continuous Conference Co-Chair, SEFI Vice-president)
- Klára Kövesi (SEFI Board of Directors member)
- Raffaella Manzini (SEFI Board of Directors member)
- Klara Ferdova (SEFI Communication Officer)
- Alexandra Schulz (representative of SEFI2021 Chair)
- Mike Murphy (SEFI2023 Conference Chair)
- Araceli Adam (LOC representative)

INTERNATIONAL SCIENTIFIC COMMITTEE (ISC)

- Santiago Silvestre (Universitat Politècnica de Catalunya · BarcelonaTech, Conference Chair)
- Balázs Nagy (Budapest University of Technology and Economics, SEFI Continuous Conference Co-Chair, SEFI Vice-president)
- Araceli Adam (LOC representative)

Academic representatives from hosting university and country (SEFI2022):

- Ariadna Llorens (Conference Co-Chair)
- Jesus Alcober
- Marc Alier
- Joana d'Arc Prat
- Ramon Bragós
- Antonio Hernández
- Marcel Macarulla
- Joan Moreno
- Antoni Pérez-Poch
- Belén Onecha
- Sebastian Tornil

Chairs of the SEFI Special Interest Groups (SIG):

- Juho Tiili (Tampere University of Applied Sciences, SEFI SIG – Physics)
- Deolinda Dias Rasteiro (Instituto Superior de Engenharia de Coimbra, SEFI SIG – Mathematics)
- Bente Norgaard (Aalborg University, SEFI SIG - Continuing Engineering Education and Lifelong Learning)
- Aniko Kalman (Budapest University of Technology and Economics, SEFI SIG – Continuing Engineering Education and Lifelong Learning)
- Inês Direito (University College London, SEFI SIG – Gender and Diversity)
- Calvin Rans (TUDelft, SEFI SIG – Open and Online Education)
- Jordi Segalas (Universitat Politècnica de Catalunya · BarcelonaTech, SEFI SIG – Sustainability)
- Katriina Schrey-Niemenmaa (Aalto University , SEFI SIG - Attractiveness)
- Kamel Hawwash (University of Birmingham, SEFI SIG – Engineering Skills)
- Neil Cooke (University of Birmingham, SEFI SIG - Engineering Skills)
- Roland Tormey (École Polytechnique Fédérale de Lausanne, SEFI SIG – Ethics)
- Manfred Hampe (Technische Universität Darmstadt, SEFI SIG – Ethics)
- Tinne De Laet (KULeuven, SEFI SIG – Engineering Education Research)
- Carlos Rioja del Rio (Universidad de Cádiz, SEFI SIG – Curriculum Development)
- Fredrik Georgsson (Umea University, SEFI SIG – Curriculum Development)
- Gareth Thomson (Aston University, SEFI SIG – Curriculum Development)
- Greet Langie (KULeuven, SEFI SIG – Capacity Building)

LOCAL ORGANISING COMMITTEE (LOC)

- Santiago Silvestre (Conference Chair)
- Ariadna Llorens (Conference Co-Chair)
- José Miguel Quiñones Ruiz (Project Manager)
- Araceli Adam (Liaison Officer)
- Eva Fernández (Administrative Officer)
- Ernests Zalitis (Student)
- Beatriz Rodríguez (CIMNE Congress Bureau)

Chemistry Engineering Department, Universitat Politècnica de Catalunya

Conference Key Areas: *Student Engagement*
Teaching methods
Keywords: *Flipped classroom; continuous assessment; leadership; self-study*

doi:10.5821/conference-9788412322262.1150

ABSTRACT

The beginning of a new Degree at UPC was the opportunity to design a Chemistry subject from the start. It was designed under the criteria of focusing the process on student learning, following the indications of the last meeting of the European Higher Education Area in Rome, November 2020.

The objective of the design was to comply with the regulatory requirements and incorporate the learning outcomes that were already defined in other engineering areas, as well as to facilitate the learning of students who had not studied chemistry in high school (between 20 and 30%).

To this end, videos have been created with embedded questions, tests, summary preparation criteria, various cooperative work methodologies, ... to which part of the subject's grade (10%) has been assigned in order to facilitate student commitment to weekly completion.

Each academic year (3 normal and one in confinement have been developed) an assessment has been made with the students, both of the methodology and the material. In all cases, they reflect that continuous work and immediate or very close feedback is one of the points that has helped them the most in their process. They have also commented (in each academic year) on possibilities for improvement in which they have been directly involved and have helped to bring it to completion.

The material is currently ready to be made public on the University website and accessible to all students.

1 INTRODUCTION

1.1 Preliminary and regulatory aspects

The design of a subject for a new degree, respecting the indicators set by the ministry, is a challenge for the team of professors and entails a prior extensive search, as well as a consensus on the contents.

The Engeneering and Economics Degree (EnEcD) was born as a fusion of an Engineering Degree (EnD) and an Economics Degree (EcD). The contents of the Official Gazette of the State of Spain (BOE in Spanish) are respected. Nevertheless, the 10.5 ECTS present in Chemistry EnD (divided into two courses) are encompassed by 6 ECTS (one course), respecting the competences.

The regulations only indicate Specific Competence (SC4): ability to understand and apply the principles of basic knowledge of general Chemistry, Organic and Inorganic Chemistry and their applications in Engineering. The Learning Outcomes (LO) are:

1. Able to predict physicochemical properties based on the composition and structure of a compound.
2. Able to correlate the physicochemical properties of pure substances or mixtures with the composition and molecular and electronic structure of the components.
3. Able to solve problems analytically or numerically.
4. Able to know the use of the material and the equipment found in a chemical laboratory.

Other contents:

1. Fundamental concepts of Chemistry. Structure of matter and chemical bond.
2. Basic relationships between the structure of organic and inorganic substances and their physical properties.
3. Reactivity of organic and inorganic substances. Engineering applications.
4. Chemical laboratory, laboratory material and security.
5. Basic chemical laboratory experiments.

In addition, the faculty of the subject incorporates general skills that are specified in aspects of methodology. For this reason, in both theorical and practical lessons as well as in exams take place discussions regarding possible solutions, aspects such as versatility, initiative, adaptation to new situations, creativity, critical reasoning, ability to communicate, understanding of statements, justification of reasoning, autonomous and critical reasoning, consolidation of habits of self-discipline, self-demand and rigor, identification of the key factors of a problem, proactive attitude, continuous improvement, among others.

With all of the above mentioned, the topics, contents and LO are decided. This information is collected in Table 1.

An important point to consider is the initial heterogeneity of the students. Since a percentage of them –between 20 and 40% – do not study Chemistry in high school, they do not understand the basic concepts upon arrival at university.

After discussing "the framework topics" –the learning objectives – the learning methodology and continuous assignments are chosen. The specific learning evidence supporting this choice can be found in the perspective of the "constructive alignment" of Biggs and Tang [1].

1.2 Reflections on the methodology of Chemistry

In the last 20 years the concept and planning of Flipped Classroom has gained popularity at all levels of education and in all areas of knowledge, from the humanistic to the technological, including Chemistry. What is important is not the name of the methodology used and following fixed rules, but to build a framework of active learning [3]. The design of a discipline through this methodology has been extensively studied, specifically regarding the benefits it brings to student learning. The effectiveness in improving student performance is no longer discussed, because it is evident with numerous studies that contrast it. It is worth highlighting an article by Reid, in Milwaukee, in which a global meta-analysis of student satisfaction on the flipped classroom is made, compared to traditional methodologies. They highlighted that flipped classroom had a weak-moderate positive effect on student satisfaction [4]. A recent experience (2019) with positive results in the teaching of Chemistry was carried out at the University of Sydney. They took advantage of the opportunity offered by the renewal of the curriculum to move part of the subject into the “inverted model”. Tutorials, videos and questionnaires were prepared so that students could work outside the classroom in the time not shared with the Lecturer. Moreover, guided work was planned, in pairs, in which the procedures were discussed and both the students and the Lecturer actively participated. The most remarkable aspects of this study are, on the one hand, the students' satisfaction with the learning resources and, on the other, the results, measured as final grades, which were statistically superior to those obtained in "more traditional" learning situations. The number of failures was similar or even lower [5].

Two studies analyzed the situation of an entire branch of Chemistry at country level. The first was held in Poland in 2009: It focused on Analytical Chemistry. However, it does not indicate or advise any type of methodology [6].

Table 1: Correlation between required legal content, learning outcomes and defined topics

BOE content	Designed content	Topic (Chemistry)	Learning Outcomes
CE4 - Ability to understand and apply the principles of basic knowledge of general Chemistry –Organic and Inorganic Chemistry– and their applications in engineering.			
Fundamental concepts of Chemistry. Structure of matter and chemical bond.	*Le Chatelier* 's principle Bond. Molecular structure Hybridization Chemical kinetics	Topic 2	Able to predict physicochemical properties based on the composition and structure of a compound. Able to correlate the physicochemical properties of pure substances or mixtures with the composition and molecular and electronic structure of the components. Able to solve problems analytically or numerically.
Basic relationships between the structure of organic and inorganic substances and their physical properties.	Hybridization. Link. Molecular structure Functional groups in Organic Chemistry and main reactions	Topic 2 Topic 3	Able to predict physicochemical properties based on the composition and structure of a compound. Able of correlate the physicochemical properties of pure substances or mixtures with the composition and molecular and electronic structure of the components.
Reactivity of organic and inorganic substances. Engineering applications.	Acid-base equilibrium Precipitation and complexation equilibria Oxidation-reduction equilibrium. Main reactions in Organic Chemistry	Topic 1 Topic 4 Topic 5 Topic 3	Able to solve problems analytically or numerically.
Chemical laboratory, laboratory material and security.	Specific laboratory sessions and self-study videos	Experimental practices	Able to solve problems analytically or numerically. Able to know the use of the material and the apparatus found in a chemical laboratory.
Basic chemical laboratory experiments.	Specific laboratory sessions and self-study videos	Experimental practices	Able to solve problems analytically or numerically. Able use the material and the apparatus found in a chemical laboratory.

The second, from 2017, was published collecting the difficulties of teaching Organic Chemistry in Russian universities. As a consequence of this meta-study, global recommendations were made to all universities, but more in line with the type of knowledge to be imparted than with methodologies [7] .

Fautch, from York College of Pennsylvania, wonders whether the flipped classroom is effective in small groups for teaching Organic Chemistry. He concludes that the students who worked with the flipped classroom felt "more comfortable" with Organic Chemistry and even became passionate about the subject, which leads him to conclude that the flipped classroom is an effective tool for teaching Organic Chemistry [8] .

In 2016, Eichler and Junelyn Peeples of the University of California-Riverside and of Claremont University Consortium, respectively [9] comment on the large proportion of Lectures in the areas of knowledge of Science, Technology, Engineering and Mathematics that continue to use the so-called master classes or expository classes, focused on what the Lectures does.

One aspect to be highlighted, due to the effort it can save teachers who want to use this methodology, is the use of videos from Khan Academia, which greatly simplifies teacher preparation. In addition, small guides and a support book are provided.

2 METHODOLOGY

2.1 Chemistry design for engineers

With all the background described, the faculty designs the subject, focusing on student learning and student autonomous work. Hence, there are two key aspects to be considered: (1) integrate the constructive alignment in the contents, methodologies and evaluation; (2) unite the three aspects from which Chemistry can be approached (macro, micro and symbolic) in the development of problems in the classroom and outside it. Figure 1 shows a global scheme of this development.

2.2 Contents

In the fifth iteration, which is the one presented here, Chemistry has been distributed in five topics. Three of them are associated with the first semester and two of them with the second semester of the previous grade.

The topics are the following ones:

Theme 1. Acid-base equilibrium (5 sessions + 1 continuous evaluation).

Theme 2. Descriptive Chemistry (4 sessions):

Bond. Molecular structure. Hybridization. Chemical kinetics. Le Chatelier 's principle.

Theme 3. Introduction to Organic Chemistry. Basic organic reactions (4 sessions and mid-term exam).

Theme 4. Precipitation and Complexation Equilibrium. Heterogeneous systems (5 sessions).

Theme 5. Oxidation-reduction equilibrium (5 sessions + 1 continuous assignment).

Presentation by teams: 1 session ; and Lab Practices: 2 sessions

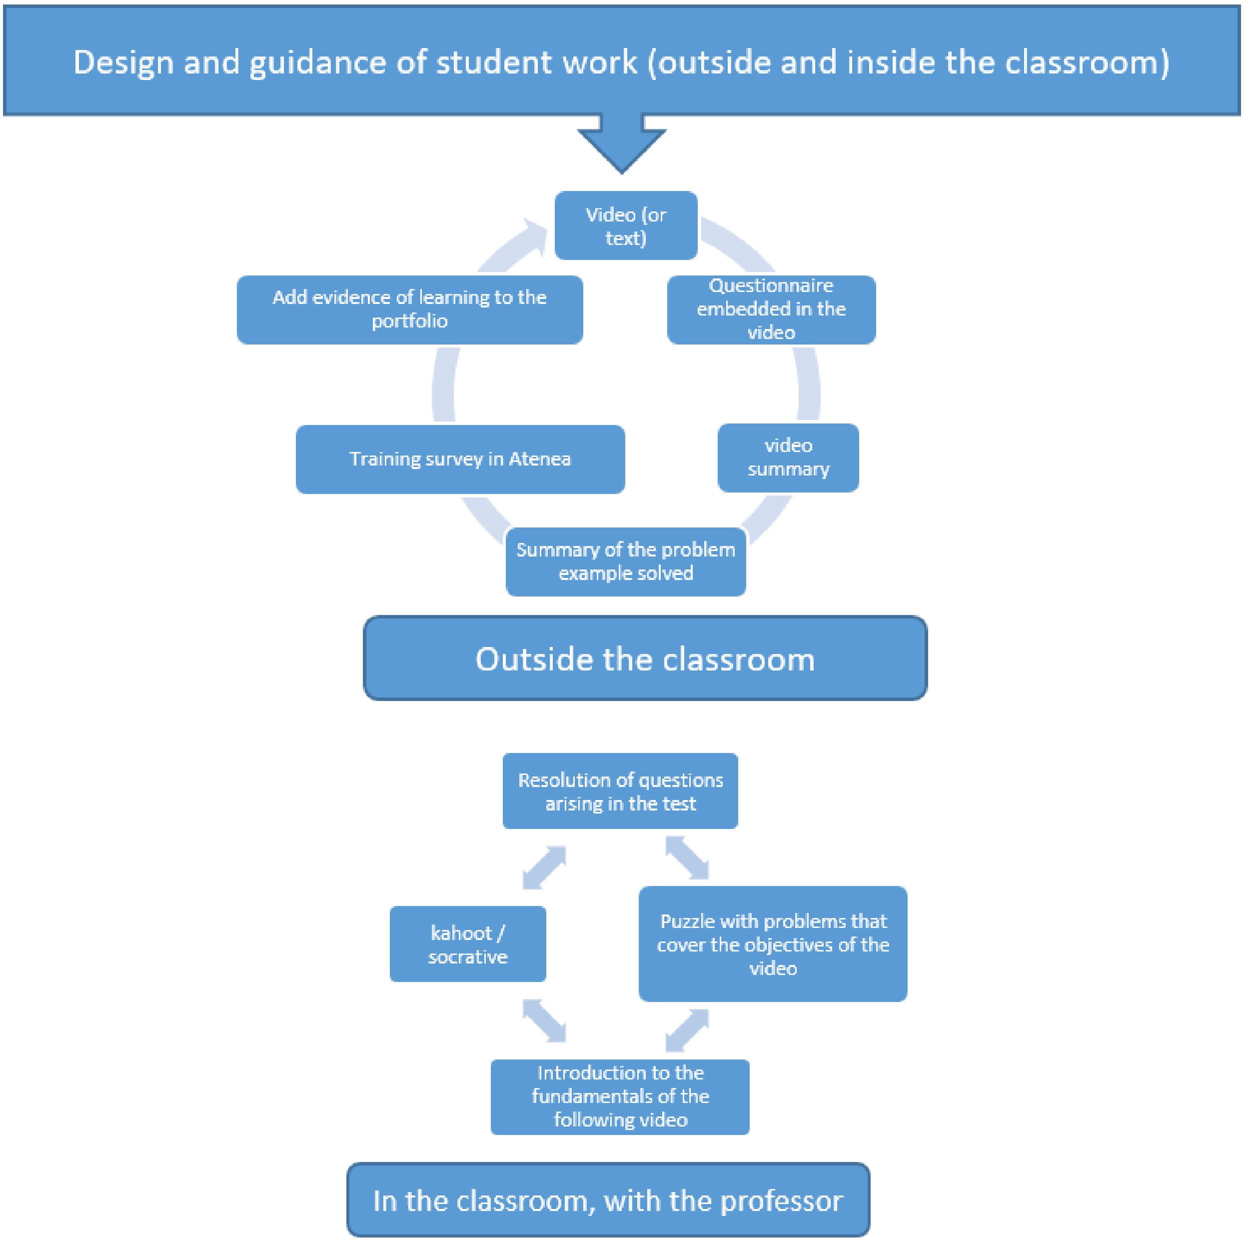

Fig. 1. Global scheme of planning inside and outside the classroom

The global evaluation is based on Eq.1:

10%CA1 + 10%CA2 + 25%mid-term exam + 10%(Portfolio+tests+lab practices) + 35%final exam (Eq.1)

being CA: continuous assignment.

The portfolio must be done weekly; the weekly deliveries must be reflected, especially summaries, exercises done in groups, the reasoning, the evidence of learning...

For this reason, it has been decided to evaluate the portfolio as a continuous work of the course, which will be posted on Moodle platform and can be consulted at any time, especially useful for those students who struggle with exams. As the tests are "self-corrected", the professor’s time is optimized and so it can be spend teaching.

With the idea of bringing together the three aspects from which Chemistry can be analyzed (macro, micro and symbolic) the statements of some problems have been changed. For example, transforming a typical pH calculation problem in a buffer solution with certain data into a laboratory video in which the same data is explicit in the footage, with a final question mark on the pH meter screen.

3 RESULTS

3.1 General comments

Figure 2 represents the evolution of grades throughout these 4 academic years. No student failed the subject during the first year, with 1 during the second year and 5 in both the third and the fourth. Nevertheless, the most remarkable feature is the increase in good grades as the methodology of the subject improves due to the enhancement of the aspects collected in the surveys with the students.

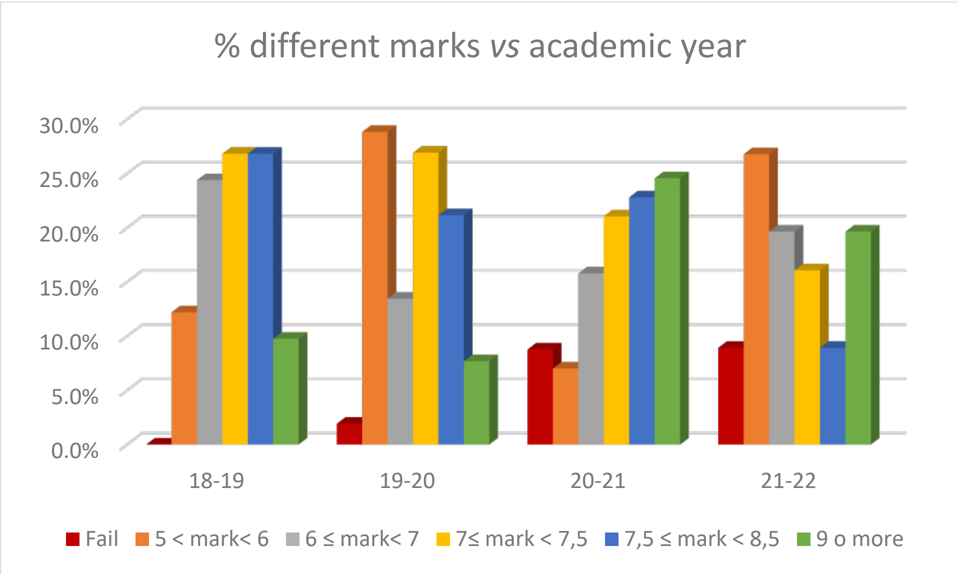

Fig. 2. Grade distribution (number of students vs intervals) in each academic year

The EnEcD entry mark requirement was 12.102/14 (18-19), 12.024/14 (19-20), 12.516/14 (20-21), 12.548/14 (21-22). These data indicate that it is a degree highly requested by students, which implies that only the best among those who have applied for it can enter. This allows for a high level of rigorousness that, for the most part, the students can keep up with. The decrease in the entry mark requirement from the first to the second year is due to an increase in the number of places.

In general, the marks obtained by the students are slightly higher (with non-significant differences except for the last academic year) than those obtained in the rest of the subjects. Nevertheless, learning satisfaction (manifested in the different surveys that have been given to the students) and the class attendance is much higher.

3.2 Course 18-19

It is perceived that after the half-term exam there is a general discouragement, not focused on Chemistry but on EnEcD. One of the advantages that active methodologies bring is continuous teacher-student contact, which allows for conversations that facilitate understanding of student behavior from a more anthropological perspective. For this reason, the possibility of personalized teacher-student tutoring is proposed to improve performance. 74% of students make use of academic tutoring.

An anonymous survey was carried out to the students, and the possible improvements for the following course were obtained:

a. Improvement and standardization of the documentation given to students.

b. Homogeneous weekly structuring, without work delivery between classes with only one day in between.

c. Elimination of deliveries of solved problems prior to joint work with the teacher.

d. As a strong point of the first definition of the subject, the students are able to work in group, which they value positively and consider that it helped them to get into the degree itself and to resolve their doubts.

e. Another positive aspect are class presentations made by students, carefully prepared by them and that allow to teach theoretical aspects in a more attractive and dynamic way.

Administrative questions via email student-professors are constant. It is decided to create a document with Frequently Asked Questions (FAQ) that will be explained on the first day and will be posted on Moodle Platform.

3.3 Course 19-20

As in the previous course, an anonymous survey was passed through Google Forms in which students had to reflect on the aspects that had helped them in learning and those that they believed could help them if present. One of the most valued aspects was the introduction of laboratory practices, and, again, group work. They value doubt-resolution classes very positively (73%) and they think that it played a role as far as passing the exam is concerned. Nevertheless, they still claim to better plan work outside the classroom (57% of students).

3.4 Course 20-21

Laboratory practices are expanded and re-planned so volunteer students (with good performance and previous laboratory experience in high school) act as mentors. This is the year of lockdown, so it had a different structure (which is not the subject of this paper). Most of the classes were online, with the exception of laboratory practices, which were obviously face-to-face. It should be noted that attendance at online classes (mostly problem solving and doubts) was between 70% and 95% (far superior to the rest of the subjects in which the percentage of connected students did not exceed 40%).

The rest of the planned asynchronous activities are maintained: (1) viewing of videos to which embedded questions have been incorporated; (2) weekly tests. The first two exams (first continuous assignment and half-term exam) were carried out online. To avoid student cheating in the exam, the time frames are adjusted downwards and random problems are generated. The next two exams were done face-to-face.

The average mark is 7.3, almost one point higher than the previous year, even though the data of the entry students were very similar. These results, which are slightly higher from those obtained in previous courses, are attributed to the fact that exams were carried out online and also to the fact that there was an increase in motivation compared to other subjects that entail greater dedication, both due to the interaction in the laboratory practices such as continuous feed back with students.

3.5 Course 21-22

The survey of the previous course reflects that the improvements introduced have been successful. For this reason, the improvements introduced focus on the aspects that the team of teachers perceive as improvable, since the students value the methodology and continuous evaluation very positively.

The subjective perception was that, in general, the subject was difficult to keep up with. However, the objective data, the grades, show that they are quite consistent with those obtained in pre-pandemic academic courses.

Class attendance was one of the poorest in this subject, around 70%. Nevertheless, it is a good result compared to the rest of subjects (it does not reach 40%). Often, those who miss classes the most present a higher level of disengagement and with the worst grades, so it is difficult to influence their learning process.

It is important to notice that all the improvements were developed with the students' help.

4 SUMMARY AND ACKNOWLEDGMENTS

This paper is not conceived as a final product, but as a step that reflects the planning and monitoring intended to be continued in the subject. The design of a subject must be dynamic and adapted to upcoming situations.
Highlights:
1. The content that students work on when they are not synchronous with the Lecturer must be fully designed. This content incorporates individual and group activities. Specifically, twelve videos have been prepared and many other ones have been selected (many of them from Khan Academia). In addition, documents, self-study tests and templates for weekly summaries have been written.
2. Self-assessment and continuous assessment have been integrated into the design of the subject, increased the number of tests taken in previous years and incorporating videos and new learning material instead of traditional learning.
3. Initial lessons of key concepts of chemistry taught in high school have been planned, to give response to the need of basic knowledge for those students who have never studied chemistry before. This is crucial for students to be able to keep up with the subject optimally.
4. Perhaps, the most important conclusion is that the implementation of a subject by Flipped Classroom requires much more effort and hours of work on the part of the

faculty than the definition of a subject focused on the explanations of the professor, and it is difficult to do in less than four years.
5. A qualification of the subject has been foreseen that counts the continuous effort collected in the electronic portfolio, as well as two continuous assignments (of a conceptual nature and similar to the self-study tests), a half-term exam and a final one that will have to show the mastery of macromolecular and symbolic chemistry and the ability to resolve everyday life situations.
6. The methodology has been used almost equally during the quarantine and results were similar. Nonetheless, the number of exceeding students rose slightly compared to previous years.
This document focuses on the design of a chemistry subject, in which the learning outcomes have been chosen and, based on them, all the necessary material has been designed using the flipped classroom methodology. The entire methodology is applicable to any subject, both newly designed and those that want to be redesigned.

The authors want to thank Alicia Izquierdo David Buesa for their help in proofreading the document.

ABSTRACT

For several years, engineering students from the Escola Politècnica Superior d'Enginyeria de Manresa have been participating in development cooperation projects as activities of the non-governmental Organization Mining for Development, with the support of the Center for Development Cooperation of the UPC. Activities were carried out in several mining sites in South American countries, mainly in Bolivia and Peru. Although the motivation for the students may have been initially a desire for adventure and volunteering, the experience turned into meaningful learning, as intended by the faculty leading the project.

This paper presents the findings of a study carried out to analyze how these experiences contributed to the learning of engineering students, within the framework of what is known as service learning. The study is based on the reports written by the students at the end of the experience and interviews conducted afterward when the experience had been fully internalized.

The characteristic elements of service learning have been identified. In addition, the analysis revealed how the experiences had a significant impact on subsequent learning, even beyond the initially intended objectives.

1 INTRODUCTION

Engineering is naturally associated with the solution of society's problems, so it can be seen naturally as a profession at the service of society in multiple fields: structures, industries, electronics, robotics, telecommunications, biotechnology, etc. It is not surprising that it is an ideal field for the cultivation of methodologies such as problem-based learning, challenge-based learning, or service-learning methodology.

However, while some educators view "service learning" (SL) as a new term that reveals a rich, innovative, pedagogical approach for more effective teaching, others view it as simply another term for well-established experiential education programs. For years, education researchers and practitioners struggled to determine how to best characterize SL. In 1979, Robert Sigmon defined SL as an experiential education approach that is premised on "reciprocal learning" [1]. In Sigmon's view, SL occurs only when both the providers and recipients of service benefit from the activities.

In the USA, higher education experienced tremendous growth in SL courses during 1990. This growth was supported by the Corporation for National and Community Service [2]. Service learning was seen as a "method under which students learn and develop through active participation in thoughtfully organized service experiences that meet actual community needs, that [are] integrated into the students' academic curriculum or provide structured time for [reflection, and] that enhance what is taught in school by extending student learning beyond the classroom and into the community..." (Corporation for National and Community Service, 1990). The National Society for Experiential Education, which for years has focused on various types of experiential education programs, broadly defines SL as "any carefully monitored service experience in which a student has intentional learning goals and reflects actively on what he or she is learning throughout the experience." (National Society for Experiential Education, 1994).

For example, Engineering service-learning and Humanitarian Engineering (HE) programs at The Ohio State University have been in existence since 1979 [3]. Another well-known SL program is Engineering Projects in Community Service (EPICS), that was initiated at Purdue University in the Fall of 1995, [4]. It was extended to many engineering service-learning projects in other universities, being the largest and longest-standing in the U.S., and/or into international experiences providing engineering services and solutions to the developing world, e.g. through cooperation with Engineers Without Borders (EWB). See [5] for updated information.

Regarding institutionalizing plans, it is worth noting that Bringle and Hatcher described in 1996, cf. [6], a Comprehensive Action Plan for Service Learning (CAPSL): planning, awareness, prototype, resources, expansion, recognition, monitoring, evaluation, research, and institutionalization.

Currently, engineers have a significant opportunity to help solve many of the world's greatest challenges. Getting involved in humanitarian engineering does not necessarily require a total change in career or lifestyle but can still have a major impact. Thus, engineering is in the spotlight with a key role in reports on Society development and challenges. See for example UNESCO report (2010), [7] or the National Academy of Engineering's (NAE) Grand Challenges, [8].

In consonance with this global context, some initiatives of SL carried out at the Universitat Politècnica de Catalunya (UPC) are presented. Section 2 is devoted to presenting the context at UPC, namely the Centre for Development Cooperation and the Manresa School of Engineering, where the SL activities we deal with in this study are designed. Section 3 details the methodology used for the analysis. Section 4 contains the results of the analysis of students' experiences, identifying the phases of service-learning and showing the relationship between students' experiences and competencies.

2 KEY AGENTS AT UPC

2.1 The Centre for Development Cooperation

The Centre for Development Cooperation (CCD) was created at the UPC in 1992. It coordinates programs related to development cooperation with the participation of UPC's social volunteers such as students and teaching staff. The cooperation programs aim to fight against poverty, inequalities, and exclusion in the form of values so that other realities can be implemented both globally and locally. The actions carried out aim to contribute to improving people's lives. Moreover, for the students of the UPC who participate, it becomes an apprenticeship that helps to train future professionals to have a more just and sustainable commitment to the planet.

The CCD organization is present in all teaching centers of the university and coordinates and gives support to development cooperation activities. The funding for the different projects comes from institutional contributions such as educational cooperation agreements and voluntary contributions from students or part of the teaching staff's salaries, collected in the so-called 0.7% campaign. It is also open to external funding such as companies and entities whose objective is the development of specific projects. During their university studies, future engineers working in cooperation and development projects not only acquire technological knowledge but also learn social values that are very remarkable once they enter the professional and working environment.

2.2 Projects from EPSEM

The Manresa School of Engineering is the school of UPC located in the city of Manresa. Students can enroll in bachelor's degrees in several Automotive Engineering areas, such as Automotive, Industrial Electronics and Automatic Control, ICT Systems, Mechanical, Chemical, and, last but not least, Mineral Resources and Recycling. It is the only university center in Catalonia where you can study the Bachelor's degree in Mineral Resource and Recycling Engineering, several Master's degrees related to Natural Resources and Mining Engineering, or the Natural resource and Environment graduate program, all of them inside civil engineering area. Among their responsibilities are the control and use of explosives in civil works projects. Like all engineering, but in this one even more so, social commitment and ethical values are very important.

The degree is organized into four years, and eight semesters. The number of students per course is not very high and the relationship with teaching staff is very good. They have dedicated laboratories with advanced equipment and a group conscience is generated, which facilitates interaction between students from different courses.

During the regular semesters, fieldwork is carried out, with visits and internships at sites in the area. In the summertime, when there is no schedule, extra opportunities to be in other mining areas around the world are offered to students. But this is not just an internship, but a real cooperation project as mining activities or, in general, the extraction of natural resources is an important issue in developing countries, especially in Latin America. In many cases, there are problems concerning environmental pollution such as the use of mercury for gold mining, the health of the workers, or economic conditions that hinder the efficient extraction of resources. Cooperation projects mainly serve to deliver improvements in sustainable mining, safe working environments, and improvements in mining performance. Thus, these projects are a real service-learning experience.

The projects involve the participation of professors, who travel with the students. The CCD provides some funds and some training course.

3 METHODOLOGY

The analyzed sample contains nine cooperation and development projects carried out at EPSEM in the field of mining and natural resources, in the years 2016-2021. All of them have been developed at mining sites in Bolivia and Peru. Because of the covid pandemic, in 2020 students did not travel there, but worked by using samples from the previous year, and keep in touch with university staff there.

For each project, a previous report was prepared, to plan the activity and to ask for financial support and the authorization of the university. The duration of the stay oscillates between 25-50 days in summer. The more technical part of the experience, related to content learning is included in the final degree project or projects belonging to subjects for the following semester. In addition, the students write a personal assessment report of the experience.

We analyzed 18 reports written by 13 participants, as 5 of them participated for 2 consecutive years. The following table lists the reference number of the projects, containing the year, and how many reports of each project were considered, indicating how many come from females or males. All the projects considered were led by Professor Pura Alfonso, who also traveled with the students.

Table 1. List of projects and reports analyzed

Project	Num. reports	female	male
P-2016-O013	2	1	1
P-2016-U006	2	1	1
P-2017-O014	1	1	0
P-2017-O013	2	1	1
P-2018-U017	2	1	1
P-2018-O026	1	1	0
P-2019-B005	4	0	4
P-2020-B006	3	0	3
P-2021-G007	1	0	1

To conduct a deeper analysis, an interview was conducted with three students corresponding to three different situations to follow up on the experience after some years:

- student A (male, aged 21), undergraduate student, between 1st and 2nd experience,
- student B (male, aged 23), master student, 2 years after the 2nd experience,
- student C (female, aged 28), graduate student, 5 years after the 2nd experience.

4 ANALYSIS OF STUDENTS EXPERIENCES

4.1 Phases of student involvemnet

The sample of students assessment have been analysed to check the progress of student involvement in SL. Five phases have been identified, according to the student development model provided by Delve, Mintz, and Steward [9]. We quote student fragments for each phases:

a) *Exploration* (naive excitement)
“Once we got to the mining area, I saw that the situation was much worse than I could have imagined”. “It has been a unique, enriching, and highly recommended experience”. “Lack of basic services such as running water, solid electricity, decent housing, and good roads, among others”.

b) *Clarification* (on values)
“Workers are at great risk, as safety measures are minimal in the mine, in many cases, it is a lack of knowledge as they have done so all their lives and do not see so much danger, so it is necessary to work to make them aware of the risk they are taking”. “Many of these problems are caused by extreme poverty, which means that the population does not have enough resources to have a good education”.

c) *Realization* (insight into the meaning of service)
“I have taken samples and will be testing these samples which will help the miners to know more about the material and learn how to make them myself, so I think it has been very positive for both parties”.

d) *Activation* (participation)
“You learn to see things from a different point of view and to make decisions in order to carry out projects with very scarce resources”. “Personally, it has been my second year traveling to the same villages and I have been able to see the first improvements, especially in terms of organization and awareness of issues such as health and safety”. ”The part of collecting samples allows to see of the way that works, what dimensions covers the exploitation and also allows to know in first person the experience of the own workers of the cooperatives”.

e) *Internalization* (the service experience influences career and life choices)
“Sharing my day-to-day life with classmates from here and with partners from there is also a lesson for me”. “I think the project can have good continuity and that the relationship we started this summer can continue for years to come. I believe that we can contribute to a more sustainable development of this area, but I hope that with the work we are doing soon we will not have to cooperate again in this area”. “I’m glad I was able to relive this experience where I was able to learn a lot again and become aware of what’s really important”.

4.2 Service Learning and the competences

Within the framework of EHEA, the need for greater development of transversal competencies in Higher Education is a topic of interest. Service-learning, as a methodology centered on students’ experience, can play a significant role.

Several authors as Fuertes et al. [10] studied how SL influenced the interpersonal skills requested by the community. Researchers recognized that it could be worked through experiential and practical methodologies in the learning process so SL could play a key role, also when employability is considered [11].

On the one hand, focusing on the importance that SL attaches to the reflection on experience, SL can contribute [12] to the development of the analysis and synthesis skills among university students in an era of great complexity and uncertainty. Also the impact of SL in other competences, interpreted as psychoeducational variables of university students variables, are studied in [13].

On the other hand, the work of students in SL is considered to be one of the most appropriate ways to develop ethical and civic competencies [14]. As an example, they remark that at the UNED, these competencies are related to the application of democratic values linked to fundamental rights and equality. They also refer to the statements by Universitat Autònoma de Barcelona "to promote values, behaviors and sustainable practices that guarantee gender equality, equity and respect for human rights”. At the UPC, and other catalan universities, similar statements are also found, even at their statutes, prior to the formulation of the EHEA.

An empirical approach to the influence that transversal competencies (soft skills) may have on the degree of employability of university students has been conducted in [11]. They found differences between the students who participated in experiential activities and those who did not, in favor of the former and explored theoretically whether the pedagogical approach of SL might contribute to a better connection between transversal competences and employability.

Our study on the students’ reports and the following up on the students participating in the projects also confirm a good correlation between the student’s perception of their skills, after the development of the projects, and external evaluation, from employers, internships, employers, etc.

5 ACKNOWLEDGMENTS

Service learning projects considered in this paper were carried out with the support of the teaching staff of the department of Mining, Industrial and ICT Engineering, and funding from the Centre de Cooperació pel Desenvolupament (CCD-UPC). Also, the NGO Mineria per al Desenvolupament contributed to the development of the projects. Our gratitude to them to make it possible. We also thank all the participants and students involved in the projects, especially those collaborating in this paper sample.

ABSTRACT

The paper describes and analyzes the service-learning experiences of various engineering students in two science and technology museums, over the years 2020, 2021 and 2022. The experience was based on the design and implementation of education and outreach activities and scaffolding material was provided.

doi:10.5821/conference-9788412322262.1458

Student learning was significant not only in terms of content but also in terms of generic and transversal competencies. In addition, this service-learning model shows a good potential to address some of the problems in engineering today, such as the declining interest in engineering among school students. Thus, it can be a win-win model for all the agents involved: museums, university, the student himself and society in general.

1 INTRODUCTION

This paper aims to analyze some effects of engineering students' experiences in science and technology museums, within the framework of service-learning, as the kernel of a study on improvement of teaching and innovation.

This section first describes what is meant by service learning and how it is applied in the field of engineering. On the other hand, we place the reader in the context of this experience with a brief description of the agents involved, museums and the Manresa School of Engineering and their relationship with each other. The second section includes a brief description of the activities carried out by the students, the relationship with other service-learning experiences and the goals and methodology of our study. The results are presented in the third section followed by brief conclusions.

1.1 Preliminars on Service-learning in engineering

Last decades, service-learning has been considered in higher education as an active learning strategy to be applied to many areas consistent with the change of paradigm in education from a focus on teaching to a focus on learning. It is a pedagogy integrating academic learning with community-based work, with a two-fold focus: learning for the student and service to the community. It can be defined as "a form of experiential education in which students engage in activities that address human and community needs together with structured opportunities intentionally designed to promote student learning and development. Reciprocity and reflection are key concepts of service-learning" [1].

Engineering has a vast potential for service learning, and several models of engineering service learning have been presented in the literature, discussing the benefits and outcomes of the program. A well known program is Engineering Projects in Community Service (https://engineering.purdue.edu/EPICS), EPICS program, initiated at Purdue University in 1995. It is described by Kirsch [2]: "(it) empowers students to work with local service organizations to apply technical knowledge to implement solutions for a community's unique challenges. In this way, EPICS in IEEE not only assists communities in achieving their specific local improvement goals but also encourages students to pursue engineering for community improvement as a career.

1.2 The Museum of Geology, a university museum

The Museum of Geology "Valentí Masachs" was founded in 1980 by Dr. Valentí Masachs. It was started with his private collection of fossils and minerals as well as collections from other founding members of the museum. In 1993 showcases of mineral applications were added.

The museum is part of the Universitat Politècnica de Catalunya (UPC), and it is therefore a university museum, like other museums around the world. It is located on the UPC campus in Manresa, connected to the classrooms and laboratories, and it is strongly linked to the university in its day-to-day research and teaching. It also serves students and teaching staff from all levels of education and it is a channel of connection between the university and the education system. The museum is also open to the general public.

The museum collection increased over the years thanks to the work of its directors, faculty and students who contributed to it through their research. At present, the museum has a collection of about 5000 minerals, 2000 rocks and 3000 fossils.

1.3 The Manresa Technical Museum

The Technical Museum of Manresa is located in the old water tanks of the city, with a capacity of 12,000 m³ of water. The museum was founded in 1993 on the initiative of the municipal company "Aigües de Manresa SA", Manresa City Council and the Museum of Science and Technology of Catalonia. Since 1992 it is part of the Science and Technology Museum System of Catalonia, and since 26 November 2004, it has been integrated into the Manresa Science Heritage Park. The Museum is also part of XATIC, the "Xarxa de Turisme Industrial de Catalunya" and the Water Museums Global Network.

1.4 The UPC Manresa School of Engineering

The Universitat Politècnica de Catalunya (UPC) is a public institution of research and higher education in the fields of engineering, architecture, sciences and technology. It is one of the leading technical universities in Europe with a widespread presence in Catalonia, through nine campuses. Manresa School of Engineering is the campus located in the city of Manresa, offering several Bachelor's and Master's degrees. The list of Bachelor's degrees covers several fields, namely Industrial Electronics and Automatic Control Engineering, Mechanical Engineering, Chemical Engineering, ICT Systems Engineering, Mineral Resource Engineering and Mineral Recycling. Students can also enroll in Master's degree in Natural Resources Engineering, Master's degree in Mining Engineering, Master's degree in Mining Engineering and Master's degree in Geotechnical Engineering, all of them very related to the Museum of Geology referred above.

2 ACTIVITIES IN THE FRAMEWORK OF SERVICE-LEARNING

2.1 Brief description of the activities

Both museums, the Museum Valentí Masachs and the Technical Museum of Manresa receive a large number of visits from primary and secondary school students throughout the academic year. Students enrolled in engineering degrees are encouraged to guide the visits and give workshops. The variety of degrees taught at EPSEM allows museums to match activities and students taking into account students' profiles. The experience is based on the design and implementation of education and outreach activities. Learning materials were provided. Training sessions are conducted by faculty to enforce students' knowledge and students' skills, in order to ensure learning for the student, and the quality of the service. Design and creation of new workshops is a challenge for the students too.

Actually, specialized training sessions have been designed, putting together sessions by leisure professionals and experts in museography and technology, face-to-face sessions in the two museums, and practical sessions in exhibition activities. Two editions have been implemented. It is worth mentioning that these were highly valued by the participants. There were no known structured descriptions of recommended training to support students to develop this kind of activity. Thus, the design, program and the two editions experience can be of interest.

Some final undergraduate and master's degree projects (TFE, in Catalan) are also related to the two museums. Thus research, development of theoretical frameworks and creation of manipulative material such as prototypes are carried out by engineering students under the supervision of several professors.

Students are also involved in collaboration projects of the museums with secondary schools with special needs. For instance, some students collaborated with the secondary school IES Guillem Catà, through the Museum Valentí Masachs to design and equip a small museum of mineralogy in the school to enable hands-on and active learning. In addition, the students participate in cooperation and development projects at the international level, mostly related to sustainability and social projects, one of the main areas of dissemination of the Museum of Geology Valentí Masachs. They are also involved in some cases of TFE.

In the context of this article, research was conducted for information on similar experiences. Most of the known examples of service-learning in engineering correspond to the model of project design, or the model of development and cooperation in another placement, International or not, which should not be confused with International volunteering or internships.

But some examples similar to our activity can be also found. A course where college students work with elementary school students is studied in [3], including a description of lessons learned and best practices. In [4], projects for 35 different undergraduate core courses are summarized, including for example the design and construction of displays to illustrate various technologies for middle school students. Several features are studied there in the context of USA universities. This paper wants to contribute to the study of some particular features in our context, in order to develop a further study in engineering service-learning experiences in universities in Catalonia.

2.2 Setting the goals of the study and the methodology

In this paper, the goal is to survey students' perceptions of their learning, referred to content and competencies, show connections to particular subjects, and collect data on the impact of academic and social projection of students through Science and Technology museums.

The main focus will be the generic competencies in UPC undergraduate curricula, cf. [5]. Our main hypothesis is that this service-learning experience has a positive impact on the achievement of competencies. It is a student-centered study, so the survey instrument is designed to be answered by students. Besides the students' perception of competencies achievement, it is intended to measure the influence of service-learning activities on students' perspectives about engineering, their career interests, and social consciousness.

The methodology consists of: (a) the careful design of a questionnaire, with valid and reliable questions, including a test and a revision; (b) the distribution of it to the population we are interested in, namely students who have been involved in outreach activities in museums; (c) data cleaning analysis, and interpretation, (d) completion of the survey with some personal interviews.

The questionnaire combines open-ended and closed-ended questions, in order to get both qualitative and quantitative responses. It is structured in several parts. The first part collects the data prior to the museum's activity. The second part collects quantifiable information on the name of the workshops in which the activity was carried out, the school year, the amount of schoolchildren involved, etc. The third part takes care of the relation with academic subjects related with the activities. The fourth part focus on their perception of improvements in general competencies. The fifth part collects the personal and professional impact. Finally, the last one reflects on the social commitment of the university and its relationship with STEAM. See figure 1.

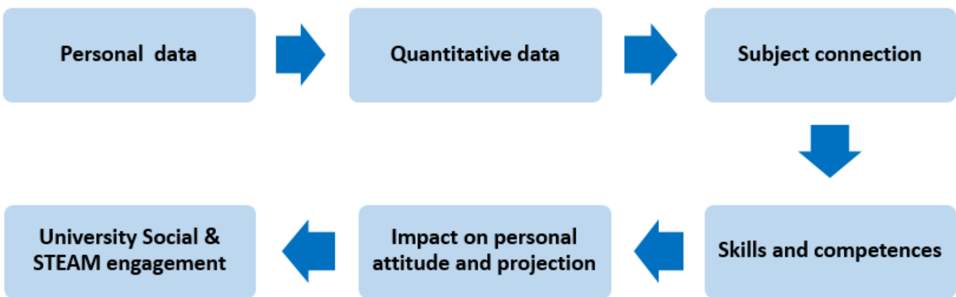

Fig. 1 . Structured parts of the questionnaire

The questionnaire can evolve to be used as a tool to encourage students to reflect on learning, a very important step to make meaning of the experience, cf. [6]. Open-ended questions and interviews can be used for further refinement of the form.

3 RESULTS

The questionnaire was distributed to students who have been involved in outreach activities in museums. After getting the responses, data cleaning allowed us to identify and remove responses from people who either didn't match our target audience (not students, or involved in museums not related to science and technology). Final sample included ten students, six males and four females, from four different engineering degrees, who participated in outreach activities in one of the two museums, related with their degree. We will denote them S1, S2, ... S10, following the order of seniority of participation, from February 2016 to the present.

Information was completed with three personal interviews: (S3) a master's student enrolled in the museum program two years ago, who is still collaborating; (S10) an undergraduate student, currently enrolled in the museum program; (S9) a former student enrolled in the program who is nowadays a teacher at secondary school.

Students responses to the questionnaire confirmed impact on subjects learning, even after finishing them. Connections with several subjects (at least three each) were stated. They admited to change their opinion about some subject value (increasing it) and discovered some contents that they have overlooked and decided to review to be more confident about, and they were more interested in the course they were studyng at the time the activity at museum was developed. For example the question: "Did the questions the students ask you and the chance to explain them some answers increase your learning?" got a 70% of the answer "yes quite often".

In terms of competencies, as expected, "Efficient oral and written communication" is the one that students are most aware of having improved with the experience in the museum. S10 states explicitly in two occasions: "explain concepts that you already know are very beneficial. It allows you to improve your skills to express concepts clearly and concisely", or "I have learned to better communicate my ideas, capture the attention of the audience, when explaining concepts, the way you do it, etc.".

But there are also other competencies that, from the student's point of view, have improved thanks to the museum activity, namely: Entrepreneurship and innovation, Sustainability and social commitment, and even Gender perspective. Figure 2 shows the comparison of results of the value given to the development of four generic competencies, derived from the regular subjects courses or from the service-learning experience. For the other competencies, there were no significant differences.

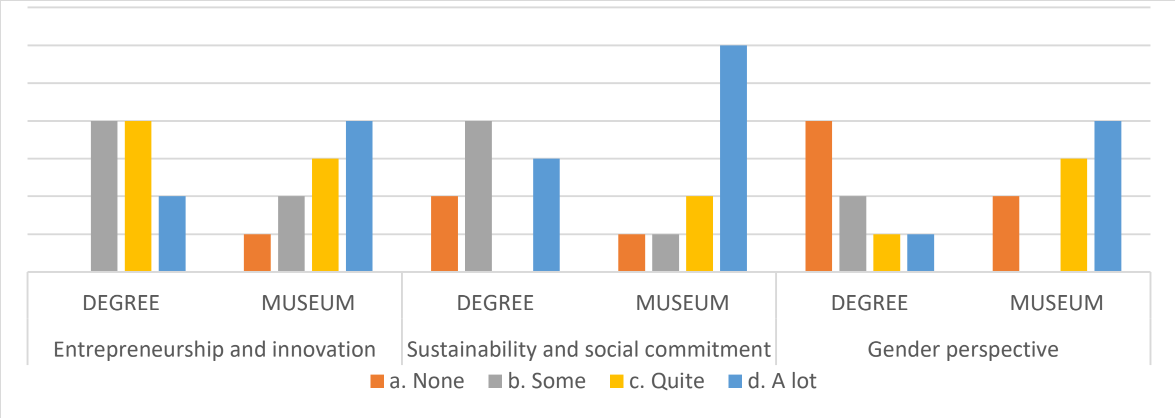

Fig. 2. Student's perception of competencies development derived from the subjects course or the service-learning experience.

As for the impact on their personal career, a clear example is S9, who says, "Literally, my job at the museum helped me find a career and ended up being the determining factor for what I now have a job that I love."

Open-ended questions revealed some ignorance about service-learning label for experiences, with the exception of some development cooperation projects, with a learning scheme. It is not clear how these experiences are offered to students, as in some cases they are only linked to optional subjects or final degree o master projects. Regarding the interest of students in these activities, a paradox similar to that cited in [7] is observed. Some students had taken part in voluntary activities related to the leisure of young children and teenagers or had taken part as a child (of course without an explicit relationship with science and technology). For them, the discovery was that they could relate it to STEAM and, in particular, to what they were studying. But the majority were students who had not been involved in such activities before. For them, the discovery has been twofold, and their learning has opened up new opportunities for them. More specifically, it has been crucial for S9, which is currently a high school teacher, and for S3, which is now targeting it.

While the activity may be more interesting to students who are familiar with the world of leisure, they often develop this facet in communities not related to university campus and do not spend time looking for such opportunities in connection with university degrees. On the other hand, students who did not participate in this type of experience confess that they discovered it thanks to the teachers who proposed it to them. It is therefore important to study the role of the teacher as well in terms of the extension of social engagement.

The interaction between students and faculty is very important for the evolution of service-learning proposals. On small campuses, such as the Manresa School of Engineering, formal and informal communication can be very helpful to significantly improve their development and analysis.

After the experience, students are much more aware of the importance of spreading their interest in engineering. They can be good STEAM ambassadors, closer to teenagers and children. Thus, apart from the win-win of student learning and the service to museums and schoolchildren, it is the whole society that will indirectly benefit.

Finally, it would be interesting to test if there is a significant positive relationship between engagement in outreach service-learning and a reduced likelihood of dropout, in the same direction as several studies on the significant positive relationship between engagement in extracurricular activities and dropout in high school (cf. [8]).

Acknowledgments.
We thank all the students who were interviewed and those who answered the questionnaire for their availability and sincerity. We are also grateful for the collaboration of the directors and staff of the participating museums. We acknowledge the support of a UPC Teaching innovation grant, via Institute of Education Sciences.

ABSTRACT

Engaging students of any discipline in meaningful and constructive research about their university experience can be challenging[1]. During the Pandemic maintaining a balanced approach to sampling and data collection when conducting pedagogical research proved to be more than a little problematic, with many students seemingly experiencing ‘online fatigue’. Moving slowly out of the Pandemic, the issues have changed, with students now hesitant to participate in face-to-face research. This short concept paper discusses the practical and theoretical challenges encountered in undertaking Engineering Education Research (EER) at a time of unprecedented social and educational change. In focusing very much on methodology this paper does not report on the emergent findings of the study discussed but instead focuses on the methodology itself.

1. INTRODUCTION

Starting with an overview of the organisation in which the study is set, this paper discusses a current project aimed at promoting a culture of scholarship and evidence-based learning and teaching across all undergraduate and postgraduate programmes within a UK Russell Group University Department of Engineering & Management.

Starting with a short precis of the literature, attention is drawn to three student-focused areas prioritised by the project team: The quality of the student experience: Blended learning: Student engagement. Following this, a reflexive account of the use of hybrid research to promote scholarship is given whereupon the paper critiques the use of an online platform as a contemporaneous structured **and** reflective unstructured data collection tool (Miro, 2022[2]).

The virtual and traditional strands of a current hybrid research approach are discussed and the benefits and challenges of using tools such as *Miro* for data collection considered. In reflecting upon some of the unforeseen challenges of engaging students in hybrid research, the paper contributes to current debates about how EER is emerging as a new research discipline in its own right.

2. BACKGROUND

One of the largest applied engineering faculties in the UK, WMG has a long history of applied research, working alongside global and local employers to produce innovative solutions to contemporary real-world engineering challenges[3]. Alongside this, a steady, but increasingly strong history of high quality, practical engineering and applied management education has emerged; producing graduates able to impact the workplace from the date of employment, whilst also being equipped to deal with the unknown problems of the future.

Like elsewhere, over the past two years or so, the Covid19 pandemic has affected a paradigm shift in how education is provided offered within WMG. Almost overnight, the

Spring of 2020 saw a c-change in how all aspects of education were provided and managed. Previously 'tried and tested' pedagogies were suddenly not available for use as, like elsewhere, WMG switched all of its education provision to being 100% online. Over two years later, as the globe begins slowly but surely to emerge out of the Pandemic, both colleagues and students find themselves metaphorically blinking in the *light of day*. Whilst some are reluctant to re-enter the classrooms and labs, others cautiously are embracing the return.

In this unprecedented situation, the notion of 'hybrid learning' has emerged. Differing from blended learning in that many 'live' lectures are contemporaneously provided online **and** face-to-face in the classroom, questions of how students' are experiencing the 'new normal' in engineering education have arisen. Tasked with evaluating students' perceptions of learning after lockdown, National Student Survey (2021)[4] results were used to identify and prioritise which programmes to evaluate as a priority.

In seeking to empirically critique what continues to be a fluid pedagogical picture, it soon became clear that capturing the student experience, whilst traditionally tricky, is now even more difficult – with many students reluctant to engage in conversations and some avoiding attending university in person. With a need to capture the views of as many students as possible the idea of a 'hybrid methodology' was born.

Aimed at providing as many students as possible with the opportunity to engage anonymously either online or in person in the evaluation, the decision was taken to use an online 'learning platform', *Miro* to explore the student experience. This paper focuses primarily on the process of developing and using an 'online' contemporaneous research tool. It highlights the benefits and drawbacks of 'hybrid research' and reflects upon how this approach may be used in future.

3. THE LITERATURE

Prior to considering how to accurately capture the breadth and depth of students' and colleagues' perceptions and experiences as we emerge out of the pandemic, a short literature review was undertaken. With the aim of thematically determining where the study should focus three key themes were explored:

- **The quality of the student experience**: Much has been written about the quality of the student experience, both in traditional, face-to-face scenarios and also with regards to online and blended learning[5,6,7,8]. Whilst acknowledging that the concept of 'quality' is in-itself much debated, the researchers' turned their attention to the need to holistically capture students' lived experiences. Conducting research at the end of the pandemic saw a number of unforeseen practical problems including a reluctance to engage with any face-to-face live activities. Manifested by what appeared to be an innate shyness in many students an initial call for participants did not heed any respondents. At a time when the vast majority of 1st and 2nd year undergraduates have not undertaken any written examinations to get into university, and postgraduate students have completed their undergraduate education alone in their bedrooms, the question of how *liveliness* of the university environment was impacting individual student's academic and social behaviour arose before the study had even started.

- **The Challenges and Benefits of Blended Learning**[9,10]: With the term 'hybrid' learning emerging out of the Pandemic, the literature review identified a range of challenges and benefits in the area of Blended Learning. A number of key areas for exploration emerged out of the literature including the need to investigate: *how* learning technologies are used at university level, particularly in the area of active learning: *what* previous technologies used in the university had proved to be successful in engendering learning and which ones had not: *why* some platforms, whilst multifunctional and able to support a range of learning approaches, were used by colleagues to simply 'dump' lecture notes and readings: *how* to better engage students in online learning.

- **Improving Student Engagement**[11,12,13]: Learning technologies have traditionally attracted both positive and negative student responses, with student engagement key to pedagogical success. The incept of mandated online learning during the pandemic saw virtual engagement increase as students had little or no choice but to engage with the various learning platforms. Yet ironically, as society is emerging out of the pandemic, students have become comfortable in their study rooms and bedrooms. Used to being able to listen to a lecture whilst perhaps not fully engaging, the question of how we can better engage learners is perhaps more pressing than ever.

As previously acknowledged, at the beginning of the study students' reluctance to engage in 'on-campus' learning was manifest by difficulties in finding participants willing to take part in qualitative research. Thus, in considering how to investigate the student experience of the past two to three years, the need for a hybrid methodology arose.

4. HYBRID EDUCATIONAL RESEARCH: AN EMERGENT METHODOLOGICAL APPROACH

Having been tasked with critically analysing student perceptions' across the undergraduate population, two of the research team initially planned to undertake a *traditional* qualitative Action Research study following a methodology based upon Grounded Theory[14]. Whilst the initial intention was to run face-to-face focus groups and interviews with students to look at the issues raised in the National Student Survey (2021), it quickly became apparent that whilst conceptually guided semi-structured interviews are indeed a tried and tested method of gaining a depth of insight of the student experience, this year's undergraduate cohorts were very reluctant to meet face-to-face and also unwilling to discuss their concerns verbally in any forum.

Difficulties in accessing the student voice using traditional methods resulted in a number of alternative approaches being considered, including online group interviews and individual face-to-face meetings (both online and face-to-face). Such approaches were quickly put to one side as some undergraduate students made it clear that they felt very uncomfortable talking in front of their peers, whilst others simply did not want to come onto campus. The primary reason for such reluctance appeared not only to be a fear of Covid, but also a lack of group cohesion and familiarity across each of the cohorts. Used to working alone and having made friends only with a very small group of peers, students simply did not want to engage in any type of activities where they needed to talk in front of each other.

Having used Miro successfully in teaching the research team took the decision to adapt this learning technology and use it for research. Numerous practical questions about how to maximise participation whilst assuring student confidentiality were dealt with within the tool itself, which automatically pseudonymised the participants as they logged in.

Three key *concepts* were written onto the Miro Board and a series of semi-structured questions asked verbally around each concept. These concepts were: Student Perceptions of Learning & Teaching: How learning is organised: The overall student experience.

Facilitated by two of the research team, with one colleague talking and the other taking notes, students were provided with the opportunity to answer the various questions 'live' online. Like traditional focus groups, additional questions were included as matters arose during the discussions. Similarly, the students, able to read each other's comments reacted in real-time, indicating approval or disagreement through the use of a 'thumbs up' or 'thumbs down' e-mojis, whilst also adding in comments about their own experiences and thoughts. Although there was no need for students to talk or to identify themselves, one or two chose to do so, however, the majority remained anonymous; typing their thoughts onto Miro under the guise of an artificially created pseudonym. This technique worked remarkably well, eliciting a greater breadth and depth of data than would usually be acquired during a focus group. Additionally, the use of a 'voting tool' formed the basis for a further discussion – providing all of the participants with an opportunity to give immediate feedback on a give question or topic.

4.1 Using Miro as a Research Tool: Was it a Success?

In total, three focus groups were conducted in February and March 2022 with 32 participants selecting to join the discussions 'live' and a number of students engaging over a period of three days following each focus group whereby the individual boards were left open with no live facilitator (56 different comments were left on the open boards, although the anonymous nature of the approach means that the number of students could not be determined). Overall, the approach proved successful, gaining an unusual breadth **and** depth of data directly from the student participants. The sample was controlled by sending the link to each cohort separately with students required to use their login details to gain access.

On reflection, some of the most notable benefits of using this 'in the moment' research technique were:

i. Students were able to type in their thoughts, feelings, reflections, and comments anonymously – meaning that some went into depth whilst others raised issues that it would have been difficult to discuss in a more traditional group (for example, the demographic mix of the groups reflected the wider student body of different ethnicities, genders and disabilities and enabled the students to anonymously raise sensitive issues indicative of their demographic background).

ii. The contemporaneous nature of the 'live' focus groups meant that problems were quickly identified, reported to senior management, and action taken almost immediately. Having a written record of students' own words added to the evidence base, enabling programme and faculty management to take informed decisions and, more importantly, to be seen to be listening to the student perspective.

iii. The online methodology and managerial response gave some students the confidence to participate in further, in-depth interviews and focus groups. Whereas the initial call for participants to take part in 'face-to-face', live research had not elicited a response, students actively approached the research team after the Miro sessions asking to be heard in person.

Conversely, in addition to the above benefits, two unforeseen problems with the technique arose – one during the focus groups, the other during the short period when the boards were left open:

i. Whilst the online nature of the technique meant that the students were able to participate anonymously, the Miro boards were hosted on MS Teams. This meant that whilst the students' comments were anonymous, the research team were theoretically able to identify which students participated in the live discussions. It is important to note that the decision was taken not to record the MS team discussion as it went live (whilst the Miro boards were recorded). Likewise, no record was made of student names or any other details.

ii. Leaving the Miro boards open for two-three days following the live events was deemed to be important as only around 1/3 of each cohort had participated in the live events. This proved to be a little risky, as a small number of the less mature students selected to write inappropriate comments on the board. Fortunately, the boards were checked frequently by one of the researchers who, whilst reluctant to remove anything, took the decision that inscriptions which could potentially undermine the very real issues raised by the majority would be damaging to the whole process and so removed inappropriate content as soon as it was noticed.

Having participated in the online research some of the students requested to further explore the issues with the research team face-to-face. A number of different tools were utilised including:

i. In person focus-groups using purposive sampling techniques provided women students and those from ethnic minorities with the opportunity to further explore some of the more sensitive issues raised in the online forum.

iii. Individual one-to-one interviews utilising a blanket sampling technique meant that all students in each of the cohorts had the opportunity to participate further. This technique enabled male and female students who felt they would like to further discuss the various issues to do so in a confidential and supportive manner. Interviews were held in the university and online with four students.

With regards to the research approach issues of academic validity have been dealt with as a matter of some importance. The questions were guided by both the literature and by the researchers' individual observations and insights. The findings of both the hybrid and face-to-face research have been recorded contemporaneously and grounded theory methodological approaches will be used to conduct a rigorous analysis. The use of 'live virtual anonymous focus-groups' using Miro proved successful, although leaving the boards open for students to 'drop in and comment' afterwards was not as useful as it was hoped. A few immature students left comments, not connected to the study, but aimed at causing mischief.

This work is very much ongoing. The emergent study findings have been reported both to senior management and to the teaching team on the programme concerned. Additionally, three 'feedback-feedforward' sessions have been held with the students to inform them of the findings and to explain what changes are being made.

5. CONCLUSION: HYBRID RESEARCH – DOES IT WORK?

The use of the Miro board as a research tool proved to be an appropriate and worthwhile methodological approach. The ongoing nature of the study means that the approach will continue to be used in ongoing research being conducted across the undergraduate body of students, with contemporaneous records kept and more traditional approaches used to follow up. Whilst this first attempt at 'hybrid educational research' has provided successful a number of ethical and practical questions have yet to be addressed, particularly in relation to the potential for identifying participants logging on through MS Teams.

In conclusion, whilst the suitability of the approach for more detailed or sensitive research has yet to be tested, there is little doubt of the potential of this approach as a way to engage students in contemporaneous educational research using a media that they are happy to work with. Engineering Education should, by its very nature, be forward-thinking and innovative; Engineering Education Research (EER) needs to reflect this. As an emergent academic field of study those of us working in EER, whatever our background, need to be seen to be leading the way in developing and testing new pedagogical methodological approaches and tools. Miro is one single tool, there are many other virtual platforms and non-digital tools that we have access to. The question this paper leaves us with is *"How can we make sure engineering* *education is empirically grounded whilst making best use of emergent technologies and thinking?"* This question is, of course, for future consideration … …

ABSTRACT

Engineering plays a crucial part in responding to the biggest challenges of our era, including the transition toward a green economy by meeting the Sustainable Development Goals by 2030 and by achieving net-zero carbon emissions by 2050. Engineering education could be the leading actor in preparing engineers for these complex tasks and spread the necessary green knowledge, interdisciplinary skills, and competences to pursue a sustainable future. Hungary's education system has improved significantly in the last decade, considering the Central Eastern European region. A new national higher education strategy in 2014 set new directions for its development in many aspects, including an emphasis on soft skill development in the curricula. The Hungarian higher education system was characterized for decades by memorizing facts and figures; therefore, the effective integration of soft skill development is a slow process. In our study, we first provide a systematic review of the international and national literature to identify fundamental sustainability skills and competences for engineering. We also examine the Hungarian higher education frameworks and the skill-related output requirements in the environmental engineering programs. In the second part of the research, we present a qualitative study of in-

depth interviews with Hungarian experts with different academic profiles and a focus group study with environmental engineering students about their views on green skills. Our results show that the concept of green skills is slowly spreading in environmental engineering university communities in Hungary; however, the effective implementation into the curricula will require some more time and work.

INTRODUCTION

1.1 General Introduction

Pressing actions are needed to reach the targets set by Sustainable Development Goals by 2030. Sustainability and climate change-related goals are complex issues where conventional answers are not adequate enough. New skill sets and toolkits are needed to face these challenges successfully. As per target 4.7 of the Sustainable Development Goals (SDGs), all learners need to acquire the knowledge and skills to promote sustainable development by 2030. Education has a crucial role in the green transition as it allows students to improve their competences and collect the necessary knowledge, skills and attitudes to take action for sustainability (1). Education systems worldwide need to integrate sustainability skills and competences into their agenda to accelerate the transition to a fairer, greener economy and society.

Environmental and Sustainability Education (ESE) has been in the highlight for the last decades. The need to include sustainability education in the educational curricula is now widely recognized globally. UNESCO dedicated a decade for Education for Sustainable Development between 2005-2014 followed by the Global Action Programme (GAP) on Education for Sustainable Development (2015-2019) (2). As part of the Green Deal, the European Commission issued the European Sustainability Competence Framework – GreenComp in 2022, serving as guidance for both learners and educators (3).

Engineering plays a crucial part in solving sustainability challenges and fostering the implementation of sustainable transition. It has also been in the focus of ESE research, among others in the Barcelona Declaration from the Engineering Education for Sustainable Development Conference in 2004 (4). The much-needed shift towards sustainability in engineering has been acknowledged theoretically; however, the implementation is not an easy task - the mindset of university leaders, professors, and those of students needs to be changed.

1.2 Research Background and Research Questions

The current paper is built on previous quantitative research from 2021 conducted in Polish and Hungarian universities (5). The research sought to answer whether green skills development appears in the environmental engineering undergraduate programmes, and if yes, how. It also examined the main barriers of implementation. A questionnaire was compiled about the integration possibilities of green skills in the environmental engineering BSc programs separately for students and professors reaching a total of 257 people in January 2021.

Both lecturers and students were open to green skills development based on the answers. They identified environmental awareness, professional knowledge, and practice as the most important green skills. Soft skills (flexibility, adaptability, creativity, group work, communication skills, empathy, etc) were less often classified as green skills by respondents.

Since the European Commission issued the GreenComp in 2022 identifying the main sustainable competences for all, we considered conducting a qualitative study to ask the opinions of both professors and students about green skills. The aim of the research is to examine how sustainable competences could be integrated into the environmental engineering programmes. Our hypothesis is that even though non-technical skill development is a legal requirement in the Hungarian environmental engineering programmes, there has not been enough emphasis on its successful implementation. The main research question we formulated is: How can we integrate sustainable competences and green skills into the curricula of environmental engineering programmes?

2 METHODOLOGY

The first step of the research project was to conduct a brief literature review in the fields of the usage of the words: 'sustainable competences' and 'green skills' and to see the legal requirements for learning outcomes of the Hungarian Environmental Engineering BSc programmes.

Environmental engineering programmes were chosen since they can be considered the closest to the topic of sustainability, and maybe the most open for the integration of sustainable competences. Students and professors for the research were chosen from the Budapest University of Technology and Economics (BME), since that is the oldest and most prestigious engineering university in Hungary.

In the practical part of the research, semi-structured interviews were conducted within the framework of qualitative research. The discussion was based on a pre-compiled thematic questionnaire, which was handled freely during the discussion. The selected academics for the in-depth interviews play important roles in the Environmental Engineering programme: directors of the entire programme or one of the specializations, and actively teach the students. The interviews were conducted in January 2021 and in April 2022, the first one online, the second one in person. Both interviews took around one hour, and they were recorded, and later on transcripted.

We also conducted a focus group with a group of students from the Specialisation in Environmental Management of the Environmental Engineering BSc programme at BME. Seven students participated in the focus group discussion in the framework of the course Complex Environmental Management Practices in April 2022.

General inductive approach (11) was used as the qualitative research analysis. The raw data (the transcripts of the interviews, and the notes from the focus group discussion) was read several times by both authors, and the emerging themes were identified and conclusions drawn as a results of several discussions between the authors.

3 RESULTS

3.1 Literature Review

In the respective literature, several terms are used to describe the necessary abilities for sustainability: green/sustainable and skills/competences. "Green" is a term that is derived from the green economy concept, and it is mostly used in relation to employment and employability (6). The term sustainability is widely used in both job and education relatedly. The difference between skills and competences is that usually, skills represent only a part of competences since competences include knowledge, skills and attitudes – as per the educational definition. However, green skills or skills for sustainability are often used instead of competences in policy and scientific works (7). Higher education institutions should implement sustainability competences into their agenda to prepare their students with the necessary green skills to be employable for green jobs.

The European Commission's science and knowledge service, the Joint Research Centre (JRC) published GreenComp - The European Sustainability Competence Framework in 2022. It defines sustainability competences as a group of skills, attitudes, and knowledge. It provides a common understanding of these competences both for students and educators. The report identifies four main competence areas and 3-3 competences within each area (Table 1).

Table 1. Competence areas and Competences of GreenComp (3)

GreenComp competence areas			
1. Embodying sustainability values	**2. Embracing complexity in sustainability**	**3. Envisioning sustainable futures**	**4. Acting for sustainability**
Valuing sustainability	Systems thinking	Futures literacy	Political agency
Supporting fairness	Critical thinking	Adaptability	Collective action
Promoting nature	Problem framing	Exploratory thinking	Individual initiative

In the Higher Education System in Hungary, the document ‘Shifting of Gears in Higher Education Mid-Term Policy Strategy’ (8) is the first policy to provide guidance in Hungary for universities on the actual application of practical education for the 21st century. It emphasized the importance of transversal skills that increase employability, such as entrepreneurial skills, digital skills, and foreign language proficiency. It also highlighted the competences that describe general characteristics such as the competences of critical thinking, independent but cooperative problem-solving, civic knowledge, digital literacy, etc. Some of these fields can be connected with the GreenComp competences such as critical thinking and problem solving correspond to the competences from embracing complexity competence area, and the active citizenship characteristic corresponds with the acting for sustainability competence area. This strategy paved the way for universities to introduce education innovations and practical education.

The learning output requirements for environmental engineering programmes are defined by law (18/2016) with detailed information of the expertise, professional abilities, attitude, autonomy, and responsibility areas. The following general skills are mentioned as a requirement for environmental engineers: environmentally conscious behaviour, demand for lifelong learning, good communication skills using technical terminology, ability to solve professional problems, digital capabilities, and openness to cooperation (9). The introduction of these learning outcomes is a significant development in the Hungarian higher education system (10).

3.2 Interviews

Throughout our interviews and focus group discussion, we focused on the possibilities and barriers of the implementation of sustainable competence development in the higher education institutions. We identified four main themes of the discussions, presenting the results around these topics.

The concept of sustainability has become widely used in the last decade.

One of the professors highlighted that the spread of the sustainability concept resulted in the word entering everyday vocabulary on a rhetorical level without people knowing exactly what it meant. Often only the environmental aspect is understood by it; there is no complex understanding of the concept sometimes even at academic level. According to the other interviewee, even though the concept of sustainability is widely spread, it is not integrated in engineering programmes except for the environmental engineering training. Both professors mentioned the concept of saving as an example – it is a fundamental concept of sustainability, still the teaching programmes do not convey that. Both professors highlighted the students' often experienced inadequate knowledge in natural sciences – without which it is hard to discuss these complex issues.

Sustainable Competences/Green skills in the environmental engineering programmes

Both professors brought examples from their teaching practices regarding practical education tasks that support green skills development during their courses. These tasks work well because they reflect on a real-world problem, such as representing an issue the local municipality or simply discussing simple everyday actions from a sustainability point of view. One of the professors mentioned that lately other professors started to see that specific skills could/should be implemented in the everyday teaching practices. Professors already have to identify the skills, knowledge, and attitudes as the output requirements for each course - unfortunately, this task is experienced by most university lecturers as a considerable burden. There is no energy to redesign lessons unless it is mandatory (eg: redistribution of classes).

Both professors agreed that certain soft skills could be a booster for sustainability, e.g., the art of debate, good communication, and networking abilities. These are more and more present in the courses but typically as part of the assessment – these skills are not taught.

According to one of the interviewees, integrating sustainability skills should not be through separate sustainability courses but built-in elements of all courses, even in mathematics, physics, and statistics as topics of certain tasks.

Multidisciplinary and interdisciplinary education

Both professors agreed that the introduction of multidisciplinary and interdisciplinary projects is very much needed in the environmental engineering courses. However, both found it too hard to implement - it would take too much energy to compile a challenge-based interdisciplinary course.

Encouragement for university professors to integrate sustainability skills

Both professors emphasized the importance of training and guidelines about innovative pedagogical methods that could support professors to move away from the frontal teaching. Lecturers need to be educated about green skills in an engineering context. One of the professors highlighted the importance of thematic calls as an incentive for researchers and lecturers to deal with green skills development. The other professor emphasized the role of networking. The implementation of green skills is currently more a characteristic of the younger generation. Having opinion leaders network with highly respected older generation of academics could support the sustainability initiations within the university.

3.3 Focus Group

We invited seven students from the Specialisation in Environmental Management of the Environmental Engineering BSc programme at BME to take part in the focus group study. Out of the seven students there were 1 female and 6 male participants. 4 of the students already worked beside their studies (as chef, manager, or intern). First, we were interested in how much they live a sustainable lifestyle by asking questions about their everyday sustainable habits. The whole group tries to avoid plastic waste and waste generation in general, and they collect waste selectively. Only 4 out of 7 students try to reduce printing, avoid using cars and buy second-hand products. The least spread actions were reducing eating meat and the usage of smart appliances in their homes. In this regards, this group can be considered better than average.

The first question was about the current teaching program's ratio of engineering and non-engineering skills / knowledge. The group agreed that currently, the non-engineering skills take about 30%-40% of their training. There was a small debate since some students thought the ideal would be around 50%, but others argued that 30-40% is also ideal.

The second question was whether it is the task of the environmental engineering bachelor's and master's programmes to support the development of green competences? Most of the group agreed that, yes, it is because the student's ultimate goal is acquiring these competences for their future jobs. In the management specialization, they feel that it is more typically present, but the technology specialization should not be neglected either.

The third question focused on how useful they find gaining sustainability knowledge during their engineering training. The students found it useful because it covers many areas as a horizontal issue. Engineers shape the physical environment and technologies; therefore, this knowledge is becoming more and more important nowadays, and it is needed for a deeper understanding of complex issues.

For the fourth question we asked the students to provide ideas based on the sustainable competences of the GreenComp on how their training programme could support these competences, and how they could improve these outside the university.

According to students, universities could support the skills and knowledge development as they teach sustainability as a complex system. Sustainability could also be represented by educators from different background fields, and through the appropriate use of resources, research work, case studies, and practical experience. Some students highlighted that universities could only inspire the attitude, but it ultimately depends on the individual student to utilize it. Both groups agreed that it is the students' responsibility to develop these competences for example in their extracurricular activities. They identified programs such as attending events, lectures, conferences, reading scholarly articles and journals, watching videos, and joining and supporting NGOs to improve their sustainability skills. Some of the students emphasized that the Environmental Engineering programme could benefit from more interactive courses, up-to-date knowledge and materials, and the development of pedagogical skills of the professors.

4 CONCLUSION

As a conclusion, we can say that our original hypothesis was right. Even though higher education laws in Hungary prescribe non-technical skills development in environmental engineering education, the interviews and the focus group study showed that these regulations are not fully implemented in many cases. There is a lack of training and a lack of resources and examples – many Hungarian educators are not prepared for the shift from traditional knowledge-centred frontal education. The redesign of university courses and giving place to pedagogical experimentation is not easy to implement.

The introduction of good educational practices into undergraduate education is a complex, systemic problem. It depends on many factors, such as the approach of the university management, the incentives given for curricula development, but also the instructor's personality, their economic situation, etc. The work with the student group, however clearly showed that the demand for this shift is real. Students had a clear view that sustainability skill development is a key factor for environmental engineers, and they expect the university to offer these to them.

To promote improvement both bottom-up and top-down approached are needed. The easiest, most effective ways as per our recommendation are to develop teachers' / lecturers' trainings, pedagogical guidelines, but also raising awareness through students' competitions. The institutional strategy in this respect could also support the transition. Furthermore, to understand better the local needs, we plan to do further research in the labour market in Hungary in the form of an alumni and labour market survey to better understand employer needs of green skill / sustainability competence.

ABSTRACT

First-year students' expectations when entering the university play a central role in how they experience higher education. While there has been a significant number of studies on first-year students' experiences, much less is known about which role expectations play on a qualitative level. In this study, we will approach the question; How students' expectations of higher education shape and are shaped by their experiences of entering the university. By drawing on a qualitative thematic analysis of nine interviews with first-year students in an electrical engineering program, we found that students' expectations to themselves and perceived expectations from others, are key elements in experiencing the learning environment and culture at the university. Grounded in the empirical material and in light of the contemporary research literature on first-year students, learning environments and university

doi:10.5821/conference-9788412322262.1363

pedagogy, we explore students' positions and aim to better understand the social mesh that they interact within during their first year at the university.

1 INTRODUCTION

Entering higher education is a major step for students and describes a significant transition in their personal and professional development. The transition into higher education is often accompanied with uncertainties and expectations. Students need to find their spaces and negotiate their role and social relations to other students and educators. On a disciplinary level, enculturation of students into engineering practices plays a central role [1]. In other words, students need to learn and assimilate knowledge, practices, and values of both disciplinary engineering cultures and social cultures surrounding their study program and the university in more general terms.

Furthermore, expectations first year students bring with them, either explicit or implicit, play a central role in how they experience higher education [2]. While there has been a significant number of studies on first-year student experiences, much less is known about which role expectations play on a qualitative level [3].

With this in mind, this study will be centred around the question; *How do students' expectations of higher education shape and are shaped by their experiences of entering the university?* We will explore this question by drawing on a qualitative thematic analysis of nine interviews with first-year students from the electrical engineering study program at the Norwegian University of Science and Technology (NTNU).

Grounded in the empirical material and in light of the contemporary research literature on first-year students, learning environments and university pedagogy, we argue that transitioning from high school to university can be challenging on many levels. By exploring students' positions, we want to better understand the social mesh that they interact within during their first year at the university.

In the discussion, we will draw upon social identity theory (SIT) and system justification theory (SJT) to provide a conceptual framework to understand students' experiences. SIT approaches identity processes as embedded in social meshes and describes how group behaviours are influenced by status differences, perceived legitimacy and overall in- and outgroups [4]. In addition, SJT provides entry points to how students justify the system and culture that they are part of [5]. We argue that a closer examination of how students' transition and adjust is of general interest for engineering education and that the findings from this study have both practical and research implications.

2 METHODOLOGY

2.1 Research context

The context of this study is a five-year integrated master's program in electrical engineering at NTNU called Electronic Systems Design and Innovation. This is a program that admits 120 students every year and is one of 17 five-year integrated engineering master's programs at NTNU. All of these are among the programs with the highest admission requirements in Norway, though with significant differences between the 17 programs.

Associated with the Electronic Systems Design and Innovation program is a student organization, Omega, that provides social and extra-curricular arenas for students. Omega is organized and run entirely by students on a voluntary basis and takes responsibility for welcoming new students to the study program through social events, parties, and inauguration rituals, being a social facilitator throughout the year, and creating connections between students and industry. With this in mind, many students experience Omega as a main social arena from day one at university. Omega is made up of various committees, which in total organizes almost all of Omega's activities.

The students can choose between different committees with different activities where for example some arrange social events, others brew beer, and some are a part of the board. The committees are tightly knit to the industry, both through sponsorships and arranging meetings between students and companies. In addition to Omega, there are various other technical student organizations, not connected to a specific program, that provide additional social arenas for students oftentimes centered around realizing a specific technical project, e.g. Formula Student.

2.2 Research design

To explore the question; How students' expectations of higher education shape and are shaped by their experiences of entering the university, we draw upon a qualitative case study approach [3] with semi-structured in-depth interviews. In total, twelve first year students were recruited and gave their informed consent to be interviewed. Eight individual interviews and one group interview with four students were conducted. The students were recruited amongst the entire student population and signed up voluntarily. The interviews lasted 45 minutes on average and covered group dynamics, sense of purpose and belonging, design thinking, diversity, culture, and interdisciplinarity. All interviews were conducted in Norwegian (the students' mother tongue), and later audio-recorded and transcribed. Only the sections used in the results were translated to English and students were given pseudonyms.

For the analysis, the interviews were pooled together and a thematic analysis approach [4] was used to identify, analyze, and describe patterns and themes within the data. The material was read and re-read to explore how students' expectations of higher education shape and are shaped by their experiences of entering the university. Through the iterative analysis process, we identified themes that emerged from the interviews. These themes were further explored by considering relevant literature and using it as an additional perspective to develop and deepen the thematic analysis. In this study, we will present three themes that emerged from the analysis: *finding themselves*, *discovering social arenas within their study program*, and *positioning their study programs in relation to others*.

3 RESULTS

Based on the qualitative, exploratory analysis, it is apparent that students' own expectations and perceived expectations from others, are key elements in how they experience their learning environment and the overall culture at the university. Their expectations influence how they view themselves and how they position themselves in relation to others in a complex social mesh of rituals, traditions, and hierarchies. The interviews also reveal a strong dynamic in how students negotiate their own positions and are enculturated into the university culture both disciplinary and social.

3.1 Finding themselves

Grounded in the empirical material, it is clear that the students hold strong expectations towards being at the university when transitioning from high school. Furthermore, these expectations are not necessarily fixed, explicit, or coherent and an apparent finding in the material is that students continuously contradict themselves throughout the interviews. While students commonly answered that they did not have any expectations, when talking about their experiences from entering higher education and being a student, they clearly build upon and draw from the expectations they hold themselves and those of others.

One area where this becomes obvious in the empirical material is relation to their choice to become engineers. Here, the answers varied from wanting to pursue a genuine interest, to utilizing grades, following in their parents' footsteps, and achieving status and power. Status and power were mostly indirectly expressed in comparison to other professions, where engineers were compared to professions which are usually associated with lower status and power. One student expressed the desire of status directly, but more as a confession than a statement.

> And a little bit due to status, I have to admit. It is a little bit like, if you can study engineering, you should (S7)

Another aspect of students' expectations that came up is that it can be tough going from being the best in your class to just being average amongst others who were also used to being the best. Becoming an electrical engineering student at NTNU requires relative high grades to be admitted. It appears that several of the students are struggling more with finding their place and building their professional identity around being one amongst many rather than being the smartest in a group. As a result of this, it turns out that they start perceiving themselves as average compared to everyone else.

> You are used to hearing that you are the best in your class. And known to others as the best. And then you come to a place where everyone has the same experience. Suddenly, you do not feel so smart anymore. You do not stand out anymore… it has to do with the fact that I was the smartest, and now I am not anymore. I am not used to struggling in school. It's not like I'm stupid, but it's hard. I planned to be a straight A student, but now I'm more like a "passed" student. Because now I've met people who are a lot smarter than me, I thought I was that person, but I'm not. (S1)

In addition, students are unsure about the social norms in the cultures around their study program. They try to find a balance between positioning themselves in a way where they are seen as neither the most nor the least intelligent.

Simultaneously, several of the students reflect on the positive aspects that come from not being "better" than everyone else. This includes using the other students as a resource, rather than competing against each other. The students point out that they do not see the point in competing against others who are on the same level as themselves.

> I have been able to use the other students more like resources now. Something that I did not feel before, before I came to the university that is. (S3)

3.2 Discovering social arenas within their study program

Upon entering the university, students start to navigate the social and professional landscape and try to find their way. The results reveal that an important part of this is becoming a part of the student organization at their study program and joining a committee. These committees appear to have great influence on the students' learning environments and overall culture. In all the conducted interviews, students have pointed out the significance of these committees. The statements made, suggest that the students perceive joining a committee as an expectation to be a part of the social life of a student.

There seems to be a plethora of information about joining a committee and what it means to join a committee. During the interviews, the students were asked about why they wanted to join and several students expressed that joining a committee was a way of getting access to important social arenas. Not being a part of a committee, can lead to the feeling of being left out.

> There was a lot of advertisement about the committees all the time. So, I don't find it strange that so many students wanted to join, when you are surrounded by this information all the time… it's a pity though, because there aren't enough places for everyone to join. So, everyone that wants to join, cannot. It is a pity because they will miss that social arena, especially since a lot of students want to join as well. (S8)

Another student reveals that joining a committee did not feel like a big deal at first, but in retrospect played a central role in the process of becoming a student. She explains that if you are not a part of a committee or the "right" committee, you are labelled as "outcasts".

> I wish I could change or influence the existing culture more. Or be more a part of it. I don't know if it is just me that has not participated enough. I didn't know that committees were such a big deal, like everyone portrayed them to be. I have applied for a committee, but I didn't know if you do not join a committee, you are practically nothing… I am in the revue committee and thought to myself "okay, this is cool". But no one views the revue as a legitimate committee. At the student organization ball, all the committees had their own table, but the revue group didn't even have a table. And the students who weren't in a committee at all, sat all the way in the back and were like "outcasts". (S1)

Yet another student reflects on her first days at the university, where it seemed like everyone had joined student organization committees quickly and without much thought. Not just one committee, but multiple ones. She later realized that this did not work for her and became a roadblock in her studies. She describes her impression when arriving at the Ada-day – a project to promote technological studies to recruit more women.

> When I arrived during the Ada-day, I got the impression that everyone had a student organization committee, a technical committee and did some other fun things and had time for hobbies in the side. And that they still had time to do the things they wanted to during the week. I found out after just to committees, that this didn't work for me. Where one of them didn't even take much work. I noticed that it was just mentally draining to just be a part of it, more draining than actually just doing the work that was required of me. Now I feel much more relaxed knowing that I can focus on my studies, without worrying about all the other stuff I should be doing. (S2)

3.3 Positioning their study programs in relation to others

When describing both the decision for choosing their study program and how they are experiencing it, the students draw heavily on comparing and positioning their study program in relation to other study programs. When choosing a study program, the common approach seems to be to choose based on your grades and aiming to be admitted to the study program with the highest possible admission requirement.

> There is an existing hierarchy within our society and university. It seems that people think that you should just swoop into your place (in the hierarchy). If you have a 6.2 GPA (grade scale= 1-6), then you are supposed to choose indøk (Industrial Economics and Technology Management, the engineering program in Norway with the highest admission requirements). If you choose something else, it will be like «what are you doing? You are not supposed to be here". Passing on the notion that if you do not max your GPA, it will be a waste. (S7)

Once at the university, several chose to portray their own situation by ranking their program compared to others, both technical and non-technical study programs. The students illustrate a hierarchy, where they have a specific place, not at the top, but not far from it. Even before being fully enculturated into the university culture, the students pick up on existing social norms that exist on how to talk, relate, and view other study program. There is a known "feud" between the technological and humanistic studies. One of the students shares a story from the beginning of the semester illustrating this.

> It might be because you don't have so much contact with people from the other study programs. I remember a situation from the initiation weeks at the university. We were at a student's house at a place in Trondheim. A person peaked through the window and asked where we studied. And I remember one girl lying about what she was studying, she said that she went to our university, because she knew that we went to this specific campus (with the technological study programs). It turned out that she went to BI (a private business school). So, this shows that there is a culture at our campus (Gløshaugen), that we are better than other studies. (S5)

When asked about where the notion of technological studies being "better" than other studies came from, the student points out that he has been told from former/senior students how the culture at NTNU and the electrical engineering program is and has always been. He emphasizes that these assumptions are unfortunate.

> It is mostly from people around you. Things I have heard from last year's students. It is unfortunate. There is no reason for walking around thinking that you are better than everyone else. I do not feel like I think like that. But you hear it from people. There have not been any bad vibes, it might be more as a joke. But then again, there is always some truth behind a joke. (S5)

Another student describes what she has encountered as a common attitude at the university. The description contains how the campus where the technology programs are at home is perceived as better than the campus for other study programs. Even within the technological studies, there is a known hierarchy. She points out that this feeling has grown stronger after being a part of the university culture for a while.

> I feel like there is an attitude at Gløshaugen (campus at the university), to start with- Gløshaugen is above all other places. This is where the hardest, toughest, smartest people study. Like a God-complex. And within, you have the really hard study programs. If you are just enrolled in a bachelor's study program you are just an engineer, not a sivil engineer… the industrial economy study program for example, is not perceived as having a very high status within Gløshaugen, but this study program has very high status elsewhere. This is a feeling I have. I did not think that it would be as strong as after I came here. I got this feeling after I came here, a lot more than when I applied. (S7)

4 DISCUSSION

Building on the empirical material, we will in the following discuss how students' expectations of higher education shape and are shaped by their experiences of entering the university. On a general level, based on the findings in this study, it is clear that the students' expectations before entering the university do not always align with their experiences after being admitted, which is in line with earlier investigations into first-year experiences [1]. Furthermore, it is apparent that their expectations of the university have a clear connection to their experiences from high school, including what they expect from themselves and others professionally.

The process of entering the university is a turbulent experience for students, where they have to realign their views of themselves to match their lived experience, a process that is shaped by their expectations, i.e. students who did not expect the social importance of the committees and feel left out when having problems joining or students who expected joining a committee would be socially important, but where the activities left them mentally exhausted.

From the interviews, it is clear that this process is tightly linked to students finding their role in the social hierarchy at the university. In the following, we will discuss three dimensions of this positioning process within the social hierarchy at the university: students' individual relations to each other, the role of social committees, and between study programs. First, when transitioning into university, the students need to reassess their own expectation of how they view themselves, including their own capabilities and knowledge, in relation to others in the same program. One of the students described it as "swooping into your place in the hierarchy". Previously, it has been found that this perception of oneself in relation to other students can affect behavior when collaborating in project courses, giving more meaningful tasks to the students that are perceived as more knowledgeable [5]. Second, the students need to position themselves in relation to other students in the same student organization, with a membership in a committee as both an indicator and a generator of social attractiveness, with strong existing assumptions that new students will want to join one. Third, the students need to understand what status their choice of study program gives them in relation to students outside their program. Lastly, the students reveal that the choice of applying to engineering somewhat motivated by status and the expectations of those around them, not necessarily meaning only their parents, but other people in their community as well.

According to social identity theory (SIT) [6], students will derive a positive self-concept from being a member of a group, thereby favoring their own in-group to create a higher self-esteem. Simultaneously, there is a clear hierarchy between groups, as illustrated in the empirical material where the revue-committee is described as an out-group amongst the committees. It is also apparent that students constantly compare their own study program and see it in relation to other study programs. Being enemies with other student organizations, is portrayed as a joke, and by doing this it is possible to create an in-group within the student organization. This recurring theme is apparently a known topic both within and outside the university.

The high status of the student organizations creates a situation where they seem to have monopoly on how and where student culture and learning environments are negotiated. Students perceive that they are required to spend a set amount of time on committee work, and most spend significant amounts of time on the social events connected to the committee. The more time they spend, the more influence the committee will hold over the members, in turn making the committee as an in-group even more important for the students' university experience.

Building on system justification theory (SJT) [7], we see the students justify the social hierarchy through ego justification, group justification, and system justification. Ego justification describes the process by which students feel better about themselves by viewing themselves as better than other students, both in their own program and other programs. Group justification captures how committees are perceived as valuable places to be and creating value for others, whereas differences between programs and campuses can be approaches on the level of system justification.

Furthermore, the empirical material gives the impression that attitudes, justifications and overall culture is being passed on from one generation to the next, even though the students reveal that there are many aspects of the culture they do not like. The strong rituals and norms within the student organization might hold on to predefined connotations and prejudices, which several of the students' descriptions illustrate.

In conclusion, the interviews reveal that the students have expectations to both themselves and to others when entering university, expectations that are quickly shaped by the process of finding one's place in the university's social hierarchy through maneuvering the strong established expectations already present in the programs, organizations, and committees, creating an experience predefined by the strong cultural norms of what it means to be a student.

ABSTRACT

The use of “digital tools” have usually played an important role in the transformation to “emergency remote teaching” during the pandemic. However, even before the pandemic there has been a strong pressure that education should become more “digital”. Nevertheless, we see several problems associated with the present discourse related to “digitalisation” of education. 1) It often unclear what is meant with “digital education”, 2) very narrow view of “digital tools” too mainly be tools for information and communication neglecting other uses of digital technology, 3) unbalanced focus on “digital tools” there other tools are either neglected or seen as inherently inferior and “old-fashioned”, 4) conflation between “digital” and “distance”, 5) adherence to either a technological determinism or a pedagogical determinism (technology is a neutral tool).

Engineering students’ courses of action have been videorecorded in design projects and in electronics labs at two universities. It can bee seen that students’ use a wealth of bodily-material resources that are an integral and seamless part of students’ interactions. They use bodily resources, concrete materials, “low-tech” inscriptions as well as “high-tech” (“digital”) inscription devices. Our results challenge that by hand – by computer and analogue tools – digital tools should be seen as dichotomies. Our empirical evidence suggests that students should be trained to not only be trained to work with “digital” tools but with a multitude of tools and resources. We, thus, advocate that a postdigital perspective should be taken in education where the digital makes up part of an integrated totality.

1 INTRODUCTION

1.1 Digitilisation of education

For about about thirty years there have been a strong focus on, and a pressure to increase the use of, computers and internet in education [1-4]. In later years the buzz words “digitilisation” and “digital education” have been coined to describe this trend. During the Covid-19 pandemic many universities and schools world-wide transformed to “emergency remote teaching”. This was enabled by the use of “digital tools” such as the internet, computers and other communication devices equipped with cameras and speaker/microphones leading to an even stronger focus on “digitilisation” of education.

Nevertheless, we see several problems associated with the present discourse related to “digitalisation” of education. 1) It often unclear what is meant with “digital education”, 2) very narrow view of “digital tools” too mainly be tools for information and communication neglecting other uses of digital technology, 3) unbalanced focus on “digital tools” there other tools are either neglected or seen as inherently inferior and “old-fashioned”, 4) conflation between “digital” and “distance”, 5) adherence to either a technological determinism or a pedagogical determinism.

The aim of this paper is to be somewhat provocative and raise questions and issues related to the “digitilisation” of (engineering) education for debate. The paper is organised as follows: In sections 1.2 – 1.6 we, as a background, describe in some more detail (than is done in this section) some of the problems we see as exhibited in the present discourse related to digitilisation of education. In section 1.7 we argue for a broad view of digitilisation and demonstrates that it, indeed, is nothing recent but has a long history and in section 1.8 we briefly introduce the consequences we see with a narrow digitilisation as presented in sections 1.2 – 1.6.

In many ways the paper is a conceptual one but we support our argumentation with empirical data collected using video recording of engineering students in action in a design project and in an electronics lab. How the data was collected and analysed is described in chapter 2 and two episodes from the data are presented as results in chapter 3. Finally in chapter 4 we briefly discuss our findings in relation to postdigital theories. As this is a conference paper with limited space it has only been possible for us to briefly discuss the issues we want to address and the questions we want to raise. We have also only included a limited number of references.

1.2 Unclear meaning "digital education"

There is a lack of conceptual clarity regarding what is meant by "digital education". In a very early paper [5] "digital education" was used to reference the training of the dexterity of a dentists' hands (remember the original meaning of digit as finger). In the 70:s when the first author was an undergraduate student in engineering "digital education" was the learning about digital electronics (seen as distinct from analogue electronics). Neither of these earlier meanings are in the foreground in present day discourse.

Nowadays two main meanings of "digital education" can be discerned in the discourse: "Digital education" (and synonyms such as e-learning, technology enhanced learning etc.) can used for educational approaches that make use of digital tools and technologies during teaching and learning such as online learning and blended learning. "Digital education" can also denote the education of the learners to enable them to use digital tools in a skilled and comptent way. For example University of Edinburgh is using the first definition (with the add on that it should be "innovative use") [6] while the European Union in its Digital Education Action Plan use both meanings [7].

1.3 Narrow view of "digital tools"

What is apparent in many reports is what a quite narrow view of "digital tools" are purported. These are commonly described as being tools for transfer of information (in a narrow sense) and communication, i.e. ICT (information and communication technology). Other uses of digital tools such as the use of digital technologies for taking measurements, making observations, displaying and visualising results from measurements and observations, controlling measurements, modelling and simulations are seldom mentioned. Figure 1 displays a typical view of the meaning of digitalisation [8]. Indeed, Walan [9] in a study of "digital technology in science classrooms" only describes digital technology as information and communication tools and in a study performed by Henderson et al. [10] the digital devices the students reported to have used in the previous four weeks were laptop or desktop computers, smartphones, tablets, and in a few cases a dedicated e-reader. Although 47.8% of the students in the study by Henderson et al. were medical, science or engineering students no other use of digital devices were reported.

Fig. 1. From a publication by The Swedish National Agency for Education describing how the agency is working to digitalise schools [8].

Despite the heavy use of digital technologies (see section 1.7) for observation, measurements, regulation and control in health sciences, natural sciences, and engineering this usage is neglected in many common descriptions as reported above. Indeed, many successful projects for the learning of physical concepts built on the use of computers, with attached sensors, to make (real-time) measurements in real experiments. Such experiments were introduced in the teaching of physics in the mid 1980:s (see, for example, references [11, 12]) and the first author have reported successful use of such (digital) technologies with Swedish engineering students [13-16]. However, contrary to the narrow view of Walan [9] Kyza et al. [17] presents a much wider use of (digital) technologies that include technologies for data collection and analysis.

A wider view, but not complete view of digital tools are discussed in section 1.7

1.4 Unbalanced focus on “digital tools”

The narrow meaning of digital tools embraced in many accounts described in previous section is problematic. This limited discourse is often further extended by digital tools beeing portrayed as something positive and “modern” as opposed to substandard, inferior and outdated pre-digital tools and techniques [4, 18, 19]

1.5 Conflation between "digital" and "distance"

It is common to describe distance meetings (using, for example, computers and software such as Skype, Zoom, or Teams) as "digital" meetings. This has resulted that in many cases there is a conflation between between "digital" and "distance" and, for example, that planning for distance laborations are discussed as making the labs "digital". This is *highly* problematic as many (on campus) labs in science and engineering already are digital in that sense that they make heavy use of digital technologies for performing (real) measurements, analysing data from these measurements, and controlling experiments.

1.6 Technological and pedagogical determinism

The topics of technological or pedagogical determinism actually are actually worth a paper in its own to be discussed in depth and have, indeed, been discussed by many authors. We have chosen to illustrate the issues involved by figure 2 taken from the works of Tim Fawns [20]. In short, technological determinism rests on the illusion that the use of a specific tool *pre-determines* the outcome. In our own research we have demonstrated that this is simply not true, but that the pedagogical design also matters [e.g. 16, 21]. On the other hand, in pedagogical determinism technology is seen as a neutral tool and the pedagogical method used *pre-determines* the outcome. In our own research we have demonstrated that different techologies, indeed, have the different affordances effecting what is possible for students to experience [e.g. 22]. In the debate and discourse regarding "digitilisation" of education both technological and pedagogical determinism can be found [e.g. 4, 20].

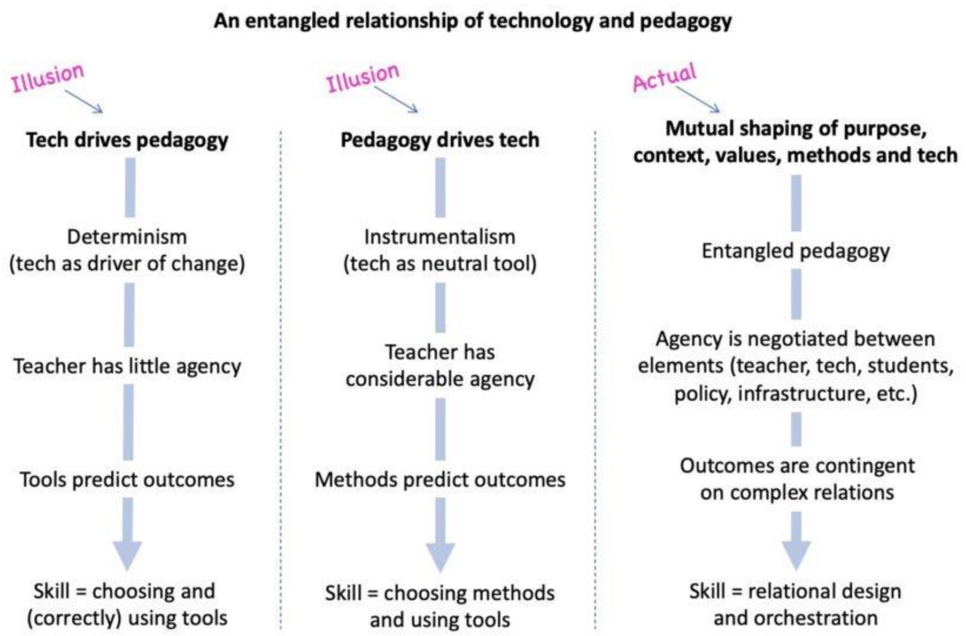

Fig. 2. An entangled relationship of technology and pedagogy (v3), CC BY SA, Tim Fawns, University of Edinburgh.

1.7 “Digitalisation” has a long history

In section 1.3 it was mentioned that often a rather narrow view of the meaning of “digital tools” are embraced. Commonly digital technology is described as a rather recent (and modern) technology and the digitalisation of society as a new phenomena. In part this is true for the aspects of digital technologies experienced by the general public. Indeed, that is seen by the public (and policy makers) is mostly digital tools as information and communication technologies. Most people are not aware about the amount, and features, of digital technologies that are operating behind the scenes and that are contributing to the well-beeing and affluence in modern society (at least in some parts of the world).

If we see digitalisation as meaning something that can be described by discrete, digital, units (as opposite to continuous, analogue, entities) it can be seen that “digitalisation” has a rather long history. One start is the invention in 1725, credited to Basile Bouchon, to use perforated tape to control looms for the veawing of ornamental patterns [23]. This idea was further developed over the following years and around 1805, using perforated cards, Jacquard was able to make the first really successful automatic weaving loom. As discussed by, for example, Randell [23] the control of the Jacquard loom inspired various developers of analytic engines manifested in 1944 with paper rools used to control one of the very first computers (Mark 1). Still, in 1973 when the first author as a first year engineering student learned programming (Fortran IV), punch cards were used to control the computer and execute programs.

There is, indeed, a rather continues line of development from the control of operating looms in 1725 by a rather primitive “digital technology” to the (automatic) control nowadays of our dishwashers, washing machines, heating, cars etc to the control of machinery, railways and even complete industrial processes. The difference is that the “card perforations” now are electromagnetically stored as zeros or ones (an intermediate step has been electrical sensing of card perforations). Digital electronics has enabled the control processes and things at a faster spead, larger scale, higher reliability and at a lower and lower cost. We claim that the use of digital tools for control is an, for society and our well-fare, important utilization of (digital) technology.

Another important use of digital technologies in modern society is the use of digital technologies in combination with suitable sensors for taking measurements and making observations and displaying results from these. This use of digital technologies are of great importance in industry as weel as in research. In health care it is almost impossible to imagine a modern intensive care unit without this use of digital tools. As mentioned in section 1.3 digital measurement technologies has been used in physics teaching [11-16] since the mid1980:s and is, thus, not something very recent.

1.8 Consequences

The greatest value of using digital tools for our society is perhaps not primarily as tools for information and communication but, in our opinion, as powerful (and often affordable) tools for control and regulation, measurement, observations, calculations and more. If these aspects are missed, there is a risk that we give students a false picture of what digital tools have provided for contributions to our prosperity and welfare. Furthermore, if these aspects are missed, there is a risk that the potential of using digital tools in teaching will not be fully utilized! (cf. references [4, 20])

2 METHODOLOGY

The intent of the background in our paper has been to present a more comprehensive and multi-facetted picture of what we see as digital tools. Based on this background, on scholarly literature [1, 4, 20, 24], and our experience from theaching our hypothesis is that the dichotomy between digital and analogue tools is artificial and barren. We, rather support the view argued by Fawns [4] (and others) that we need to take a "*postdigital* perspective [in education], in which the digital makes up part of an *integrated totality*" (our emphasis).

We have, over a period of more than 15 years, collected a rather extensive set of video recordings [25] of (primarily) engineering students' interactions during engineering design projects and during physics and electronics labs. This video data have been recorded in regular teaching sessions at two universities in two different countries.

We have re-analysed the videos driven by our research question what kind of tools contributing to their fullfilment of tasks, and contributing to their learning, are students' using? As the material is, indeed, very extensive we will in this paper present evidence from two episodes:

Episode 1: Students in the fifth semester of the PBL-based master's program Architecture and Design at Aalborg University, Denmark, have been videotaped. The students work in groups of 5–6 students and have the task of constructing a real office building.

Episode 2: Students in the fifth semester of the master's degree program Electronics Design at Linköping University, Sweden, have been videotaped during a laboratory in high-frequency electronics. The task is to make a model of unknown (analog) circuit.

Because of the importance to illustrate the materiality of the settings and students' use of different tools and gestures, the results are not represented by traditional transcript. Instead we have put student dialogue (translated from Danish or Swedish into English) into speech bubbles. All names are pseudonyms and not students' real names. Informed consent was obtained from all, involved, students and the material have been handled according to the laws, ordinances and other regulations valid in Denmark and Sweden. The results and our analysis is presented in the next chapters.

3 RESULTS

3.1 Episode 1

The episode is taken from a videorecording of a preparation (lasting the whole day) the students are making for a presentation in a feedback seminar the next day. In the excerpt four of the students are sitting around a table working individually for a while. In the first group of two pictures Ina calls for Mette's attention to discuss a design decision. Mette rools over to Ina and in the exchange they use an iPad, a drawing, a styrofoame model, and their own fingers to highlight the issues involved. In the next group of pictures they use a 3D-styrofoam model to reason around and the make ample use of gestures. In the next step they move over to Mette's computer to look at a CAD-drawing and Ina is using her fingers to "walk" around the building in the drawing and finally Ina is pointing to a photo on the board where the group keep materials used for inspiration. She is pointing to a similar design already implemented in reality.

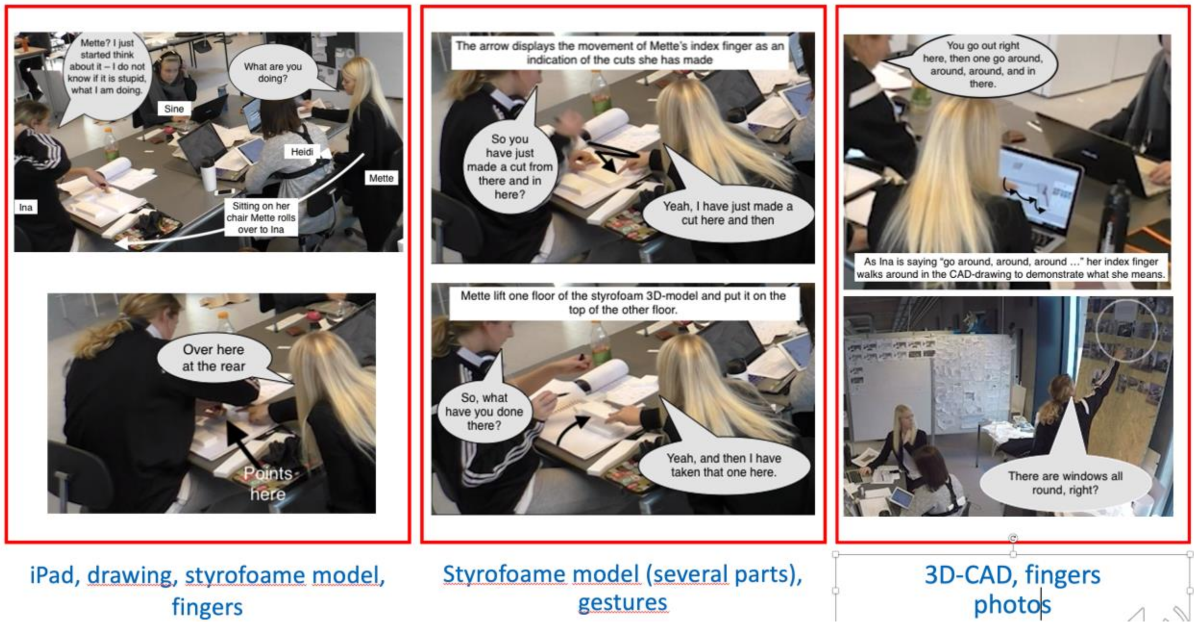

Fig. 3. Still pictures, with speech bubbles, taken from the videorecordings of a student group in a design project at Aalborg University. Below each pair of pictures are written the "tools" students are using.

We are here only showing a very short excerpt. A fuller presentation of this material can be found in references [24, 26-28].

3.2 Episode 2

In this episode students investigates an analogue high-frequency circuit with help of a digital oscilloscope and digital measurement technology. The task students are facing is to make measurements on several circuits consisting of unknown elements and to model the unknown circuit. For measurements a digital oscilloscope is used. The oscilloscope is connected to a computer enabling the results to also be displayed on the computer screen. A complication for the students in solving this task is that in high frequency electronics many of the idealization assumptions on which basic electric circuit theory and electronics are not valid.

In figure 4 a short excerpt from the lab is shown with the students Leif and Rune. In *a*) the oscilloscope can be seen in the upper left corner and the measurements are also displayed on the computer screen seen to the right. Moreover in *a)* Leif is responding to Rune by pointing at a graph feature displayed by the oscilloscope and in *b)* Leif continues by hand movements and gestures to indicate high and low frequency characteristics. He continues in *c)* by now indicating flank using a pen to point on the computer screen and moving the pen up and down. In *d)* Rune suggests that the circuit consists of a coil and a capacitance making a sweeping hand movement along the measured graph. For about a minute the students are continuing discussing the circuit, they go back to a previous measurement on another circuit to compare, and make some sketches. Finally they feel confident that the circuit consists of a coil and a capacitor and as a confirmation Leif points to the peak as displayed in *e*) and moves the pen as is indicated by the arrow.

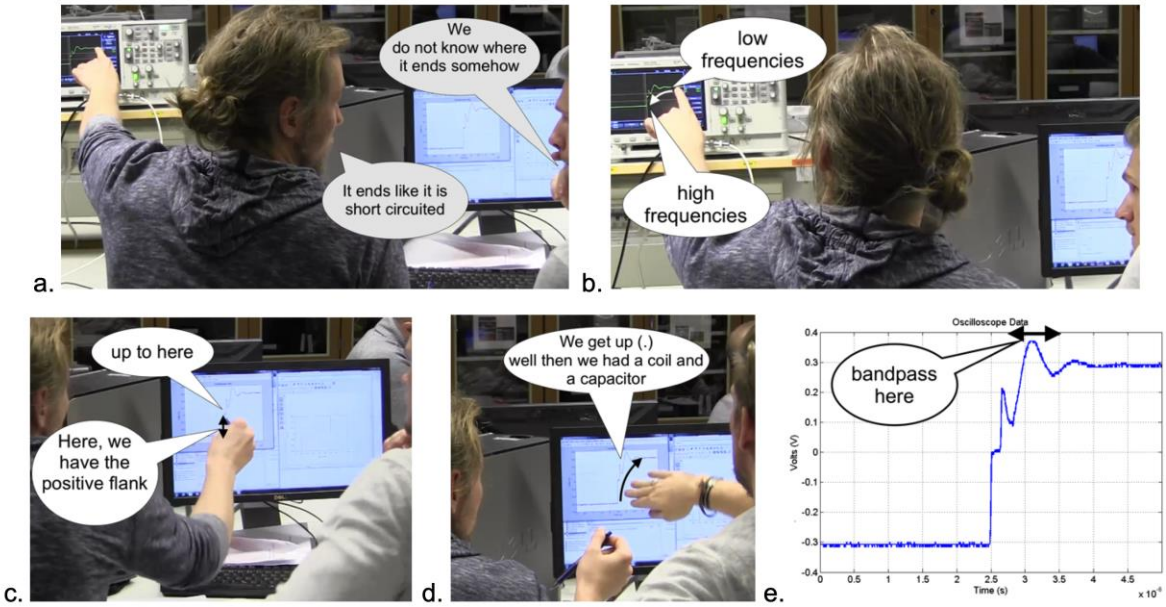

Fig. 4. Still pictures, with speech bubbles, taken from the videorecordings of a high frequency electronics lab at Linköping University.

We are also here only showing a very short excerpt. A fuller presentation of this material can be found in references [29, 30].

4 DISCUSSION

In both episodes, the students used in their interactions a rich repertoire of physical and material resources in an integrated and seamless way: Physical resources (eg. gestures, opinions, bodily orientation), concrete models (eg. 3D styrofoam models, paper models), low-tech inscriptions (eg. sketches, drawings on paper, post- IT notes) and equipment for "high-tech" inscriptions (eg. iPads, CAD drawings, digital measurement technology, simulations).

As mentioned in the introduction there is concurrently an urge that education (and society) should become more “digital”. As a consequence, if tools and resources are considered at all, it is common to see these as synonymous with “digital technologies”. For example, at the European engineering education conference 2018 in Copenhagen Flaata and Pitera [19] almost excused themselves for their students use of “old-fashioned” sketching and drawing by hand as they were supposed to become engineers in the “modern world”. However, our study shows that a focus only on “high-tech” resources would be problematic and that we in engineering education research should rather attempt to understand how students use many and varied bodily-material resources and in engineering education encourage their use [cf. 31, 32]. An apparent finding in this study is that students made ample, efficient and fluent use of gestures, sketches and hand drawings and that these procedures seems to be beneficial to the design process and/or the learning process as different tools and resources had different affordances [see also, for example, references 32, 33, 34]. It is important to note that the students did not use the “low-tech” resources because they lacked the necessary skills to use the “high-tech” resources. On the contrary we argue that the students displayed that they were highly skilled in using digital tools, but they, in each situation, used the tools and resources they deemed to be most beneficial for the task at hand.

Indeed, more than 20 years ago Henderson [33] in her study *On Line and On Paper: Visual Representations, Visual Culture, and Computer Graphics in Design Engineering* offered a critique of the dominant ideology that paper was soon to be a thing of the past to be replaced by the use of digital tools. In her work she showed the centrality of sketching and sketches in professional engineering work and argued that CAD lacked the flexibility needed to fully support collaborative design. In our study we can see that the students use sketches and sketching, physical models and gestures as these tools and procedures offered greater flexibility and that the students mainly turned to 3D CAD drawing when finalizing design and make more (final) formal drawings.

Moreover, our results challenge that the distinction between by hand and by computer, between analogue and digital tools, should be seen as a dichotomy. Rather, our results show a blurred distinction. We see that it is essential that engineering students are trained to work “by hand” *and* “by computer” and that it is *not* a question of “by hand” *or* “by computer”. Indeed, Fawns (and others) argue that we need to take a “*postdigital* perspective [in education], in which the digital makes up part of an *integrated totality*” [our emphasis, 4].

As we only, in this study, have studied two cases and only have looked on students’ interactions (not on teachers’) we can, of course, not draw a general conclusion (if this even can be made) of the optimal use of different tools. Neverheless, we suggest that engineering teaching should not be focused on “digitalisation” in a narrow sense, but should seriously consider a postdigital perspective where digital tools are part of an integrated whole together with other tools and resources. All the tools in the educational toolbox are needed and they are good for different things!

ABSTRACT

Sustainability and responsible use of the resources at our disposal are among the most important goals of our time. Employees are looking for next-generation employees with ever more skills. To ideally foster these in engineering and prepare them for future challenges, the integration of education for sustainable development (ESD) with a linkage of technical and sustainability-oriented issues in the curriculum is essential. This paper takes up two points: Firstly, an analysis of the research landscape in Engineering Education Research (EER) on the topic of "sustainability" is undertaken. For this purpose, more than 3500 conference papers of EDUCON and FIE of the years 2014 to 2018 as well as 2021 (EDUCON only) are evaluated. The methodology of the analysis as well as the set of main and sub categories (among them "sustainability") will be presented at SEFI 2022. The results of the analysis of the research landscape show that the topic of sustainability has so far played a negligible role in the conference contributions. Secondly, the focus is on the implementation process and the linking of technical and sustainability-oriented issues. The study programme concept of the Leuphana University offers two options for sustainable technical education by combining major and minor study programmes. The interdisciplinary combinations are presented and explained using module examples. In total, this paper provides a research-based contribution to sustainable engineering education in research and practice.

doi:10.5821/conference-9788412322262.1441

1 INTRODUCTION

Sustainability and responsible use of the resources at our disposal are among the most important goals of our time. Employees are looking for next-generation employees with ever more skills. In order to optimally promote these in engineering and prepare them for future challenges, the integration of education for sustainable development (ESD) with a linking of technical and sustainability-oriented topics in the curriculum is essential. Worldwide, studies show that the topic of sustainability is insufficiently addressed in engineering curricula [1-4]. For example, the study by [1] assesses the Nigerian engineering curriculum and shows that sustainability dimensions are poorly included, with environmental concepts mentioned most frequently and social issues least frequently. An analysis of the presence of sustainability issues in 16 Spanish higher education curricula in education and engineering show that they are more homogeneously represented in education curricula than in engineering curricula [2]. A survey of students in the Civil and Environmental Engineering (CEE) programme at the Georgia Institute of Technology investigated students' interest, knowledge and experience in sustainability. The results show that students are interested in sustainable development, but there is still potential to improve sustainability education [3]. An investigation of the integration of social sustainability into engineering education at the Royal Institute of Technology (KTH) in Sweden based on interviews and indicates that curriculum managers and teachers at KTH have difficulties understanding the concept of social sustainability [4]. Other studies show positive developments in relation to sustainability [5-6]. An analysis of the current state of Australian universities shows that a large proportion have successfully introduced sustainable engineering education, while the rest are currently focusing on integrating it into their curricula [5]. In addition, [6] describe the progress made over the last 25 years in incorporating sustainability and green engineering content into chemical engineering curricula.

The above analyses and studies show that there are some universities that have mastered the challenges and are well on their way to implementing education for sustainable development in engineering. However, a majority of the studies show that sustainability aspects are strongly neglected in engineering education, especially social sustainability aspects. Which is where this contribution intervenes. An analysis is made of the research landscape in engineering education research (EER) on the topic of "sustainability". For this purpose, 3570 conference papers of EDUCON and FIE from 2014 to 2018 and 2021 (EDUCON only) are analysed. The methodology of the analysis will be described in the following section. **Sec. 3** presents the evaluation with a focus on the issue of sustainability. Furthermore, the focus is on the implementation process and the linking of technical and sustainability-oriented questions. Therefore, the last **sec. 4** shows a successful implementation of sustainable engineering education. By the study programme concept of Leuphana University with the combination of major and minor study programmes, two options for a sustainable technical education are presented.

2 METHODOLOGY

The systematisation of the EER landscape is carried out as design-based research work, e.g. [7-8], which contributes to theory building by providing a categorisation of the international research field, but also leads to the structuring and bundling of research findings in practical application. For the purpose of gaining knowledge at the interface of engineering and sustainability, two leading IEEE conferences of the international EER research landscape, the FIE and EDUCON, were selected as the basis for the systematisation, whose publications appear annually in a two-stage blind review process. With the aim of an international and up-to-date analysis, contributions to EDUCON and FIE from the years 2014 to 2018 and 2021 (EDUCON only) were systematically analysed and categorised using a catalogue of categories developed in advance. In doing so, EDUCON, like SEFI Annual conferences, focuses more on the European research landscape, while FIE expands the research work to include a more international (especially American) view. This approach addresses the critiques of Williams and Wankat [9], Williams et al. [10] as well as Borrego and Bernhard [11], who point to existing disciplinary and geographical divisions in the research landscape. Although the research presented does not provide a complete overview, basic statements and research trends on sustainable engineering education can be derived. The number of articles from the respective years that were used to categorise the scientific articles is presented in **Table 1**.

Table 1. *Number of published and categorised papers of the international EER conferences Global Engineering Education Conference (EDUCON) and Frontiers in Education Conference (FIE) in the years 2014 - 2021, own data.*

Year	EDUCON	FIE	Total
2014	196	519	715
2015	154	403	557
2016	191	410	601
2017	289	306	595
2018	300	537	837
2021	265	-	265
Total number of categorised paper			**3570**

2.1 Methodological procedure, implementation and critical reflection

In the content-structured procedure according to [12], the categories for the systematisation of the EER research field were developed inductively from contributions of the EDUCON and the FIE of the years 2014 to 2018. The methodological design of the systematisation and selected partial findings were put up for discussion within the research community [13-14]. The result is a research-guided category system consisting of ten main categories and 78 subcategories, which encompasses the main aspects of the research field, their specification and the relations and delimitations of the individual categories to each other (exemplified with a focus on sustainability in **sec. 2.2**). To increase the quality of the research process and to minimise the subjectivity of the analysis, intersubjective validation was used consistently from the beginning of the research process. In order to check the uniform understanding, several papers were randomly selected from the total amount of contributions, individually categorised by at least two people and the categorisation subsequently discussed in the team. The discourse about the individual perspectives and the achievement of a consensus in the categorisation led to a secure handling of the category system and consequently to a reliability of the categorisation within the research team. Subsequently, 3570 contributions were systematically analysed and categorised using the category catalogue developed and are available as an Excel list. The topic of “Sustainability” is represented as a sub-category in the category system. For a more in-depth analysis, a keyword analysis within the Excel file was used in the submitted contribution. This in-depth analysis followed the procedures for systematic literature review regarding engineering education research, e.g. [11]. The titles, keywords and abstracts of the papers were searched for the keywords: "sustainability", "sustainable" and "climate change". The results of this extended analysis have been incorporated into the evaluation in **sec. 3**.

2.2 Theory-based positioning of sustainability in the EER landscape

The category system developed consists of ten main categories with up to 12 subcategories each, extracts of which are shown in **Table 2**. In addition to the categories, there are coding rules that describe the assignment criteria for the respective category and add concrete anchor examples or demarcation notes to other categories. For example, the publications sorted into the main category "Teaching and Learning" focus on the teaching-learning process and its design. The category "Topics related to Engineering" categorises publications that place the thematic focus on topics that are not subject-specific but are related to engineering content. One of the subcategories belonging to this main category is “Sustainability” (see **Table 2**). Each contribution was assigned to at least one and at most two main categories. The selection of two main categories ensures that interdisciplinary contributions and contributions that form a transfer between individual topics can also be considered in two different categories. One suitable sub-category can be selected for each main category.

Table 2. *Main categories and exemplary subcategories of the category system for systematising the EER landscape, own data.*

Main categories	
Assessment and Evaluation	**Student Motivation and Decision Making**
Curriculum Design	**Target Group Related Issues**
Discipline Specific Issues	**Teaching and Learning**
Diversity in STEM Fields	**Topics related to Engineering**
Research	**Digitalization**

Sub categories of the main category "Topics related to Engineering"	
• Language Issues • Philosophy in Engineering • Professional Ethics • Professional Skills • Entrepreneurship	• **Sustainability** • International • Academic Writing Skills • Interdisciplinarity & Education

The categorisation carried out according to the systematic and rule-guided procedure described above made it possible to examine the location of sustainability in the area of EER, and the results are presented below.

3 FINDINGS WITH A FOCUS ON SUSTAINABILITY

3.1 General statements of the overall evaluation

The total of 3570 FIE and EDUCON conference articles from 2014-18 and 2021 (EDUCON only) were each assigned a minimum of one and a maximum of two main and sub-categories. A total of 6627 categories were assigned. What is noticeable in the overview of the results of the category allocation is the lower number of allocations in the contributions to EDUCON, which can be attributed to the different absolute number of contributions to the respective conference (see **Table 1**). In both conferences, topics in the context of teaching and learning processes (main category "Teaching and Learning") were addressed most frequently by far. Articles dealing with project and problem-based learning were particularly prominent. Many of the contributions at both conferences also focus on issues and topics of a specific engineering discipline (main category "Discipline Specific Issues") or deal with the development, expansion or re-design of modules or entire curricula (main category "Curriculum Design") in the field of engineering. For limited reasons, a more comprehensive overall evaluation is not included in this paper, as the focus is on the evaluation of the topic area of sustainability.

3.2 Results with focus on the subcategory sustainability

As previously pointed out in the introduction, many educational institutions are lacking a reference to the topic of sustainability and thus to education for sustainable development. In the following, the number of contributions dealing with the topic of "sustainability" will be examined.

Fig. 1 gives an overview of the categorisations of the articles of the FIE and EDUCON to the sub-category sustainability over the years. Out of a total of 6627 categorisations, 48 (0.72%) were made in the sub-category "Sustainability". By way of explanation, it should be added that a category is only awarded if the *majority of the contribution* deals with the theme. Most articles mentioning sustainability issues were identified in 2017. In general, the proportion of articles that address the topic of sustainability is extremely low at 0.72%, which illustrates and supports the situation described in the introduction. Contrary to expectations, there is no trend to be noted in the results.

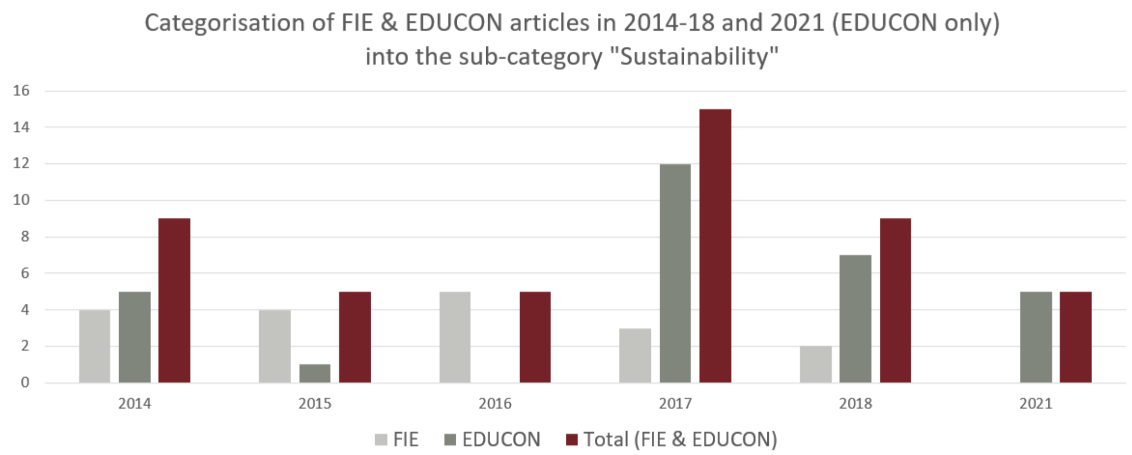

Fig. 1. *Categorisation of FIE & EDUCON conference articles in 2014-18 and 2021 (EDUCON only) into the sub-category "Sustainability", own data.*

In order to find out whether the topic of sustainability nevertheless plays a role in the categorised articles, a "COUNT IF" query was carried out in Excel. It was analysed how often the word "sustainability" was written in the title (9 times), in the keywords (20 times) and in the abstract (39 times). In addition, the words "sustainable" and "climate change" were filtered. The word "sustainable" appeared in a total of 18 out of 3570 titles, in 17 keywords and 55 abstracts. "Climate Change", on the other hand, was only mentioned once in the title and keywords and 3 times in the abstract. The occurrence of the word "sustainable" should be interpreted with caution, as it refers not only to sustainability aspects, but also, for example, to long-lasting projects that do not directly include sustainability issues. With a total of only 5 mentions, the occurrence of the word "climate change" can be neglected. **Fig. 2** shows the frequency of the word "sustainability" in the title, abstract and keywords depending on the year.

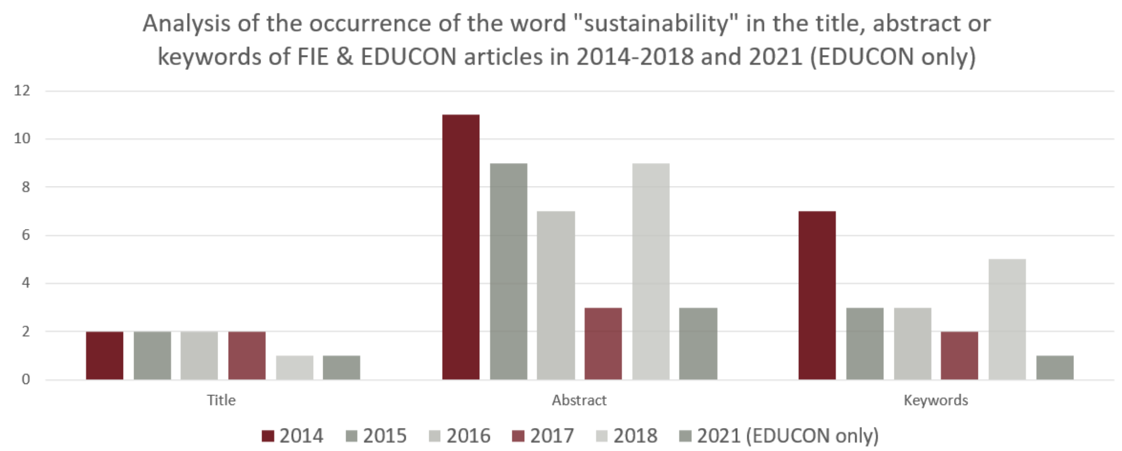

Fig. 2. *Analysis of the occurrence of the word "sustainability" in the title, abstract or keywords on FIE & EDUCON conference articles in 2014-18 and 2021 (EDUCON only), own data.*

The latter analysis confirms the results of the categorisation, as the frequency of the keywords is in similar dimensions to the allocation of the articles. Basically, however, it becomes apparent that very little relevance is attributed to the topic of sustainability in engineering education research and practice, which urgently needs to be changed. An approach for integrating sustainability aspects in engineering education is therefore presented in the following chapter.

4 INNOVATIVE TEACHING CONCEPT FOR SUSTAINABLE ENGINEERING EDUCATION PRACTICE

The interdisciplinary study model of Leuphana University provides a successful framework for the curricular connection between technology and sustainability. The individual study program is created from Leuphana first semester (30 CP), major (90 CP), minor (30 CP) and complementary studies (30 CP). Students even have the opportunity to customize their study focus and to freely combine their major and minor subjects. For the realisation of a sustainable engineering education, there are two possible combinations with different weighting of the technology and sustainability components, see **Fig. 3**.

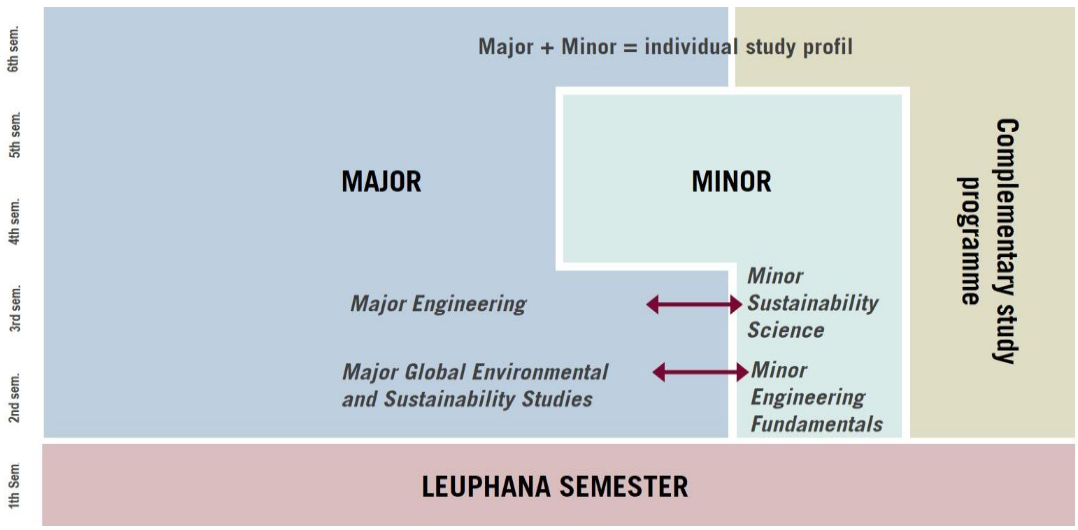

Fig. 3. *Leuphana Bachelor - Possibility of individualised profiling at the interface of technology and sustainability*

The M**ajor Engineering** provides a sound engineering and scientific knowledge as well as a deeper understanding of the controlling, optimising and controlling processes in digitised production and prepares students for the complex challenges of industry 4.0. Students of the **Major Global environmental and sustainability studies** acquire skills which will enable them to actively contribute sustainable development on a global level with an international perspective. The **Minor Sustainability Science** focuses on issues pertaining to the future of sustainable development. Students pursuing this minor will analyse the consequences of global change and develop sustainable solutions to real social problems that arise from unsustainable practices. The **Minor Engineering Fundamentals** provides an overview of the most im portant technologies and technology-oriented processes in the manufacturing industry. To illustrate the close interlinking of engineering and sustainability, the content of the course “Electrical and Automation Engineering” is presented as an example, see **Table 3**. The course is one of six courses of the Minor Engineering Fundamentals (among others Mechanical Engineering, Manufacturing and Information and Communication Technologies).

Table 3. Topics of the course “Electrical and Automation Engineering” with focus on sustainability, own data.

Course Topics and technical contents	Integration of technological innovations and industrial trends in the context of sustainability
Electrical engineering basics (DC and AC technology)	Renewable energies, solar cells
Measurement and sensor technology	Smart Sensors, VR/AR and vision application for sustainability-oriented issues and responsible use of the resources
Control and actuator technology	E-Mobility

The course takes up on innovative trends, on the interaction of technical components in complex and interlinked systems as well as on a strong focus on transfer between theory and practice. Students get basic knowledge of selected systems, models, and parameters in the range of automation technology (**Table 3**) in the context of digitalization and sustainability. Students and lecturers willingness and motivation to “bring to life” the interdisciplinary discourse, and their readiness to deal with interdisciplinary problems as well as new scientific fields independently, leads to an profound preparation of students for their future career in interdisciplinary and diverse teams in the interface between sustainability and technology.

5 SUMMARY

The paper proves in a research-based manner that the topic of sustainability has so far been underrepresented in the engineering sciences, which is why evidence-based interdisciplinary implementation procedures such as those presented in **Sec. 4** are highly relevant. At SEFI 2022 conference the authors will discuss the experience of the curriculum implementation and future perspectives within the discipline of engineering education and research.

Keywords: *Interdisciplinary engineering education, practice-based learning concepts, theory-based engineering course, design for non-engineering students*

ABSTRACT

This paper proposes a new lecture structure for an introduction to Sliding Mode Control (SMC) for a wider audience of undergraduate students. In particular, the intuitive derivation of the sliding variable and choice of the sliding surface is emphasized in order to obtain an intuitive understanding in a gradual manner. The structure of the lecture is conceived in an inclusive way, considering only the common mathematical high school background and basic knowledge about simple differential equations and their solutions. In this sense, SMC can represent a possible application of the already acquired knowledge and in the meantime provide contact with one of the most important control techniques in theory and application. The paper intends to give a possible structure of an interdisciplinary lecture in SMC for teachers and students (in particular, non-technical students). By presenting the research-based approach and the results of the implementation, the paper contributes to the discourse on interdisciplinary education in engineering.

1 INTRODUCTION

Global transformation processes lead to challenges and changed framework conditions that the engineering and education sciences have to face. In view of digitalization and increased demands for the efficient use of resources, the challenges for control engineering solutions are constantly growing. These new issues are characterized by a high degree of complexity and responsibility as well as the need for broad knowledge at the interfaces of the disciplines. Graduates must be prepared to develop adequate solutions in diverse teams in order to contribute to change processes towards a smart and sustainable future [1–3]. On the one hand, this requires interdisciplinary approaches and an increasing awareness of the automatic control importance in our society. On the other hand, there is a massive shortage of qualified specialists in the technical field. Against this background, engineering sciences have to face the challenge of offering suitable engineering programmes for a broader target group (e.g. non-technical students) and an interdisciplinary education. The aim is to prepare the students for creative and responsible action in today's society in which the concept of complementarity, which means interdisciplinarity and transdisciplinarity, is essential for most leading positions in our complex society. This ambitious program calls for new lectures: inclusive, interdisciplinary and more based on the common background of the students. This paper contributes to this research discourse by presenting an innovative theory-based lecture

structure for introducing the concept of Sliding Mode Control (SMC) to undergraduate students in non-technical fields and the related empirical findings on implementation.

1.1 Research-based didactic framework

Our objectives are standing for both theoretical understanding and educational practice. Therefore, we have chosen Design Based Research (DBR) as multi-faceted approach that provides valuable results for both, [4]. With a focus on engineering education for a sustainable and smart future, our contribution specifically addresses the theory-based approach for students who do not come from an engineering background. The very heterogeneous group of students requires an innovative teaching and learning concept to integrate different disciplinary cultures and to specifically support these *non-traditional* students in acquiring competences, as in [5]. The student-centered course design is based on Educational Reconstruction [6] as the research framework. In [7], this framework is further developed with a focus on engineering education. In order to take students seriously as an active starting point for the construction of knowledge, the Educational Reconstruction model can be of great help, see [6], especially for the special target group of non-technical students. In the Educational Reconstruction model, scientific concepts and the learners' perspective are related to each other, and from the comparison a conclusion is drawn for the design of student-centred learning environments. From this it can be concluded that teaching content must not simply be dictated scientifically, but must be created pedagogically meaningful through the conception of the learners themselves, as in [8]. With this framework, implementation results for heterogeneous student groups are available [9, 10], which have been incorporated into the new concept of the control lecture.

1.2 Institutional implementation and math. requirements

The newly developed lecture addresses the challenges for teaching in the engineering sciences described at the beginning. The lecture is offered at the Leuphana University Lüneburg in Lüneburg, Germany, which provides a conducive setting. Bachelor studies at Leuphana not only lays a solid foundation for the future professional career, but also aims at providing access to a university that values interdisciplinarity and emphasizes wide-ranging practical and theoretical competence. At Leuphana College, the individual study programme is created from major, minor and complementary studies, see Fig. 1. It forms a gateway to the academic world by exposing students to a wide range of scientific methods and offering a holistic education through individual choice of a major, minor, and complementary study electives. The College programme encourages students of all disciplines to look for solutions beyond the boundaries of academic discourse and to build a personalized and inclusive path of study. Therefore, such liberal education demands and encourages the intellectual and personal development of each and every specific student profile, in which new ideas to teach and to connect naturally or technically with human sciences represent a prerequisite. In addition, studies with a view to gender aspects underline the positive effects of an interdisciplinary design of study programmes on the selection of women [11,12]. Offering a control engineering lecture for an interdisciplinary target group can also contribute to securing and increasing young talent in the field. The presented lecture can be used in different contexts: in Bachelor courses for engineers as well as for courses dedicated to non-engineers (non-engineering minor programs, complementary study). In this way, the paper provides important insights into how to teach the first and only control course in non-control engineering programs. The lecture requires mathematical high school knowledge. Nevertheless, it is important that these courses start recalling basic knowledge of differential equations and, before starting with this lecture dedicated to SMC, the courses should introduce elements of nonlinear differential equations considering the fundamental direct method of Lyapunov related to the stability of a solution of a differential equation. Figure 1 shows the structure of the proposed course in which this lecture in included. In fact, as is visible there, the lecture closes by recalling Lyapunov's direct method in the context of sliding mode control. The goal of this contribution is to present a possible structure of a lecture concerning SMC which is held in the programs of study described above, and which realizes the possibility of an inclusive lecture in which just basic high school knowledge, such as computation of derivatives

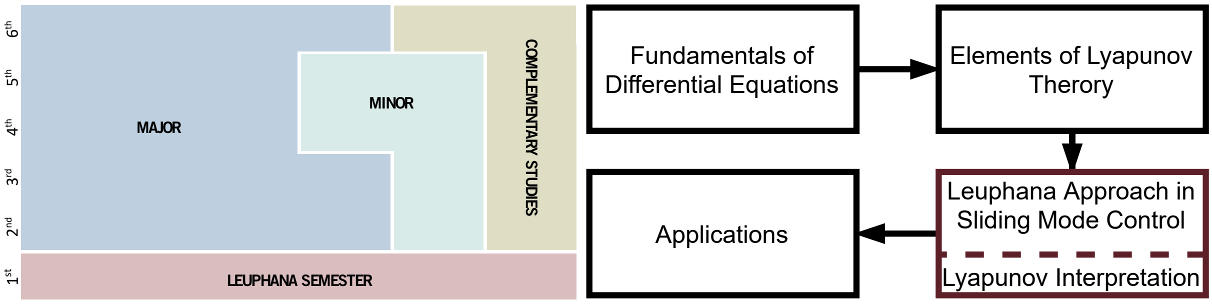

Fig. 1. Leuphana College model, see `https://www.leuphana.de/en/college` (left) and structure of the proposed course (right)

and integrals is necessary. The intuitive nature of the lecture and in the meantime the formal and rigorous explanation of some fundamental concepts of control realize an important contribution in the context of a new didactic treadoff between natural and human sciences. The course focuses on a broad-based education and at the same time developing individual essential skills, such as analytical and reactive thinking, clear and convincing argumentation, well-founded and perspective assessment. This takes place through intensive interactions with teachers and fellow students as well as in self-study, both during university events and extra-curricular activities. The protagonists of these lectures are the students. Therefore, this paper is written in collaborations with some of the students who attended these lectures and this emphasizes the inclusive nature of the course.

The paper is organized in the following way. Section 2 introduces the concept of Sliding Mode Control (SMC) in an intuitive way. Section 3 introduces the concept of an integral sliding surface for first-order systems. In Section 4, related empirical findings on implementation and future perspectives are presented for the engineering research and education community. Conclusions close the paper.

2 SLIDING MODE CONTROL

SMC is a robust control method which can handle both linear and nonlinear systems with uncertainties and unmeasurable disturbances.

2.1 Preliminary and Fundamental Aspects

Considering a plant with one state variable x and control input u, the goal is to steer the state to zero:

$$\frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} = u(t) \tag{1}$$

with $x(0) = \pm x_0$, where $x_0 > 0$ is the absolute value of the initial condition.

2.2 Obvious strategy

The intuitive solution is to select

$$x(t) > 0 \rightarrow \frac{\mathrm{d}\,x}{\mathrm{d}\,t} \overset{!}{<} 0, \qquad x(t) < 0 \rightarrow \frac{\mathrm{d}\,x}{\mathrm{d}\,t} \overset{!}{>} 0. \tag{2}$$

From this consideration, a control law $u(t)$ should arise.

2.3 First strategy

A surmisable first approach is to use a linear state-feedback control $u(t) = -kx(t)$ in which $k > 0$. Using this controller,

$$\lim_{t \to +\infty} x(t) = 0. \tag{3}$$

In fact, the simple closed-loop system

$$\frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} = -kx(t) \tag{4}$$

yields the well-known solution

$$x(t) = \pm x_0 \exp(-kt). \tag{5}$$

2.4 Second strategy

Since eq. (5) converges to zero only in infinite time, another strategy is to set $u(t) = -k\,\mathrm{sgn}(x(t))$, which renders the closed-loop system nonlinear

$$\frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} = u(t) = -k\,\mathrm{sgn}(x(t)). \tag{6}$$

The solution depends on the sign of the state,

$$x(t) = x_0 - kt \text{ for } x(t) > 0 \tag{7}$$

$$x(t) = x_0 - kt > 0 \to t < \frac{x_0}{k},$$

$$x(t) = -x_0 + kt \text{ for } x(t) < 0 \tag{8}$$

$$x(t) = -x_0 + kt < 0 \to t < \frac{x_0}{k}.$$

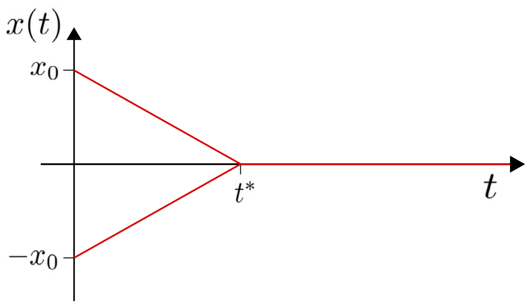

Fig. 2. Finite time dynamics

Considering $t > 0$, the solutions are valid as long as $0 < t \leq \frac{x_0}{k}$. Figure 2 shows the obtained finite time dynamics using the *static-friction-like* nonlinear component $\mathrm{sgn}(x(t))$. We obtain $x(t) = 0$ for $t = \frac{x_0}{k}$. For $t = \frac{x_0}{k} \to \mathrm{sgn}(0) = 0 \to \frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} = 0$. This means that we do not have variations, and thus we remain at zero $(x(t) = 0)$ – at least in a mathematical sense. This generates the following solution for $x(t) > 0$:

$$x(t) = \begin{cases} x_0 - kt & \text{if } t \leq \dfrac{x_0}{k} \\ 0 & \text{if } t > \dfrac{x_0}{k}. \end{cases} \tag{9}$$

For $x(t) < 0$, the solution is

$$x(t) = \begin{cases} -x_0 + kt & \text{if } t \leq \dfrac{x_0}{k} \\ 0 & \text{if } t > \dfrac{x_0}{k}. \end{cases} \tag{10}$$

Often, the discontinuous function sgn is approximated as $\mathrm{sgn}(x(t)) \approx \mathrm{sat}\left(\frac{x(t)}{\phi}\right)$, see Fig. 3, where $\phi > 0$ is the *thickness* of a boundary layer in which we may remain without switching:

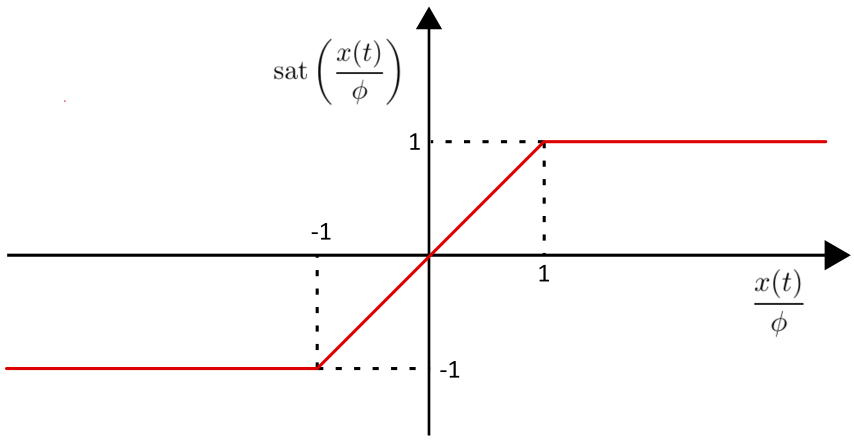

Fig. 3. Saturation function

$$\text{sat}\left(\frac{x(t)}{\phi}\right) = \begin{cases} \frac{x(t)}{\phi} & \text{if } \left|\frac{x(t)}{\phi}\right| \leq 1 \\ \text{sgn}\left(\frac{x(t)}{\phi}\right) & \text{otherwise.} \end{cases} \tag{11}$$

Considering an uncertainty Δ in the system model,

$$\frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} = u(t) + \Delta(x(t), t) \text{ with } |\Delta(x(t), t)| \leq \Delta_{\text{max}}. \tag{12}$$

If we apply the first strategy to this uncertain system,

$$\frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} = -kx(t) + \Delta(x(t), t). \tag{13}$$

In this case, we do not have the possibility to steer the state to zero. If we apply the second strategy, however,

$$\frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} = -k\,\text{sgn}(x(t)) + \Delta(x(t), t). \tag{14}$$

We simply need to choose $k > \Delta_{\text{max}}$ i.e. $k = \Delta_{\text{max}} + \eta$ with a positive η. If this expression is placed in (12):

$$\begin{cases} x(t) > 0 : \frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} = -\eta - \Delta_{\text{max}} + \Delta(x(t), t) \\ x(t) < 0 : \frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} = \eta + \Delta_{\text{max}} + \Delta(x(t), t), \end{cases} \tag{15}$$

which is now manipulated as

$$\begin{cases} x(t) > 0 : \frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} + \Delta_{\text{max}} - \Delta(x(t), t) = -\eta \\ x(t) < 0 : \frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} - \Delta_{\text{max}} - \Delta(x(t), t) = \eta. \end{cases} \tag{16}$$

If we consider that

$$\Delta_{\text{max}} - \Delta(x(t), t) \geq 0, \tag{17}$$

$$-\Delta_{\text{max}} - \Delta(x(t), t) \leq 0, \tag{18}$$

the following inequalities can be derived

$$\begin{cases} x(t) > 0 : \frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} \leq -\eta, \\ x(t) < 0 : \frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} \geq \eta. \end{cases} \tag{19}$$

Thus, η represents the minimal convergence rate. We can write this expression in a more compact form by multiplying both sides with $\text{sgn}(x)$:

$$\begin{cases} x(t) > 0 : \text{sgn}(x)\frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} \leq -\eta\,\text{sgn}(x) \\ x(t) < 0 : \text{sgn}(x)\frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} \geq \eta\,\text{sgn}(x) \end{cases} \Rightarrow \begin{cases} x(t) > 0 : \frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} \leq -\eta\,\text{sgn}(x) \\ x(t) < 0 : \frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} \leq -\eta\,\text{sgn}(x). \end{cases} \tag{20}$$

So, in general the closed-loop system results as

$$\frac{\mathrm{d}\,x(t)}{\mathrm{d}\,t} \leq -\eta\,\text{sgn}(x(t)), \tag{21}$$

where η represents the reachability condition.

2.5 SMC for higher-order systems

Now a system with two states is considered:

$$\frac{\mathrm{d}\, x_1(t)}{\mathrm{d}\, t} = x_2(t), \quad \frac{\mathrm{d}\, x_2(t)}{\mathrm{d}\, t} = u(t), \quad x_0 = \begin{bmatrix} x_{1,0} \\ x_{2,0} \end{bmatrix} = \begin{bmatrix} x_1(0) \\ x_2(0) \end{bmatrix}. \tag{22}$$

The goal is the same as before: steer the state to zero. Assuming that we can apply a state-feedback controller to achieve $x_2(t) = -c_1 x_1(t)$ with $c_1 > 0$, the dynamics result as

$$\frac{\mathrm{d}\, x_1(t)}{\mathrm{d}\, t} = -c_1 x_1(t). \tag{23}$$

If this is possible, $x_1(t) = x_{1,0} \exp(-c_1 t)$. This yields

$$\lim_{t \to +\infty} x_1(t) = 0, \quad \lim_{t \to +\infty} x_2(t) = 0. \tag{24}$$

However, it is problematic to assume the relationship $x_2(t) = -c_1 x_1(t)$. We are not able to set this condition through linear state-feedback control. In fact, if we consider a mechanical system, this means that the velocity must be proportional to the position. To remedy this, we introduce an abstract **sliding variable** $s(t)$ defined in the following way:

$$s(t) = x_2(t) + c_1 x_1(t) \quad \text{with } c_1 > 0. \tag{25}$$

Now, if we reach $s(t) = 0$, we have

$$0 = x_2(t) + c_1 x_1(t) \tag{26}$$

and thus $x_2(t) = -c_1 x_1(t)$, which is exactly what we wanted to obtain. Now the goal is to steer the system to $s(t) = 0$. Recalling system (22), if we differentiate s(t), we obtain

$$\frac{\mathrm{d}\, s(x_1(t), x_2(t))}{\mathrm{d}\, t} = \frac{\mathrm{d}\, x_2(t)}{\mathrm{d}\, t} + c_1 \frac{\mathrm{d}\, x_1(t)}{\mathrm{d}\, t} = u(t) + c_1 x_2(t). \tag{27}$$

Since we want to obtain

$$\frac{\mathrm{d}\, s(x_1(t), x_2(t))}{\mathrm{d}\, t} = -k \operatorname{sgn}(s(t)), \tag{28}$$

similar to (21), it is easy to see from (27) that we require

$$u(t) + c_1 x_2(t) \stackrel{!}{=} -k \operatorname{sgn}(s(t)) \tag{29}$$

which means that the controller *to stabilize* $s(t)$ is

$$u(x_1(t), x_2(t)) = -c_1 x_2(t) - k \operatorname{sgn}(s(t)) \tag{30}$$

The graphical interpretation of the dynamics is represented in Fig. 4. If we consider a saturation function with boundary layer instead of function sgn, we obtain the behaviour described in Fig. 5.

2.6 Recalling Lyapunov point of view

The proposed solution is now considered in a Lyapunov sense. The obtained sliding surface dynamics (28) can be multiplied by $s(t)$, yielding

$$s(t) \frac{\mathrm{d}\, s(x_1(t), x_2(t))}{\mathrm{d}\, t} = -k s(t) \operatorname{sgn}(s(t)) \tag{31}$$

and thus

$$\frac{1}{2} \frac{\mathrm{d}\, s^2(x_1(t), x_2(t))}{\mathrm{d}\, t} = -k|s(t)|. \tag{32}$$

Equation (32) is the Lyapunov stability condition, which the students are taught earlier in the course (see Fig. 1), and can be obtained starting from

$$V(s(t)) = \frac{1}{2} s^2(t) \tag{33}$$

and thus [13]

$$\frac{\mathrm{d}\, V(s(t))}{\mathrm{d}\, t} = s(t) \frac{\mathrm{d}\, s(t)}{\mathrm{d}\, t} = s(t)[-k \operatorname{sgn}(s(t))] = -k|s(t)| < 0. \tag{34}$$

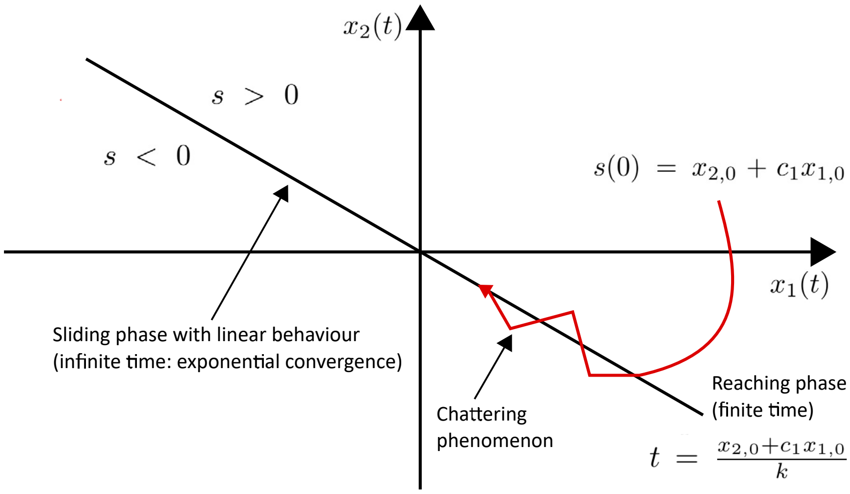

Fig. 4. Sliding phase

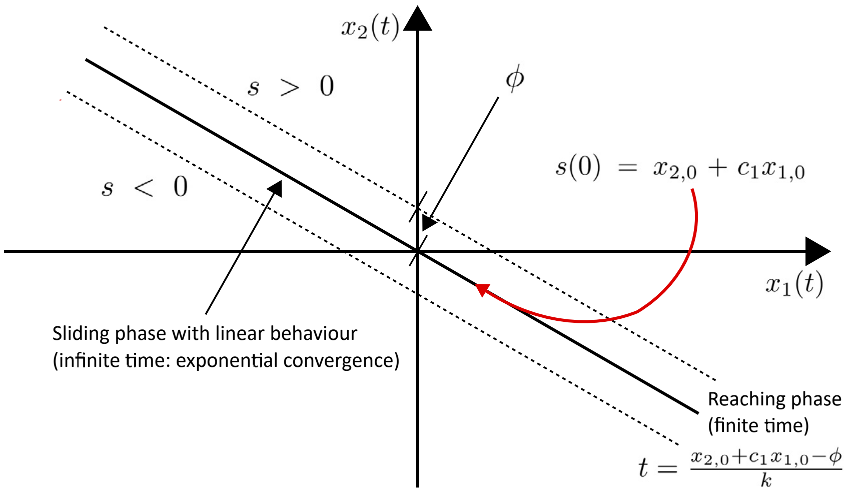

Fig. 5. Graphical representation of the dynamics in the presence of a boundary layer

3 INTEGRAL SLIDING SURFACES

Let us consider the following sliding surface structure as proposed in [13] and a system with just one state x (i.e. $n = 1$). The conventional sliding surface, based on an error $e(t) = x(t) - x_d(t)$, can be chosen as

$$s(t) = \left(\frac{\mathrm{d}}{\mathrm{d}\,t} + \lambda\right)^{n-1} e(t), \tag{35}$$

in which $n \in \mathbb{N}$ represents the number of states of the system. The exponent of this expression represents the derivative order as well as the *polynomial exponent*. If $n = 1$, then $s(t) = e(t)$. This is the simplest possible surface which is exactly the state error. This surface allows to reach error $e(t) = 0$ at a finite time ($s(t^*) = 0 \to e(t^*) = 0$). Let us now consider the following sliding surface, with the assumption of a non-impulsive control error $e(t)$

$$s(t) = e(t) + \lambda \int_0^t e(\tau) d\tau - e(0), \tag{36}$$

with $\lambda > 0$. Assuming that the trajectory reaches condition $s(t) = 0$ at $t = t^*$, then for $t > t^*$

$$0 = e(t) + \lambda \int_0^t e(\tau) d\tau - e(0), \tag{37}$$

and thus

$$e(t) = e(0) - \lambda \int_0^t e(\tau) d\tau. \tag{38}$$

Equation (38) is a linear one and admits just one unique solution, which is

$$e(t) = e(0)\exp(-\lambda t). \tag{39}$$

The trajectory remains on the surface, but the convergence is obtained in infinite time. This implies that, if the initial condition of the system state error is known and $e(0) = 0$, then $s(0) = 0$. In this case, the duration of the reaching phase is reduced to zero, but we introduce an infinite sliding time with respect to the sliding surface $s(t) = e(t)$.

Let us compare this result with those obtained using a slightly different surface:

$$s(t) = e(t) + \lambda \int_0^t e(\tau)d\tau. \tag{40}$$

Considering that (40) is obtained if $e(0) = 0$, the unique solution results as (39) with $e(t) = 0$. Using surface (40) instead of surface (36), the reaching phase cannot be reduced to zero because $s(0) = e(0)$, but once the surface is reached at t^* ($s(t^*) = 0$), then $e(t) = 0$.

Remark 1 *Another interesting consideration is that both surfaces (40) and (36) guarantee the invariant condition $\dot{s}(t) = 0$ (to remain at $s(t) = 0\ \forall t$) for each initial condition. In fact, both cases*

$$\dot{s}(t) = \dot{e}(t) + \lambda e(t) = 0 \tag{41}$$

admit the solution

$$e(t) = e(0)\exp(-\lambda t). \tag{42}$$

From a mathematical point of view, when $s(t) = 0$, then $\mathrm{sgn}(s(t)) = 0$ and considering (42), $s(t) = 0$ and $\dot{s}(t) = 0$, $\forall$ initial conditions $e(0)$.

4 FEEDBACK FROM STUDENTS AND FROM THE SCIENTIFIC COMMUNITY

Introducing the basic concept of sliding mode control, we received positive feedback from our scientific community which accepted our communications in different conferences and journals, see [14–18]. In an interview of a student from Arkansas University [19], who has published a paper in [14], it emerges that the students appreciated the intuitive idea to introduce this effective and robust (and in this sense, practical) method, despite the difficulty of the courses. Moreover, our community appreciated the contributions of our students which in some cases received best paper awards in the student papers competition [15]. In one case, a paper was selected as one of the best papers of the conference [16] and, in another one, a paper was selected for an extension within a reputable journal, see [17].

5 CONCLUSION

This paper deals with a new structure of an introductional lecture in the context of Sliding Mode Control for undergraduate students. SMC is one of the most used control techniques in industrial applications. This is due to its robustness and its straightforward structure to be implemented, at least in its basic form. Therefore it is worthwhile to introduce this techniques directly in the Bachelor's-level lectures together with the classical basic knowledge of control systems, such as control in Laplace domain and linear state space methods. In fact, concepts like differential calculus and integrals are already known when the students start lectures in control system.

ABSTRACT

This paper reports on a feasibility study on including ethics and social issues in the current curriculum of a school of engineering and information technology in an Australian university. The study has three goals: first, to understand the current status of inclusion of ethics and social issues in engineering courses. Second, to understand the willingness of staff within the school to include ethics and societal issues in their courses. Third, to understand the opportunities and challenges for inclusion of ethical and societal issues in the coursework. Our methods include interviews with school staff and subject matter experts as well as analyses of textual artifacts such as course outlines, course readings, student assignments, and accreditation reports. The analysis of textual artifacts runs partially via an automated text analyzer that search for words that have ethical connotation, such as safety, responsibility, privacy, harm, etcetera in the dataset of course materials. A manual (human) analysis of the coursework was done for those courses that give insufficient results in the automated text analyzer. We looked for opportunities to include ethics and societal issues in coursework. The conclusion is that there is general consensus amongst staff that ethics and societal issues deserve more attention in the school. At the same time, there is concern that including ethics and societal issues takes away valuable teaching time for technical material. There is preference for an integrated way of ethics teaching, rather than one seperate engineering ethics course.

1 INTRODUCTION

What constitutes a good engineer? What are the standards of excellence for a technical designer? Our research responds to the increasing demand from society for engineers that are socially and ethically responsible, especially in the face of current technological developments such as autonomous vehicles and AI [1]. The way engineers and designers are trained, not merely in their technical skills but also in their understanding of societal impact and ethical aspects of the things they design, may tacitly or explicitly influence design choices. Design choices that lead to concrete products or services may impact our societies for better or worse. Famous examples include Moses' low hanging bridges in New York that prevented the poor, travelling by bus, to visit the Long Island beaches, exacerbating socioeconomic inequality [2]. The recent collapse of the apartment building in Miami, Florida [1], is another example of the importance of nurturing and fostering ethically and socially responsible engineers. To better understand the role of ethics in engineering and design education, we conducted a feasibility study to probe the UNSW Canberra SEIT (School of Engineering and Information Technology) curriculum on where engineering and design students have space to critically reflect on and creatively play with societal and ethical aspects of their coursework. An explorative feasibility study in the context of curriculum improvement in higher education is a proven way to understand the potential for embedding a new element into a curriculum [3]. Numerous studies exist in the field of engineering ethics education, each stressing a different aspect of the challenge, such as cultural contexts [4], pointing to a decision focused method [5], addressing ethical and social aspects in AI education [6] or advocating a broader understanding of the task of the engineer [7]. For example, Taebi and Kastenberg [8] report on their experience on setting up engineering ethics education in UC Berkeley. They identified institutional and academic hurdles during their implementation phase. Our aim was to explore these and other hurdles and opportunities to systematically map the current approach in SEIT regarding social and ethical reflection in engineering and design courses. We were interested in understanding the opportunities for students to think through the effects of design choices on ethical issues in the short and long run (e.g. acquiring and recycling of used materials), on safety in use, on opportunities for transparency and honesty in functionalities, and social issues, such as: how do design choices constrain or enable patterns of social behavior, and how accessible and affordable does a technology become for certain groups in society? We agree with Grunwald (2000) [9] that the role of ethics in technology development is not equally important in all subjects of engineering and technology education, so one may question the degree and kind of ethical and social reflection that is required in certain areas of technology development or engineering subfields. Mapping the current situation in SEIT helps us better understand where there is space for ethical reflection and where not. Taebi and Kastenberg [8] furthermore note that faculty members from engineering departments are often the ones who can best relate to and identify the ethical aspects of their own specific field of engineering, hence our justification for interviewing staff in SEIT. Since the Australian context is rather specific [10][11][12], and as engineering education in Australia is accredited by professional bodies (Engineers Australia (EA)), we included Engineers Australia as participants in our interview round. This research is essential, as it fills a gap in knowledge around to what degree ethics can and should inform the engineering curriculum in UNSW Canberra's SEIT.

2 METHODOLOGY

This project used a qualitative research methodology, deploying the following data collection method/s:

1. Semi-structured interviews with SEIT staff and subject matter experts

2. Scoping, coding, analysing of existing textual artifacts (course materials such as syllabus, EA accreditation report, blank assignments, Moodle sites).

This two-fold methodology (data gathering through document analysis and interviews) satisfied our aim to understand the current situation of ethical and social reflection in engineering and design courses in SEIT and helped us understand the opportunities or hindrances to enhance this.

SEIT staff were selected for interviews through the UNSW Canberra Handbook for students, which lists teaching staff per course. Courses that were more inclined towards ethical aspects such as security, data handling and automation were chosen along with theoretically intensive courses such as engineering mechanics or radar technology. This was done keeping in mind the research aim: to capture insight from key insiders on where ethics can and cannot be implemented within the course structure. Subject matter experts on engineering ethics were selected from the professional networks of the researchers. All interviews were conducted online.

For the coursework materials analysis, we developed a simple regex based matching algorithm in Python, against ethics related keywords (e.g. honesty, trust, responsibility, danger, harm) and then manually checked those sentences, to find spaces where ethics is already incorporated or if there is room for the same. Regex stands for Regular Expressions, which are a sequence of characters that specify search patterns in a text. They have been developed in theoretical computer science for use in keyword find or find-and-replace algorithms.

3 RESULTS

In the following subsections, we present the results from interviews with SEIT Staff and subject matter experts as well as the coursework analysis. We interviewed a total of six SEIT staff members and three subject matter experts (SMEs). We coded the data collected in the interviews, and then clustered the codes into broader categories they fell into. From the clusters, seven themes came up. These themes are discussed in the following subsections. Our general observation was that five out of six staff members were in favour of incorporating ethics in the curriculum, while one staff member was not in favor, as they thought there was not enough space and necessity to incorporate ethics in the curriculum. We will now systematically address our interview findings based on the clusters that were made. The second part of the results section reports the automated and manual coursework analysis.

3.1 Interviews:

What is ethics according to SEIT Staff

Interviewed staff mentioned a range of aspects to be “ethics”, from values such as honesty, personal morals, to the professional aspects of taking responsibility, decision making and dealing with complexity. A relationship between ethics and systems engineering came up especially when staff related ethics to the professional aspects of taking responsibility and ensuring verifiability. For example, a staff member with a systems engineering background said, “engineering is often about design and when you design, the choices you make are related to stakeholder requirements, and those stakeholder requirements are strongly related to ethical aspects.”

The importance of ethics in engineering

SEIT staff mostly pointed out that ethics is important for engineers. They mentioned the impact of technology and the role engineers play in every aspect of the current society, hence the importance of teaching political, financial and intent related aspects in engineering. The staff also related the importance of ethics in engineering to safety, privacy and preserving lives. Furthermore, that technology can be used for both good and bad was often mentioned. All SMEs seemed to agree that a greater awareness of ethics in engineering is required. This was mostly attributed to the growing responsibility attributed to engineers who are today working in so many interdisciplinary sectors.

Possibilities to incorporate ethics in SEIT course content

When asked whether the staff think they can incorporate ethics in the curriculum, we were met with mostly positive responses either in terms of an intention to incorporate more of ethics in the curriculum, or ethics already being incorporated in the curriculum. Staff 3 for example, said that "[Ethics] is a very important aspect of the Master space postgraduate program. We have some world leading space ethicists, a very multidisciplinary team…Ethics is at the very core of what we are trying to build." Other staff members mentioned ethics is being implemented via role-modelling and inviting top-level executives and through teaching how to comply with professional codes in applied settings.

Barriers to incorporation of ethics in SEIT course content

Staff thought it less feasible to incorporate ethics into coursework in theoretically or mathematically intensive courses. Staff 3, for example, mentioned that "For me it's easy, but for someone who teaches fluid mechanics, would maybe not be as positive." Lack of expertise to teach ethics is also a common concern among staff. However, most staff were willing to put in the effort to improve upon their expertise in teaching ethics. Another concern is the lack of time, which results in staff being concerned about having to compromise the technical content of the course to be able to include ethics, such as Staff 6 said, "If specifically asked, we will have to take something out from the course, which means technical skills get taken out. Are we developing engineers with good technical skills or good soft skills?" As this quote indicates, some staff consider ethics a soft skill. Some think that it can be obtained later during the job, or they think of ethics in terms of personal or private values and that teaching ethics is pointless. Furthermore, some think that students might not be interested in ethics teachings. Other staff who have already successfully implemented or are trying to implement ethics in curriculum did not bring up this lack of interest from students. According to the SMEs, one of the barriers in incorporating ethics in an engineering curriculum, is the challenge in explaining ethics to engineering students who lack foundational knowledge. Some SMEs pointed out the importance of philosophical knowledge of ethics while others stressed the need for its application to engineering.

Incentives for incorporation of ethics in SEIT curriculum

Internal motivation and value based incentives, in terms of awareness amongst engineers about honesty and their general responsibility towards society was evident in most of our staff interviews. Another equally important incentive that came up in our interviews was accreditation. Both Engineers Australia and Australian Computer Society are responsible for accrediting engineering institutions in Australia. The staff raised concerns about the recent accreditation visits by EA and the resulting discussions at all organizational levels to incorporate ethics in the curriculum. SME 3 pointed towards an upcoming increased relevance of ethics in EA and International

Engineering Alliance (IEA) competency standards. They said, "International Engineering Alliance has updated their professional competency terms with an increased relevance of ethics. EA is aligned with IEA competency and therefore accreditation requirements will increase."

How to incorporate ethics and social issues in SEIT curriculum

Staff raised concerns about a lack of direction on how to implement ethics in the curriculum. Staff 4 mentioned that "we want to do it, but don't know how to do it" and, likewise, Staff 5 said, "There is definitely space for [incorporating ethics] but the challenge is how to fit it in naturally." Most SEIT staff interviewed think that a coherent integration would be the best way to incorporate ethics in the curriculum. Another relevant method that staff positively mentioned in interviews was a case-study based teaching of ethics, which is expected to be interesting for students. Staff 1 for example, said, "The thing is that it is a bit easy for me because I teach cyber, which is a hot topic, so new set of use cases all the time, and most of them have some or the other ethical aspect in them." An ethics course may be perceived as a box to tick, as Staff 5 mentioned, "A separate class would feel like a box to tick. It somehow needs to be authentically integrated into the project and I don't know how." Ironically, a forced implementation of ethics is also not preferred, as Staff 6 said, "If specifically asked, we will have to take something out from the course… If at the end of the day you NEED to teach it to engineers, then engineers should be doing it."

Who should include ethics and social issues in SEIT courses?

In general, SEIT staff showed a preference towards ethics being closely integrated within the curriculum and that it should be internal SEIT staff teaching it. Some staff expressed concern about potential lack of respect from engineering students for teachers from non-engineering faculty. However, some staff also had concerns about their lack of expertise in ethics, as mentioned in section 4.4. To mitigate this, some staff suggested the involvement of a multidisciplinary team. Staff 5, for example, said, "I am from a very technical background where things are clear but with ethics there is not necessarily wrong or right answers, although this is where humanities comes in to weigh." SMEs mentioned that commitment from the school leadership and support from course coordinators is vital for the success of enhancing ethics in engineering education.

3.2 Coursework Analysis

Most courses returned meanigful results through the text analyzer algorithm, which looked for ethically charged words in the text. The last two courses listed below and indicated with "*" did not return sufficient results via the analyzer, because of the document formats, so they were manually analysed by the researchers.

Course on Big Data and Decision Analytics for Security - This course takes a case-study based approach to ethics education. It incorporates readings such as "Losing Humanity: The Case Against Killer Robots", and "Discriminating algorithms: 5 times AI showed Prejudice", which cover ethical aspects such as human rights, moral and social responsibility, value of life and risk assessment. However, it is important that these aspects are not only introduced through readings but also explicitly discussed from an ethical perspective rather than merely a security breach perspective.

Course on Software Security Lifecycle - This course refers to the complete software development lifecycle, and therefore refers to notions of responsibility and verifiability. These notions however are not exactly emphasised from an ethical perspective. In other words, failures are interpreted from a pragmatic or economic point of view, without elaborating on how a software development lifecycle can fail in an ethical sense through its effects on society. There is room for discussion about stakeholder involvement, which is important for determining societal issues in design, as well as the ethical importance of the end-of-lifecycle: what are the risks if the software becomes outdated? Points for ethical elaboration exist in the security development lifecycle, where attention for threats, privacy, responsibility could be broadened.

Course on Computers and Security - Ethics is discussed in the first lecture of the course in a very explicit manner, under the heading of “Ethics and Cyber Ethics.” It discusses the importance of ethics to computer security professionals. The course often mentions security, rights and legal procedures and discusses the ethics of professional organisations such as the International Information System Security Certification Consortium and that of the Computer Ethics Institute. However, the course does not go into the details of ethics further down in the syllabus. There is room to mention ethics when discussing various aspects and case studies related to cyber security.

*Principles of Electrical Engineering** - This technical course has very limited opening to discuss ethical issues, but there are opportunities to discuss environmental effects or safety aspects of electrical design choices. For example, controllers used in the automotive industry where it is important to get controls and timings right due to potential harms in breaking, steering or airbags. An environmentally relevant issue relates to power consumptions in circuits, which can be optimized via smart switching methods and smart use of transformers.

*Cyber Offence: Threats and Opportunities** - This short course mainly focusses on cybersecurity. Given its topic, it includes methods of creating safe software and preventing cyber-attacks. It therefore emphasises on ethical keywords such as legal, illegal, safety and security. The course however approaches these aspects from a purely technical perspective and there is indeed more room for mentioning ethical and societal aspects using case examples.

4 SUMMARY AND ACKNOWLEDGMENTS

A majority of the interviewed SEIT Staff was in favour of including ethics into the SEIT curriculum in a more systematic manner. But this conclusion should be considered in light of two considerable limitations of our study. First, that our sample size of six staff members is small and not representative of the entire teaching staff in the school (approximately 90 staff members). Second, this majority inclination towards incorporating ethics and social issues in engineering and design coursework does not quantitatively imply a major support for it in the school at large, since staff that are not interested in ethics and social issues in engineering courses, are less likely to participate in research that explores these issues. Low interest and participation, pertaining to the undervalued perception of interdisciplinary research and the lack of incentive and organisational support on behalf of the institution, was also encountered by Taebi et. al.,[8] in running the first edition of a graduate engineering ethics course at UC Berkley.

Skinner et. al.[12], argued that engineering ethics is a special case of professional ethics and this is in line with what the majority of SEIT staff reported, together with often mentioned honesty and personal morals. Furthermore, we could see traces of the microethical model (cf. Martin et al) in SEIT staffs' understanding of ethics in engineering. A microethical model is "characterised by a strong emphasis on the individual responsibility of engineers" [13]. This was evident, for example, from the importance of an increased attention towards existing EA code of ethics that was pointed out in the interviews, by SEIT staff.

For most SMEs, on the other hand, the understanding of ethics in engineering was directed towards macroethics model, which, according to Martin et.al [13], looks at the engineering profession as a whole and the profession's responsibility towards development and society. This distinction between macro-and micro-ethics is further reflected in our interviews, as SEIT staff were a lot more inclined towards interweaving ethics in the curriculum compared to SMEs who thought having a separate course could play a role in laying the foundation and explaining ethics in much more detail from a more philosophical standpoint.

The way SEIT staff think about ethics in relation to engineering and design covers most, but not all content areas of engineering ethics education identified by Martin et al.[13]. There is awareness of responsibility, sustainability, professional ethics, societal context, value sensitive design, business studies and military applications, while less or no mention was made of health and safety, legislation, academic and research integrity or ethical theories.

One of the most popular methods of teaching engineering ethics[13][14] which was often mentioned in our interviews, is to use case studies. Cases are one of the three general models of teaching engineering as identified by Herkert [15]. Case studies can be incorporated in all coursework without much effort. A general approach is to decide upon the ethical goals related to a particular subject and then carefully choose cases. This also ensures that the incorporation of ethics is interesting for students as it is related to their own areas of study, as had been pointed out by many staff and SMEs.

Furthermore, an interesting observation from some of our staff interviews was how they related ethics to a systems engineering approach and to the ideas of responsibility, professional conduct and verifiability. A promising approach to incorporating ethics within an engineering curriculum is the VASE approach [16][17], which adds a values theory step to the pre-existing steps in a design thinking approach. This added step of values theory is targeted towards naming and teaching specific values and approaches to ethics and then relating them to values in design. Studies such as one by Lee et. al. [18], have shown how systems engineering approach can be moulded towards a human-centered/value sensitive design approach. We suggest that the VASE approach[16][17], in combination with systems engineering and value sensitive design [18] could lead to a well-rounded incorporation of ethics into something that engineers and software developers are already studying. Further research would indeed be required to come up with the exact steps of this implementation.

Although we may tentatively conclude that SEIT staff favours that ethics implementation is done by the SEIT staff, research suggests that implementation of ethics benefits from multidisciplinary attention, and it is important to have the say of philosophers and social scientists when designing it within the curriculum. Furthermore, as Skinner et. al. [12] point out, the inclusion of a formal course on ethics is not well received by all the school's staff. There is also "suspicion among the faculty of such interdisciplinary material 'diluting' the technical education of engineers" (ibid). It is therefore important to develop an understanding that teaching ethics will not take away the core theoretical engineering background but rather enhance it, if it is done in a coherent manner. It could be the university administration's responsibility to help incorporate ethics in the curriculum in a way which ensures the engineering topics are covered while including ethical and social issues. It is important for all levels of the institution to be actively involved for a successful implementation of ethics in engineering curriculum. Finally, it is important to pay attention to the cultural, educational, academic and life-experience based diversity within the student body and its effects on how a course on ethics is received by the students [12]. Engineering students may not be naturally interested in ethics, and, Skinner's[12] findings are promising, as they conclude that "students were initially suspicious, but they move beyond it over the weeks and find it liberating for their imaginations."

ABSTRACT

The access mark to engineering studies is often used as an a priori success estimator. In our institution, we have observed that the correlation of the access mark with the grades obtained in project-based courses (R=0.52) is slightly lower than the one obtained with the average of the other non-project-based courses (R=0.58), and is especially low in capstone projects (R=0.31). Project-based and Challenge-based courses are one of the most acknowledged ways of promoting the learning of transversal skills, specifically innovation and entrepreneurship skills. In our institution, ICT engineering bachelor students perform a project-courses path, with three subjects of growing complexity in the 2nd, 3d and 4th year. While the first two are partially guided and with challenges proposed by the faculty members, the 3d one is a 12 ECTS capstone project with challenges proposed by industry or external institutions. In this study, we have analyzed the performance of the students along 10 academic years (2011-2012 to 2020-2021). Not only the correlation with the access mark in these courses is lower but the prediction interval is also different. While it is almost impossible that a student with a low access mark gets an outstanding average mark in the bachelor and vice-versa, there are students with a low access mark which have an outstanding performance in the capstone project and students with a very high access mark and with high results in analytical courses but with a poor performance in capstone projects. Therefore, a different kind of skills are promoted in these courses.

1 INTRODUCTION

1.1 Project-Based courses

Nowadays it is widely acknowledged that what is expected from future engineering graduates is far more than technical skills or disciplinary engineering knowledge. Initiatives and institutions like ABET, CDIO, NAE or ENAEE–EUR-ACE have stablished lists of personal, interpersonal and professional competences. This need of competences' development has been widely addressed from the academia in several ways. Project-Based Learning and, specifically, Capstone design courses where student teams develop "real" projects using their theoretical knowledge on a system level [1], [2] are considered among the more successful tools to promote that kind of skills.

The Bachelor in Telecommunication Technologies and Services Engineering at the School of Telecommunications Engineering of Technical University of Catalonia, in Barcelona, includes three project-based courses in order to provide a framework to facilitate the learning of personal, interpersonal and professional skills. The CDIO model [3] was used in the design of the program, which was completed 10 years ago. The three project-based courses are "Introduction to Engineering" (2nd year, 6 ECTS), "Basic Engineering Project" (3rd year, 6 ECTS) and "Advanced Engineering Project" (AEP, 4th year, 12 ECTS). In the first two subjects, students work in small teams (3-5 students) following a partially guided plan which also includes some disciplinary contents learning and in which the project topic is proposed by the supervisors. Although the goal of the three courses is to provide a context close to the practice of engineering, the first two are closer to PBL methodology [4], providing both context and contents through a known and guided sequence of activities. On the other hand, AEP, the third one, follows the Product Development Project (PDP) model, which can also be assimilated to the New Product Development model [5]. In this course, bigger working groups (8-12 students) carry out the design of a complete product or service, including its business model. The teams generate the requirements and specifications of the product or service from the initial interaction with the stakeholders, define the system block structure and the work packages and then distribute them among subgroups of 2-3 students. They must design, implement and test the subsystems, integrate them, define a business model based on the product or service and perform the sustainability and ethical analysis. In the first years (2011-2014) the challenges of the AEP projects were proposed by the teaching staff. Since then, external agents were gradually incorporated and currently, 7 out of 10 challenges are proposed by companies, hospitals, foundations or NGOs. This subject is compulsory and 1440 students have passed through it. They have worked in 138 different projects, being 81 of them proposed by external agents. Some examples of project challenges are: image processing software for rehabilitation of facial paralysis due to facial nerve injury, human-machine interface techniques for car cockpit, development of sensors for 3D printers, blockchain-based payment distribution system in the music industry or low-cost IoT sensor system for detection of irregular discharges in wastewater. A comparative study of the performance of the student teams according to the kind of stakeholders (internal/external) and other features of the projects has been reported in [6]. The AEP course is performed twice per academic year. There are around 10 different projects in the Fall term and around 7 in the Spring term. In the Fall term, 10-15 students perform AEP in a different way, following a Challenge-Based Learning (CBL) model [7] in multidisciplinary teams. A quantitative and a qualitative study on the differences in the learning of innovation skills among PDP and CBL modalities have been reported in [8] and [9] respectively. The learning outcomes of the course are mostly the ones of the involved personal, interpersonal and professional generic skills. Of course, there are learning outcomes associated to the disciplinary topics involved in the project development but they are considered as a reinforcement of the previous or parallel disciplinary subjects.

1.2 The effect of previous academic achievement

Previous academic achievement is usually considered a good a priori estimator of academic success in higher education. Most studies, for example, [10] are centered in the success in the first-year attainment and in the drop-out rate. Putwain et al [11] studied its effects in academic self-efficacy. The literature about its effect on the project-based courses is less abundant. Garry [12] concludes that student groups with high GPAs, on average, do well on their capstone projects after studying several success factors. Joo et al [13] state that PBL benefitted low performing students to a greater extent and decreased the achievement gap, but applied to secondary education.

The secondary education system in our country defines a University access exam when the students finalize their High School years. This exam includes several disciplines, some of them are common to all student and some others are specific for the kind of bachelor the students are going to enroll (scientific/humanities). The resulting mark is averaged with the mark of the last two years of the secondary education and provides a grade in a scale of 10 points. This grade can be improved by performing two additional exams on subjects specifically indicated for the kind of bachelor the students are going to enroll (usually Advanced Mathematics, Physics, Chemistry or Technology for Engineering studies), which can provide up to 4 additional points. Then, the University Access Mark is defined on a scale of 14 points. It is used as a ranking criterium to determine the access to each bachelor in each institution when there is more demand than available positions.

The initial hypothesis of this study is that the regular courses (the non-project-based courses) marks will be correlated with the access mark of the students and that the project-based courses mark, and specifically the AEP mark, will not be so correlated because a set of different skills, non-so analytical, are developed in these courses.

2 METHODOLOGY

Out of the 1440 students that have carried out the AEP capstone course between the academic years 2011-2012 and 2020-2021, we have included in the study the 1257 that had finished the bachelor when doing the analysis, so they had completed all the courses of the program. Their access marks are included in the range 5.00 – 13.78 (in a 14 points scale), with an average mark of 9.97 and a standard deviation of 1.93 (7.12 and 1.38 in an equivalent scale from 0 to 10). Half of the students are included in the range 8.70 – 11.50, while 25% joined our school with more than 11.50 points (8.21/10) and 25% with less than 8.70 (6.21/10). The students that enter our engineering degrees with an access mark lower than 8/14 have a high drop-out rate. Only the ones that reached the AEP course and finished the bachelor have been included in this study.

To check the validity of the hypothesis, we have performed a correlation study between the access mark and several performance indicators, most of them derived from the AEP subject individual mark. Assuming the limitations of the individual final grade as a valid metric to assess the performance in the course, we have chosen it as performance index for this study because of its integrative character. According to the learning outcomes of the course, the project supervisors assign a team mark, which reflects the assessment of the process (50%) (Preliminary and Critical Design Review, team dynamics) and the final result (50%) (Solution Technical Performance, Business Idea, Final Report, Final Presentation and Video). The individual marks are obtained from this team mark after applying a triple modulation (30% max): The Supervisors' Assessment of the individual performance, the Team Leader assessment (batch of points) and the Peer Assessment using a 10 criteria rubric. Therefore, the final individual marks are quite integrative of several aspects. The average of the individual marks along the 10 years of the study is 8.44 in a scale of 10, with a standard deviation of 1.17.

The parameters included in the correlation study are:

- The average of the grades of the regular courses (non-project courses), most of them with a high analytical content.

- The average of the grades of the two first project-based courses (PBL courses mark).
- The individual grade of the AEP course.
- The relative increment or decrement of the individual AEP mark respect of the team mark (individual boost).
- The individual grade of the AEP course separating the cases in which the project main stakeholder was internal or an external company or institution.

For each of them, the Pearson's R correlation coefficient was obtained and the linear regression between each indicator and the access mark was represented, including the +/- 95% prediction interval around the regression line. The analysis tool we used was SigmaPlot 14.5 (Systat Software, UK).

3 RESULTS AND DISCUSSION

3.1 Results

The results of the correlation analysis are displayed in the following graphs and tables. Table 1 displays the mean and standard deviation for each indicator and also the Pearson's R coefficient for the correlation between each indicator and the access mark.

Table 1. Mean and STD of each indicator and Pearson's R coefficient for the correlation between each indicator and the access mark.

Indicator	Mean	STD	R
Non-Project mark	6.75	0.69	0.58
PBL courses mark	7.25	0.88	0.52
AEP mark	8.44	1.17	0.31
AEP % individual boost	0.7%	13.0%	0.21

Figures 1 to 4 display the linear regression between each indicator and the access mark. The thick red lines display the linear regression line and the 95% confidence interval of the regression while the dashed red lines indicate the +/- 95% prediction interval of the indicator if the regression is used for this purpose. All graphs have the same axes scale in order of making easier their comparison.

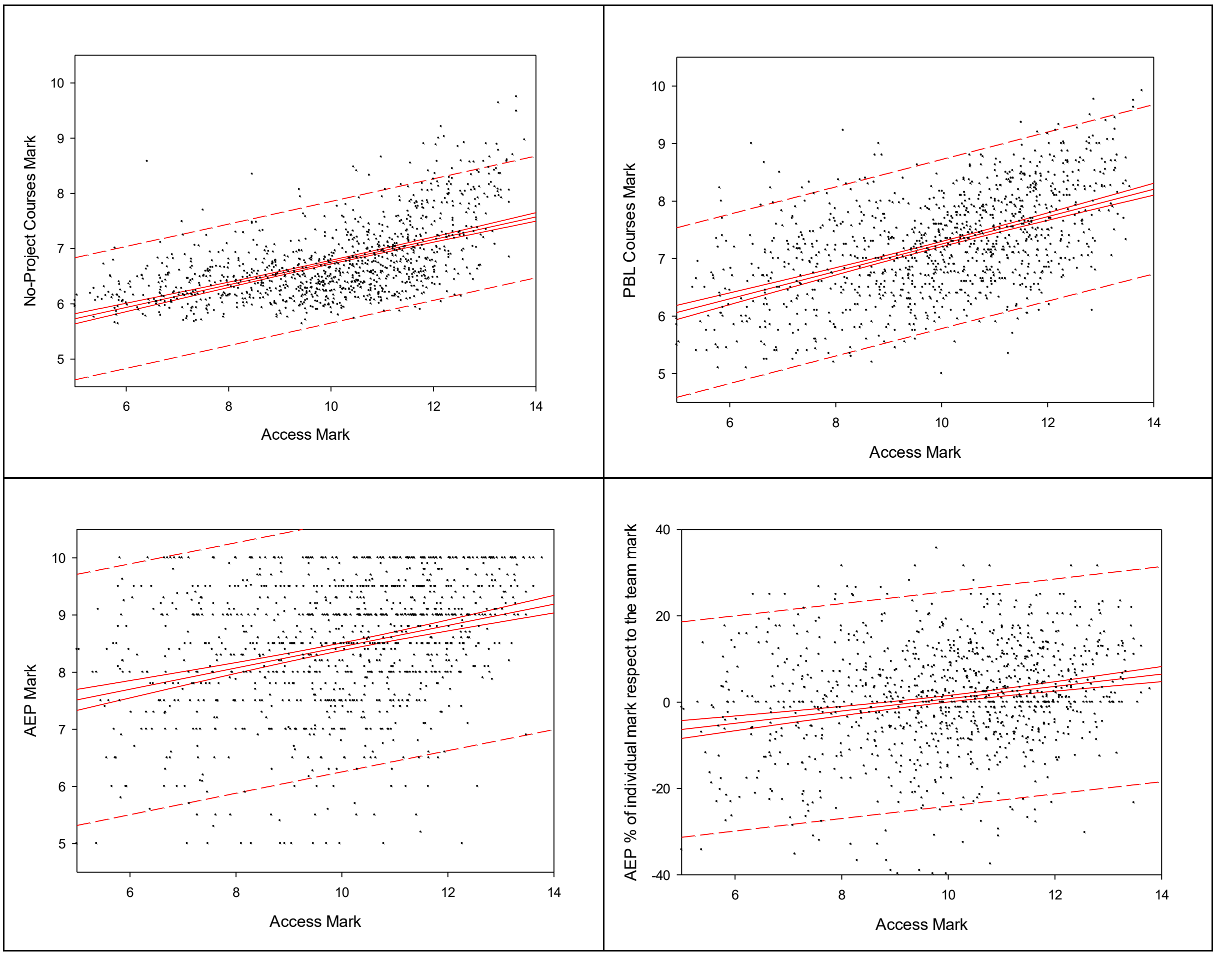

Fig. 1. Correlation Access Mark – Non-Project Courses Mark (top, left); Correlation Access Mark – PBL Courses Mark (top, right); Correlation Access Mark – AEP capstone course individual Mark (down, left) and Correlation Access Mark – relative increment or decrement of the individual AEP mark respect of the team mark (down, right).

In order to compare the likelihood of obtaining a good indicator having had a low access mark or a bad indicator having had a high access mark, the regression value (RV-6) and the upper 95% prediction value (UPV-6) for an access mark of 6 and the regression value (RV-13) and the lower 95% prediction value for an access mark of 13 (LPV-13) are provided in Table 2.

Table 2.Regression and prediction limit values for an access mark of 6 and 13

Indicator	RV-6	RV-13	% RV	UPV-6	%Improv	LPV-13	%Improv
Non-Project mark	5.94	7.37	21%	7.06	19%	6.25	-15%
PBL courses mark	6.30	7.97	23%	7.75	23%	6.52	-18%
AEP mark	7.70	9.00	15%	9.90	29%	6.80	-24%
AEP % individual boost	-4.9%	5.1%	10%	20.1%	25%	-19.9%	-25%

The individual grade of the AEP course separating the cases in which the project main stakeholder was internal or an external company or institution has not delivered significative differences among them, providing a Pearson's correlation coefficient of 0.30 for the first case and of 0.29 for the second one, very close to the global AEP one and a low correlation in any case.

3.2 Discussion

As we can see in Table 1, all the Pearson's R correlation coefficient are positive, displaying some better performance for the students with a higher access mark but is not high in any of the cases. The 0.58 value obtained with the correlation study between the Access Mark and the Non-Project Courses Mark can be considered as moderate [14], although we can observe in the corresponding linear regression graph in Figure 1 a clear dependency among both variables and a tight confidence interval for the regression. The correlation for the average of the two partially guided PBL courses is slightly small (R=0.52) but still moderate. The relevant difference can be observed with the AEP course, for which the correlation is weak (R=0.31). Looking at the corresponding graphs in Figure 1, we can see that, while it is almost impossible that a student with a low access mark gets an outstanding average grade in the bachelor and vice-versa, there are students with a low access mark which have an outstanding performance in the capstone project and students with a very high access mark and with high results in analytical courses but with a poor performance in capstone projects. This feature has been systematically observed by the project supervisors and commented in the coordination meetings, but we did not have a quantitative evidence. To avoid the possible bias eventually induced by the fact that the students with low access mark were assigned to projects that obtained higher marks (which is not reasonable), we also calculated the "Individual Boost" of each student, the relative increment or decrement (%) of the individual AEP mark respect of the team mark. A student with a high and positive Individual Boost has been acknowledged by his or her colleagues, by the Team Leader and by the supervisors as a valuable contributor to the success of the Team. The correlation between the Access Mark and the Individual Boost gives the very weak correlation of R=0.21, displaying that almost any student, independently of his or her access mark can receive a good or bad assessment by the peers. We have not done a study of a parallel assessment of the skills associated with the Team Work related skills such as commitment or leadership, which may be independent of the analytical skills, but they are probably playing a relevant role in this result.

In order to obtain quantitative indicators of the likelihood of obtaining a good indicator having had a low access mark or a bad indicator having had a high access mark, we have taken two extreme cases of access mark, 6 and 13 (in the scale of 14 points), which only have a 3% of the cases below and above respectively and have compared the estimated average indicator value through the regression line (RV-6) and the upper 95% prediction value (UPV-6) for the access mark of 6, to display the ability of obtaining a high indicator with a low access mark. Also the estimated average indicator value through the regression line (RV-13) and the lower 95% prediction value for an access mark of 13 (LPV-13) to display the ability of obtaining a low indicator value with a very high access mark. The results can be seen in Table

2. The 4th column, %RV, expresses the relative advantage of a student with an access mark of 13 respect to the one with an access mark of 6, calculated as the percentual change respect to the overall average of the indicator. We can see how, for the non-project courses, this advantage is 21% and similar for the PBL courses, but is reduced to 15% for the AEP capstone course and to 10% for the Individual Boost. In columns 5 (UPV-6) and 6 (% improvement) we can see how big is the maximum expectable value (95% confidence) for a student with a low access mark, respect to its average indicator value according to the regression. While a maximum of 19% can be expected for the non-project courses, up to a 29% can be expected for the AEP course and a 25% for the Individual Boost. On the opposite side, a student with a very high access mark can only expect a global result of -15% of decrement respect to his or her average mark in non-project courses according to the regression but up to a -25% in the AEP mark and the Individual Boost.

Further and specific research on direct measurement of the personal, interpersonal and professional skills involved in the performance in PDP projects would be needed to be able to determine up to which extent they are independent of the analytical skills, more relevant in the non-project based courses, but we consider that it is clear that a different kind of skills are promoted in these courses. We also consider that it is very positive that students that are not brilliant in most of the analytical courses could find a place to stand out. It enhances their self-confidence.

In any case, both the correlation coefficients, although weak, and the slopes of the regressions are positive and statistically significative ($p<0.001$ in all cases), which indicates a slightly better performance of the students with high access mark in the capstone AEP course, but what we consider relevant as result of this study is the evidence that students with low access mark are able of performing really well in that kind of courses, which are key for the complete education of graduate engineers. We recommend the institutions that perform or plan to perform that kind of courses to identify and highlight the good performance in capstone projects in students with average or even low marks in order to boost their self-confidence and self-efficacy.

1 INTRODUCTION

This paper reports on the development and evaluation of a 23 item Situational Judgement Test (SJT) with scenarios tailored to the engineering profession. The SJT was developed around the PREFER model, with the support of professional engineers and academics in 11 panel discussions. In total 53 engineering professionals and academics were consulted during the development of both the item stems and the item responses of the SJT. Subsequently, the SJT was rolled out to 334 final year and masters students enrolled in engineering programmes at TU Dublin and KU Leuven respectively. After taking part in the test, students were sent automated reports on their performance and the test which highlighted how their response compared to a response gathered from a professional engineer with feedback on how they might improve their competence in a particular area, while also commending their performance in other areas. The results of this study highlight that 8 SJT items had significantly lower mean scores when compared with the test-mean. These items, which were related to *perseverance, client focus, vision, planning and organising, solution orientation, team player, work organisation, clear communication* and *networking* all represent potential competence deficits in the population of final year and master students that were tested. This work adds to engineering education scholarship by providing an engineering-specific SJT that enables educators to identify areas of relative strength and weakness in students' professional judgements in order to better prepare them for their future careers.

1.1 Rationale

Over the past three decades, there has been a strong emphasis on improving the employability of engineering students in order to address the mismatch between graduate skills and labour market expectations in the field of engineering (1). A recent meta-analysis by Passow & Passow (1) discovered fifty-two articles published over the past three decades regarding the professional skills that engineering programmes should emphasise. Looking at just the past decade, a strong emphasis on professional skills in engineering programmes has resulted in the development of a multitude of learning resources, courses, interventions and assessments (2) that attempt to address students' lack of competence in these professional areas, and as alluded to in a previous paper, the vast majority of which rely on student self-assessment of their competence via pre and/or post intervention (2).

Despite three decades of research and intervention into students' professional skills, the skills mismatch for engineering professions in Ireland and Belgium is not reducing (3). Action needs to be taken to provide a more direct means of assessment of students professional competence, assessment that can also be used to provide prompt and directive feedback to students about how their professional competence can be improved. The type of assessment that brings us back to Boud's reframing of the purpose of assessment, which shifts the focus from viewing assessment as confirmation of the achievement of a particular learning outcome, to the use of assessment as a tool for informing judgement (4).

1.2 Literature review

The practice of including Situational Judgement Tests (SJT's) in the candidate selection process, particularly in job interviews, has become increasingly popular in recent years (5).This section presents the taxonomy of a SJT item, how SJTs are scored and how success in SJTs relate to job performance. SJT's have been used in psychological assessment for almost a century, with the first documented SJT appearing in the George Washington University Social Intelligence Test (6). The first section of the test was entitled J*udgement in Social Situations* which contained a number of social situations that presented problems, each followed by four possible solutions to that problem (6).

The items of an SJT are composed of two principal components (7).The first component is called the *item stem*, this is usually set in a professional work environment and involves a conversation between two or more actors. The contexts present a dilemma which is outlined in dialogue by one of the actors. The second component of an SJT item area the potential *item responses* that the second actor can provide to the first actor who presented the problem statement to attempt to address the issue.

There is substantial variation in how SJTs instruct the participant to select responses. Asking the participant for only a single most preferred response can result in faking, particularly in high stakes scenarios, and guessing or failure to engage thoughtfully with the test. A number of strategies have been developed to address this, one of which is to ask the participant to identify a best and worst response, forcing the respondent to reflect on why a response is appropriate or inappropriate rather than simply selecting the optimal response (7). This of course introduces ipsativity (8) to the test, in that a ranking is introduced to the responses. This can lead to issues with reliability analysis as the data collected are far less *granular* i.e a four-response SJT item scored Ipsatively has a theoretical maximum score of four. A more favourable method of *rating* responses or normative rating, can be employed instead and allows a more granular score to be attached to each item rating and so a four-response SJT item scored normatively on a 5 point Likert scale produces far more variation in score than an ipsatively scored item. This is a general issue faced in all Multiple Choice Question (MCQ) testing, but the use of normative scoring has particular significance to the scoring of SJT's as it allows more nuanced data to be collected from subject matter experts, who's responses may shape the scoring key of particular test items.

Patterson (9) carried out a systematic review of the use of SJTs in the evaluation of a number of non-cognitive factors including empathy, integrity and resilience. The review found that SJTs compared favourably with IQ tests and personality tests in predicting job success and represented a cost-effective means of candidate selection when compared with direct observation through structured interview. In the assessment of candidates' interpersonal skills Lievens (10) found "significant added value" in using SJTs over cognitive tests alone in predicting interpersonal skills. Motowidlo, Dunnette & Carter (11) found poor correlation between test scores and the GPA of participants but significant correlation with interpersonal skills $r = .21$ and negotiation $r = .50$ respectively, which were evaluated in interviews with test participants. An SJT developed by O'Connell et al.(12) shared variance with cognitive ability $r = .33$, conscientiousness $r = .33$ and agreeableness $r = .31$ which are established predictors of job success and the results are in good agreement with previous findings (13–15). The above literature seems to suggest that while SJTs are not predictors of academic success they are reliable predictors of future job performance when aligned with the appropriate professional skill.

1.3 Research objectives & question

In order to answer the research question: *"can a SJT be an effective means of assessing engineering students professional competence?"*, four research objectives were identified:

1) Develop an novel SJT with items tailored specifically to engineering professional scenarios.

2) Evaluate the SJT with all stakeholders including students, academics and industry professionals.

3) Identify the areas of professional strength and areas for improvement in the sample of engineers tested.

4) Provide students with prompt feedback on these strengths and areas for improvement.

2 METHODOLOGY

This research utilised a fixed mixed methods design, in which the quantitative and qualitative methods employed were predefined, and did not emerge from research findings in a previous stage of the research (16). The development of the SJT required the application of qualitative methods to evaluate respondents accounts about the content of the SJT items. The roll out of the SJT required the application of statistical tests to make inferences about the data collected from students who took part in this phase of research.

2.1 Methods

The method used in this study builds on a previous study of Craps et al (2021) who developed a validated Professional Roles Model for early career engineers (PREFER model) (17). A list of skills was developed by Binder Dijker Otte (BDO) (a consultancy with a division in Human capital) using a seminal piece of research by Bartram in which 29 validation studies (n= 4861) of his skills framework "the eight great professional skills" were meta-analysed (18). This list was brought to 13 expert panels in Belgium, Ireland and the Netherlands, all of whom employed engineers. Fifty-five panellists took part in the research; 47 male and eight female panellists who were predominantly engineers (44 engineers, 8 HR managers and 3 engineering managers with HR expertise) comprised the thirteen expert panels. In these panels, the competencies listed were mapped to the three professional roles outlined by the PREFER model, which describes three roles that early career engineers can take on when entering to the labour market: product leadership roles (focusing on radical innovation and research and development), operational excellence roles (focusing on product or process optimisation and increasing efficiency) and customer intimacy roles (focusing on tailored solutions forspecific clients).As well as these three role profiles, the outcome of these panels was a set of twenty-three skills and their descriptions. Once these had been identified, these skills were used as the basis for the development of the SJT items. The advantage of this approach was that items could be framed in a

particular context by design, basing each item on one of the twenty-three skills that had been identified. Designing the items from scratch also allowed the situations to be kept to an appropriate length. More detailed questions result in higher validity but this must be tempered by keeping the cognitive loading of the items to a minimum (19).
In this study, once the items had been initially drafted, the test was reviewed by a further set of 11 panels, this time made up of academics and industry professionals alike. In total, 53 people took part in the panels; 33 males and 20 females. Three panels were academic, made up of lecturing staff from the schools of civil & structural engineering, school of mechanical engineering and school of electrical engineering at TU Dublin and KU Leuven respectively, who reviewed the item stems. The items stems were also reviewed by panels from industry, with ESBI, Siemens and ENGIE. Once the items stems had been reviewed and the feedback integrated, The item responses were scored by panels from ARUP, Siemens (2 panels), Bosch, and Materialize to generate a scoring key that would be used to compare with students responses to the items.

Once a revised draft of the SJT items had been created, the test was divided into 3, resulting in 3 tests with between 7-8 items each. It was decided to keep the items grouped by role, rather than randomly assigning items to each test. The tests were brought online using BDO's test platform and links were disseminated to 334 final year undergraduate engineering students and masters students at TU Dublin and KU Leuven The rationale for selecting final year and masters students was that they represented the students who were closest to joining the labour market. Through their potential exposure to work placements, internships, guest speakers and site visits it was posited that their responses should align well to the responses collected from the panels with industry, and where they did not align well, a mismatch could be identified in their competence. All students who took part in the rollout of the SJT received a feedback sheet that compared their responses on each item to the responses of industry professionals, to provide them with a means of reflecting on their competence. The feedback was sent automatically through the BDO online platform via pdf.

2.2 Qualitative data treatment

The first stage of the evaluation of the SJT began with a desktop review of the 23 test items by staff from TU Dublin and KU Leuven; their qualitative feedback was documented. In the second stage, the test was brought to three expert panels. These panels were comprised of junior engineers, senior engineers, engineering management and HR professionals from ESBI, Siemens and ENGIE. During these panels, the participants were asked to evaluate the item stems to check if the items were suitable representations of the professional skill which it had been related to while their qualitative remarks were recorded. In the third stage, the test was brought to three expert panels comprised of lecturing staff at TU Dublin with backgrounds in the engineering industry and psychology from the schools of Civil & Building Services engineering, Mechanical & Design Engineering and Electrical & Electronic Engineering. In these panels, the participants were asked to assign two or three skills to each SJT item to check for alignment between the item and the skill it was written to represent.The data from the third review stage were compiled and reviewed by the researcher. Following revision of the content of the test items a fourth review stage began where the four possible responses to the scenarios presented in each item were reviewed in a further four expert panels with practicing engineers, engineering management and HR professionals at ARUP, BOSCH, Materialise and two panels with Siemens. The participants were asked to indicate their level of experience and their role along with their scores of the level of appropriateness of *each* item response on a 1-5 Likert scale, their qualitative remarks were also recorded. The scores provided by the experts were compared to the theoretical scoring key established by the researchers to establish a hybrid scoring key.

2.3 Quantitative data treatment

At an item level, where scores on each of the four possible responses could be aggregated, providing a theoretical maximum score of 24, the data were found to be normally distributable, and parametric statistics were utilised (20). T-tests were carried out to look for differences in sample means between different items, in order to determine students relative strengths and weaknesses in their evaluation of the scenarios presented in the SJT items. Participantion in the research was voluntary and di not form part of the students final assessment for any module. This research was conducted with Ethical approval from the TU Dublin ethics committee (REC-17-112).

3 RESULTS

3.1 Box and Whisker plots

The distribution of the students' scores for each item are displayed in figures 1.1, 1.2 & 1.3 respectively, with the mean score represented by the black line on each box plot and the data which fall within the normal distribution represented by the shaded area. Data was tested for normality using the Shapiro-Wilks method and determined not to be significantly different from a normal distribution. Results of the t-tests are available in Appendix A.

As illustrated in Figure 1.1, *planning and organising, solution orientation, team player* and *work organisation* had lower mean scores than the other items. It was unsurprising that *planning and organising and work organisation* were of similarly low scores as the operationalisation of these items was very similar; in both instances a cognitively loaded item was avoided, for example an item where an optimised schedule had to be created – as this would not fit well within the taxonomy of an SJT item. Instead, responses outlining consistent and inconsistent plans were created and the respondent was asked to rate each of these in terms of their utility for completing a particular task.

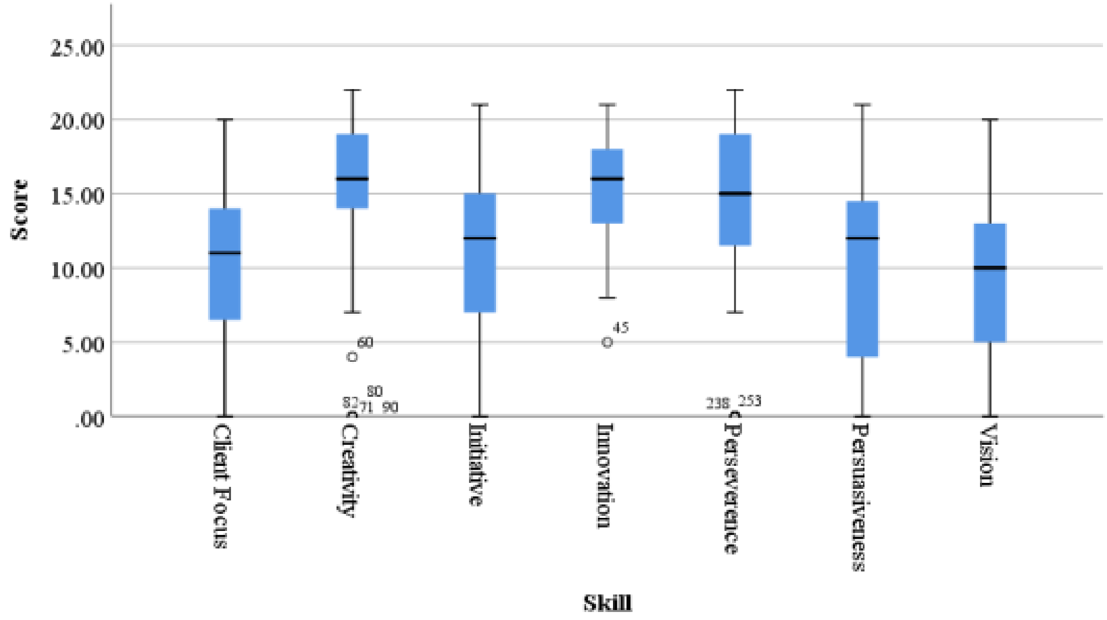

Figure 1.1 Box-Whisker plots for Product Leadership test

With reference to Figure 1.2, the *work organisation* item was of particular concern due to the low mean score, but also the variance in the score. The distribution of scores within the normal distribution presented as the shaded boxes in Figure 1.2 illustrate that the tail of the distribution of scores for *work organisation* was firmly placed between a score of 0-5. This was also the case for *planning and organising*, although to a slightly lesser extent These presented areas of weakness in the students' professional skills that should be addressed.

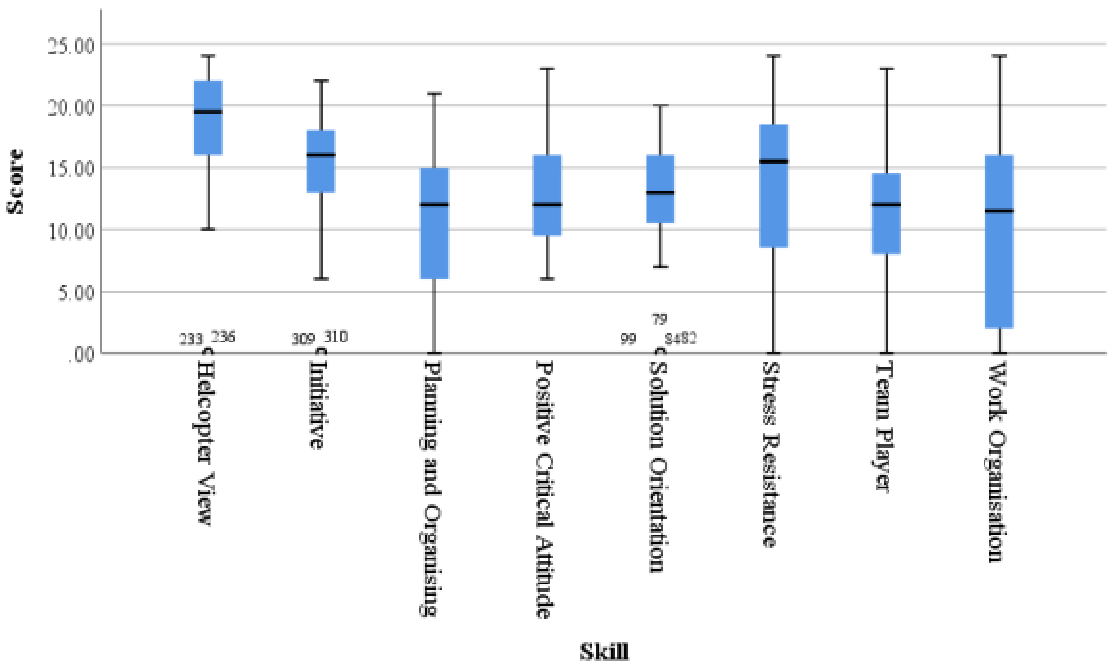

Figure 1.2 Box-Whisker plots for Operational Excellence test

With reference to Figure 1.3, *clear communication* and *networking* were found to have significantly lower mean scores than the test mean. The *networking* item was operationalised around a willingness to proactively network with an auditance of potential clients, or to stand back and take a more passive approach. This item may have been mediated by the introvert-extrovert personality trait, however it does suggest that on average, students are unwilling to engage proactively at a networking event.

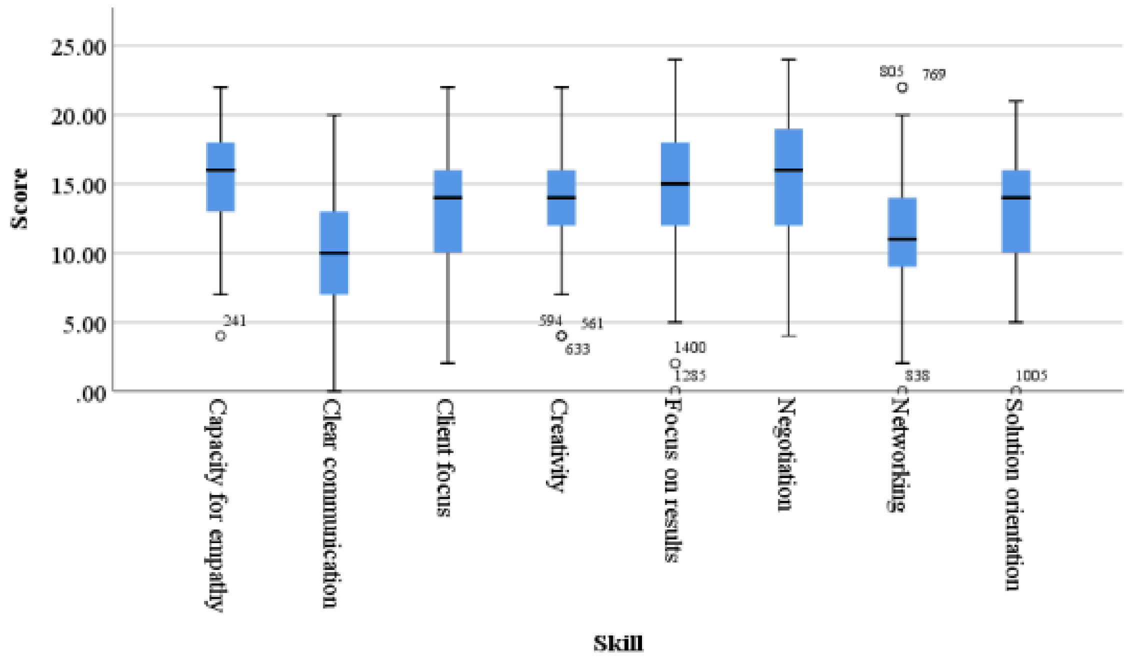

Figure 1.3 Box-Whisker plots for Customer Intimacy test

3.2 Paired sample t-tests

Items with the lowest mean score were identified and t-tested by comparing the item-mean to the test mean for each of the 3 tests, the results of these paired sample t-tests are presented in Appendix A. Eight of the twenty-three items of the SJT had significantly lower mean scores than the remaining thirteen items. These items, which were related to *perseverance*, *client focus*, *vision, planning and organising*, *solution orientation, team player, work organisation, clear communication* and *networking* all represent potential skill deficits in the population of final year and master students that were tested.

4 SUMMARY AND ACKNOWLEDGMENTS

As the students tested in this study are now in the labour market, it is useful to thinking about the ways in which these engineers may begin to bridge their skill gaps. As the sample of students tested are now in the labour market, implementation of the 70:20:10 model (21) of training may be useful, in which 70% of these gaps may be addressed through engagement with challenging projects, 20% engaging with a mentor to identify potential avenues, both formal and informal to bridge these gaps and 10% with further formal learning by engaging in courses offered by third level institutions and engineering professional bodies alike. Beyond the immediate needs of those students who were tested, further use of the SJT as a means of identifying skill gaps could be used proactively to inform engineering curriculua at third level, and also inform organisation's graduate development programmes regarding the types of training required of the incoming cohort of engineering talent.

This research was funded by the PREFER (Professional Roles and Future Employability of EngineeRs) project, a European commission funded research project under the Erasmus+ funding scheme (Reference: 2014-1-BE02- KA200-000462).

ABSTRACT

A significant number of universities where engineering is taught acknowledge the influence on society and the environment of the scientific and technological practice, as well as the ethical problems it presents, and the need to provide their students with courses covering this as a subject. The accelerated pace of innovation in these fields amplifies the issue.

Computer Engineering schools are no exception. So, the IEEE/ACM Computer Science Curriculum 2013, identifies social issues and professional practice as key knowledge areas that computer undergraduate students must learn. Students should be knowledgeable about the interplay of ethical issues, technical problems, and aesthetic values that play an important part in the development of computing systems.

The authors have taught for many years an optional course about the social, and environmental aspects of ICT as well as ethics. In this paper, the authors propose an approach to study ethics in Computer engineering schools. The approach consists in providing students with general ethic frameworks to reason about moral dilemmas as well as providing the basics of deontology. The lessons are complemented with case studies where technology is a key factor. Students are assigned roles to work on the cases and in the end, a discussion is done in the classroom.
After the lessons, the authors have observed that students are able to understand and use the tools provided by the teachers to reason about moral dilemmas.

1 INTRODUCTION

1.1 Section 1

The existence of computers and computer networks has been identified as a source of a new class of ethical and social issues since the early days of digital computers [1]. Today it is obvious the pervasiveness and ubiquitousness of the moral, ethical, social, legal, and political issues related to information technologies (ICT).

For example, the technological not-so-distant promise of Self Driving Cars raises complex questions in a lot of dimensions: (1) moral "If technology is proven statistically better at preventing deaths and accidents than the humans, should we use it? should we make it mandatory?"), (2) ethical "Can we delegate ethical decisions to machines whose behavior we don't fully understand?", (3) social "Do we want a significant percentage of the labor force with automation? ", (4) political "How are we going to deal with the consequences and the loss of economic and political power of the ones laid off? ", (5) geo-strategic "What nations control the technology behinds the self-driving cars moving around in our country?", (6) legal "How do we structure a legal framework to regulate self-driving cars?", (7) security "How do we ensure the cyber-security of our cars and utilities?". But these questions and even more complex ones appear again for almost any new technology: smartphones, drones, 3D printers, the internet of things, social networks, the web, face recognition technologies, big data, and every single application of (shallow) AI (artificial Intelligence).

But all of the cited technologies, their sophistication, capabilities, and impact are connected with exponential-like tendencies like the ones expressed by Moore's Law (the number of transistors per square inch in a processor doubles every 18 months), Metcalfe's Law (the potential utility of a network is proportional to the square of the number of nodes), and similar observations that strongly suggest that the curve of technological change is exponential. According to Kurzweil, the technological development we are going to experience during the 21st century will be equivalent to 20,000 years of progress at today's pace [2]. So, we should at least pay attention to the technological singularity hypothesis: "The technological singularity—or simply the singularity—is a hypothetical point in time at which technological growth becomes uncontrollable and irreversible, resulting in unforeseeable changes to human civilization" [3]. Last but not least, biology now has become a technology subject to exponential-like patterns, which makes the term "singularity" even more intriguing.

Hence the introduction of engineering ethics into the curriculum makes a lot of sense. The IEEE/ACM Computer Science Curriculum 2013, includes social issues and professional practice in the key knowledge areas that computer undergraduate students must learn. Graduates should recognize the social, legal, ethical, and cultural issues inherent in the discipline of computing. They should be knowledgeable about the interplay of ethical issues, technical problems, and aesthetic values that play an important part in the development of computing systems [4].

The Barcelona School of Informatics (Facultat d'Informàtica de Barcelona - FIB) at Universitat Politècnica de Catalunya (UPC) on 1991 started including the subject of ethics in a specific course in the Informatics Engineering graduate program [5] For more than 30 years this course has been a space for experimentation on how to teach the subject of ethics to informatics engineering students. This paper describes one of the teaching strategies applied.

There are many approaches on how to introduce the study of ethics in ICT curricula. Some are focused on the importance of the process of ethical decision making, which places an emphasis on the process it takes to reach conclusions [6,7]. Other researchers focus on professional practice considering that ethics education should focus on practical applications, on the ability to solve ethical problems morally or technically [8]. In this line of work, Johnson proposes ethics education as a set of activities that provides students with basic knowledge about codes of ethics. The goal is to develop their skill at interpreting and applying these codes and standards because this will provide students with the necessary skills to handle ethical issues once they enter in their professional lives [9]. Samson [10] adds that codes of ethics provide valuable guidelines to achieve ethical behavior and to assess moral responsibility in a profession.

Nygard [11] thinks that apart from ethics it is necessary to teach the social implications of a given technology, because it helps students in ICT develop their ethical reasoning skills and an appreciation for the complex impact that technologies have on society. They work by exposing the students to as many of the cultural, social, legal, and ethical issues in the discipline of computing as possible in order to broaden their appreciation and understanding of complex issues. Barceló at UPC, and Gordon at the University of Hull [12] took a similar approach.

Bowden proposed an ethics course based on case problems, ethical theory, acting in the public interest (or whistle-blowing), the study of codes of ethics, and the role of the professional society. A similar approach is presented in [13,14].

Reviewing the related work authors propose an example of a case study in a mandatory course in a master degree in sustainability to reason about moral dilemmas using philosophical thinking. The case study includes the particularities of computer science that requires technical understanding of the domain.

The rest of the paper is organized as follows: Section two describes the methodology used for the lectures about ethics as well as an example of a case study and how we worked this case in the class. Section three presents the findings provided after working the case and section four presents the conclusions of this work.

2 METHODOLOGY

2.1 The course

The case study we proposed is applied in a mandatory course of the Master's degree in Sustainability offered by the Sustainability Institute also at UPC. The course is called "Fundamentals of business ethics and innovation" (FEEI from now on) and is taught in English language to an audience of local and international students. FEEI has three main topics: 1) Ethics applied in the field of engineering and legal frameworks for the development of professional activity in engineering, 2) Corporate social responsibility and Ethics in companies and organizations, and 3) Innovation. The course is taught in English language and the students are local, national and international, they are aged between 25 and 40 years old and they split evenly in genders.

Our approach to teach ethics is explained next. First, we cover the basics of ethics, morality, and culture, and how they are connected. Then we present ethical theories as tools to make moral decisions. We differentiate workable ethical theories from now workable ethical theories, and then we go through a selection of ethical theories and we analyze how they work by working on examples and short cases. The chosen theories (in the order they are taught) are Kantianism, Rule and Act Utilitarianism, Social Contract, and Virtue Ethics.

This part provides us with frameworks to identify and reason about moral dilemmas where the application of technology is involved. We can also make moral decisions about it and present and rebate arguments in favor or against it. With these two lectures we provide the basics of philosophical thinking.

Then to put these lectures into practice we present two cases to the students. The first one is about identifying important moral values when reasoning about morals. We use them to do a role play case where students have to argue in favor or against certain moral issues.

The second case is usually something of high profile in the news, where technology is involved - and the nuances of understanding right the technology are important - and where we can find a moral dilemma. Again, the case is a role play where students have to use ethical theories to argue in favor or against certain moral issues. This case is the focus of this paper.

Then, we have a final lecture about codes of ethics and acting in the public interest (whistle blowing) that are followed by a case study.

In this paper we are going to focus in the cases we use to work ethical theories. We think that technical knowledge cannot be separated from the reflection about its impact or how it affects society. No technology is neutral, usually the pros are presented as benefits for society as arguments in favor of its introduction, but often cons or negative side effects appear when the new technology is being used. So, engineers must have a critical spirit about new inventions and how they will affect society. To do so the philosophy, sociology and history are good tools as proposed in the framework of CTS (Science, Technology and Society).

2.2 The case example

Here is an example of a case study presented to the students in winter 2022. The case title is "*Crowdfunding the war in Ukraine with Cryptocurrencies*".

Since the start of the invasion of Ukraine by the Russian army, a lot of reactions have ensued: From the almost unanimous condemnation of the UN to logistical aid to the Ukrainian defense forces not in the form of humanitarian supplies but also war vehicles, weapons, and ammunition.

The MAD doctrine (Mutually Assured Destruction) advises that countries with nuclear weapons should not engage directly. Hence NATO and EU countries have started to apply unprecedented economic sanctions, like the exclusion of Russian banks from the SWIFT international banking communications, the ban of imports and exports from and to Russia (not including oil and gas by the time being), and the direct seizing of actives owned by Russian oligarchs in western countries, including Switzerland and Monaco. Media associated with the Russian government (like Russia Today) have been canceled on platforms like Youtube, Twitter, and Facebook in several countries. And this is just the tip of the iceberg of the cyber-war that arguably was already ongoing. For example, the cyber activist group Anonymous has declared war against Russia and has allegedly hacked media servers in Russia to expose news about the war in Ukraine to the Russian population. The Russian government has passed legislation that makes spreading "false information" about the war a crime punishable with up to 15 years of prison.

In this scenario, thousands of citizens worldwide have started donating cryptocurrencies (Bitcoin and Ether) to wallets owned by the Ukrainian government. This constitutes an unprecedented fact in history: the crowdfunding of a war effort in a country by foreign citizens. The Ukrainian government has decided to take advantage of this situation and promised the airdrop of tokens to the Ethereum wallets that had donated until a given deadline. This caused a significant increase in donations, including hundreds of thousands of micro-donations not motivated by solidarity but as speculation.

2.3 The assignment

The students were presented with the previous text introducing the study case and were given a week to prepare arguments in favor or against the actions described. They had to work in groups on the Moodle platform of the school. A special Moodle grouping (https://docs.moodle.org/400/en/Groupings) was created where the students were put in groups randomly. Each group was tasked to develop arguments in favor or against the case and using only arguments consistent with one or two specific ethical theories (Kantianism, Virtue ethics, Social Contract Theory and Utilitarism). The students had available a specific Moodle Forum to collaborate online to prepare the case.

After a week, a two-hour debate was conducted in the classroom, moderated by the professor. The more relevant arguments and rebaits were written on the blackboard. And at the end of the session, the class voted on the more compelling arguments.

3 RESULTS

In this section we are going to discuss the findings of the case study in the classroom.

The groups that work using the Kantianism ethical theory provided with arguments in favor and against the donations using cryptocurrencies. The most voted arguments in favor of the dotation were the next.

If roles were reversed one would welcome the help. This was the most voted argument. The second most voted argument was that the action springs from good intentions (not treating others as means to an end).

Students identified three arguments to rebate the previous ones. The arguments are:

1. Is it not self-interest? Isn't the action done out of fear and using the Ukrainian land as a shield for the West?

2. Good intentions should not lead to providing weapons.

3. This donation could backfire and make wars more gruesome (like Napoleonic wars after the French revolution, when all the people of the state got involved in the war effort) and it would certainly benefit and incentivize the weapons industry.

The groups using the utilitarian morals agreed that they had to minimize human and animal suffering. Those in favor of the donation argued that in the long term, stopping an authoritarian tyrant with a record of invading countries is necessary to prevent suffering. Ukrainians will suffer more under the Puttin's yolk than if they surrender.

Those against the crowdfunding argued that in the short term the best bet to stop suffering is to stop the war. Crowdfunding Ukrainian's defense only makes it worse, and what will come later is unknown. These two points are in heavy dispute with a slight majority on the side in favor.

The groups using the social contract theory in favor of the crowdfunding explained that the donation is an example of participatory democracy (vote with wallet). They also base their arguments using the United Nations Charter Preamble (first paragraph) that states: "We the people of the United Nations Determined to save succeeding generations from the scourge of war, which twice in our lifetime has brought untold sorrow to mankind, and to reaffirm faith in fundamental human rights, in the dignity and worth of the human person, in the equal rights of men and women and of nations large and small, and to establish conditions under which justice and respect for the obligations arising from treaties and other sources of international law can be maintained, and to promote social progress and better standards of life in larger freedom".

The groups that argued against the crowdfunding stated that a social contract for believers in the Christian religion states that you shall not kill.

4 SUMMARY AND ACKNOWLEDGMENTS

This paper presents an example of case study used to work the ethics topic in a mandatory course in the master degree of sustainability at UPC. The case study is an example of didactical resource that we use in our lectures to help students develop their philosophical thinking. This resource can be adapted to other courses where ethics is taught to engineers. The idea is to adapt the case to de specific domain of the engineers so that it presents an ethical dilemma.

ABSTRACT

Covid19 outbreak has seen eLearning becoming a viable alternative to the traditional face-to-face teaching globally. Software Engineering education has not been an exception to these changes. The use of multimedia enhanced eLearning communities is also on the increase in the teaching of software engineering. However, there is limited research on the acceptance of such technologies by African learners. Some of the multimedia being used to enhance these learning communities includes animated pedagogical agents (PAs) combining text, animation, audio, and video. Considering learner differences and aiming to achieve personalized learning, there is a need for institutions to understand how such technologies are being accepted by learners and the factors that influence the acceptance. This study focuses on the acceptance of pedagogical agent enhanced eLearning communities by Southern African learners in the teaching of Software Engineering. The aim of the study is to identify the factors that influence the acceptance of such communities. This will help eLearning designers to try and address the needs of learners in different contexts to achieve personalized learning. This study involved 137 software engineering students from South Africa and Zimbabwe who were being introduced to eLearning community enhanced with PAs. The unified theory of acceptance and use of technology2 (UTAUT2) was used in this study. The study revealed that only performance expectancy, and hedonic motivation constructs had an effect on behavioral intention to use these eLearning communities enhanced with PAs.

1 INTRODUCTION

Imagine an online software engineering course in which students learn the content being presented online using a combination of narrated slides, and pedagogical agents (PAs) on the screen, which is are human-like characters intended to facilitate instruction [1] and the learner's learning [2]. The PAs engage in a variety of activities, such as role-playing as characters in a case study or as a fellow learner, helping learners solve problems, asking and answering questions or even providing encouragement. The use of PAs has been on the increase in education. This is due to the increase in the need to animate and keep the learners engaged [3]. Pedagogical agents are frequently integrated in online learning environments because they may be capable of providing cognitive support to the learner and being able to enrich socially the learning experience [4]. Lane, [5] suggested that properly designed and deployed pedagogical agents have a small, but significant impact on learning while [6] said PAs do not improve learning]. With these kinds of conflicting findings on the effect of PA integration, it shows that this area of educational research still needs to be explored further. Other researchers suggested that future research should include the deployment of agents in naturalistic contexts and open-ended environments, and investigation of agent outcomes and implications in long-term interventions [3].

With the technological advancement having led to the development of many efficient methods for innovative pedagogies in the field of education [7], these technological advancements have seen the adoption of eLearning communities in institutions that used to be face-to-face, and lecturer centered dominated. That traditional teaching was found to have no ability to meet the needs of students' comprehensive practical ability [8]. There is a shift from the traditional approach to a student centric approach in which the learner plays an active role in the learning process. That shift has been taking place at a slower pace prior to 2020, but the emergence adoptions of eLearning due to COVID-19 changed everything. A survey by [7] on engineering education depicts that there is a change in the teaching and learning process from teacher-centric education to learner-centric education.

On learning technologies to support learner centric education, reaerch pointed out that the learning technology might be poorly adopted, discontinued or rejected by learners, due to a number of reasons [9]. This raises the need to investigate acceptance issues associated with the introduction of new technologies in different educational contexts.

There is limited research evidence on adoption of these learning technologies in Southern Africa. As the issue of learner motivation and engagement remain topics of interest for researchers [10], there is need for such research even so in the African context and in the study domain of software engineering.

With the shift towards technology driven education for the achievement of personalized learning, a lot of innovative ideas are being implemented in higher education to try and address educational challenges. Some of these initiatives include the use of eLearning communities that are integrated with multimedia in the form of pedagogical agents which may be capable of providing cognitive support to the learner and social enrichment to the learning experience [4]. The acceptance of these technologies needs to be investigated in the context and different study domains to achieve the intended objectives.

The use of these animated pedagogical agents APAs in the study of software engineering requires that acceptance and impact of such technologies be investigated in the context of African learners, hence the focus of this study. The concept of one size fits all approach does not apply when it comes to predicting academic success of technology usage in education [11]. Therefore, there is need to investigate different students' contexts without generalizing using the findings from a different environment.

In the context of student-centered learning in which students are made to realize that it is their responsibility to engage, absorb, and retain while the instructor's job is to prepare an environment in which that can happen [12]. In an attempt to achieve personalized learning in which learning environments are expected to enhance the learning experience by providing tailor-made services based on learner preferences [13], several questions can be asked when technologies are being introduced. Behavioral intention to use blended learning was found to have an effect on the actual usage [14]. The link between behavioral intention and acceptance requires that acceptance be investigated when introducing new technologies in education.

This study focuses on the acceptance of PA enhanced eLearning communities by Southern African learners in the study of software engineering. This study seeks to answer the following key questions:

- Are communities enhanced with PAs accepted by software engineering students?
- What are the factors that influence the software engineering students' behavioral intention to use eLearning communities enhanced with PAs as an elaboration of multimedia?

2 THEORETICAL FRAMEWORK

The theoretical model employed in this research is based on the widely used models of technology acceptance. In particular, this study was based on the UTAUT2 model of [15]. The use of the UTAUT2 model is still scarce when studying learning technology acceptance in higher education contexts [16].

In the interest of selecting an appropriate model covering all constructs in determining Southern African students' intention to use and adoption of eLearning communities enhanced with multimedia in the form of PAs, the UTAUT2 has been found to be the most appropriate theoretical framework for the conceptual model to be used in this study. Following [15], Figure 1 below shows the main constructs in the model, which were proposed as direct determinants of behavioral intention to use Technology.

Very few studies have used UTAUT2 model to investigate the factors that influence the intention to use new technologies in higher education. Some of the studies that used UTAUT2 include [16],[17], however most of these studies were carried out with students outside the African continent.

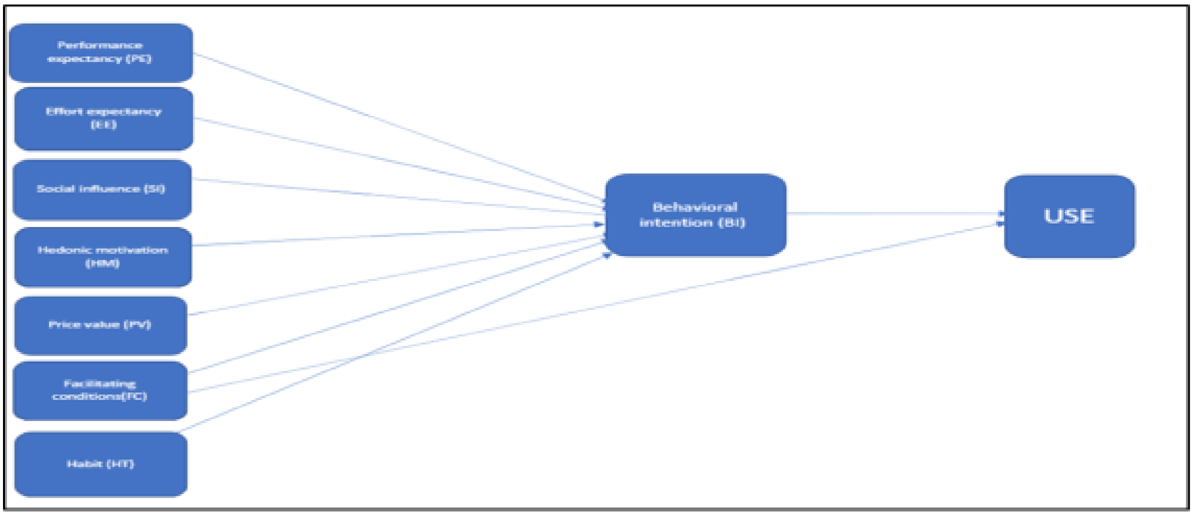

Fig. 1 The UTAUT2 model (Venkatesh et al. 2012)

From the UTAUT2 model two factors namely behavioral intention (BI) and facilitating conditions (FC) were seen as key predictors of adoption behavior [15]. The discussion of the model's constructs and how they contribute to the study is given below.

Performance expectancy (PE) is a key construct and the strongest predictor of BI to use a technology [15]. In this study, it has been defined as the degree to which students perceive that using eLearning communities enhanced with PAs will enable them to achieve improved performance in their studies.

Effort expectancy EE was found to be a determinant influencing people to BI, [18] and [19]. Wang and Wang [20] also found that constructs associated with EE will be stronger determinants of personal intention to use new technology. This study operationalised EE as the level of easiness related to using the eLearning environment enhanced with PAs.

Social influence (SI) has been operationalized in this study to refer to a student's belief in what significant others expect them to do.

Facilitating conditions (FC), in this study has been thought of as the degree to which students believe there is sufficient organizational and technical infrastructure, to support the use of PA enhanced learning environments in their studies.

Hedonic motivation (HM) is operationalized to mean perceived enjoyment. It refers to the fun, pleasure or enjoyment resulting from the students' use of the technology [21]. Previous research reported that perceived enjoyment significantly influences technology acceptance and use for learning [20].

Price value (PV), was found to be a predictor of Behavioral Intention to use a new technology. That was in other research where it could be operationalized like adoption of mobile phone [22]. PV could not be operationalized in this study because the students were expected to just use this environment for free without any direct costs linked to their use.

Habit (HT) considers results of previous experiences with community usage [15]. However, in this study the learners did not have any previous usage experience of such communities.

Behavioral intention (BI) was found to be a significant determinant behind the actual use of technology in different intention models [15]. In this study it refers to the extent to which students intend (and continue) to use environments enhanced with PAs.

USE behavior (USE), construct was not covered by the scope of this study because this study only focused on the acceptance of the environment. The study is being conducted during the initial stages of introduction to assess how the learners are receiving the new approach.

PV, HT, and Use having them operationalized as the stated above, these construct were excluded from some of previous studies [23],[24]. Although the constructs were also included during data collection. Due to students not being able to cognitively compare the enhanced environment with the financial cost that could be associated with using such an environment [15], and a lack of a lot of experience to talk of habitual behavior, meant that the construct HT could also be dropped. Although data was collected using all the constructs, it was left for the data analysis to confirm if those constructs were to be dropped or not.

The process of finding the appropriate model that fits the current study confirmed that the three constructs were supposed to be dropped. Model fit was only achieved after dropping the three constructs and a few items from the other PE and BI. This could be because of some challenges in operationalizing those constructs in this study as stated earlier and that could be due to the different circumstances of the learners.

Dropping those suggested constructs meant that the finally adopted model for the study reported in this paper was as shown in figure 2.

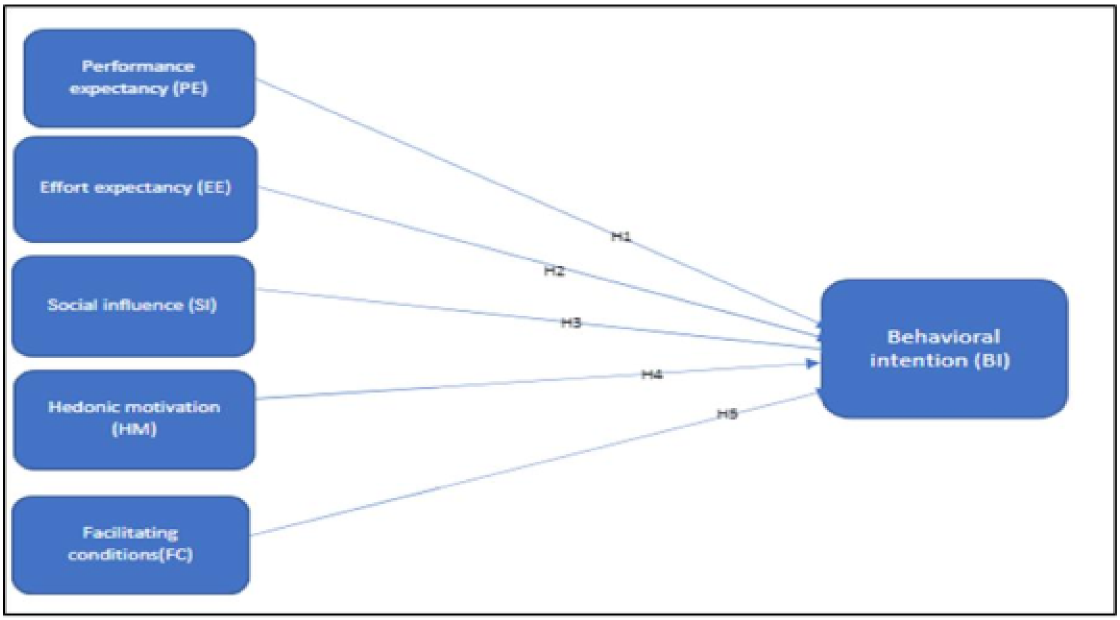

Fig2: Adopted model for the study.

3 HYPOTHESES

Using the given research evidence and according to Fig. 2, for the purpose of this study, the following hypotheses were formulated and tested:

H1: PE has an effect on software engineering students' BI to use PA enhanced eLearning communities.

H2: EE has an effect on software engineering students' BI to use PA enhanced eLearning communities.

H3: SI has an effect on software engineering students' BI to use PA enhanced eLearning communities.

H4. FC has an effect on software engineering students' BI to use PA enhanced eLearning communities.

H5: HM has an effect on software engineering students' BI to use PA enhanced eLearning communities.

4 METHODOLOGY

4.1 Participants and procedure

The sample consisted of 137 software engineering students from universities in South Africa and Zimbabwe as shown in Table 1. A questionnaire was completed by second year students studying at different universities. The participation in the survey was voluntary. The ethical standards of the institutional research committee were followed. The students were informed that the questionnaire is anonymous, and the data collected will be used solely for research purposes (confidentiality and privacy issues were followed). Students who accepted were placed in a WhatsApp group where the link for the questionnaire was posted. Anonymity was guaranteed because no personal information was added when students were submitting their responses.

4.2 The research instruments

The data were collected using the UTAUT2 questionnaire as described by [15]. The same items were operationalized to the context of this study. The questionnaire consisted of two parts. The first part consisted of 32 questions (items) to collect the data about the different constructs. Of the 32 items, 4 items measured PE, 4 items measured EE, 3 items measured SI, 4 items measured FC, 3 items measured HM, 3 items measured PV, 4 items measured HT, 3 items measured BI, and 4 items measured USE behavior. In responding to the items, the students were rating their views on a 5-point Likert-type scale (1 = strongly disagree to 5 = strongly agree). The second part of the survey question 33 and 34, were designed to collect demographic data namely gender and social category. The questionnaire was created and distributed using survey monkey link as well as hard copies. A total of 200 questionnaires we distributed and 148 were returned, 11 of them were not properly completed and were discarded.

The content validity of the questionnaire was evaluated by eleven experts and lecturers in the field of software engineering and information systems development, and blended learning. The questionnaire was found to be reliable; the questionnaire's Cronbach's alpha coefficient was calculated, and it was (0.936).

4.3 Data analysis

In terms of the demographics of the participants, of the 137 students participating in this study, 72.3% were female and 27.7% were male.

The validity of the model was assessed using Amos for both Convergent validity and discriminant validity. For convergent validity, the FL, CA, CR and AVE values were calculated. FL in all items were higher than 0.70. For all constructs, the CA reliability coefficients were higher than 0.70. In addition, the CR and AVE indexes were above 0.70 and above 0.50 respectively for all constructs. The results showed that convergent validity was at an optimal level. The index was evaluated using the square roots of the AVE. The square roots of AVE of factors were found to be greater than the correlational coefficient of the factors; because of that we could state that there was an excellent discriminant validity. The excellent model that emerged had the values CMIN/DF 1.794, CFI 0.936, SRMR 0.060, RMSEA 0.076, PClose 0.011

Structural Equation Modeling (SEM) was used to analyze the study hypotheses. The significant level was set at $P \leq 0.05$. The results of the structural model test are as presented in fig 3 below. The PE ($\beta = 0.144$, $P = 0.069$), EE ($\beta = 0.128$, $P = 0.273$), SI ($\beta = 0.080$, $P = 0.249$), FC ($\beta = 0.164$, $P = 0.216$) and HM ($\beta = 0.368$, $P \leq 0.01$).

In this model only HM constructs had a significantly positive effect on the students' behavioral intention to use eLearning community enhanced with pedagogical agents. PE was found to be at the borderline considering a P value of 0.05.

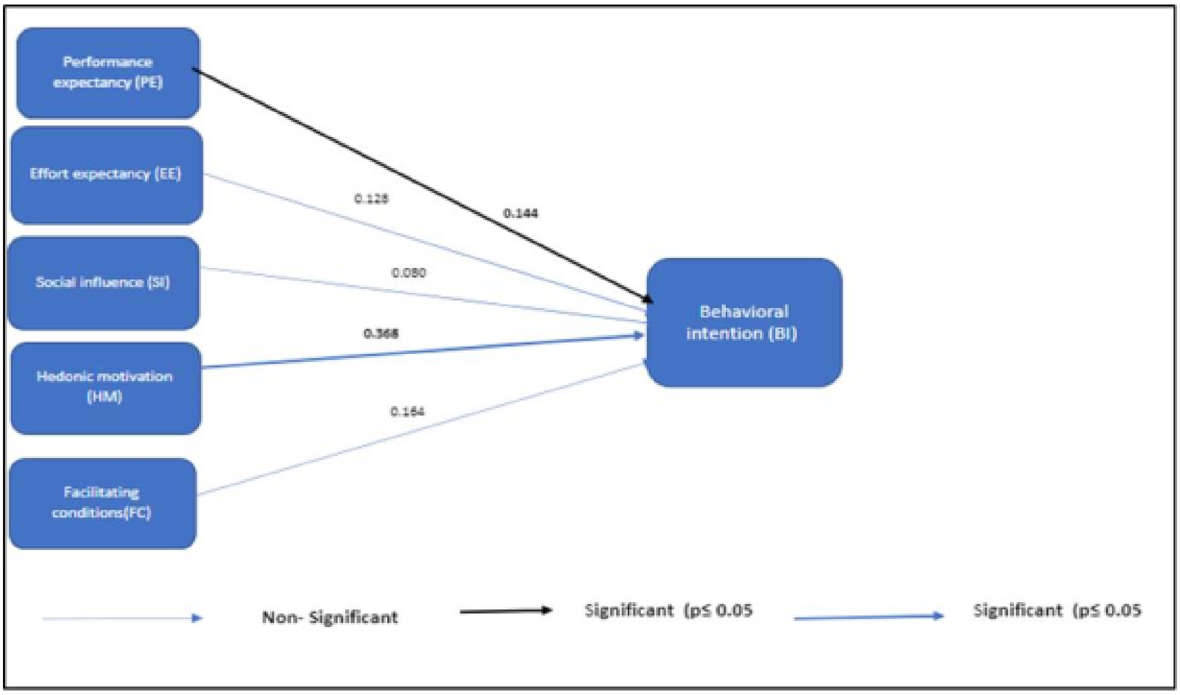

Fig 3: Structural model results

5 DISCUSSION

The results revealed that performance expectancy (PE) had a positive effect on the students' behavioral intention to use such PA enhanced communities. Although this was a border liner, this could be due to the sample size, since only 137 learners were used in this study, this finding was in line with [16] and [17].

The study revealed a significantly positive effect of HM on the students' behavioral intention to use eLearning communities enhanced with PAs. This finding was also in line with findings of [16].

However, EE had no effect on the students' behavioral intention to use communities enhanced with pedagogical agents. These results were in line with other studies that found no effect of EE on behavioral intention to use a new technology [17].

Also, social influence had no effect on the students' behavioral intention to use such communities. This was consistant with [16],[17] who also found the same results.

The findings of this study showed that software engineering students are willing to use eLearning communities that are enhanced with pedagogical agents as an elaboration of multimedia.

This study was not without limitations, some of which include the use of a self-reporting scale to assess the behavioral intention to use the community.

Having found the factors affecting intension to use PA enhanced communities, our suggestions for future work include investigation of the influence of other factors such as gender and social categories on the acceptance of such communities. We therefore recommend investigations to find if the usage of such communities will translate into some forms of educational benefit for the learners.

Caution must be taken when trying to generalize the findings to the whole of African learners and for all study domains, since only software engineering students from South Africa and Zimbabwe universities were involved.

6 CONCLUSION

This study revealed that the model emerged from the unified theory of acceptance and use of technology 2 (UTAUT2) is applicable for studies that seek to investigate the factors influencing the acceptance of eLearning communities designed using alternative elaborations of multimedia in different study domain.

Only PE, and HM, constructs had an effect on behavioral intention to use eLearning communities using pedagogical agents.EE, SI, FC, PV, and HT constructs have no effect on the software engineering students' intention to use such communities. Our findings were consistent with other studies.

This study can be used as a good reference for other studies researching on eLearning community design, multimedia integration, and eLearning acceptance in other study domains.

Keywords: *Peer mentoring, needs assessment, mentorship, phenomenology*

ABSTRACT

Peer mentorship is a mutually beneficial relationship that allows two individuals who are at approximately the same experience level to interact with one another with the goal of providing personal, professional, or both types of support. It has been found that peer mentorship within academic settings have generally positive retention, persistence, and student experience outcomes for both mentors and mentees. While peer mentoring research and initiatives are growing, very few instances exist of determining student perceived needs regarding peer mentorship. As such, at a western institution in the United States, students were surveyed to self-report their perceived peer mentorship needs. This survey occurred during Fall 2021, just after the onset of the COVID-19 pandemic.

Out of 223 participants, 79 students indicated that they currently had a peer mentor at the time the survey was administered. Students were given both a definition and examples of peer mentorship before indicating they had a peer mentor. Their mentors may have been formally assigned through an existing program at the college of engineering of interest or informally obtained through their own efforts. These 79 participants were asked what additional support they wish their peer mentor could provide. Through phenomenological analysis of open-ended responses, common avenues for additional support were determined. These findings allowed for development of recommendations for shaping the future implementation of more targeted and beneficial peer mentoring initiatives. The recommendations include providing flexibility in peer mentorship, training on resources and events, and a variety of peer mentoring opportunities early and consistently.

1 INTRODUCTION

1.1 Defining Mentorship

The National Academies of Sciences, Engineering, and Medicine state, “There is a gap between what we know about effective mentoring and how it is practiced in higher education” [1, p. x]. The variety of definitions of mentorship and lack of needs assessments throughout research serve as evidence of that gap in knowledge. In general, mentorship is accepted as a mutually beneficial relationship in which two or more people work together to support eachother in their personal and/or professional growth [1]. Peer mentorship specifically is when the participants in mentorship are at the same or nearly the same stage of their journey [1], [2], namely in this study, their academic career. This is in contrast to traditional mentorships where the mentor may be more advanced, for example in age or experience, which may cause a power differential to exist when compared to the mentee [2].

Peer mentorships can be advantageous in the sense that participants in the mentorship may feel an increased level of interpersonal comfort when compared to traditional mentorships [1]. It has also been found that peer mentorship can positively increase self-efficacy, satisfaction, retention, success, and support, both for mentors and mentees [1], [3]–[6]. This is especially important in cases with underrepresented students who may traditionally receive less mentoring support [1], [7], [8]. Unfortunately, oftentimes peer mentorship is underutilized as a resource for supporting students, even though peer mentoring may be a more practical method of mentoring when compared to traditional mentoring in academic settings. Administrators, faculty, and staff may have overwhelming responsibilities to manage, which may not include, recognize, or prioritize mentoring with the same level of significance as other duties, such as teaching and research [1]. Peer mentoring allows for a lower cost method of providing support by drawing through a much larger pool of potential mentors who can effectively share similar perspectives, identities, and recent experiences while still providing role modelling in a way traditional hierarchical mentoring may not be able to [3].

1.2 Determining Needs

Throughout research in the realm of engineering peer mentorship, there is a lack of consensus on what student needs with regard to peer mentorship are; while the number of engineering peer mentorship initiatives are growing, there are few examples, especially in engineering, of student needs being examined when developing peer mentoring initiatives, as well as a lack of documentation on the continual improvement and success within these initiatives [1], [9]–[12]. As such, Christensen [9] developed a mixed methods assessment of needs for determining students’ perceived needs when it comes to peer mentoring activities. Within this study, responses from a single qualitative question, which was not explored in Christensen’s original study [9], were utilized to focus on students’ perceived gaps in support from their current peer mentors. The approach to this analysis will be discussed in the methodology section.

2 METHODOLOGY

2.1 Research Instrument & Rationale for Additional Analysis

As mentioned previously, Christensen [9] developed and validated (i.e., quantitative Cronbach's Alpha = .783; qualitative content and face validation in multiple rounds) an exploratory mixed-methods instrument to obtain students needs regarding peer mentorship. The instrument included a total of 33 quantitative Likert-scale questions, 8 qualitative questions, and 8 participant identifier questions [9]. Originally, only two of the eight qualitative questions were analyzed in Christensen's study [9], calling for a deeper dive into additional qualitative insight from other qualitative questions. The full content of the research instrument can be found in Christensen's study [9]

The first block of questions that participants were introduced to in the survey included a definition and question, as follows [9, p. 258]:

> Q2 **Peer mentorship** is a relationship between two or more people at a **similar stage** in their personal, educational, or professional development. They work together to support each other.
>
> In the case of **undergraduate engineering education,** an example of a peer mentor would be **another student** (undergraduate or graduate) that is in the **same semester or ahead of you** in their university education. This person could either be simply someone you **consider** to be a peer mentor or someone who has been **formally** assigned as your peer mentor.
>
> Do you currently have a **peer mentor**?

Participants could choose one of four options for "Yes, I have a peer mentor", which indicated whether their peer mentor was in engineering at this institution or not, or "No, I do not have a peer mentor" [9, p. 258]. Based on their response to this question, participants were given a block of questions, depending on whether they responded with one of the "yes" options or the "no" option. While multiple questions were asked in each of these blocks, the focus of this research paper is on the perspective of those who chose one of the four "yes" options. The qualitative question responses analyzed were in response to the question "What additional support do you wish the peer mentor could provide?" [9, p. 270].

2.2 Research Question

The qualitative question of interest stated previously provides an opportunity to explore gaps that exist in current peer mentoring relationships. These relationships may have been self-established through personal networks or they may have been formally assigned by the small, existing program at the institution of interest. As such, the research question for this analysis was, "What common additional support are students who currently have a peer mentor in need of?"

2.3 Researcher Positionality

The first author for this publication was a part of the engineering student population of interest studied while completing undergraduate and graduate studies. This allowed her to bring a unique, insider perspective [13] with a variety of personal experiences as a student, leader, and instructor, both in the classroom and in extracurricular activities. As such, she was intentional about keeping her positionality in mind throughout the study to allow for ethical analysis. The second author brought necessary experience in mentorship, teaching, and research to further verify and expound the findings in an impactful way. As a team, the authors acknowledge the gap in peer mentorship and recognize the critical nature of exploring and sharing well-researched recommendations for the future effective implementation of peer mentoring initiatives.

2.4 Recruitment

Recruitment and research study procedures were approved by the Utah State University Institutional Review Board (IRB) [9]. Because of the timing of the study, all recruitment and survey participation happened virtually because of the COVID-19 pandemic hybrid learning situation. All survey responses were completely anonomyous. Of the respondents, 199 participants shared their information in a separate form, not tied to their survey response, to enter a gift card randomized drawing. All the participants were undergraduate students in the College of Engineering at a western institution of the United States. Of the 325 survey submissions, 223 responses were kept for further analysis after cleaning the data. Of the 223 complete responses, 79 participants indicated “yes” to the question “Do you currently have a **peer mentor**?” These 79 participant responses are the focus of this study. Of the 79 participants, only 5 (6.3%) left their response blank to the question of interest. The demographic information for all 223 participant responses as well as the 79 participants of interest are shown in Table 1. This population was considered representative within the university of interest as well as United States averages where applicable [9].

2.5 Qualitative Analysis Approach & Coding Procedures

The purpose of the qualitative coding was to determine the common experiences among participants when they were asked about additional support needed from their peer mentoring relationships. Thus, similar to Christensen [9], a phenomenological approach was taken. Using phenomenology-like strategies allowed the researchers to summarize the essence of the peer mentoring experience of students at the institution of interest [14]. Recognizing the first author’s positionality as an insider to the college of engineering of interest, a hermeneutic approach was chosen to allow the researcher to interpret in conjunction with her experiences and background, yet always being aware of the influence those experiences may have on the analysis [15].

Of the 79 responses, 30 were randomly chosen, organized, and initial coded on a participant-by-participant basis to find significant ideas within the data, remaining open and preserving student perspectives by using in vivo coding [16]. The initial in vivo codes with conceptual similarity were then focused coded into thematic categories [16]. A codebook was developed to describe the categories. The focused coding results and codebook were provided to two undergraduate researchers external to the institution of interest to perform intercoder agreement to further check and correct for any potential biases [16]. This process resulted in an average agreement of 92% across the 30 responses, which is considered adequate [16]. The commentary for misalignment was considered in order to come to a consensus on the refinement and assignment of focused codes. The refined codes were then used to code the full 79 participant responses by the primary author. Additional codes were added and categories were rearagged as necessary, resulting in a final total of eight coding categories, which will be provided in the results.

Table 1. Demographic information for all 223 participants (abbreviated "part.") and the 79 participants who indicated that they currently have a peer mentor [9]. *While more options may have been included in the question statement, only responses that participants chose are shown in the table. All other options can be found in Christensen* [9].

Year in Undergraduate Engineering			**Declared Major**		
Category	**All Part.**	**"Yes" Part.**	**Category**	**All Part.**	**"Yes" Part.**
Freshman	19.7%	16.5%	Mechanical	55.6%	58.2%
Sophomore	13.0%	13.9%	Civil / Environmental	18%	11.4%
Junior	40.4%	39.2%	Biological	6.7%	10.1%
Senior	24.2%	25.3%	Electrical / Computer	15.7%	15.2%
Other	2.7%	5.1%	Intend to Pursue	0.9%	0.0%
			Other	3.1%	5.1%
Self-Identified Gender Identity			**Of Hispanic, Latinx, or Spanish Origin**		
Category	**All Part.**	**"Yes" Part.**	**Category**	**All Part.**	**"Yes" Part.**
Male	74.0%	72.2%	Yes	3.0%	5.0%
Female	23.8%	25.3%	No	90.0%	89.0%
Prefer not to	2.2%	2.5%	Prefer not to answer	7.0%	6.0%
First Generational Status			**Race**		
Category	**All Part.**	**"Yes" Part.**	**Category**	**All Part.**	**"Yes" Part.**

No	91.5%	92.4%	Person of Color	3.2%	2.5%
Prefer not to	0.9%	1.3%	Prefer not to answer	5.8%	5.1%

3 RESULTS & DISCUSSION

This section contains the results and discussion of the qualitative coding analysis. All participant quotations that are communicated in this paper are direct copies of survey responses; thus, any spelling or grammatical errors are included. As previously mentioned, eight final coding categories were established, which are shown in Table 2 with frequency counts and representative quotes. Overall, there were 81 total code occurrences amidst the 74 non-blank participant responses.

When examining the additional needs not met by the participants (Table 2), different types of needs are recognized, alluding to Maslow's Hierarchy of Needs [17], [18]. Students mentioned physiological needs, such as finances and food (Table 2, Participants1 & 59) and others mentioned esteem needs, such as being told they are doing a good job (Table 2, Participant 26).Others had belongingness and love needs that could come through friendship and informal socializing (Table 2, Participants 47 & 60) as well as professional connections (Table 2, Participants 43 & 74). Many students desired more guidance and help in self-actualization, such as determining future paths, classes to take, and how to take advantage of resources in building their future self (Table 2, Participants 53, 63, & 20). Finally, many of the students felt their needs were being met or were unsure how a peer mentor could help (Table 2, "No Suggestion" row). This emphasizes the overall complexity of developing peer mentoring initiatives to meet a variety of students' needs.

3.1 Recommendations & Implications

As structured in Garringer et al. [19], there are fundamental best practices in developing mentoring programs. The process of implementing these best practices allow adequate delivery of the perceived additional support reported by students in the aforementioned analysis. The six standards of practice are: (1) recruitment; (2) screening; (3) training; (4) matching and initiating; (5) monitoring and support; and (6) closure [19]. A proposal of how these six standards of practice are connected to each of the coding categories (Table 2) are shown in Fig. 1. While exploratory in nature, this figure gives an idea of the many spaces available within peer mentoring initiatives that students needs can be met through development, planning, monitoring or adjusting.

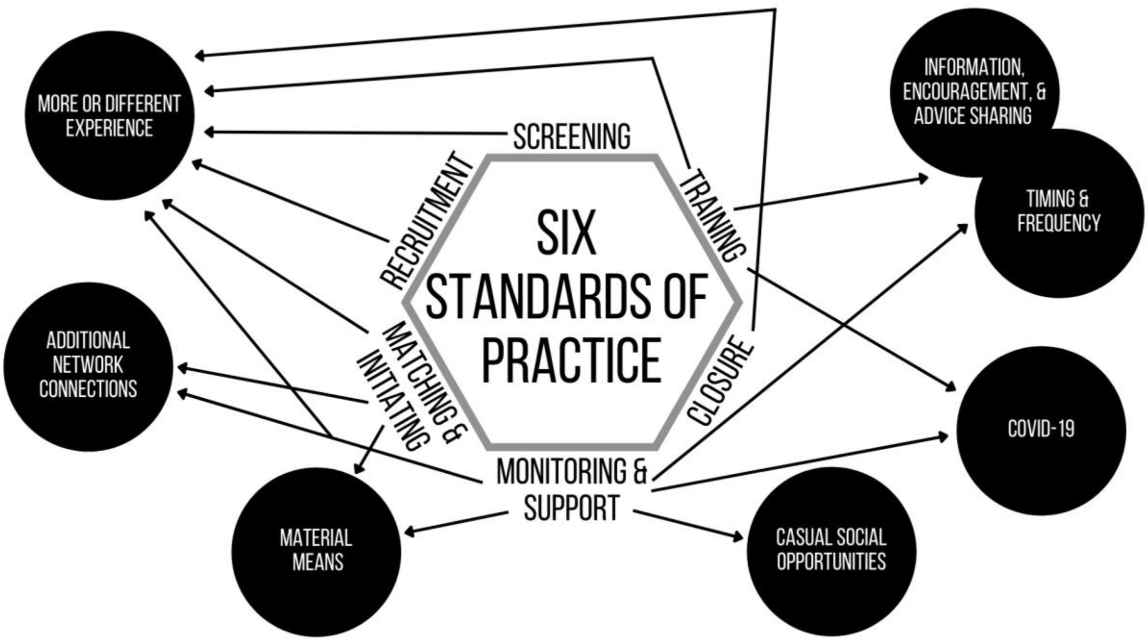

Fig. 1. Connections between the six standards of practice for developing and sustaining peer mentoring initiatives (sides of hexagon) and coding categories (circles). Coding categories that are touching have the same associated practices.

Table 2. Coding categories with frequencies, definitions, and representative quotes included

Code Category *(Frequency)*	**Definition**	**Representative Quote(s)**
No Suggestion *(37)*	Unsure of additional support that could be provided or they were satisfied with the support their current mentor(s) were providing	• "None. I feel like they cover all my needs" (Q16, Participant 2) • "I'm not sure." (Q16, Participant 41) • "I literally don't know how he could have been better. He help me accelerate my career for almost three years." (Q76, Participant 76)
Information, Encouragement, & Advice Sharing *(24)*	Desired sharing of general information about events and best practices, tutoring, providing advice on classes, guiding in future opportunities and decisions, and providing encouragement	• "I just need to be told I'm doing a good job and I am on the right track even if I mess up." (Q16, Participant 26) • "I wish they could help me secure internships and help me in the professional side of Engineering." (Q16, Participant 31) • "Networking or finding temporary jobs or long term jobs that prepare me for my future as an engineer." (Q16, Participant 43) • "Advice in figuring out what specialty/subfield to pursue" (Q16, Participant 63) • "Give me some advice about classes" (Q16, Participant 53) • "Remember all the information from the classes they took so they could help me more" (Q16, Participant 34) • "More clarity as to how to use clubs and the career service center." (Q16, Participant 20)
More or Different Experience *(6)*	Desired a mentor who had more experience, was farther ahead of them in school, or was in the same field as them.	• "It would be nice to have someone from my same major, so they can help me with things specific to biological engineering" (Q16, Participant 10) • "Ahead of me in the program by a semester or a year" (Q16, Participant 48) • "Be better at some subjects than me. So it won't be as one sided." (Q16, Participant 69)
Timing or Frequency *(5)*	Desired having a peer mentor earlier or having more frequent contact with the peer mentor.	• "Earlier in my engineering career. Since we have become peer mentors it has been great but I wish it could have happened earlier" (Q16, Participant 28) • "I wish she contacted me more often, she usually only reaches out to me about once month unless I contact her first." (Q16, Participant 40)
Casual Social Opportunities *(3)*	Desire time outside of formal opportunities to interact & socialize	• "More contact outside of school classes." (Q16, Participant 47) • "Time outside of work or homework to interact as people" (Q16, Participant 60)
Additional Network Connections *(3)*	Desired additional support in connecting to potential network members	• "Having more connections outside of education." (Q16, Participant 74) • "If I were getting more help from my peer mentor it would probably be networking" (Q16, Participant 43)
Material Means *(2)*	Desired additional material means were as support	• "Financial, but we both know that won't happen." (Q16, Participant 1) • "Food?" (Q16, Participant 59)
COVID-19 *(1)*	Desired implications of COVID-19 to change	• "The major thing I wish could change is COVID, as social distancing made it hard to make those peer mentor relationships." (Q16, Participant 14)

To summarize based upon the connections shown in Fig. 1, the following three recommendations are provided to support the future development, monitoring, and implementation of peer mentoring initiatives:

- **Provide Flexibility in Peer Mentorship:** Especially when formally assigning peer mentors, allow students adequate space and opportunity to match with different or additional peer mentors.
- **Provide Training on Resources and Events:** At the beginning but also continually as new resources or events arise, provide training to peer mentors on how to use take advantage of the resources or events as well as how to adequately share them with their peer mentee.
- **Provide a Variety of Peer Mentoring Opportunities Early and Consistently:** Students need peer mentorship consistently, regardless of what stage they are in, and desire both formal (e.g., professional support, tutoring, etc.) and informal support (e.g., socializing, student life events, etc.) through a variety of ways (e.g., texting, email, face-to-face, etc.)

As these recommendations are taken into consideration, a range of student needs from Maslow's Hierarchy [17], [18] can be met by allowing for consistent, flexible, and well supported peer mentorship.

3.2 Limitations & Future Work

The primary limitation of this study is that the survey was given under COVID-19 pandemic circumstances, which may have influenced student responses since students were in an emergency hybrid learning situation. This unique perspective may also have brought to light potential impactful practices that would have not otherwise been recognized. The short-answer, anonymous qualitative question format may have provided some limitation as well since students self-reported their answer and no follow-up for elaboration or clarification was possible. This leaves room in the future to pursue more in-depth methods, such as interviewing, in exploring student perceived needs.

This analysis did not take into consideration any participant demographic information or descriptions of who their peer mentors were. Future work will examine these aspects as well as participant explanations of what their peer mentor does effectively to complement the gaps identified in this study.

4 CONCLUSION

The three recommendations provided in this study, while not comprehensive, provide a foundation for designing, monitoring, and adjusting initiatives to address potential gaps in peer mentoring relationships. By providing flexibility, training on resources and events, and a variety of opportunities early and consistently, more students can receive the support they need. Whether that is by finding different or more mentors, receiving help in both formal and informal spaces, or simply finding support earlier, the benefits associated with peer mentorship (e.g., interpersonal comfort, retention, self-efficacy, satisfaction, etc.; [1], [3]–[6]) will be expanded.

ABSTRACT

Building on the Theory of Planned Behavior, the aim of this paper is to investigate the moderating effect of entrepreneurship education in the relationship between attributes like attitude, social norms and perceived behavioral control, and the entrepreneurial intention of university students. Specifically, the moderation effect of entrepreneurship

programs that adopt a Challenge-Based Learning approach is analyzed. To do so, the Italian sample of university students who participated in the 2021 Global University Entrepreneurial Spirit Students' Survey (GUESSS) was used. Results confirm that participation in entrepreneurial programs that adopt a Challenge-Based Learning positively moderate the relationship between Theory of Planned Behavior attributes and entrepreneurial intention of the students. Specifically, the results show that participation in Challenge-Based programs increases the positive effect of attitude on entrepreneurial intention.

1 INTRODUCTION

Increasingly in recent years, particular attention has been paid to the phenomenon of venture creation by young people and especially university students (Loan et al. 2021; Meyer and Krüger 2021; Wach and Bilan 2021). This phenomenon, defined as student entrepreneurship, is of particular interest because of the positive impact it can have on the local economy, especially in terms of youth employment, but also because of the important role entrepreneurship plays as a source of innovation and technological change (Schumpeter 1934). Entrepreneurship, and in particular the identification of an entrepreneurial opportunity, is crucial for technological innovation to influence economic development (Shane 2000) and high-skilled young people can give a strong contribution in this direction.

In order to foster the growth of entrepreneurship among students, universities play a key role in terms of Entrepreneurship Education (EE) (Zahra and George 2002; Colombelli et al. 2021b). In this context, it is crucial to identify both behavioral and skills-related aspects that can influence students' decisions to pursue entrepreneurial careers. Many studies show that Entrepreneurship Education fosters students' propensity to pursue entrepreneurial careers and is effective in enabling students to acquire or improve their entrepreneurial skills and abilities (Martin et al. 2013; Bae et al. 2014). Kuratko (2005) through his study demonstrated how such competencies and skills can be shaped by education. Other works have tryed to develop models capable of predicting entrepreneurial behavior through entrepreneurial intention (Shapero and Sokol 1982; Krueger and Brazeal 1994). Intention is indeed considered the best predictor of behavior (Krueger et al. 2000). In particular, in the context of entrepreneurship, entrepreneurial intention is able to predict entrepreneurial action (Kautonen et al. 2015).

In the context of student entrepreneurship, the understanding of the elements that influence entrepreneurial intention is of particular importance, so as to design EE programs that are more effective in improving that intention. The most widespread model that allows us to investigate the drivers that guide the development of an intention and consequently a behavior is the Theory of Planned Behavior (TPB) (Ajzen 1991). This theory is based on three elements: attitude, social norms and perceived behavioral control. Schlaegel and Koenig (2014) suggest that these three elements underpin the development of entrepreneurial intention. The model of intention based on the Theory of Planned Behavior can be moderated by other elements and situations that influence the relationship between the three predictors and intention (Mathur 1998). One of these elements is Entrepreneurship Education. Previous works have revealed that TPB and EE can influence each other in order to improve students' entrepreneurial characteristics, including intention (Gorman et al. 1997; Kuratko 2005; Rauch and Hulsink 2015).

However, the literature investigating the effectiveness of EE on entrepreneurial intention and in relation to the Theory of Planned Behavior, has mainly neglected the impact of individual educational approaches. Consequently, the impact of entrepreneurial education programs could be investigated in relation to specific learning approaches, because different approaches may have different effectiveness in improving skills and intention of students (Rae and Carswell 2000). One of the approaches implemented in EE is Challenge-Based Learning, a learning methodology in which students learn in a real context, and deal with challenges and real problems proposed by them or by existing firms (Chanin et al. 2018; Colombelli et al. 2022a).

In line with these arguments, the aim of this article is to investigate the effectiveness of the Challenge-Based Learning approach on the development of entrepreneurial intention in the context of the Theory of Planned Behavior. Specifically, we sought to understand whether participation in a Challenge-Based Learning entrepreneurship program can intensify the effect of attitude, social norms and perceived behavioral control on students' entrepreneurial intention.

To investigate this, the database of the GUESSS (Global University Entrepreneurial Spirit Students' Survey) 2021 project was used, specifically the data collected in Italy on about 30 universities for a total of 346 valid observations. The data were analyzed through t-tests and multiple linear regressions. The results show that participation in a Challenge-Based Learning program increases the positive effect of entrepreneurial attitude on students' entrepreneurial intention.

The article is structured as follows. In section 2 the theoretical framework is described. Section 3 presents the methodology, describing in detail the sample used and the analyses carried out. Then, in section 4, the results of the study are analyzed. Finally, in section 5, the conclusions and limitations of the study are presented.

2 THEORETICAL FRAMEWROK

In the literature, there is an increasing interest in investigating the drivers that lead young people, and in particular students, to embark on an entrepreneurial career by starting their own business. This interest is also focused on identifying EE practices in order to exploit these drivers. In this context, scholars place great attention on intention models, because they are the most robust models to predict the intention to start a business (Krueger 2007; Koe and Majid 2014). Ajzen (1991) developed what is considered the theoretical reference model regarding intentions as main predictors of behavior, also in the entrepreneurial field (Entrialgo and Iglesias 2016). This model is based on the Theory of Planned Behavior and states that the greater the intention of an individual in undertaking a certain behavior, the greater the probability that this behavior will be performed. The TPB model adds a second concept to this first statement, namely that an individual's intention is in turn influenced by three elements: attitude, social norms and perceived behavioral control.

Attitude is the concept that represents perceptions of personal convenience with regard to performing a behavior. The more positive the perception of the outcome that can be obtained from a behavior, the greater should be the attitude towards that behavior and consequently the intention to perform it (Autio et al. 1997; Krueger et al. 2000; Luthje and Franke 2003; Segal et al. 2005; Pruett et al. 2009). The second concept is social norms, i.e. the social pressures from social reference groups (e.g. family and friends) that one perceives when performing a certain behavior (Ajzen 1991). With respect to attitude, social norms are not always agreed upon by researchers with regard to their impact on entrepreneurial intention. Ozaralli and Rivenburgh (2016) and Kautonen et al. (2015) in their studies point out that social norms are a relevant predictor of entrepreneurial intention. At the same time, in other studies a weak or even non-significant relationship between these two elements emerges (Krueger et al. 2000; Autio et al. 2001; Liñán and Chen 2009; Nishimura and Tristán 2011; Wach and Wojciechowski 2016). The third and final concept underlying the Theory of Planned Behavior is perceived behavioral control. This concept represents the ease or difficulty that the individual perceives in performing a certain behavior (Bandura 1986; Swan et al. 2007). The literature shows how perceived behavioral control has a positive and significant impact on entrepreneurial intention (Fayolle and Gailly 2004).

Several studies in the literature demonstrate the direct impact of the three constructs of the TPB on entrepreneurial intention (Kolvereid 1996; Krueger et al. 2000; Lüthje and Franke 2003; Souitaris et al. 2007; Kautonen et al. 2015). Yet, the impact of attitude and perceived behavioral control is more widespread and relevant than that of social norms. Consequently, this evidence allows the following hypothesis to be formulated:

H1: There is a positive relationship between attitude, social norms and perceived behavioral control, and entrepreneurial intention.

Within the context of TPB and entrepreneurial intention, entrepreneurship education plays a key role. Studies in the literature show that there is a positive and significant impact between Entrepreneurship Education and entrepreneurial intention (Turker and Selcuk 2009; Gubik 2014; Maresch et al. 2016; Kramarz et al. 2019; Karyaningsih et al. 2020). In particular, Bae et al. (2014) state that knowledge acquired through education is decisive in developing entrepreneurial intention. Furthermore, Entrepreneurship Education acts as a moderator by influencing the relationship between the elements of the Theory of Planned Behavior and entrepreneurial intention. This moderating effect is found to enhance the positive impact of attitude on entrepreneurial intention (Maresch et al. 2016; Shah et al. 2020), because in EE programs entrepreneurship is positively positioned relative to other career options, reinforcing positive attitudes for an entrepreneurial career. In addition, participation in EE programs allows students to improve their knowledge about entrepreneurship by becoming more aware of embarking on an entrepreneurial career and thus making them less dependent on the opinions of social groups (Kautonen et al. 2015). Consequently, the moderation effect in this case leads to a reduction in the positive effect of social norms on entrepreneurial intention (Shah et al. 2020). Regarding to perceived behavioral control, EE enables the acquisition of knowledge and skills, increasing confidence in own abilities and further improving entrepreneurial intention (Shah et al. 2020).

This evidence allows to understand the relevance of Entrepreneurship Education. However, when analyzing the impact of Entrepreneurship Education in these studies, it is done by considering education programs without distinguishing between different training approaches. Within this study we want to focus on the Challenge-Based Learning approach, an experiential learning methodology that allows students to apply knowledge and skills in a real context. Compared to other learning approaches, such as Project-Based Learning and Problem-Based Learning, it is characterized by the joint presence of a practice-based methodology and a real context due to the presence of a challenge proposed by existing companies.

Studies in the literature demonstrate the positive impact of Challenge-Based Learning on students' entrepreneurial intention (Johnson et al. 2009; Palma-Mendoza et al. 2019; Martinez and Crusat 2020; Colombelli et al. 2021a; Colombelli et al. 2022a). Moreover, these studies show that Challenge-Based Learning improves students' entrepreneurial skills and competences. A result that according to Bae et al. (2014) would favor the development of entrepreneurial intention.

Given the evidence from the literature on the moderating effect of EE in the relationship between TPB and entrepreneurial intention and the relevance of the Challenge-Based Learning in the context of EE. The study presented in this paper aims to investigate the influence of the Challenge-Based Learning approach within the relationship between Theory of Planned Behavior and entrepreneurial intention. Accordingly, the following hypothesis are proposed:

H2: Participation in a Challenge-Based Learning course increases the positive effect of attitude on entrepreneurial intention.

H3: Participation in a Challenge-Based Learning course decreases the positive effect of social norms on entrepreneurial intention.

H4: Participation in a Challenge-Based Learning course increases the positive effect of perceived behavioral control on entrepreneurial intention.

3 METHODOLOGY

3.1 Sample

This study was carried on using the data collected through the survey conducted by GUESSS in 2021 in Italy.

The GUESSS survey is part of an international research project on student entrepreneurship, conducted since 2003 by the "Swiss Institute for Small Business and Entrepreneurship" of St. Gallen University: it covers different research topics, from entrepreneurial intention to nascent entrepreneurship, highlighting factors of influence at the individual, family, contextual and university levels.

The sample includes 3294 students who answered the questionnaire and of these 32% declare to have at least a parent who is an entrepreneur; the average age of the participants is 24 years and in terms of gender, males represent 52% of the sample while females are 48% (Fig. 1). The survey has been proposed to all the students of the Italian participating universities, thus belonging to different fields of studies. The distribution of students by fields of study (Fig. 2) is skewed toward the engineering (incl. architecture) and economics areas (58,4%), compared to the other areas, which individually count less than 10%. Considering the level of studies, more than 63% of participants are pursuing a Bachelor's degree, 35% a Master's degree and less than 2% a PhD or an MBA (Fig. 3). Finally, analyzing the role of Entrepreneurial Education (EE), Figure 4 shows that 1829 students (~55% of the total) have never taken a general entrepreneurship course while 346 have at least once participated in a Challenge-Based Learning course.

3.2 Description of variables and analysis

The variables of the econometric analysis of regression were built starting from the proposed research model in the theoretical framework section.

The dependent variable of the model is the Entrepreneurial Intention (EI) which is assumed to capture the motivational factors that influence a behavior: EI is an indication of how hard people are willing to try, of how much of an effort they are planning to exert, in order to perform the behavior.

The variables of the Theory of Planned Behaviour, in this research considered independent, are Attitude (ATT), Perceived Behavioral Control (PBC) and Social Norms (SN): they respectively refer to the perception of personal convenience, perceived ease or difficulty and perceived social pressure to perform or not to perform the entrepreneurial behavior.

The GUESSS questionnaire has a set of questions (or items) – prevalidated by literature - for each of these 4 variables cited above. Each question allows for the measurement of a single item of the considered variable and each question can be answered on a Likert scale from 1 to 7 (1=totally disagree, 7=totally agree). The arithmetic mean of the item values was calculated to obtain the value of these variables.

The Confirmatory Factor Analysis and the Cronbach's α - calculated for each of these 4 variables and higher than 0.7 for all of them - gave further confirmation of the reliability of the scales used.

Given the continuous nature of the dependent variable, the model's assumptions has been tested via a multiple linear regression.

Considering that the main focus of this work is to analyze the impact of Entrepreneurship Education courses, four dichotomous independent variable keys have been built, namely EE_general, EE_elective, EE_compulsory, EE_challenge: they respectively assume the value 1 if the subject has participated at least once in a general, elective, compulsory or Challenge-Based Learning course and 0 otherwise.

In addition, control variables such as age (continuous), gender (dummy), level_study (categorical), field_study (categorical), parent_entrepreneur (dummy) and home_university (dummy) were included to investigate aspects of individual character and socio-demographics and to improve the inference of the OLS estimator.

Finally, in order to meet the requirements of multiple regression, the correlation matrix and the calculation of Variance Inflation Factors – all less than 5 – excluded the existence of imperfect collinearity or multicollinearity.

4 RESULTS

T-test

As anticipated in the methodology section, statistics were initially developed to compare the average values of students' entrepreneurial variables distinguishing between those who participated and those who did not participate in Challenge-Based Learning courses.

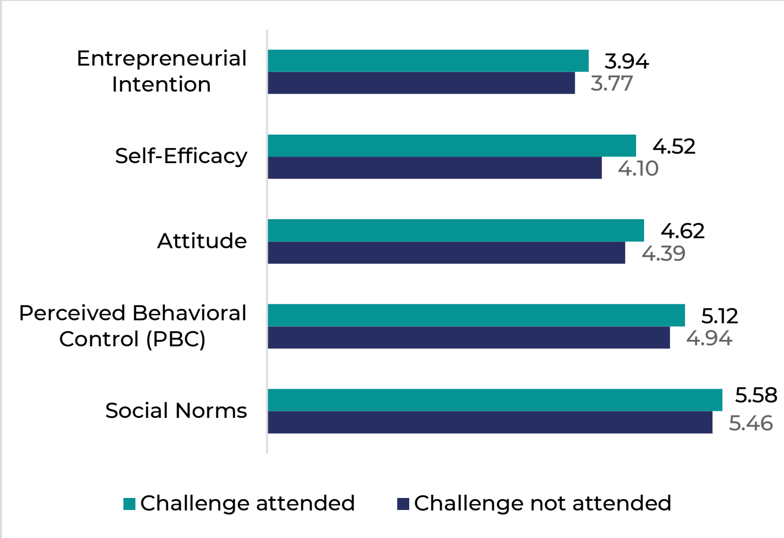

Fig. 5. Entrepreneurial characteristics by participation in challenge-based courses

Figure 5 reveals the existence of an always positive difference between the averages of entrepreneurial attributes distinguished for participation in a Challenge-Based Learning course. Similarly, the same trend emerged distinguishing by participation in general, elective or compulsory courses.

To test whether such differences between entrepreneurial attributes, in addition to being positive, were also statistically significant, a t-test was performed.

With regard to the Challenge-Based Learning courses, between participants and non-participants, there was a positive and statistically significant difference, at the minimum level of 5%, between the averages of all entrepreneurial attributes; an exception is the difference between the averages on entrepreneurial intention, which was only significant at the 10% level. The most marked increase concerned entrepreneurial self-efficacy: this preliminary evidence shows how the practical approach of Challenge-Based Learning courses instils a greater awareness of one's entrepreneurial skills.

Table 1. Output t-test by (EE_challenge)

Variables	**Average Challenge attended**	**Average Challenge NOT attended**	**diff = Avg Challenge Attended - Avg Challenge NOT Attended (H0: diff=0)**	**p-value Ha: diff>0**
Entrepreneurial Intention	3,94	3,77	0,17	0,06
Self-Efficacy	4,52	4,10	0,42	0,000
Attitude (ATT)	4,62	4,39	0,23	0,009

Perceived Behavioral Control (PBC)	5,12	4,94	0,19	0,007
Social Norms (SN)	5,58	5,46	0,12	0,037

The results obtained are in line with the reference literature (Colombelli et al. 2021a, 2022a, 2022b). Further distinguishing by field of study, Challenge-Based Learning courses even have negative effects on social or natural sciences students; on the other hand, the only category on which the effects are all positive is the sample of engineering (incl. architecture) and business students. On these categories, the most statistically significant effects of CBL courses concern the PBC, social norms and self-efficacy variables. These preliminary results confirm that the range of action of the Challenge-Based Learning courses is still limited to the sphere of entrepreneurial skills and less oriented to that of intentions-actions.

Finally, distinguishing by participation in general, optional and compulsory entrepreneurship courses, with the exception of social norms, the differences between the averages of the two groups were all positive and statistically significant at the level of 1%.

Regression Analysis

Results of the regression analysis are shown in Table 5. Models I and II are calculated in the absence of moderation effects while III and IV are the full models.

The results show that the Theory of Planned Behaviour is confirmed: having a positive entrepreneurial attitude (ATT) and a high perceived behavioral control (PBC) - that is, believing in the feasibility of one's idea - increases entrepreneurial intention (EI). A social opinion that encourages entrepreneurship more, on the other hand, would lower the level of entrepreneurial intention but the effect is not statistically significant except in model IV: however, in this model, the joint hypothesis test ($F = 1.19$; p-value = 0.3133) - conducted by imposing social norms = 0 & its interactions (*EE_elective X SN, EE_compulsory X SN, EE_challenge X SN*) = 0 - confirms the null hypothesis: the overall effect of social norms on entrepreneurial intention is therefore not significant.

Let us now consider the effect of entrepreneurship courses. As shown in model I, participation in general entrepreneurship courses has a positive and significant effect ($p<5\%$) on entrepreneurial intention. Although in model III the coefficient of EE_general is not statistically significant, the joint hypothesis test ($F = 2.37$; p-value = 0.0507) - conducted by imposing EE_general = 0 & its interactions (*EE_general X Attitude, EE_general X PBC, EE_general X SN*) = 0 - confirms the significance of the overall positive effect of EE_General on EI.

Unlike elective or Challenge-Based Learning courses, in general entrepreneurship courses there is less self-selection: participants in general courses usually arrive with a low level of entrepreneurial intention that is increased by participation in the course.

Also, for this reason, participation in specific entrepreneurship courses (elective, compulsory, challenge-based) has not statistically significant effect on entrepreneurial intention. However, considering the time gap between intention and its translation into entrepreneurial action, it is good to conduct longitudinal studies to assess the direct impact of these specific entrepreneurship courses. Considering instead the moderating role played by Entrepreneurship Education, it emerges that only participation in a Challenge-Based Learning course modestly increases the positive effect of attitude ($\beta = 0.0677$, $p<0.10$) on entrepreneurial intention; the remaining interactions are not statistically significant. Finally, the analysis of the control variables shows that graduates compared to postgraduates, males compared to females, those who have a parent who is an entrepreneur compared to those who do not, the former all have a higher level of entrepreneurial intention than the latter.

5 CONCLUSIONS

This paper investigates the effectiveness of Entrepreneurship Education methodologies. In particular, the effectiveness of the Challenge-Based Learning approach was investigated within the relationship between the Theory of Planned Behavior and students' entrepreneurial intention. The study was based on data collected through the GUESSS (Global University Entrepreneurial Spirit Students' Survey) 2021 project, specifically on data collected in Italy on about 30 universities. The results show that students who attended a Challenge-Based Learning program show a greater positive effect of entrepreneurial attitude on their entrepreneurial intention, compared to students who attended a program with a different approach. In general, the results confirm the findings of studies in the literature, i.e., the Theory of Planned Behavior positively influences entrepreneurial intention.

The contributions to the literature from this study are several. The first concerns the impact of the Challenge-Based Learning approach in the context of Entrepreneurship Education. This impact is still under-explored in the literature and it is essential for universities to understand it in order to foster the creation of enterprises by students (Zahra and George 2002; Colombelli et al. 2021b) and consequently foster an improvement in the economic context. A second contribution concerns the Theory of Planned Behavior, where we provide further evidence of how this theory can be a predictor of entrepreneurial intention (Schlaegel and Koenig 2014). A further contribution concerns the interaction between the Theory of Planned Behavior and Entrepreneurship Education. There are still few studies in the literature that investigate this interaction, and a closer look in this direction helps to understand the conditions for achieving a high level of effectiveness in Entrepreneurship Education.

After summarizing the results of the study and highlighting the contributions to the literature it is useful to describe the limitations of the study in the hope that they will become insights for future studies. In the literature, intention is referred to as a predictor of behavior and in this study the predictors of intention were investigated. However, there is a time lag between intention and its translation into entrepreneurial action. Consequently, it may be useful to conduct longitudinal studies in order to assess the actual impact of the Challenge-Based Learning approach on the phenomenon of venture creation by students.

ABSTRACT

The shortage of engineering talent leads to a loss in economic output. This shortage-combat has to be fought on several fronts, one of them is attracting and retaining more currently underrepresented students. This paper discusses the need to improve a sense of belonging and to increase professional awareness, or the understanding of the different roles an engineer can take on, in order to increase diversity in engineering. Based on an extensive literature review an overview is given of previous research on this topic from an interdisciplinary perspective.

Research has shown that professional identity development has high impact on persistence and study success. Although identity development is a hot topic in engineering education research, several studies indicate that engineering students still have difficulties in grasping what it is to be an engineer and often fall back upon the rather stereotypical, harsh technological, male image. However, research also shows that it is important for students to know what to expect and value in order to develop feelings of belonging or fit. The former European project PREFER has developed promising tools in this regard. However, these tools have not been tested regarding inclusiveness.

The paper also outlines the next steps that will be taken by the authors as part of an interdisciplinary project URGENT to increase attractiveness and retention of underrepresented groups in engineering education. This URGENT project proceeds on the outcomes of the PREFER project and will focus on the attraction and retention of female students and students with a migration background.

1 INTRODUCTION

In this rapidly changing world, facing many global challenges, engineers play a crucial role. However, the demand for engineers has never been greater [1], [2]. To decrease the engineering shortage, education and industry should focus on a relatively large but unexploited talent pool that lack the opportunities necessary to prepare for engineering careers [3].

The project URGENT (UnderRepresented Groups in Engineering Technology) that was launched at KU Leuven (Belgium) aims to improve motivation and persistence for female students and students with a migration background in engineering education. Research conducted in an earlier European project PREFER (Professional Roles and Employability for Future EngineeRs) indicated that different groups might have different role preferences [4], [5] and that professional awareness (the knowledge and understanding of different engineering roles) is important in making career choices [6].

The objectives of the URGENT project are threefold. First, the project aims to increase insight into the constraints to recruitment and retention in terms of cultural or gender expectations and stereotypes. Are the initial beliefs and predispositions on engineering the same for male and female students and for students without and with a migration background? Second, possible differences in interest and motivation between the different student groups will be investigated using the recently developed PREFER tests [7], [8]. These tests were designed to initiate and stimulate reflection among engineering students about their professional identity. In order to be able to implement them in an inclusive learning environment, the tests will be evaluated on gender and cultural inclusivity and validity. Final, the third objective builds on the insights from the first two objectives and aims to develop and pilot a number of interventions in secondary schools and in university to break through the stereotypical perspectives on engineering.

In order to realise the URGENT objectives, a well-balanced interdisciplinary consortium was built involving partners from university, secondary education and industry in Belgium. Research expertise in engineering education, sociology and social psychology are brought into the project. The project is actively supported by university's central offices of Communication and Recruitment, Diversity, and Career Guidance. Also, different secondary schools, companies and STEM organisations engaged in the project, as well as ie-net, the Belgian engineering federation.

This paper reports on a literature review that laid important foundations for the project. First, the context of this study is described, emphasizing the need to increase the representation of different groups in engineering (education) (Section 2). Section 3 presents theoretical insights from sociology and social psychology regarding the importance of a sense of belonging to the engineering field. Section 4 brings the perspectives from engineering education research, in particular on professional identity development. Final, the paper concludes with a summary presenting the next steps of the URGENT project.

2 BACKGROUND

2.1 Different hurdles for different groups

The characteristics of a target group determines what actions a university should take to attract and retain different groups. For example, in 2021-2022, female students made up half of the first-year students at KU Leuven[2] but only 18,9% of the students who enrolled in a Bachelor's programme in Engineering Sciences is female and even less in the Bachelor's programme in Engineering Technology (10,2%) [9]. However, their retention is better compared to male first-year bachelor's students [10].

Engineering students with a migration background also face a recruitment problem. If we look again to KU Leuven, they make only 8,4% of the first year students in Engineering Technology (and 13,1% in Engineering Sciences) [9]. However, by a large extent, this can be explained by their underrepresentation in the higher tracks in secondary education that prepare for the engineering programmes. Since students with a migration background, on average, show lower retention at university than the students without [11], engineering faculties should try to improve the retention of this group of engineering students.

[2] KU Leuven is a comprehensive university, offering a broad range of programmes in Humanities and Social Sciences, in Biomedical Sciences, and in Sciences, Engineering and Technology.

This shows that universities should remove different barriers to increase the representation of different groups in engineering, such as barriers during recruitment for female students and hurdles during their studies for students with a migration background leading to lower retention. Removing these barriers will increase the representation of diverse groups in engineering, which will be beneficial for industry and the society at large [12].

2.2 Different groups for a smarter industry and a prosperous society

Increasing diversity in engineering, like the representation of female engineering students and students with a migration background, has never been more important. When businesses truly embrace diversity and inclusion, they create a powerful team that is unbeatable together [13] and outperform homogenous groups on complex tasks. These "diversity bonuses" include improved problem solving, increased innovation, and more accurate predictions, all leading to better results [12].Today, more effort is needed in this regard as stated by Hilary Leevers, Engineering UK chief executive [14]: "Workforce diversity improves innovation, creativity, productivity, resilience and market insight and the engineering workforce could and should be much more diverse." Also, SEFI and ASEE, the European and American Societies for Engineering Education, recognize that higher education should find better ways to retain and support individuals who are commonly underrepresented [15]. Historically, the demographic of practicing engineers has not reflected societal heterogeneity.

The recruitment of more female students and the retention of students with a migration background will improve the diversity of these groups in the community of professional engineers. This will make the industry smarter and society more prosperous. The next question is: how? Making a choice for a (future) career is a complex process, in particular when one does not feel that they belong to or fit in a (professional) group. In the next section, we look for theories and insights, in particular from the perspective from social psychology and sociology.

3 FEELING A SENSE OF BELONGING

3.1 What do I expect?

Young people's educational decision-making is a complex process, and many approaches have been taken to understand it in the STEM field (for an overview, see e.g., [16]). One key approach is the expectancy-value model of achievement-related choices [17]. The underlying premise of this theory is that choice, persistence and performance can be explained by individuals' beliefs about how well they will perform in a particular activity ('Will I do well and succeed?') and the subjective values they attach to the activity (e.g., 'Do I like this?', 'Is it useful?', 'Does it fit with what is important to me or others around me?'). Both expectation of success and subjective value predict career choices [18]. These beliefs are a result of gender and cultural socialization.

3.2 What do I value?

Although young women and people with migration backgrounds may have equal formal access to higher education, informal constraints in terms of cultural or gender expectations and stereotypes still restrict access for certain groups. For example, stereotypes about women's mathematics capacities and about ethnic minorities' intellectual capacities can reduce their expectation for success [19]. Importantly, expecting to succeed is not enough to choose a field, the subjective value is key too. Due to gender and cultural socialization, women and ethnic minorities often attach less value to engineering. For example, in STEM fields, characteristics such as brilliance and independence, being self-focused and agentic traits are strongly valued [20]. Additionally, the STEM fields are much less associated with communal characteristics (working with and helping others [21]). Although these characteristics in itself seem neutral, they are stereotypically associated more with the majority groups, and subtly exclude minority groups, such as, in the male dominated STEM fields, women and ethnic minorities [19] (also called 'majority group defaults' [22]). Brilliance and agentic traits are much less associated with women and ethnic minorities [23], [24], and communal characteristics are typically valued more by women and ethnic minorities [21], [25]. As a consequence, these minority groups tend to feel less sense of belonging in these fields and they tend to be less interested in fields such as engineering [26]. Within engineering, women also tend to be less likely than men to value technological leadership but more likely to value social consciousness [27]. The intersection of the two target groups is studied by Phalet et al. [28]. They discovered that women with a migration background in Belgium show the same relative educational advantage as the women without a migration background: they are more inclined than men to start university and to stay on.

3.3 What do I want to become?

The role of subjective value in career choices has also become stronger with increases in economic prosperity in many Western countries and having more alternatives to choose from [26]. As put by Yalcinkaya and Adams ([29], p. 363): "Our review of cultural-ecological variation in STEM gender gaps suggests that freedom from financial or relation-maintenance concerns and freedom to pursue personal dreams may [actually] insidiously constrain women, who seem otherwise liberated, to conform to particular stereotypes about gender and academic pursuit." In our rich western societies, we value the idea of free choice. The question 'Who do I want to be?' becomes more and more important during the process of choosing [26]. As a consequence, the concept of professional identity development has become increasingly relevant, and this concept needs more empirical attention. Identity development is a particularly important part of young people's lives. For students it is not only a question about what they want to study, but also of who they wish to become, i.e. of constructing an attractive identity, or an ideal possible self [30], [31]. Moreover, study choice is not an isolated event but a continuing process, also after entering higher education.

4 REFLECTING ON THE ENGINEERING IDENTITY

Research about professional identity and value creation within the field of engineering is hot [32]. The incentives to focus on this specific topic within the engineering community are numerous. The professional possibilities of engineers are diverse but that makes it also vague for students. Students are not aware that they should reflect about the ideal match, resulting in a possible mismatch [33], [34].

4.1 Knowing what to expect or value: the importance of professional awareness

Engineering students who choose a discipline through a deep exploration of the field and who believe the choice matches their interests, skills and prior experiences, are more likely to have positive beliefs about their competencies in engineering and the value of an engineering discipline [35]. The importance of professional awareness (knowing and understanding different engineering roles) and career exploration was confirmed in a recent study: engineering students who showed more career exploration and a better understanding of the possible future engineering roles were more confident that they would fit their future role [6], young graduates perceived also a higher job satisfaction [36].

4.2 Knowing what to become: the PREFER instruments

To aid students in getting a grip on the variety of engineering jobs, Craps et al. [37] developed a competency based professional role model describing three roles that early career engineers can take on when entering the labour market. These roles, independent of discipline, are product leadership (focusing on radical innovation and research and development), operational excellence (focusing on product or process optimisation and increasing efficiency) and customer intimacy (focusing on tailored solutions for particular customers). This PREFER model is a unique reflective instrument that offers a compact view of engineering practice in the early stage of the career in a flexible manner. The model was validated with both education and industry stakeholders, and 13 expert panels including engineers and HR representatives identified the professional competencies that industry requires to be successful in these roles [37]. Based upon the PREFER model, two innovative tests were developed: PREFER Explore is a personal preference test, aiming to inform students about the three professional roles and their personal preference for one (or two, three) of them [7], [38]. PREFER Match is a situational judgment test, aiming to trigger a process of reflection on students' drives by measuring to what extent engineering students are able to judge professional situations [8], [39].

4.3 Breaking through stereotypes: the interventions

Recent findings from a large-scale review of interventions focusing on identity development consistently point to an increased representation of minority students in STEM in the US [40]. This encourages us that it will also work in Belgium and, by large, in Europe. However, it is important that the instruments that are used in these interventions are validated by the different target groups, and not only by the majority ‘white, male’ students. Quoting from Morelock’s systematic literature review [32, p. 1255]: “The interventions – with their focus on more engineering experiences or more professional ones – may help change individuals’ perceptions of the field, but none ask students to connect their beliefs, values, or other aspects of identity to engineering.”

The PREFER tools seem promising instruments to fill this gap. The extent to which these PREFER tests counteract a sense of belonging in and fit with the field, experienced by females and students with a migration background, was not yet examined. However, a small exploratory study with a limited group of students (N=67) suggested that the customer-related role in which competencies such as empathy and creativity are essential, was more attractive to female students than to male students [5], although the university traditionally focuses on the product leadership and operational excellence roles in engineering programmes. Similar indications were observed in a comparative study on role preferences in Belgium and Ireland [4]. In her study on gender-troubled engineering identities, Faulkner [41, p. 351] concludes that “engineering as a profession must find ways to foreground and celebrate heterogeneous understandings of engineering and heterogeneous engineering identities”. Such a broader view of what engineering is, and what one can do with engineering, benefits all [future] students trying to find a good fit.

5 SUMMARY

Increasing diversity in engineering has never been more important. In order to choose and to stay within a field it is key to feel like you belong and like the field fits with your sense of self [40], [42]. However, in engineering these are lower for women and people with a migration background because of the stereotypes of the field and majority group defaults (characteristics that seem neutral but are associated more with majority groups) that fit less with these groups’ sense of self. An important objective of the URGENT project is to collect empirical evidence within the field of engineering for the majority group defaults (aim 1).

The PREFER tools seem valuable instruments to break through the stereotypical thinking of engineering and increase a sense of belonging in and fit with the engineering field. However, the extent to what these tests counteract this sense of belonging or fit by female students and students with a migration background has not yet been examined. This will also be an objective of the URGENT project (aim 2). If the tests are validated with different groups of engineering students, they can serve as instruments to set up different interventions. These interventions are set up to examine the effects of broadening the view on the field of engineering and of helping (potential) students see the different professional roles they could take in engineering (aim 3).

It is expected that this will help a broader group of students (including women and ethnic minorities) to feel a sense of belonging in and fit with the field, aiding their professional identity development and increasing both their recruitment and retention.

ABSTRACT

At Aalborg University in Denmark, engineering, science, and mathematics students usually spend half the time each semester working in groups on projects within a problem-based learning (PBL) curriculum. These projects are assessed through group-based exams where students receive individual grades. A previous survey of all engineering, science, and mathematics students showed significant differences in how they, respectively, view various aspects of the group exam. However, students also differ when comparing engineering programmes. This paper focuses on potential gender differences in perception of the group exam. Studies of other exam types showed, e.g., that female students report higher levels of text anxiety, have different reactions to exam pressure, and are less overconfident than male students. The present survey was answered by 915 students (617 males, 298 females) from all semesters and study programmes in engineering, science, and mathematics. The analysis showed that on the majority of questions, there were no significant differences between males and females. However, female students are significantly more in favour of an individual exam, and significantly more often experience they need to speak before having finished thinking. Significantly more male students find that participating with their peers during the group-quizzing phase of the exam gives a sense of security, and they are significantly more tactical about when to speak. The paper discusses the areas of significant differences among males and females and the areas without such differences, and concludes that a group exam might be a more gender neutral type of exam for engineering students.

1 INTRODUCTION

1.1 Problem-based learning (PBL) and how they are assessed

At Aalborg University (AAU) in Denmark, problem-based learning (PBL) is the comprehensive curriculum model and PBL-projects usually take up half the study time each semester. Students here work in groups of up to seven participants. In PBL, projects evolve through a process starting with an ill-structured initiating problem, through an analysis of this problem leading to a specific problem formulation, and finally the problem solving [1].

At AAU, PBL projects are currently assessed through oral group-based exams. At the two engineering faculties, the rule is 45 minutes per students, but the exam should never take longer than five hours in total, including giving students the grades. The group-based project exam consists of three phases in which both an internal examiner (the project supervisor) and an external examiner (usually from another university) take part: (1) Group presentation of the project where students take turn. (2) Group-quizzing in which the examiners asks the group questions, students voluneteer to answer, and the students may comment on each other's answers. (3) Each individual students is asked questions aimed specifically at them, either by polling a random question or by being given a question within an area in which the examiners have noticed that the student has not yet talked about. Each student then receives an individual grade, and the grades may not be similar. During 2006-2012, the Danish government banned group exams. AAU PBL-projects continued as before, but the projects became assessed by an individual oral exam of around 30 minutes per student. When the group exam was again allowed in 2013, the third phase mentioned above became a new addition [2].

The present paper focuses on potential gender differences in this type of exam. A previous study [3] argues that PBL, including engineering programmes with more contextualised content, could result in increased recruitment of women. However, as exams play a central role in any curriculum, a part of an assessment of PBL from a gender perspective, must also include the type of exam.

2 THEORETICAL FRAMEWORK

2.1 Assessment of the PBL group-based project exam

The banning of the group-based project exam was researched by, e.g., [4] who concluded that the students, the academic staff, and the external examiners preferred the group-based project exams. It was also concluded that the individual exam could not assess core PBL process competencies such as collaboration and teamwork, which created misalignment between PBL and its assessment method.

Studies done after the reintroduction of the group-based project exam again found that the majority of students were in favour of the group-exam, but with significant differences in how engineering, science, and mathematics students, respectively, viewed various aspects of the group exam; and students also differ when comparing engineering programmes [2]. These studies, however, did not have a focus on how male versus female students experience the group-exam.

2.2 Studies of other types of exams and the issue of gender differences

Some studies focus on achievement, where, e.g., [5] argues that exams define achievement as the type of work which is valued higher may be areas in which either boys or girls are more able. UK upper secondary education in English is used as an example where boys are better at keeping to the point, take more risks, and show more confidence, which is valued higher, while girls, take less chances, write more lengthly, and are less courageous to discard irrelevant material.

Not only achievement is studied, but also emotional aspects such as anxiety and confidence. As also indicated above, female students appear more cautios than males, which is also the case for university students where females usually report higher levels of test anxiety than males even though they do not have lower academic achievement than males [6]. Emotial aspects are also seen with female students having a lower level of overconfidence in terms of grade expectations than males [7]. Emotions may also impact achievement as studies on secondary students found that females perform relatively better on low stake tests, but this difference is reduced or disappear when stakes increase. Males perform slightly better than females on high stake test such as national exams [8]. Other studies did not find gender differences, e.g., [9], who compared performance when switching from a traditional paper-and-pencil exam to a computer-based exam.

2.3 Research questions

Given that gender differences exists in many other types of exams, which gender differences, if any, exist in the students' assessment of the group-based project exam in PBL? This paper therefore re-analyses the questionnaire from 2013 as this was not part of any of the previous analyses of the questionnaire.

This paper focuses on the differences among male and female students taking all the engineering and science students as a whole. One might also have chosen to focus on differences and alikeness between male and female students in each study programme, or engineering versus science versus mathematics. This would be interesting, also given that previous research shows some differences between these student groups. However, given that the students answering the questionnaire came from 38 different programmes, and given that the female student population is often a lot smaller than the male, some programmes were only represented with very (female) students making statistical analysis irrelevant. For instance: Computer Science (34 males – 5 females), Physics (7 males – 4 females), Mathematics (6 males – 8 females), Software engineering (47 males – 4 females), Energy (39 males – 10 females), Electronic (47 males – 1 female), Building (49 males – 14 females).

3 METHODOLOGY

The quantitative survey from summer 2013 reused some tems from a previous study from 2006 [4] in order to (1) compare results now and then, and (2) enhance the validity of the present study by building upon items that previously worked well. In addition, new items were formed, some of which were based on comments from a survey to all first-year engineering, science and mathematics students after the January 2013 exams. The January survey functioned as a pilot study prior to a larger study in June 2013. An email provided the link to the questionnaire in SurveyXact to all 4,588 engineering, science, and mathematics students at all semesters after the June 2013 exams. 1,136 answered the questionnaire of which 928 completed the whole of it. 915 of these indicated gender (not a mandatory item). This gives a 25% response rate, which is low. This is usual for online surveys, but still relatively efficient compared with paper-based surveys, particularly for cohorts above 300 [10].

The questionnaire consisted of 20 items, of which most had several sub-items where respondents should indicate their level of agreement on Likert scales. In total 97 items. Five of these asked background questions about study programme, semester, gender, physical campus, and if they had experienced the previous individual project exam. Hence 92 items were directed at their experience with the group-based project exam. The analysis uses chi-squared tests of independence to assess the relationships between the male and females variables.

4 RESULTS

Of the 92 items, there were significant differences among male and female students on 32 of them. Below items with and without significant differences are analysed.

4.1 Items with no gender differences

On the three items where students were asked about their overall experience of each of the three phases of the group-based project exam, there was not any significant differences between the male and females students (e.g. Figure 1).

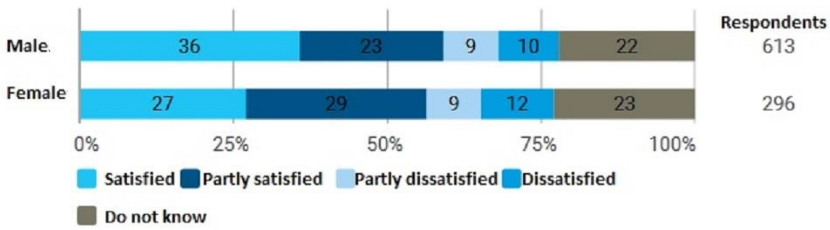

Fig. 1. Item: Are you satisfied with how the individual questioning took place? X^2*(1, N = 705) = .576, p = .448*

Each of these three phases had several subitems, and in terms of the first presentation phase, most items showed no significant differences among the male and female students. For instance: the items asking if they had enough time to talk about central phases in the project, if the distribution of topic was made more difficult by the fact that the presentation counts towards the grades, if the presentation became better knowing that this part counts towards the grades, that one can show one’s competencies, it gives a sense of security to present together with others in the group, and that the presentation made one relax more.

Concerning the second phase, the group-quizzing, around half the items showed no significant differences. For instance: the items about if you can hide, some students dominate through their personality, the examiners asked questions about my deeper understanding, experiencing that others said something they themselves were about to say, and that the group-quiz more shows the individual student's initiative in answering question than showing group-work.

In terms of the third individual phase, on most items, the male and female students agreed: the presence of the other group members gives sense of security, I do not need to understand all the content, I can show my knowledge, there was too much difference in the level of questions asked to each group member.

Concerning the students' view of their assessment and grades, there was not a significant difference on items asking if all students got the assessment they had expected, if the assessment shows who is good at selling themselves at the exam, and that there is a correct spread of grades in the group.

In particular, on issues relating to anxiety, students agreed on many items, which is different from the results of the studies referred to above. When looking into some of the details of the phases, and the grading, some differences appear between the male and female students, which are discussed below.

4.2 Items with gender difference

In terms of the first presentation phase, only two items showed gender differences: Group members mainly present things they wrote themselves (males agree more), and they learn something new through doing the presentation (Figure 2). Although the majority of all students agree, the female students agree significantly more.

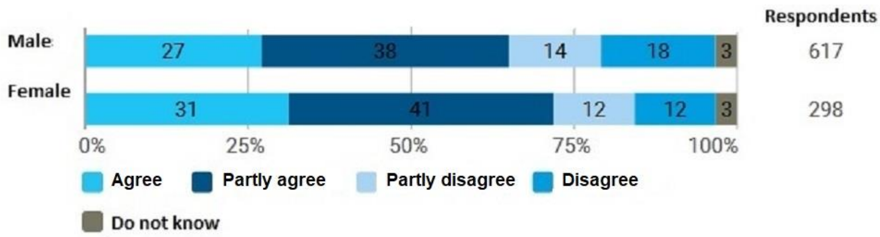

Fig. 2. Item: I learn something new through doing the presentation? X^2*(1, N = 884) = 4.525, p = .033. The legend is similar below, unless otherwise stated*

In terms of the second group-quizzing phase, there was significant differences between the male and female students on items asking: sitting together with ones group gives a sense of security, you do not need to know all the content, you can follow up on what others have said, there is time for me to tell my knowledge (males agree the more on these items), I feel I should say something before I have finished thinking (females agree more; Figure 3, top) and I am tactical about when I offer a comment (males agree more; Figure 3, bottom). These two items are somewhat connected with males perhaps better at being tactical while females somewhat being stressed during this phase.

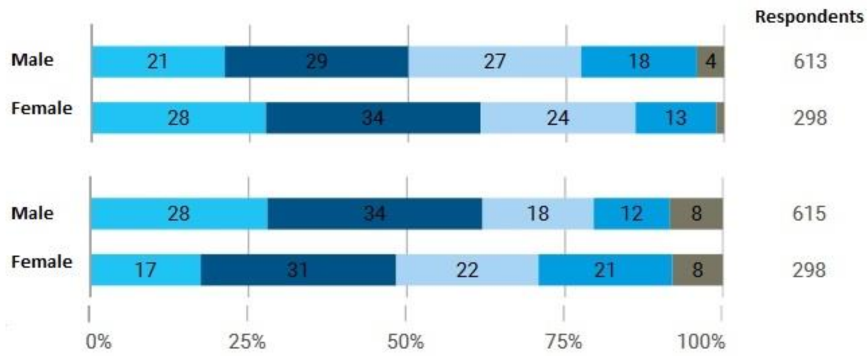

Fig. 3. Item (3, top): I feel I should say something before I have finished thinking. X^2*(1, N = 880) = 7,706, p = .006. Item (3, bottom): I am tactical about when I offer a comment.* X^2*(1, N = 837) = 18.017, p < .001*

In terms of the third individual questioning phase, males and females answered significantly different on items such as: I would prefer that the other group members are not present during this phase (females agree more; Figure 4), and there was time enough for me to tell my knowledge about the project (males agree more).

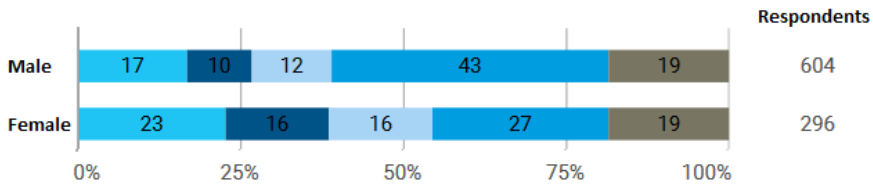

Fig. 4. Item: I would prefer that the other group members are not present during this phase. X^2*(1, N = 733) = 14.668, p < .001*

Concerning the item illustrated in Figure 4, only a minority of students do not want the other students present during the individual phase, however among these, the female students significantly more often prefer this.

In relation to the students' view of their grade assessment, there was a significant difference on the item asking if all group members had received a fair assessment (males agree more) and the item that some had received a better assessment than they had deserved (females agree more; Figure 5).

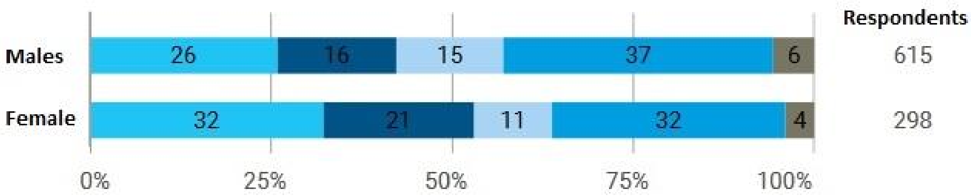

Fig. 5. Item: Some received a better assessment than they had deserved. X^2*(1, N = 866) = 8.324, p = .004*

4.3 Overall – individual versus group-based project exam

In terms of an overall assessment of individual versus group exam, although only a minority of the students preferred an individual project exam, female students were significantly more in favour of an individual exam (Figure 6).

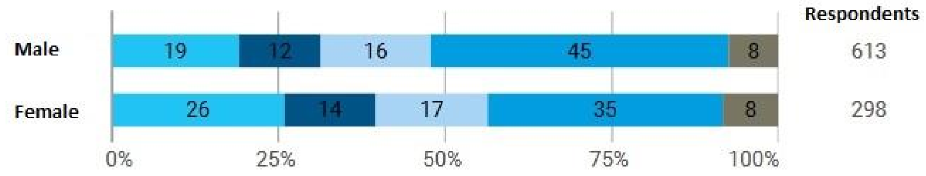

Fig. 6. Item: I would prefer an individual project exam. X^2*(1, N = 840) = 6.935, p = .008*

In exams, the opportunity to get a fair assessment is essential. Above showed mixed views about grades. On the items asking students who had experienced both the individual and the group exam about the grades, there was no difference among males and females about the opportunity to get a fair grade (Figure 7):

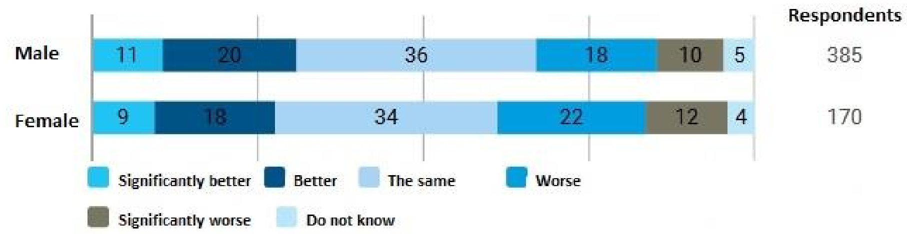

Fig. 7. Item: If you compare the new group-based project exam with the previous individual project exam, how did you experience the opportunity to receive a fair grade? X^2*(2, N = 530) = 2.225, p = .329*

The students were also asked if they experienced a bigger differentiation of grades in the new group exam compared to the previous individual project exam, and again there was not significant difference between males and females (Figure 8).

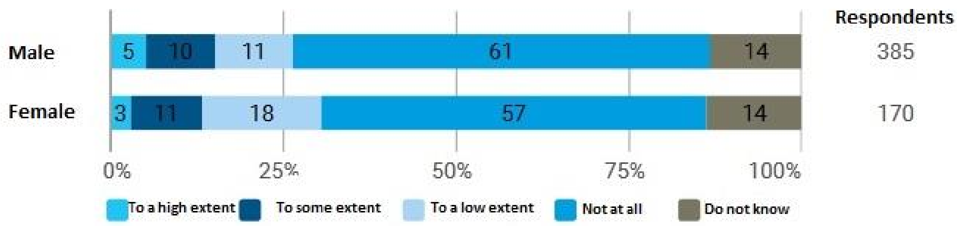

Fig. 8. Item: Have you experienced a greater differentiating of grades at the group-based project exam compared to the individual project exam? X^2*(1, N = 489) = 0.319, p = .572*

Combining the results shown in Figures 5, 7, and 8 suggests that females are more sceptical about the fairness of the group exam compared to the individual exam, including that the differentiation of grades may be less in group exams. The latter was also seen in some of the comments provided in the questionnaire. Some also mentioned that larger groups may make grading more difficult than smaller groups.

4.4 The sense of security

Sections 4.2 and 4.3 showed that in terms of the first phase of the group-based project exam, the students overall agreed (73%) that sitting together with their group members, gave a sense of security, with no gender difference. However, concerning the second phase, the group-quizzing, there was a significant difference in the male and female answers (Figure 9). Overall the students agree (75%), but with the males students agreeing significantly more than the females.

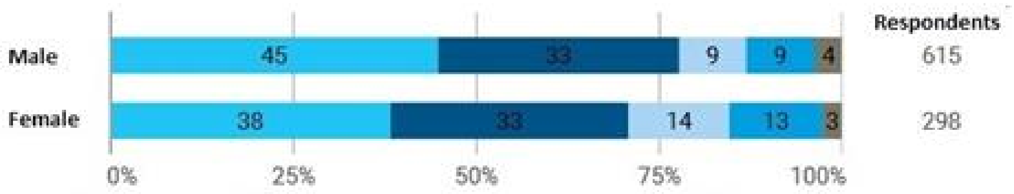

Fig. 9. Item: Sitting with the group members give a sense of security [about the group-phase]? $X^2(1, N = 882) = 7.26, p = .007$

In terms of the individual phase, again there is no difference between male and female students, with overall 46% agreeing and 35% disagreeing that it gives a sense of security having the other group members present.

5 CONCLUSION

Does this study show that the group-based project exam is a more gender neutral type of exam? The analysis showed that on most of the items (approximately 2/3), there are no gender differences. Also, the items asking for an overall assessment of each of three phases showed not gender differences. This indicates a type of exam that is at least relatively gender neutral.

Some items, however, showed gender differences such as being tactical (males agree more) or feeling rushed (females agree more) to say something during the second group-quizzing phase. The second group quizzing phase is the one with most differences between males and females. The majority of females favoured the group exam, however significantly more females than males prefeered the individual exam. Hence, the picture is not unambiguous. Significantly more males find that participating with their peers during the group-quizzing phase of the exam gives a sense of security, which may be surprising giving that the studies refeered to in Section 2.2 pointed to that males are less cautious than females and more willing to take risks. Compared to the studies in Section 2.2, this study found that females did not appear to have more anxiety than the males.

These results provide insights for examiners on design of a group exam, e.g. should all group members be present during the individual third phase, optimum size of groups for fair assessment, etc. The study points to areas in which examiners may need training to be able to administer a group exam, e.g. how to make sure all have time to tell their knowledge, that students do indeed need to know the content, etc.

A limitation of the study is that females are very likely to have been the minority in the groups, which may or may not have affected their answers more than the fact that they are female. I.e. “minority” students might feel more comfortable in individual exams than “majority” students. A further study might reveal this.

ABSTRACT

In times of a pandemic many university courses have to be taught in an online learning format to respect the requirements of social distancing. Online learning takes place between the poles of self-direction by the student and guidance by the lecturer. In this paper a first-semester course in industrial economics for engineers, which was taught in the self-directed learning format of flipped classroom, was enhanced with lesson activities in the Learning Management System (LMS) Moodle as a means of guided learning with student-content interaction. The paper describes the design and the evaluation of the lesson activities. For the evaluation a student survey to gather the opinions and self-assessments of the students was conducted, and statistical data from Moodle on the performance of the students were collected. The results of the student survey show an overall positive evaluation of the lesson activities by the students who participated in the lesson activities. Furthermore, the results of the statistical data about the students' performance show a relation between participation in the lesson activities and exam success. As a caveat, however, the results also show that the majority of the students chose not to participate in the lesson activities.

1 INTRODUCTION

1.1 Research motivation

Due to the Corona pandemic many university lecturers were forced to switch their teaching approaches to accommodate the new reality of social distancing. For the authors this meant that their first-semester introductory course of industrial economics in engineering with more than a hundred participants had to be taught as an online course. In the course of this change the teaching approach of flipped classroom with learning materials on the Learning Management System (LMS) Moodle and an online consultation-hour with the instructor via MS Teams was introduced. Learning materials included lecture videos, lecture slides, multiple choice tests and calculation exercises with master solutions which required a high degree of self-directed learning.

The student feedback from the course evaluation showed that although students valued the independence of time and space the teaching material offered, many students struggled with the freedom of self-directed learning. Furthermore from an analysis of the exam results it could be seen that students who failed had mostly difficulties with the calculation questions of the exam. Hence, it was concluded that students in this introductory course seem to need more structure and guidance in their learning activities. It was decided to support the students in this regard by introducing the interactive format of lesson activities in Moodle and to measure the impact of this format.

1.2 Theoretical foundation

This paper deals with the format of online learning. Although there is no common understanding of the term online learning and related terms (such as e-learning), many authors agree that online learning offers learning experiences via web-based technologies [8]. Ally [1] for example defines online learning as “the use of the Internet to access learning materials; to interact with the content, instructor, and other learners; and to obtain support during the learning process […]”.

Empirical research in didactics shows that personal control as well as structure and clarity are – amongst others – proven characteristics of successful lessons [11]. This leads to a certain paradox that effective learning needs to on the one hand respect the freedom and individuality of the learner. On the other hand learning also requires a certain structure or guidance from the teacher, at least in an institutional context with predefined learning goals and outcomes. In learning theory this is connected to the concepts of self-directed learning and guided learning as well as interactive learning.

Self-directed learning typically requires that a large part of the initiative and responsibility for the learning process is with the learner. This implies that learners have at least some personal control over learning needs, goals, resources, strategies and outcomes [7]. Also for online learning one key implication is that learners have a certain extent of control over the learning process [1].

One concept of self-directed learning is the concept of flipped classroom by Bergmann & Sams [4]. In a flipped classroom, students work through pre-defined content on their own (e.g. watch pre-recorded lectures via an online platform), before they attend the lecture. This way, the lecture time can be used to solve problems by applying the content and clarify issues in understanding the content.

Guided learning can be defined as “a process in which learners initiate and advance their learning guided by more experienced partners and socially derived sources, such as tools, text, and/or other artifacts” [5]. Hence, the guidance can either take the form of interaction with other persons or with some form of learning material or tool. In online learning the content is typically provided by a Learning Management System (LMS) such as Moodle. The structure in Moodle is typically linear or hierarchical, and the display of information takes the form of folders and subfolders, as in the folder structure of MS Explorer. Apart from that there are some tools in Moodle that offer personal interaction such as forums, chats and messaging as well as tools offering interaction with content such as tests and lessons [6]. Thus, LMS such as Moodle offer the opportunity for interactive learning which can be defined as “[…] a process involving some form of digitally enabled reciprocal action between a teacher or designer and a learner. Interactive learning requires access to content, tasks, and problems by at least one human being (a learner) using digital technology (e.g., a computer with Internet access)” [9].

This paper deals with interactive learning in the form of student-content interaction in an asynchronous form according to Anderson [2, 3]. In online learning, the learning material should be sequenced in ascending complexity (“from simple to complex”) and novelty for the learner (“from known to unknown”) [1]. Apart from sequencing, interactive learning material should also include a chance for self-monitoring [7] which in online learning can be achieved via feedback loops and repeated trials [1, 3]. This implies that there is not only the question of sequencing, but also questions of branching and looping to generate learning feedback and enable self-monitoring of the learner. The goal of this paper is to show how the authors combined the concept of flipped classroom as a means for self-directed learning with the concept of lesson activities in Moodle as a means of guided learning with student-content interaction and how the authors measured the success of the approach.

2 METHODOLOGY

2.1 Designing lesson activities

The goal of the lesson activities was to provide freshmen with a more efficient learning process through interactivity in learning. A total of seven lessons were offered on the various topics of the course. These are lessons on the topics of business, management, accounting, cost accounting, marketing, financing and investment. The lessons were structured in such a way that existing learning materials such as exercises, lecture videos, multiple-choice tests, etc. were put into a logical order suitable for online teaching (see fig. 1).

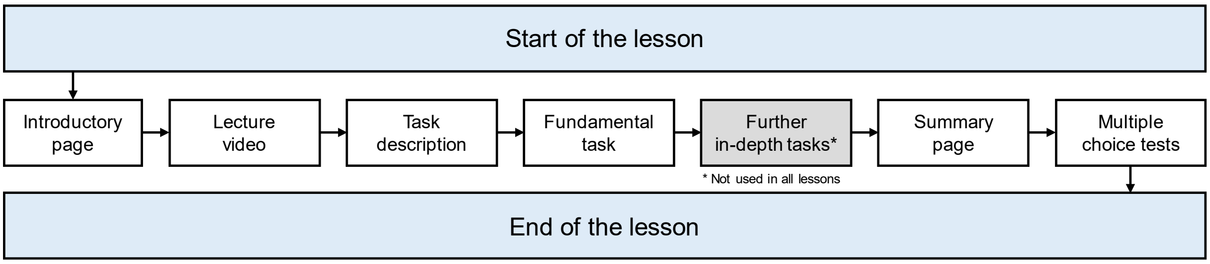

Fig. 1. Structure of the lesson activities

Each lesson starts with an introductory page that presents the educational objectives of the lesson. Moving on to the next page, the student is taken to a lecture video where the main content of the particular topic is presented. The next step is the task page, where the task is introduced and hints on how to complete the task, such as important formulas, are given. This is followed by the actual exercise task, which must be solved by the students. To ensure interactivity, students are given the opportunity to self-monitor by being guided into a feedback loop after each solution they submit. If the answer is correct, the students receive the message that their answer is correct and they can move to the next page. If the answer is wrong, the students receive the information that their answer is wrong and they get the opportunity to repeat their answer several times. After a specified number of attempts, the learner is automatically directed to the next page.

In order to customize the lessons as much as possible and thus increase the learning effect, common answering errors were identified and entered into the system when the lessons were designed. The authors' many years of teaching experience were used to identify typical answer errors on specific tasks. For each error, a suitable hint was entered into the system so that each student receives an individual answer depending on the error he or she made and hence is guided to the correct solution in as specific a way as possible. Furthermore, video snippets from the lecture video have been included as an answer aid so that the student can explore certain topic points in more depth.

In some lessons, the basic task is followed by a more in-depth and complex task to reinforce what was previously learned. Here, the methodology of sequencing the learning material in ascending complexity (“from simple to complex”) was applied [1]. Before the theoretical knowledge is tested by multiple-choice tests at the end of the lesson, there is an overview page including the sample solutions to all questions, corresponding formulas and a memory box with the most important theoretical content.

2.2 Evaluating lesson activities

In order to evaluate the effectiveness of the lessons, student surveys were conducted and statistical data were analysed. The student surveys took place in two ways. First, intensive feedback communication was performed with students via MS Teams prior to each consultation-hour during the semester. Second, a questionnaire was developed for students to submit their assessment at the end of the semester, which was then evaluated. The statistical data was analysed from Moodle.

The feedback discussions with the students represent a kind of group discussion and hence are part of the qualitative research. The qualitative research approach is particularly suitable when individual opinions and impressions are in demand, suggestions for improvement are to be collected, and certain causes are to be explored (e.g. reasons for satisfaction or dissatisfaction of the participants) [10]. The feedback sessions were intended to fulfill the mentioned purposes and were held after each completed lesson so that the following lessons could be improved or adjusted according to the students' requests.

To measure participation in the lesson activities for the survey, the authors divided the students into two groups: In the group “lessons accomplished” students completed at least three out of the seven lessons. Students with fewer than three lessons completed were counted as “lessons not accomplished”. For the first group, a nine-item online questionnaire was designed in which students rated aspects of the lesson activities such as structure and interactivity and performed a self-assessment on several items such as understanding and enjoyment. The items were rated on a Likert scale with five response levels. For the second group, a questionnaire including the reasons for not participating was designed.

The statistical data from Moodle were analysed after the exam to determine, if working on the lessons had an impact on passing the exam. For this purpose, participation in the lessons was related to exam grades and exam success. In a final step, it was analysed whether the time period in which the lessons were worked on had an impact on the score achieved in the exam. For this purpose, two time periods were defined: during the lecture period and after the lecture period. For the analysis of the statistical data, the same two groups of students were used as before to measure participation.

3 RESULTS

3.1 Student survey

A total of 27 students participated in the student survey. Five of them indicated that they had worked on fewer than three lessons. Thus, according to the criteria we specified, those five students did not work intensively enough on the lessons to be able to give a meaningful review. When asked why they did not work intensively on the lessons, they all indicated that they wanted to work on the lessons just before the actual exam. This leaves a total of 22 students who worked intensively enough on the lessons to be able to give a meaningful assessment.

The results of the assessment of the 22 students are displayed in the chart in fig. 2. Overall, the students give a positive evaluation of the lesson activities. Most of them agree or strongly agree that the lessons had a clear structure (90%) and enhanced their understanding (86%) and that they enjoyed working on the lessons (68%). This is in line with the finding that most students would recommend the lesson activities to fellow students (86%) and would like to have more lessons in this course (77%) as well as in other courses (82%). The most critical part of the lesson activities is the feedback system, i.e. getting the branching right. Only 41% of the students agree or fully agree that the feedback helped them to identify the correct answer, while 14% diagree (45% remain neutral), as some of the feedback had to be adapted during the lecture time. The lesson activities are seen as an add-on rather than a substitute for other learning materials. Almost 86% see the lessons as a good addition or variation to the learning materials they already have, while only half of the respondents feel that working through the lessons has prepared them well for the upcoming exam (10% disagree on this point).

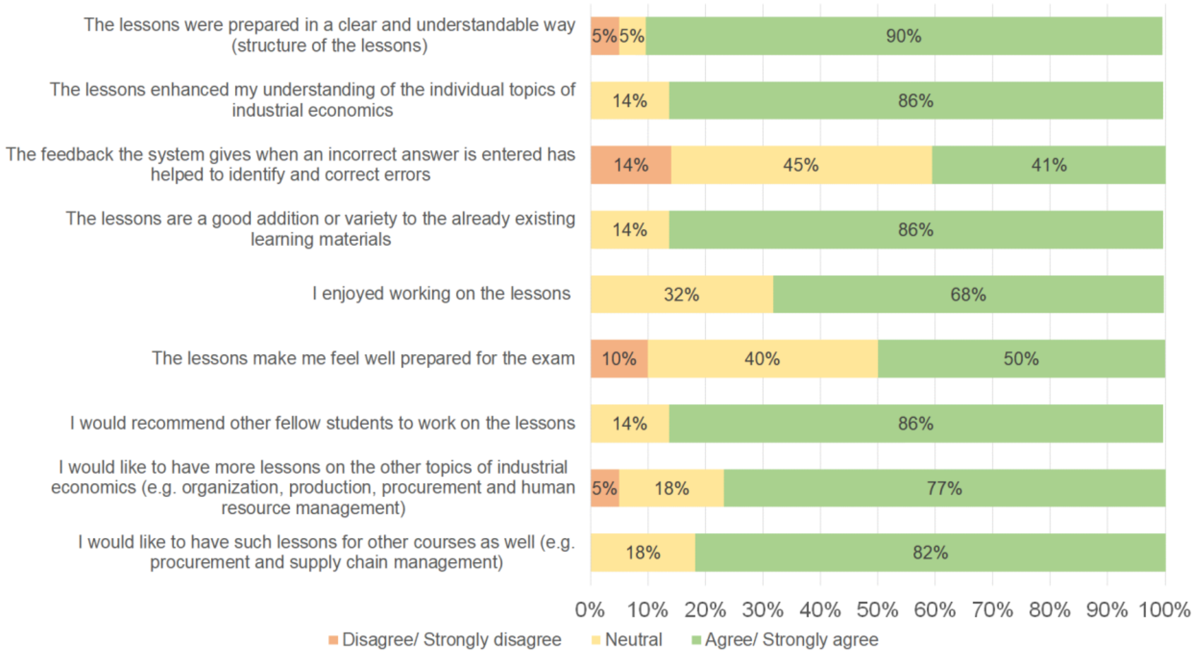

Fig. 2. Assessment of the students who accomplished the lessons (n = 22)

The evaluation of the questionnaire reflects the impression the authors gained from the feedback interviews during the semester. In each interview, the students gave a mainly positive feedback on the lessons. They said they were well guided through the lessons and especially found the video snippets helpful. Because of the feedback sessions it was possible to identify and correct small errors that were overlooked or not taken into account when the lessons were created, such as incorrect links or the setting of larger rounding tolerances. Also, suggestions for improving the branching of lessons, such as reducing the number of failed attempts, could be obtained from the interviews with the students.

3.2 Statistical analysis

Analysis of the data in Moodle showed that 103 students participated in the exam. Of these 103, a total of 36 students accomplished the lessons and 67 students did not accomplish the lessons, i.e. worked on fewer than three lessons or did not work on them at all. 92% of those who accomplished the lessons passed the exam, and 8% failed. Of the group of those who did not accomplish the lessons, 61% passed the exam and 39% failed.

Looking at the number of points achieved in the exam by both groups, it can be seen that the average score of those who accomplished the lessons is around 70 of the maximum 100 points achievable in the exam (arithmetic mean and median). In comparison, the score of those who did not accomplish the lessons is about 53 points. Furthermore, the group of students who accomplished the lessons has a higher maximum score (96 points in comparison to 87 points), a higher minimum score (42 points in comparison to 21 points excluding two outliers) and a higher and narrower interquartile range (see fig. 3).

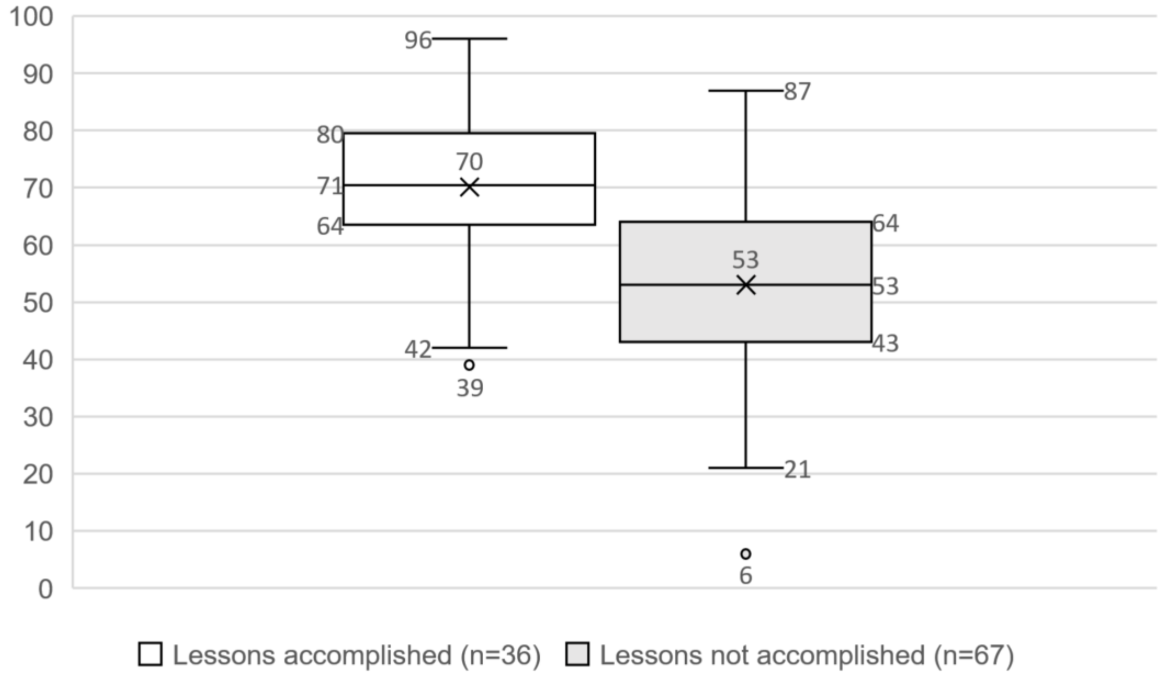

Fig. 3. Participation and exam grade

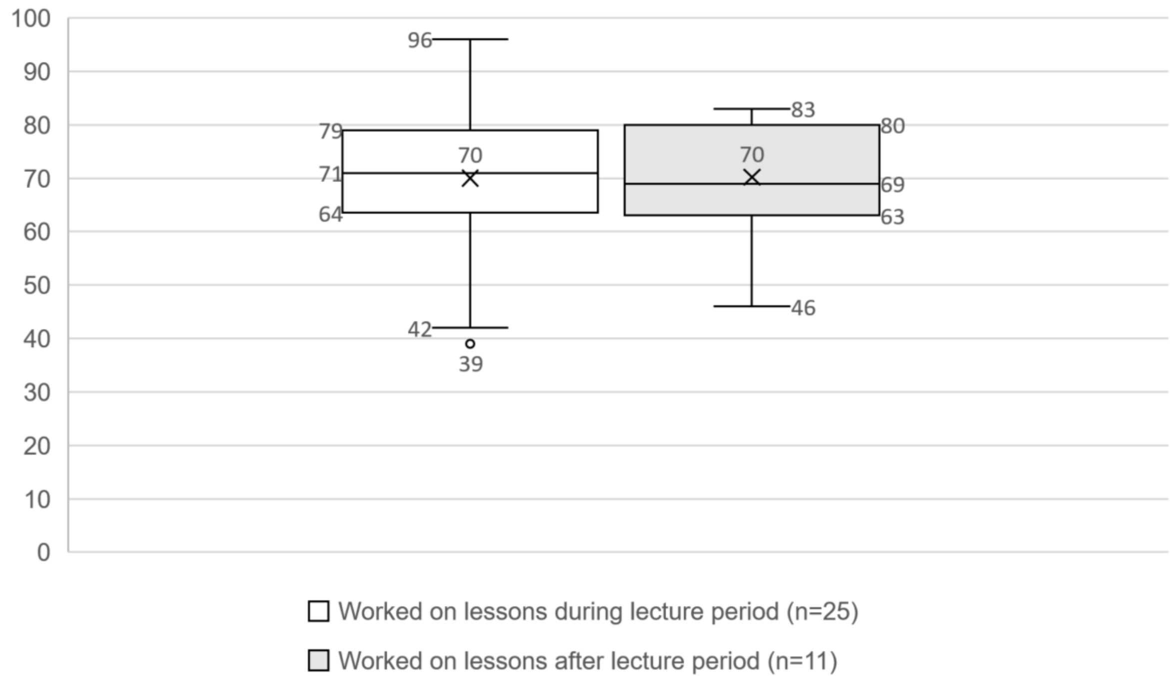

Fig. 4. Participation period and exam grade

The evaluation of the participation period (i.e. when students worked on the lessons) shows that 25 of the 36 students who accomplished the lessons did so during the lecture period. The remaining 11 worked on the lessons after the lecture period. Despite the different periods, the average score achieved by both groups is almost identical at about 70 points. Similarly, the median is also nearly the same with 71 points for those who worked on the lessons during the lecture period and 69 points for those who worked on them after the lecture period. Finally, both also have similar interquartile ranges. A main difference is the larger spread of the upper quartile for students who worked on the lessons during the lecture period (see fig. 4).

4 SUMMARY

The results of the student survey show an overall positive evaluation of the lesson activities by the students who participated in the lesson activities. The lesson activities are seen as a valuable addition to the existing learning material. Furthermore, the results of the statistical data about the students' performance show a relation between participation in the lesson activities and exam success. Furthermore, the results show that it makes no real difference when the lessons are worked on (during or after lecture period).

These findings, however, do not establish a causal link between lesson activities and exam success. It could be that students who accomplished a lot of lessons also took more effort in general, e.g. participated in the consultation-hour or used further learning materials. As the course comprises first-semester students who just started their study programme as well as students from previous semesters who have to take the course as a resit, and the first group usually has a lower failure rate and is generally more active, this may at least explain part of the positive relation. To test this assumption data on the overall activities of the students would have to be collected and included as confounding variables. It could also be that students who are more successful are also more open for new learning approaches.

The most crucial element of the lesson activities is the feedback system. Apart from the right sequencing of content, it is the right branching that guides students in their learning progress. For this, lecturers have to forecast possible errors and develop helpful hints to help students understand their errors and find the correct solution. This is by far the most difficult and time-consuming step in designing the lessons.

As a caveat, the results also show that the majority of the students chose not to participate in the lesson activities. As a lot of work goes into designing the lessons (e.g. getting the branching right), lecturers have to decide if the effort is worth the benefit based on the number of students and the student evaluation for their specific courses. Overall it can, however, be said that lesson activities show promising first results to provide aspects of guided learning in online courses with a high number of freshmen, but further tests are needed to establish a clear link between lesson activities and learning success.

Conference Key Areas: *Ethics in Engineering Education. Student Engagement*
Keywords: *Ethics by design, Education using case studies, Privacy by design, Tracing apps for Covid-19*

ABSTRACT

Including ethical concepts and considerations in engineering education has attracted significant interest in recent years, mainly due to the impact of some AI applications in different areas of our life. The use of case studies in teaching ethics is a well-known and useful approach. The debate related with a given case study helps students think about the implications, motivations and foreseeable impact of the technologies. This fact is in contrast with the common easy-thinking that technologies are neutral and that an engineer should not bother about ethics and does not have any responsibility at all. While many basic technologies may be considered neutral, more developed and complex systems are not so neutral; they have a motivation and some foreseeable impact and consequences. Thence, the main message is that engineers have a responsibility when developing these systems.

This paper presents a case study used in a course for Ph.D. students in a Technical University to introduce the concept of ethics by design and to stress the idea of responsible conduct in engineering. The case under study is the design and development of tracing applications for fighting against the Covid-19 pandemic in 2020. The analysis of the case requires to understand the basic technologies proposed, the different alternatives considered at that time, the basic facts related with the contagion chain and the main factors to be addressed, the consideration of the balance between public health rights and individual privacy rights, and the social aspects related with the acceptability by citizens.

1 INTRODUCTION

1.1 Introducing ethics for engineers

The first challenge addressed is how to introduce a topic such as ethics in a Technical University where there are no other degrees than strictly engineering ones (including electrical, mechanical, civil engineering, computer science and architecture). There are no major and minor degrees. Students have never taken a course on philosophy, history or anthropology, to mention some subjects, at the University. This fact limits the concepts and terms that may be used in the class.

For the experience presented in this paper an optional course offered to Ph.D. students is selected. The main target are students in any of the Doctoral Programs of the University, so that a broad view of many areas in engineering are covered. Also, being Ph.D. students from different countries, their background knowledge and cultural environments are diverse. This approach helps to cope somehow with the intrinsic limitation of the lack of humanistic formation provided by the Technical University and provides a much richer discussion with different points of view than with a more homogeneous group.

The method presented and the same case study, or a similar one, may be used for undergraduate students.

1.2 The use of case studies

Using case studies for teaching ethics is a common practice and there is a general agreement that they are very useful. Discussing cases helps students to recognize ethical issues, to foster their analytical skills in ethics, to stimulate students' ethical imagination, to promote a sense of responsibility and to help students to deal with disagreement about ethical issues [1].

The first issue to be addressed, at least based on my experience, is the general perception that engineers deal with technology only and their job is neutral from the point of view of ethics. Despite the students enrolled in this optional course may have some curiosity about ethical implications, the underlaying perception is that technology is neutral and this easy-thinking approach is dominant among engineering students.

The analysis of cases allows students to recognize the presence of ethical problems where initially we saw only technical issues, help them to develop their reasoning and assessment skills about the consequences and impact, help them to stimulate their moral imagination looking for possible alternatives, help them to acknowledge the limitations of the codes of ethics and regulations, and help them to understand that sometimes there is no best solution [2].

The use of case studies is of utmost relevance in teaching ethics because, as commonly agreed, "ethics is not so much taught as caught".

The case study selected is the development of tracing systems for Covid-19 that was the hot topic during spring 2020. This case presents a variety of approaches and requires understanding the technical background; this catches the attention of engineering students.

The development of tracing applications for Covid-19 was undertaken immediately once the pandemic was declared worldwide. The design of these systems took many different paths, perhaps as many as countries, because politicians and healthcare authorities were overwhelmed by the impact on the pandemic and the need to have a tool to help cutting its spread was urgent.

2 METHODOLOGY

The main objective of the discussion of this case is to mimic to some extend the situation of the development of the tracing systems since their early conception and design choices. This implies to work with the information available about the pandemic and the behaviour of the virus, information that was evolving, and the considerations about the feasibility of real deployments of the new systems.

In order to highlight the importance of the interdisciplinarity of the problem the debate is introduced step by step. First of all, a deep understanding of the contagion chain and the conditions to stop its spread is required. Next, a sound assessment of the technology available and of the different alternatives is a key aspect that must be analysed. Then, the view of the healthcare staff involved, the capacities and participation required from the citizens (social impact), the existing regulations about how the information is managed and who has access to the data (which may depend on each country), and the analysis of privacy aspects are introduced in the discussion. The objective of the debate is to follow the whole design process of the system, impersonating the roles involved and reassessing past views when required.

The discussion is organized in two sessions in consecutive weeks. For the first session the students should read a short paper with the basic concepts about the spread of the infection and the requirements to cut the spread chain together with the technological approaches available. Before the discussion they are asked to fill a questionnaire to get an idea of the comprehension of both the health-related aspects and the technological ones.

The first session is dedicated to reach a common agreement about what is needed from a tracing system and what alternatives may be available from the technical point of view. Nowadays, how the infection spreads is mainly understood but some of the technical approaches considered at that time require some detailed explanation in order to assess their relevance and the effectiveness of the tracing system.

This session is sought to be very interactive, discussing the different points of view and understanding of three main issues: how the contagion spreads and how the identification of groups at risk may be done, the information needed by healthcare staff to undertake the notification process, and the possibilities provided by the technology using a smartphone.

Before the second session the students read a longer paper. This article introduces some ethical issues and, in particular, the consideration of rights: public and individual health and safety, and privacy. Also, it includes some references to documents published during spring 2020 about the ethical issues of tracing systems [3], [4], [5], [6]. Again, students are asked to take the questionnaire before the discussion in class. The comparison of the answers allows to assess how the first session helped the students to understand the technical requirements and how introducing new aspects modify their previous assessment.

2.1 The questionnaire

The first part of the questionnaire aims to make an assessment about how a better understanding of the problem and of the techniques changes the answers of the students and their initial assessment. The poll is anonymous, so individual changes of opinion cannot be analysed.

A set of questions in the questionnaire deals about the understanding of the effectiveness of different technologies used for the identification of the close contacts of a new diagnosed patient. Another set of questions introduces the issue of privacy and asks for a comparative assessment of the alternatives considered.

The goal of the questionnaire is to compare the opinions of the students about the effectiveness and privacy issues of the proposed tracing approaches before discussing about the ethical challenges and after doing so. The expected result is that when ethical issues are included in the discussion some design options are discarded or avoided while others may require some changes in their design.

2.2 The main aspects to be addressed during the discussion sessions

A list of the different aspects analysed during the sessions follows.

Understanding the effectiveness of testing, not only to detect a contagion but as a requirement for all people identified to be at risk because of being a close contact.

The identification process of the group at risk and its conditions: to be close enough (about 1 or 2 meters) during a minimum period of time (about 10-15 minutes) during the past two weeks.

How automatic identification helps to cut the spread of the contagion and the effect of false positives and false negatives. The accuracy of the technology used for the identification process is a key factor in the overall usefulness and performance.

The importance of the notification process and how an automatic notification can be made preserving the privacy of the patient and of the people detected as close contact. A successful notification requires not only the collaboration of the patient but of the notified people too, as they should go voluntarily to take a test as soon as possible.

Next comes the analysis of the effectiveness of different technical approaches: mobile operators may be required to provide the locations of user’s phones (this aggregated information allows to follow the spread of the contagion but cannot identify close contacts); the collection of venue QR codes, the collection of personal

QR codes (these may not work well enough as many people may be in the same place but not close to each other); the use of GPS geo-location to track people (this may be seen as a massive surveillance system and it may not work properly indoors); the use of Bluetooth for detecting nearby devices during a continuous period of time and estimating their proximity (to do this an improved version of the drivers is needed and it may be easily distributed in an update of the smartphone's operating system).

In a broad sense there are two approaches for developing a tracing system. The centralised approach collects routinely all the information provided by the applications (basically, location, date and time, and user's or device identification) in a central server. The information is available to the healthcare staff at any time.

On the other hand, the decentralised approach keeps all the information stored in the mobile device. This information will be used to help tracing possible groups of people at risk only if the owner of the device is diagnosed as infected. Respect for privacy depends on how the information provided by the tracing application is managed and used.

The idea of using non-personal identification is introduced and the effectiveness of this "ideal" approach should be assessed. Though no personal identification is used the effectiveness of the identification and notification processes may be the same as implementations using personal identification which may lead to privacy issues. The privacy-preserving tracing concept is introduced.

The last set of questions in the questionnaire asks for an assessment of the privacy of the technical alternatives considered before.

At this point, while analysing the answers of the questionnaire it is the time to introduce other technical and non-technical aspects, such as the accuracy measuring the distances using Bluetooth, the relevance of false negatives, some characteristics of decentralized and centralized systems, the necessary level of social acceptance (that is, the required percentage of citizens using the tracing application for the system to be useful) and some other issues related with privacy rights.

It is expected to be the turning point of the discussion that requires a back step and reconsider the previous alternatives to make a proper assessment.

3 RESULTS

The results of this experience are presented following the discussion of the answers of the questionnaire. This section is organized in three subsections: effectiveness of the methods, identification of privacy issues of the methods under study, and an assessment of the privacy issues of the methods and systems proposed.

3.1 Effectiveness of the technology used for tracing

Table 1 presents a comparison of the results of the first and second questionnaires (labelled as “a” and “b”) related to the effectiveness of the eight different technologies proposed. The answers grade from “not useful” (1), “somewhat useful” (2), “useful” (3), to “very useful” (4).

Due to space limitation, a detailed description of each of the methods (identification and notification processes) are not included.

Table 1. Effectiveness of the method as a percentage of the answers

Method	Answers	Questionnaire 1 (a)	Questionnaire 2 (b)
1- Collect phone id from Base Station	2	50%	50%
	3	25%	7%
2- Collect personal QR at venues	1+2	58%	49%
	3	25%	50%
3- Collect QR of the venues in the phone	1+2	67%	43%
	3	16.5%	43%
4- GPS coordinates sent to a server	1+2	68%	50%
	3+4	32%	50%
5- Store GPS coordinates in the phone	1+2	67%	43%
	3+4	33%	57%
6- Collect BT data in a server	3	41.7%	21.4%
	4	8.3%	57%
7- Store BT data in the phone	3+4	33%	57.2%
8- Store BT anonymous data in phone	3+4	58%	50%
	4	17.7%	35.7%

As expected, a better understanding of the method is reflected in the answers of questionnaire 2 (b). For instance, collecting phone numbers in the coverage area of a mobile base station is not really useful (7%). The effectiveness of QR codes depends on the continuous effort of the citizens to scan the codes. That is why the effectiveness of the method cannot be really assessed. On the other hand, it is difficult to explain why storing GPS coordinates in the phone is considered more efficient than sending them to a server (57% vs. 50%). Finally, using anonymous Bluetooth identifiers is perceived as less efficient than using the real Bluetooth identifier (50% vs. 57.2%). This suggests that the complete mechanism was not well understood even after reading the second article.

The discussion during the second session confirms this point. A detailed explanation about how using random identifiers for the devices may allow the identification and notification of close contacts took a significant amount of time.

3.2 Identification of privacy issues

The questionnaire includes several situations and asks for an assessment about privacy respect in each case. The answers are graded as: “no issues”, “some issues”, and “not acceptable”.

There are some surprising results. For instance, asked about the privacy of collecting the name, date, location and the name of nearby people (potential close contacts) is seen as acceptable by 25% of the students before the first session and it drops to 14% only after the session. Clearly, privacy has different perceptions in different cultures. It is seen as unacceptable by 50% of them in questionnaire 1 (a) and raise slightly to 57% in questionnaire 2 (b).

Other results are as expected. For instance, making public the list of tracks of infected people (including location, date and time, but not the name) is considered to be unacceptable (91.7% and 100%, respectively).

3.3 Assessment of the privacy issues of the methods proposed

Figure 1 shows the assessment about the privacy issues raised by each of the eight methods proposed. The assessment about the privacy has four options: i) no privacy issues, ii) health rights prevail over privacy, iii) a balance between health rights and privacy rights is required, and iv) there are serious privacy issues and the method must be avoided. The method is numbered from 1 to 8 (as in Table 1). Answers in questionnaire 1 are labelled as “a” and the ones in questionnaire 2 as “b”. That is, column 8b corresponds to the results of questionnaire 2 about the method “store Bluetooth anonymous data in the phone”.

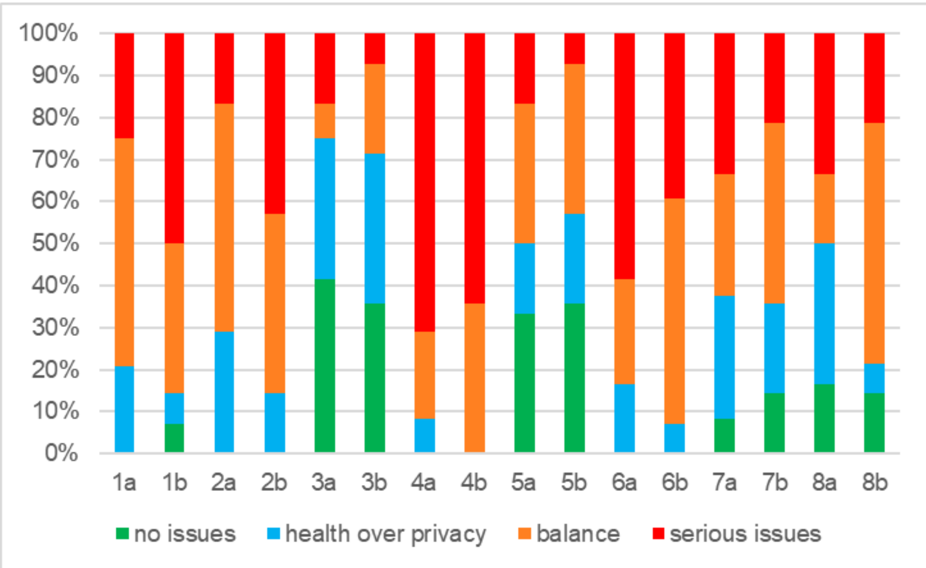

Figure 1. Assessment of the privacy issues

Centralised systems (columns 4 and 6) show a significant level of rejection (serious privacy issues). This corresponds to the social rejection of anything that may be used as a mass surveillance system.

Column 8b shows that the use of anonymous Bluetooth identifiers was not really understood after reading the papers. At the end of the second session the majority of the students agreed that some privacy aspects should be balanced but basically privacy is properly preserved.

4 SUMMARY

The discussion sessions highlight the difficulty of understanding the details of the problem and its real requirements. Also, the description of the characteristics of the different technologies requires to go into some detail about the possible implementation of the tracing system.

In particular, the privacy preserving approach using random Bluetooth identifiers is not intuitive and requires some effort to understand that it can provide the same information that the approach using personal identifiers while preserving personal privacy from the very beginning. A useful explanation may be found in [8] and [9].

The consideration of the social impact is related with the voluntary collaboration of the citizens, first installing the tracing application and afterwards accepting to provide their information to identify close contacts, and second, the collaboration of close contacts for taking a test. This point raises the key issue of trust. Citizens must trust healthcare authorities, politicians, and developers of the system. Without trust the acceptance ratio is too low for the system to be useful as a tracing tool. Trust includes also that the data collected will be used only for the declared purpose and by authorized staff only.

During the discussion, a detailed comment of the statement published by ACM [5] helps to understand the concrete requirements derived from the personal privacy right in order to design and deploy a privacy-preserving tracing system.

Including the assessment of the privacy issues in the different approaches helps to avoid some of them or, at least, some of the possible implementations. Imposing a high requirement for privacy lead to groups of engineers to find privacy-preserving methods that were implemented in the most common support for tracing systems developed jointly by Apple and Google for their mobile operating systems [9].

This is a nice example of “ethics by design”. Ethical considerations were put at the starting point of the design and that allowed to find an innovative way to implement the system.

ABSTRACT

Challenge-based learning (CBL) exposes students to the complexities of open-ended and real-life challenges and encourages them to be in the lead of their learning. The role of teachers remains important but shifts from being the expert to the role of a coach who gradually scaffolds students into becoming independent learners. Accordingly, the interplay between teachers' and students' regulation of

teaching and learning can result in friction and influence students' learning experience. This study explores incidents of constructive or destructive friction between student and teacher regulation during a 9-week CBL course for first-year engineering students. Thematic analysis is employed to identify critical incidents of friction during students' learning via analyzing students' weekly learning portfolios. Results suggest that students' experience in CBL is not linear, and there is a constant interplay between students' ability to regulate their learning and teachers' scaffolding. Initial exposure to CBL was characterized by friction in student and teacher interactions. Several students increased their self-regulated learning skills by resolving the initial friction by adopting a more proactive approach to their learning by actively asking questions and feedback from their teachers. The findings of this study are particularly relevant for CBL, where much attention is paid to students' autonomy, self-directedness, and collaboration. Building on the insights of this research, we make recommendations for further research and educational practice.

1 INTRODUCTION

Engineering universities are increasingly adopting active learning pedagogies to foster students' disciplinary and professional knowledge and skills [1]. Challenge-based Learning (CBL) is a pedagogical approach that engages students in learning knowledge and skills through open-ended and real-life challenges [2]-[5]. The concept of self-regulated learning (SRL) is central to CBL [2]. Learners in CBL are expected to show increased agency, autonomy, and self-directedness individually and as a group [3].

Given the self-directedness expected by students in CBL, the role of the teacher is different compared to traditional teaching approaches [2]. The teacher is viewed as a coach and subject expert who guides students toward self-regulated knowledge construction [2],[3].

Currently, little is known about students' SRL in CBL and teachers' role in this process. A recent systematic review on the implementation of CBL in engineering curricula highlighted that teachers have various roles in a CBL course. These include designing the challenge and developing learning material to provide students with theoretical input, coaching students and providing feedback, and assessing students' achievement in terms of competency development and project outcomes [6]. However, one of the main challenges experienced by teachers and students was the imbalance between expected SRL from students and teachers' provided guidance and scaffolding [6].

Thus the present study aims to assess how students experience the friction between their regulation of learning and teachers' regulation in CBL.

1.1 Theoretical framework: interaction between students' and teachers' regulation of learning

In CBL, students are expected to be in the lead of their learning [1]. Self-regulated learning is a process that describes how students manage their thoughts, behaviors, and emotions in order to successfully navigate their learning experiences and attain learning outcomes [7].

Vermunt and Verloop [8] identified three categories of learning functions that students engage in during a course. These include cognitive, meta-cognitive, and affective/motivational functions. Students engage in cognitive processing functions to process the subject matter, and those activities can directly lead to learning outcomes in terms of knowledge, understanding, and skills. Metacognitive regulation functions are those used by students to regulate and steer their learning processes and lead indirectly to learning outcomes. Finally, affective/motivational functions involve regulating emotions that arise during learning and lead to affective states that may influence students' learning process and progress in a positive, negative or neutral way.

SRL develops through the interaction between the student and the learning environment [9]. The role of the teacher is crucial in students' development of SRL and influences students' learning and motivation [8],[9]. The interplay between students' self-regulation and teachers' regulation can have various forms. For example, in complex learning environments, where the uncertainty and complexity of learning tasks are high, tension and friction can arise [9].

This friction can promote (constructive friction) or hinder (destructive friction) students' learning [9]. For example, constructive friction can occur when students experience the course requirements challenging enough but feel they have the necessary skills to match the requirements. On the other hand, destructive friction occurs when the learning environment does not provide support, but students have a problem in self-regulating their learning.

1.2 Research objectives

In this study, we aim to understand better how students regulate their learning in a CBL course and how they perceive their interaction with teachers in cases of friction. The research questions we formulated include:

- What incidents of friction do students experience in a CBL course?
- How does the interaction between students' and teachers' regulation in incidents of friction influence students' development of SRL?

2 METHODOLOGY

2.1 Context and participants

This study focuses on one CBL course, taking place in Eindhoven University of Technology. This course is part of the educational initiative E3 (Eindhoven

Engineering Education). The course E3-Challenge2 is a 10 ECTS course, with 5 ECTS on the ethics of technology and 5 ECTS on data analytics. The course took place during the academic year 2021-22 and it lasted 11 weeks. Forty-three first-year bachelor students from different engineering departments were enrolled. Students were asked to apply and contextualize the data analysis skills and ethical considerations to a real-life challenge related to smart grids, smart health, and smart mobility. Students in E3- Challenge 2 course worked in multidisciplinary groups consisting of 4-5 members.

2.2 Teaching and learning activities

SRL is a core principle of the E3- Challenge 2 course. Students were expected to be proactive and act autonomously, individually, and as a group. The course consisted of an interdisciplinary team of teaching staff (one ethics lecturer, one data analytics lecturer, three coaches, five expert generalists, and nine teaching assistants (TAs) supporting students in their learning process.
The course included different learning activities to support students' learning. The Ethics workshops brought in ethics materials and evoked ethics discussions. The teaching assistants provided feedback to student groups. Students could ask the remaining questions in the expert meeting and stakeholder meetings. An assigned coach met weekly with each group of 4 students for 30 minutes to discuss matters related to their professional development and individual and group learning process. Fig 1, provides an overview of a typical week of the course. To support students' self-regulated skills, students had to write at the end of every week a 1-page reflection on a learning experience that was important for them during the week and discuss their learning development with their assigned coach every week.

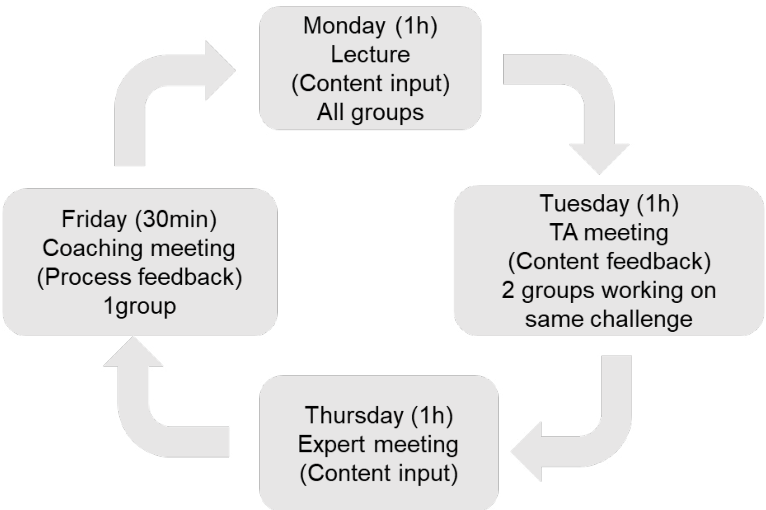

Fig. 1 Weekly cycle of learning activities in E3Challenge2

2.3 Data collection

Students participating in the Challenge-based course E3-Challenge 2 were invited to participate. Forty-three students participated in the course, and thirty-nine of them have permitted us to use their weekly learning portfolios as input for this research. Each student's portfolio consisted of 9 weekly reflections and 1 final reflection, which resulted in 10 submissions per student and in total in 380 submissions, as some students skipped some submissions during the course. The Ethics Review Board of the University has approved this study.

2.4 Data analysis

Thematic analysis was used to identify, analyze, and report patterns within data [10]. Our analysis included a balance of deductive coding (derived from the theoretical framework developed by Vermunt and Verloop [8] and inductive coding (emerging from a student's portfolio). For the analysis, the portfolios were read, and emerging codes were assigned to segments independently by the first author. We identified 1) all incidents of friction where students described their interactions with the teaching staff, 2) identified learning functions that students described in those interactions, and 3) reported tecahers'regulation of the aforementioned learning functions. The data analysis was conducted using ATLAS.ti [10]. The main researcher analyzed all portfolios, and an auditing procedure among all researchers was conducted to discuss the results of the coding process.

3 RESULTS

3.1 Students' SRL through their weekly reflections

The portfolios provided a good way to assess students' skills in regulating their learning and their development throughout the course. For most students, the initial weeks were characterized by **a) uncertainty** related to the **content of the course** and how to apply ethics and data analytics in the challenge and **b) uncertainty** related to **the learning process** and how to navigate such an open-ended course individually and as a group.
Among the most frequently mentioned difficulties for students in the course included 1) establishing an understanding as to what is expected in the course 2) narrowing down the broad challenge to a specific problem to focus on and setting clear goals 3) applying content knowledge (ethics and data analytics) to the challenge 4) diving the tasks among group members 5) managing the time 6) managing group processes.

3.2 Incidents of student-teacher interactions

We analyzed 92 reported interactions between students and the teaching staff involved in the course. Students engaged with all teaching staff during the course, but interaction with teaching assistants was the most frequently mentioned (see Table 1).

Table 1. Summary of reported interactions between students and teaching staff

Student- Teacher interactions	N
Teaching Assistants	67
Coaches	13
Experts/lecturers	12
Total	92

3.3 Experienced friction in CBL

After carefully analyzing the 92 reported interactions, we identified sixty-six incidents that offered in-depth information about friction experienced by students**.** When analyzing the incidents of constructive and destructive friction, we identified which learning function students needed support with and what was teachers' regulation. Table 2 summarizes the most important

Table 2. Reported frequencies of learning functions and teachers' regulation activities as reported in students' weekly reflections

Learning function	N	Teacher regulation
Cognitive	89	• Feedback on reports, and presentations (N= 22) • Answering questions related to the challenge purpose (n=19) • Helping students narrow down the problem they had to tackle (N=9) • Providing support on data analysis or ethics applications (N=16) • Providing explanations of concepts/examples/ (N=9) • Teaching new concepts (N=9) • General discussion on topics related to ethics and ethics application (N=5)
Motivational/affective	10	• Dealing with students' frustration (N=6) • Dealing with students' lack of motivation (N=4)
Meta-cognitive	15	• Provide support in goal setting (N=7) • Provide support in the planning of tasks and activities (N=5) • Provide support/coaching on team functioning and task division (N=3)

The majority of incidents represented ***incidents of constructive friction***. They were related to a) perceived unclarity of the course in terms of what was expected from students and how to apply content knowledge and b) perceived lack of guidance by teachers. More specifically, the openness and freedom of the course were appreciated by students but in reality, in combination with the limited time frame, many of the students wished for more guidance and clarity on what they were expected to deliver.

We identified 89 references to ***cognitive functions*** where students received support from teaching assistants and experts/lecturers. The most frequent topic of interaction among students and teaching assistants or experts/ lecturers was asking for feedback on ongoing progress and deliverables or asking questions. Teachers supported students by asking questions, clarifying concepts, teaching new ones, and helping students with knowledge application. Support from experts and lecturers was experienced as helpful in learning.

> *I did not know where to start so I asked for help during the TA Session. TA and some fellow students explained the concept of business ethics and gave me the hint to start with writing down the vision of XXX. In that way, I could write an ethical issue based on XXX vision. This was a good tip that helped me to get started. Eventually, I wrote about how to protect the users' privacy and how to prevent discrimination when tracking the users' data because in my understanding, business ethics is about the rules a company has to follow to be ethically responsible. However, when finishing my first draft, I still doubted if I did implement business ethics in our report as it should be. Therefore, I asked [the ethics expert] for feedback (Student 1, Challenge A, week 5).*

When students reported difficulties related to ***motivation and metacognitive functions***, students discussed that with teaching assistants or the coaches. In these cases, teaching assistants and coaches provided support to students to make necessary changes in the working plans, discussed different ways to deal with team processes, set goals and make appropriate plans, and define all necessary tasks to be completed. For example, one student reported

> *My learning experience occurred during the coaching session: my teammate and I had a key discussion with our coach. We were explaining how confused we still felt about the course, not knowing clearly in which direction to move forward. We were suggested to take the initiative of choosing our own challenge, rather than waiting for precise instructions from the professors, as in most courses. This gave us the freedom to choose our own goals: we decided on two main objectives, one ethics-related and the other concerning the data analysis. As the week evolved, we gathered feedback from the experts about our ideas (Student 2, Challenge B, week 2)*

Teachers emphasized the importance of self-regulation, but many students, especially at the start of the course, were not capable of demonstrating SRL skills.

Incidents of destructive friction were mainly reported in the first few weeks due to perceived uncertainty and stress related to the course's overall aims and inability to go from a broad and vague challenge to defining a specific problem to tackle. Below is an example of destructive friction where students feel that their concerns about uncertainty are not addressed and that the provided set-up of the course does not meet their need for clarity and guidance.

> *This course started, though, because we were all so confused about the goal of the challenge and about what it was the client wanted from us. Therefore, the first two/three weeks were a bit unpleasant. We did not really like the set-up of the course, which resulted in less motivation for this course (at least this was the case for me). The TA and expert sessions were very time-consuming and not helpful (because we did not really have so much to share at those moments) (Student 4, Challenge C, week 4).*

Destructive friction was also experienced when students showed reluctance to share with their teachers their uncertainty and ask for guidance. Below, a student described an incident of destructive friction arising from his fear of asking questions.

> *During the coaching session, the question that was brought up was, "Why didn't you talk to the TA?". I find this question very difficult to answer, but the first answer that comes to mind (I also learned this is often the best one) is "respect". I always look up to teachers and TAs and they deserve a lot of respect in my opinion; that's why there was (and probably still is) some mental barrier that is stopping me from just reaching out and telling them my concerns or struggles (Student 3, Challenge B, week 3)*

3.4 Resolving the friction and development of SRL

Several students increased their self-regulated learning skills by resolving the initial friction and by adopting a more proactive approach to their learning. Students realized the importance of being proactive in asking questions to get better feedback, showing a proactive attitude as a group, spending time establishing a common understanding with other group members, and establishing teamwork processes early in the course.

> *The first week was intimidating in terms of the lack of structure provided by the organizers. The expected outcome was not clear, and I was expecting more input to proceed. However, this week I figured that this was not the right approach. During the TA Session, I stepped out of my comfort zone by asking questions and suggesting ideas without worrying about their quality of them. The improvement in my understanding was significant. I now have a direction,*

> *and I am aware that I will not be fed with the information that I need. This acknowledgment taught me to be confident in my opinions also when talking to authorities. (Student 4, Challenge B, week 2)*

Final reflections were analyzed for references to students' interactions with teachers and SRL development. Students mentioned a positive overall experience with teachers as supportive during the course and they appreciated the multiple opportunities and sources of feedback they had on a weekly basis.

4 DISCUSSION

This study aimed to explore the student-teacher interactions reported in students' weekly portfolios in a CBL course. The role of teachers was very important, especially at the beginning of the course, when students needed more scaffolding in terms of content and working processes. The greatest need for support was related to students' cognitive functions, This finding can be explained because the content students had to learn as well as the challenge they had to tackle was new to them. On the other hand, students reported fewer incidents of interaction with teachers related to motivational/meta-cognitive functions by the teachers. This can be because students who selected this course were already intrinsically motivated and had prior experience with group work and planning group work from previous courses or because they relied on themselves and their peers to regulate those functions and did not expect teachers' support.

The majority of students gradually adopted a more proactive attitude by asking actively for help when things were unclear, going better prepared for meetings with teachers, and using the feedback more critically.

Within the duration of 11 weeks course, it is not possible to identify significant changes in students' SRL, but the portfolios revealed that students at the end of the course were much more aware of the proactive attitude students need to exhibit in CBL as well as how to make use of all the available resources.

To conclude, the interplay between teachers' regulation and students' self-regulation in CBL can be complex [11], [12]. Friction can arise especially if students have no prior experience with the increased autonomy that CBL entails. Given the autonomy and self-regulation expected from students, the role of teachers is also different compared to traditional teaching approaches [6]. The teacher in CBL is viewed more as a coach than an expert who guides students through the process [3], [5], [6]. The role of teachers in CBL courses is essential to reduce the gap between teaching and learning by providing the right amount of scaffolding and guidance by supporting cognitive, meta-cognitive, and motivational aspects of students' learning [12].

4.1 Recommendations for practice

The study suggests that SRL is important in CBL, but students need more support and scaffolding in regulating their learning, especially cognitive functions. Therefore, the study highlights the importance of teachers' role to support students' regulation of

learning via frequent feedback activities, especially at the early stages of learning [14]. Depending on students' educational level and prior experience with CBL, teachers should set clear boundaries in the project and within those boundaries adapt the amount of support and scaffolding they provide to students [12]
In addition, we found that reflective assignments can provide opportunities to dive deep into the processes that allow students to take control of their learning [13].

4.2 Limitations and Future directions for research

The study focused on a specific course, and the included sample was small. Thus more general conclusions can not be drawn. Another limitation of the study is the focus on SRL within the limited time of one course. In addition, learning in CBL is not only individual but also collaborative. Thus, other forms of regulation, which occur with a group of students, are also relevant and should be explored. Future studies should explore the influence and experiences of the aforementioned social types of regulation as well [15]

Acknowledgments

We thank all students of E3 Challenge 2 course (2021-22) for participating in our study

ABSTRACT

This paper focuses on the study of discontinuities in the teaching of mathematics in engineering within the framework of the anthropological theory of didactics (ATD) and, in particular, attempts to characterize the internal discontinuity between the teaching of mathematics and the role of mathematical activity in engineering subjects through an interview campaign with mathematics and engineering teachers. The first step of this research was the work piloting the interview protocol [12]. We now try to improve this protocol to overcome the fact that, even when both engineering and mathematics teachers seem to talk about the same content (solving linear systems, for example), the activity they are addressing is very different. Splitting the interview into two separate parts has allowed us to have a first online questionnaire that gives an explicit introduction about the notions of praxeology, the type of tasks and the technique of ATD to the interviewer and allows him/her to internalize them before conducting the live interview. The first analysis of the results shows that the interviewees are able to describe the mathematical activity (existing and desired) in terms of types of tasks and techniques previously introduced and seems to indicate that there is an important level of consensus on the important contents to be taught in the first year courses. However, some differences appear in the applicationist conception and its justification. Mathematics teachers seem to agree on a conception in which mathematics is a tool to be applied in engineering courses while engineering teachers see mathematics as an intrinsic component of engineering.

1 INTRODUCTION

1.1 Transitions and discontinuities in engineering education

Numerous research works take as object of study phenomena associated to discontinuities and transitions between institutions. For example, there are works addressing the epistemological differences in different courses in engineering schools [1] or others analysing the existing discontinuities in mathematics education [2]. In fact, this field of study is not new: in 1908 Felix Klein announced its famous double discontinuity concerning the professional development of future mathematics teachers [3]. The first discontinuity announced by Klein concerns the transition problems that students experience when they enter at the university, and the second discontinuity relates to the transition between the university and their activity as secondary teachers.

The first discontinuity has been widely addressed, not only in mathematics education but also in engineering education, particularly because of the high level of dropout rates in this field [4] [5]. The second discontinuity in the engineering education - between engineering schools and workplace- has also been extensively addressed and reveals diverse challenges to soften the existing gaps between the institutions [6] [7].

The work presented here addresses the study of phenomena associated with discontinuities and mathematical education in engineering. Discontinuities are associated to a transition between institutions (defined in a wide sense, see theoretical approach section). The starting point of our work is that we hypothesise that the path followed by engineering students' experiences what we could call a triple discontinuity (see Figure 1), making an analogy with Klein's famous double discontinuity. The first and third discontinuities are homologous to those announced by Klein in mathematics teacher education. The second is the one that would be more specific to engineering education: it is an internal discontinuity in engineering education institutions due to the transition between the mathematical courses for engineers and courses in engineering courses, in line with what has been observed in previous studies [8].

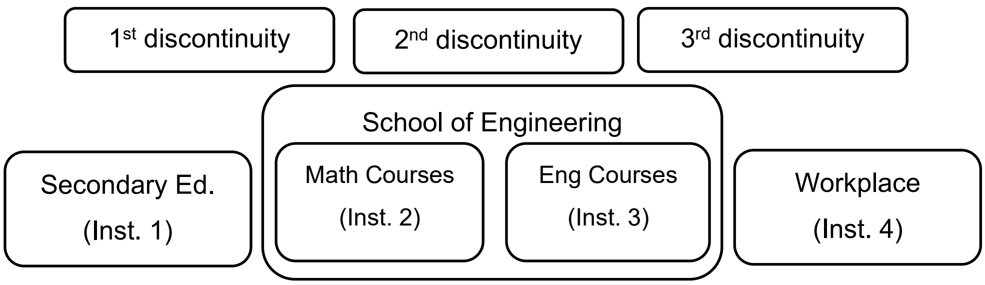

Fig. 1. Triple discontinuity in engineering education

1.2 Previous works

There are diverse works that have studied the differences in the mathematical activity existing in mathematics and in engineering courses. For example, González-Martín and Hernandes-Gomes [9] have studied the role of integrals in mathematics courses and in courses of mechanics of solids, in the same line, Hochmuth and Peters [10] conducted a study analysing the different discourses in mathematics and in signal theory courses. Both studies are framed within the ATD and mobilise the notion of praxeology [11] to model the existing mathematical activity in each course.

The first work developed to study our hypothesis was a qualitative study that allowed us to pilot an interview protocol addressed to both mathematics and engineering teachers at an engineering school in Barcelona (Spain). The study wanted to characterise the epistemological conception of these two positions: first-year mathematics teachers and engineering courses' teachers and to analyse to what extent these conceptions revealed a discontinuity [12].

The crucial fact that appeared as one of the main findings is that both mathematics and engineering teachers show an elevated level of consensus in the selection of the important contents in the fields of linear algebra and analysis. However, an analysis of statements of each collective reveals that under the "label" of "solving linear systems" or "finding the derivative of a function" the targeted activity is very different.

2 THEORETICAL FRAMEWORK

Our work is framed within the ATD initiated by Yves Chevallard during the decade of 1980s in the field of mathematics education but that has widely spread in the field of sciences and engineering education during the last 10 years. Particularly, in this work we use two theoretical developments of the ATD: the notions of *institution* (and institutional relativity of knowledge) and that of *praxeology*.

In the ATD an *institution* is any created reality of which people can be members (permanent or temporary). Accordingly, the group of teachers of engineering courses and the group of teachers of mathematics courses are institutions under the ATD conception. In addition, ATD considers that knowledge conception is institutional-dependent. In other words, in the same engineering school, the kind of activity existing in mathematics courses under the label "functions" differs heavily on what is considered under the same label in engineering courses.

The second notion is that of *praxeology.* To present the concept, we rely on this statement by Bosch and Gascón [13, p. 68]: "ATD postulates that any activity related to the production, diffusion, or acquisition of knowledge should be interpreted as an ordinary human activity, and thus proposes a general model of human activities built on this key notion of praxeology". A praxeology is formed by a quadruplet [T/t/θ/Θ] consisting of a type of tasks to perform T, a technique t which allows the completion of the task, a discourse (technology) θ that explains and justifies the technique, and a theory Θ that includes the discourse. The praxeology consists of two blocks: the praxis block (including T and t) and the logos block (including θ and Θ).

Characterising the mathematical activity in praxeological terms allow us to detach from the knowledge described in terms of contents that in our previous work hided relevant differences between interviewees.

3 RESEARCH QUESTIONS

The research questions we address in our work are:

- RQ1: To what extend the modification of the initial interview protocol in terms of praxeologies allow us to characterise the differences in the epistemological conceptions of engineering and mathematics teachers?
- RQ2: Characterise and identify the characteristics of the 2nd discontinuity in engineering education through a qualitative study.

4 METHODOLOGY

4.1 Questionnaire and interviews design. From pilot to the final version.

We present a qualitative study that intends to characterise the internal discontinuity in the mathematical education in engineering degrees. The first step of this research was the work where the interview protocol was piloted [12]. In this work we figured out that the interviews were too long (more than 1h) and that the analysis of the answers revealed important differences at the level of the targeted activity while the selection of the contents showed up high levels of consensus. The structure of the interview was not able to make these differences emerge.

The original interview protocol had four sections (personal background, research background, mathematical elements, and their role in engineering subjects, and mathematical contents in the course teached).

In the new interview protocol, we have decided to split the interview in two parts to shorten the face-to-face interview: a first moment where the interviewee fills in an online survey and a second part of a semi-structured interview. The online survey has 4 sections:

1. Personal background (including research background)
2. Evaluation of the applicationist conception of mathematics education in engineering according to the work of Barquero and colleagues [14]. The characterisation of the applicationist conception is done through the level of agreement (5-level Likert scale) to five statements proposed in [14]. In addition, we allow the participants to add a short text field justifying their answer.
3. Mathematical contents in engineering: selection of common subjects in linear algebra and analysis in terms of relative importance (five level Likert scale ranging from “I do not consider it a critical content; it belongs to the 10% less relevant” to “I consider it a crucial content; it belongs to the 90% more relevant”)

4. Regarding the teaching activity. In the survey we asked the participants to choose one of the taught courses and to select the mathematical content that they consider as more relevant.

The semi-structured interviews had 4 sections. In the first one (1) we introduced explicitly to the interviewees the notions of praxeology, type of tasks and technique from the ATD. The interviewees were asked to describe the mathematical activity in these terms and to avoid the classical labels of contents to avoid the fake consensus found in the first edition. In the second section (2) we introduced two mathematical activities that had been proposed in first-year courses and we asked them to identify potential type of tasks and techniques that would emerge.

In the third section (3) the interviewee was confronted to the results of the third block of the online survey, and we asked them to describe the contents selected as more important in terms of type of task and techniques. Finally, the fourth block (4) the interviewees were asked to propose three types of tasks and techniques that they consider important but which they believe are absent in engineering education. The entire interviews are available at https://sites.google.com/euss.cat/sefi2022

4.2 Description of the interviewees and institutions of origin

The interviews were carried out at the Escola Universitarià Salesiana de Sarrià (EUSS) and the Institut Químic de Sarrià (IQS). Five engineering degrees are taught at EUSS (Electronics, Mechanics, Automotive, Industrial Organisation and Renewable Energies and Energy Efficiency) whereas IQS offers degrees in Chemistry, Chemical engineering, Biotechnology, Pharmacy, Biomedical Sciences and in Industrial engineering. Both Institutions are strongly interested in the implementation of teaching innovation processes and have extensive experience in this field.

Mathematics teaching in all EUSS degrees is concentrated in three subjects: two in the first year and one in the. second one. Mathematics is offered in the first semester with 7 ECTS, calculus in the second semester with 8 ECTS and statistics in the fourth semester with 6 ECTS.

The distribution of mathematical content in the IQS depends to a greater extent on the degree programme studied, but if we focus on engineering studies, we can see that all three degrees (in Biotechnology, in Industrial Engineering and in Chemical Engineering) offer a 12 ECTS subject called mathematics during the first two semesters. Chemical engineering students also see a 6 ECTS course in computer science and numerical methods in semesters 1 and 2 and an additional 6 ECTS in applied statistics in semester 4. Biotechnology students take a 5 ECTS course in statistics in semester 4 whereas for industrial engineering students there is a 6 ECTS course in statistics in the 1st semester, and 2 courses of 4,5 ECTS each in the 3rd and 6th semester named mathematics II and III. The syllabi of each degree can be consulted in detail on the centre's websites: www.euss.cat. or www.iqs.edu.

The first institution, formed by the group of teachers of mathematical courses, has the following profiles. The first mathematics teacher (MT1) has a degree and a PhD in Mathematics and has always been involved in university teaching and research, with more than 30 years of experience. MT1 teaches mathematics, calculus, and statistics at EUSS. The second lecturer (MT2) has a degree and a PhD in Chemistry, and, except for a one-year break, he has always worked in the academic field, where he has been teaching for the last 9 years. He teaches mathematics and other engineering subjects. The third teacher (MT3) has a degree in Mathematics and a master's degree in Applied Mathematics. MT3 teaches mathematics, calculus and statistics and has more than 30 years of teaching experience. The fourth lecturer (MT4) is an Industrial Engineer with a PhD in Chemical Engineering with more than 18 years of teaching experience and involved now in mathematics II and physics teaching at IQS. The fifth one (MT5) has a Mathematics degree and is currently a doctoral student in Philosophy. MT5 has been teaching only for one year and he currently teaches mathematics I at IQS.

The second institution, made up of the teachers of engineering subjects, has the following profiles. The first teacher in the engineering field (ET1) has a degree in Physics and holds a PhD in Materials Engineering. She has always worked in the field of research and university teaching in the degree of Mechanical Engineering, specifically in the field of strength of materials, elasticity, and structures. ET2 holds a PhD in Telecommunication Engineering and after his doctorate he worked for a short period in industry and then returned to research in supercomputing. He currently teaches in the degree of Electronic Engineering, specifically in the field of industrial computing and communications. ET3 is a Mechanical Engineer and holds a PhD in Material Science. He started his professional career as a laboratory technician and ended up developing a PhD in Biomaterials. He teaches in all the school's degrees in the field of materials, manufacturing processes and strength of materials. ET4 has a degree in Industrial Organisation and a PhD in Business. He only teaches on the school's Industrial Organisation Engineering degree. His professional career has always been in academia, and he teaches strategic management and quantitative methods for management. ET5 is an engineer with a PhD in Civil Engineering. She has developed her professional career in academia and teaches in all degree programs, specifically in physics, strength of materials, machines and mechanisms and fluids. ET6 has a degree and a PhD in Marine Sciences. After a period of 9 years in the field of research and university, he worked for 7 years in industry, as a consultant, as data Analyst and modelling expert. He come back to the University 4 years ago, teaching in all the school's degrees in the field of electrical physics, manufacturing processes and fluid engineering.

4.3 Analysis of results: surveys and thematic analysis

The results of the online survey have been analysed qualitatively while the interviews have been fully transcribed and will be analysed using deductive thematic analysis [15].

The deductive coding is based in the identification of different types of tasks and techniques and their justification. Specifically, includes the identification of the following themes: (1) paper-and-pencil techniques, (2) computer-based techniques, (3) calculator-based techniques, (4) research-based techniques, (5) tasks involving the solution of short mathematical exercises, (6) tasks involving contextualized mathematical exercise, (7) tasks involving the use of engineering models, (8) justification based on cognitive effects on students, (9) justification based on the application, (10) justification as a way to introduce engineering models. The thematic analysis is now being conducted and only partial results will be presented in this paper.

5 RESULTS

5.1 Online questionnaire

The main results of the online survey reveal important differences between the mathematics and the engineering teachers in diverse items. Regarding the second block, that related with the applicacionist, one of the differences that appear concerns the conception of mathematics as a tool to be used in engineering courses. The positions to the statement “A relatively deep study of engineering phenomena and models could be done without using mathematics” are very different in mathematics and engineering teachers. While mathematics teachers fully disagree, considering that any study of engineering phenomena could be done without mathematics, engineering teachers have a less consensual position. For example, ET6 complements her answer with the following statement: “many engineering phenomena or models can be understood without a deep understanding of the mathematics backing them” (translation by the authors).

Another interesting aspect where the answers between engineering and mathematics teachers diverge is about the position on the following statement: “In education, mathematics is generally introduced independently of physical or engineering systems that can be modelled mathematically.” Engineering teachers show full agreement on that: for example, ET1 states: “Mathematics are treated as an entity of their own, detached from other disciplines. At most, they are presented as a tool, but just as detached from the other disciplines” (translation by the authors). However, mathematics teachers present less consensus and one (MT2) states that “it is necessary to learn some mathematical mechanisms and concepts in order to apply them in engineering courses. I think that application examples in each chapter might help…” (translation by the authors).

In the third block of the online survey, where participants had to prioritize a list of contents, the level of agreement is very high, in coherence with was already observed in the piloting survey. Solving Linear Systems with Matrices, Derivation and Integration are the contents considered as more important in both groups. These results, again, are very close to the previously obtained during the piloting of the study.

5.2 Interviews

As said before, the full coding of the transcripts is still in process, and we will present, for now only preliminary data. One of the main goals to introduce the notion of type of tasks and technique to the interviewees was to make the description of the mathematical activity more explicit. The introduction of the notions was clear enough to all of the interviewees and after the first block no one showed any problem when describing mathematical activity in praxeological terms.

Regarding the second block of the interview, it seems that some differences appeared. For the first activity, the type of tasks identified were the same: “find the derivative of the function”, “solve the equation of the derivative equal to zero”, “find the second derivative”, etc. Regarding the techniques, both groups of teachers identified similar techniques and both groups assign paper-and-pencil techniques to the first-year courses while allow other techniques in engineering courses. For example, ET6 stated: “in first-years mathematics, they would find the derivative by-hand, using derivation rules, however in engineering subjects we would never do that, and we would use a calculator or maybe an online symbolic calculator…”. Other statements from mathematics teachers showed up these differences: “in first -year courses we would calculate derivatives and solve the equations using paper-and-pencil…but I am quite sure that in other courses, the students would graph the function using google…”.

Concerning the second activity (about population growth) and with and inquiry-based approach, the answers start to diverge between the two groups. ET1 stated, for example that considers that this second activity “allow to show mathematics involved with other disciplines, such as biology to solve a real or close-to-reality problem”. In a very close line, ET6 states that the students would mobilize tasks that do not appear usually in the first-year mathematics at her institution. She highlighted the data analysis, forecasting and validation of the results against a real setting.

When the teachers were asked about the type of tasks and techniques that do not appear in the mathematics courses, it is particularly interesting the answer of MT4; he is aware of the prominence of the algorithmic approach in their courses (paper-and-pencil work) but he considers that it is a matter of resources. He states: “I think that the manual calculation can have a value for itself, but I am aware that devoting more time do work with modelling would be better for engineering training…however I cannot see how to make a lot of students work on modelling…the mechanical work is a way to deal with a big number of students”. Another mathematical teacher states (MT5) that “I think that in engineering the students see very little algebra, however, I do not really know to what extent what algebra is needed for engineers…”.

6 CONCLUSIONS

The first analysis of the results, especially the interviews transcripts, show that the interviewees are able to describe the mathematical activity (existing and desired) in terms of type of tasks and techniques. This fact allows us to, at least partially, answer RQ1. The statements and the discourse analysed to the point confirm that the modification of the survey and of the protocol overcomes the limitation of describing mathematical knowledge in terms of contents. We hope that the further analysis of the data will help to make differences and similarities between groups emerge.

Regarding de second question we only can answer it preliminary using data from the online survey. The results obtained and their justifications seem to indicate that there is an important level of consensus on the important contents to be taught in first-year courses. However, some differences appear in the applicationist conception and its justification. Mathematics teachers seem to agree on a conception where mathematics are a tool to be applied in engineering courses, engineering teachers see mathematics as an intrinsic component of engineering. This dependency between mathematics and engineering models is not coherent with the detachment between mathematics and engineering courses.

Further analysis work will be conducted, incorporating more data with participants from other engineering schools in order to validate this preliminary results.

ABSTRACT

Technology is evolving at a rapid rate, thereby introducing more complex problems that engineers must be able to engage with. Increasingly complex problems require new ways of thinking, and more innovative, creative, and collaborative responses. To lead this technological evolution, engineers are challenged to engage with lifelong learning and ongoing problem solving. The learning and creative thinking skills needed for innovation relies on an open and receptive mindset – a key component of mindfulness. Mindfulness has previously been shown to enhance creativity, focus, mental clarity, and divergent thinking skills required for problem solving. Furthermore, mindfulness has been shown improve interpersonal relationships and communication – paramount to effective collaboration when working on solutions to complex problems as a team. In this paper, the perceptions of mindfulness and its effects on engineering professionals in the workplace are explored. Data were collected using structured interviews with a purposive sample of practicing South African engineers, and a survey sent out to a larger sample. Data were analysed using content analysis for the interviews and statistical regression analysis for the survey. It was found that engineers believed that consistent learning was a vital aspect of job performance. Findings revealed that mindfulness was correlated to lower stress, fatigue, and turnover intention, while improving productivity, innovation, emotional intelligence, and communication. Results indicate that through cultivating mindfulness, engineering professionals will be more equipped to continuously learn, create, and innovate in a productive manner. The study proposes that mindfulness is introduced at undergraduate level in engineering education as a key skill in preparing graduates for the workplace.

1 INTRODUCTION

1.1 Background to the Research

The rapid rate of technological evolution is likely to continue for the foreseeable future. As technology progresses, more complex challenges and problems present themselves. Engineers play an important role in technological evolution, and as challenges become increasingly complex, and work environments change, engineers must be able to adapt and engage with change in an effective, generative, and productive manner. Such change may require certain knowledge and skillsets possessed by engineers, so that they can continue to contribute with the latest knowledge and advancements while still being able to offer valuable input [1]. This can enable engineers to be suitably equipped when engaging with the increasingly complex challenges, which require new ways of thinking, as well as more innovative, creative, and collaborative responses. Lifelong learning, problem solving, and divergent thinking skills are vital in empowering engineers to continue to lead the technological revolution, while offering creative and innovative solutions to challenging problems.

The learning and creative thinking skillsets needed for innovation rely on an open, curious, and receptive mindset, which includes divergent thinking. Instead of focusing on the development of these skills, engineering education mostly focuses on narrow, analytical, and convergent thinking skills [2]. This comes at the expense of learning creative, divergent thinking skills which are essential in aiding engineers in developing innovative solutions to increasingly complex engineering problems. Rather than focusing solely on developing narrow, analytical and convergent thinking skills, engineering education should begin to focus on the cultivation of creative, innovative, and divergent thinking skills [3]. This does not mean that analytical, convergent thinking skills should be ignored, but rather both sets of skills should be emphasised to ensure that graduate engineers are well-equipped to deal with a rapidly changing industry.

Mindfulness is a practice that has its roots in ancient Buddhist psychology and philosophy. The practice of mindfulness has been adopted as a way for individuals to quieten the mind, which can lead to a range of mental, emotional, physical, and physiological benefits. Previously, there have been negative stigmas attached to mindfulness and meditation, and many academics and scientists previously perceived it as an esoterical and spiritual practice. In recent decades however, research into mindfulness has increased exponentially. Empirical research and studies have demonstrated that a wide variety of benefits can be experienced by individuals through engaging in mindfulness practice (e.g. Rieken, et al. [2], Good, et al. [4], Kersemaekers, et al. [5]). Furthermore, developments in Magnetic Resonance Imaging (MRI) have allowed researchers to observe the effects that mindfulness practice can have on the brain. Existing research has proven that regular mindfulness practice leads to new neural pathways growing, as well as the beneficial altering of the size and structure of the brain, such as an increase in grey matter (responsible for the processing of memory, emotions, sensory perceptions, speech, self-control, and decision making), the thickening of the hippocampus (responsible for helping memory and learning), and a reduction in the size of the amygdala (which leads to a reduction in stress) [6]. More objective data, such as those offered by brain scans through MRI, have led to increased interest in mindfulness amongst scientific communities and therefore an increasing number of mindfulness-related studies emerging as time progresses.

Existing research has indicated that regular mindfulness practice can enhance individuals' learning ability [7], innovation and divergent thinking skills [2], and wellbeing; while reducing stress and emotional exhaustion [8]. Mindfulness can therefore equip practitioners more effectively for dealing with the challenges of a dynamic, changing work environment that engineers often face. Moreover, engineers with experience in mindfulness will improve their learning ability, innovation, and divergent thinking skills, which can give them an advantage when it comes to learning new concepts and keeping pace with the rapidly advancing technological evolution.

1.2 Value of the Research

Through ongoing learning and the development of innovation, and creativity skills, engineers are more likely to be able to produce effective solutions to complex challenges that society faces. The nature of these challenges are likely to become more complex with time, as natural resources begin to dwindle, new ways of doing things need to be established, and new challenges present themselves as society adapts and evolves.

Mindfulness has been shown to enhance learning ability, creativity, divergent thinking, innovation, job satisfaction, employee well-being and overall perceived quality of life. Through the cultivation of these skillsets and traits, engineers will be more suitably equipped to engage with complex challenges and commit to a process of lifelong learning. Graduate engineers with mindfulness practice experience are more likely to produce more innovative, creative, and novel solutions to the challenges faced by an evolving society and rapidly advancing technological industry. This has the potential to enhance their careers, as they will not only be able to provide more value to the engineering industry but will also be more suitably equipped to managing and reducing their stress levels and mental health, while improving their overall wellbeing and job satisfaction.

1.3 Research Aims and Questions

This paper reports on a study that investigates the relationship between mindfulness and learning in engineering professisonals. The following research questions were addressed:

1. *How does mindfulness enhance learning in engineering professionals and students?*
2. *How can mindfulness practice be used to enhance lifelong learning, creativity, and innovation in engineering professionals and students?*

2 CONCEPTUAL FRAMEWORK

2.1 Mindfulness

A widely used definition for mindfulness in scholarly literature was formulated by Kabat-Zinn [9], and states that mindfulness is: *"the awareness that emerges through paying attention on purpose, in the present moment, and nonjudgmentally to the unfolding of experience moment by moment."* (p. 145). Dane [10] proposed a definition for mindfulness that also included an aspect of presence, describing it as "*a psychological state in which one focuses attention on events occurring in the present moment*" (p106). Evidently, fundamental aspects of mindfulness include presence and attention to present-moment experiences. Going forward, when the term 'mindfulness' is used, Kabat-Zinn's definition of mindfulness will be referred to as his definition holistically encapsulates the foundations of mindfulness in a clear, unambiguous manner. For the purposes of this research study, mindfulness will be viewed as a state, as proposed by Dane [10].

In most scholarly literature, the fundamental bases of mindfulness are attention and awareness. Almost all conceptual models of mindfulness include these characteristics. Brown, et al. [11] describe awareness as "*the conscious registration of stimuli, including the five physical senses, the kinaesthetic senses, and the activities of mind*". While attention and awareness interact, they are still distinctive from one another – attention is engaged when a stimulus is strong, and it is possible to lack awareness while paying attention. Conversely, it is possible to be aware that one is paying attention or paying attention to being aware of a phenomenon. Good, et al. [4] used a conceptual model that suggests the key pillar of mindfulness is solely attention, and that all benefits that arise are due to the cultivation of attention; namely in the areas of stability (how consistently one can hold focus), control (directing attention amid competing demands), and efficiency (referring to the economical use of cognitive resources). For the purposes of this research study, the conceptualised model of mindfulness will include aspects of attention and awareness, with a focus on present-moment awareness, owing to Kabat-Zinn's (2003) definition of mindfulness.

The attention and awareness that arises when an individual is in a mindful state should be non-judgmental and non-discriminatory in nature, and rather as objectively as possible without attaching any emotional value to any events unfolding. In other words, when mindfully processing phenomena, there is no comparison, categorisation, or evaluation on the current experiences that are unfolding; nor is there any contemplation, reflection, or rumination on events or experiences based on memory or preconditioning. Instead, mindfulness promotes non-interference and non-judgment towards any experience that may arise, and simply allows inputs to enter an individual's field of awareness by simply *noticing and observing* what is taking place. Mindfulness involves experiential processing of phenomena unfolding [11], which refers to phenomena occurring in both one's internal world (consisting of thoughts, feelings, and emotions) as well as one's external world (consisting of external stimulus and sensations) while simply *observing and noticing* what may arise. It is important, however, not to judge or to attempt to assign meaning to anything. In addition to these qualities, the attention and awareness that is cultivated due to mindfulness is also flexible, meaning the field of awareness can be adjusted accordingly – it can move back to gain a larger perspective on what is taking place (known as clear awareness), or it can 'zoom' in on situational details (focused attention) [11]. This feature can allow mindful individuals to alter their perceptions and limiting thoughts to obtain greater clarity and understanding in certain situations where it is required that the bigger picture is seen.

When the topic of mindfulness is discussed, the construct of past, present, and future is taken into account. Brown, et al. [11] suggests that humans' minds oscillate between memories of the past and projections into the future. Too seldom, do humans experience the present moment for what it is. This is often caused because humans 'forget' that we only exist in the present, and that there is no tangible, direct contact with either the past or the future – they are both simply constructs of our imagination. While this 'oscillatory time travel' serves a useful biological purpose of protecting, maintaining, and improving the self, or one's identity (which is a set of ideas about oneself that defines *who* they are in relation to the world), it often comes at the detriment of one's mental and emotional well-being (by dwelling on painful past memories or excessively worrying about future outcomes). Mindfulness helps to increase the amount of mental time spent being aware in and of the present moment, through the cultivation of *present-oriented consciousness*. Zimbardo and Boyd [12] importantly point out that this is not to be confused with 'living for the present', which is associated with hedonism, impulsiveness, and fatalism. On the contrary, mindfulness has been inversely related to these characteristics.

2.2 Salutary Effects of Mindfulness in the Context of Learning, Wellbeing, and Performance

An open, receptive mindset, necessary for learning and creative thinking, is a key component of mindfulness. Mindfulness has previously been shown to enhance creativity, focus, mental clarity, innovation, and divergent thinking skills required for problem solving. Existing research has revealed compelling evidence that there is a causal relationship between mindfulness and creative innovation achievement, and therefore learning [6]. However, psychologists are still attempting to establish the exact mechanisms through which mindfulness can aid innovation [13]. Mindfulness may be able to enhance learning indirectly as one of its most common applications is for stress reduction [14]. Vogel and Schwabe [15] found that stress can limit an individual's ability to retrieve memories and learn effectively, suggesting that mindfulness could be used as an effective tool to counteract stress-based learning difficulties.

The effects of a changing and challenging environment, such as the environment that presents itself in the e engineering workplace in the face of rapidly evolving technology, can be mitigated in employees through mindfulness. It has been shown that organisational mindfulness held value for organisations to help respond to a changing and challenging workplace, while mindfulness also provided benefits to organisations which included improved learning, increased job satisfaction, and reduced employee turnover and absenteeism [16]. Mindfulness has been shown to enhance individual learning ability, as it leads to increased activation in the prefrontal cortex – the region of the brain responsible for higher-order thinking, judgment, decision-making, and planning. Researchers found in long-term meditators that the cortical regions responsible for processing sensory input were thicker, and that meditation increased brain activity involved with learning and memory processes, emotional regulation, self-reflection, and perceptiveness [6]. Ching, et al. [7] conducted a study involving 359 university students who engaged in regular meditation practice. Results showed that through regular meditation, students possessed improved mental and physical stamina and school performance, enhanced learning ability, increased memory, and faster reaction times.

Mindfulness has been shown to enhance personal well-being, both directly and indirectly. Well-being can be directly enhanced as mindfulness can add clarity and vividness to current experiences; encouraging closer sensory, moment-to-moment contact with life without first interpreting, analysing, and judging everything that is going on. This can reduce the emotional and mental distress that could arise due to the judgment and discrimination towards current events unfolding, thereby allowing a state of peaceful equanimity to arise – a quality that significantly enhances an individual's sense of well-being.

Indirectly, mindfulness can lead to enhanced individual well-being by improving self-regulating functioning that comes with sustained attention and awareness of psychological, somatic, and environmental stimuli [11]. These claims of improved well-being have been backed up by studies, where significant correlations have been found between mindfulness and: mental health, lower levels of emotional disturbance (such as depression, anxiety, and stress), higher levels of subjective well-being (higher positive effect and satisfaction with life), and eudemonic well-being (vitality and self-actualisation) [17]. Baer, et al. [18] found that mindfulness was negatively related to neuroticism, while Walach, et al. [19] proved that mindfulness was negatively correlated to psychological distress. Furthermore, mindfulness is associated with greater general awareness, understanding, acceptance of emotions, and improved ability to correct mood states [17]. It has been shown that mindful individuals were less likely to be emotionally volatile and less negatively reactive, and that an 8-week mindfulness intervention training program reduced participants' neural reactivity and negative reaction to sadness-inducing stimuli [20]. This has been proven not only through empirical research, but also neurologically through brain scans of the amygdala and prefrontal cortex associated with threat response [21]. When individuals experience higher levels of well-being, they are more likely to feel motivated satisfied at their workplace, enabling them to produce higher quality work in an efficient manner. Therefore, through improving employee well-being, mindfulness is likely to improve individual's workplace performance, including engineering professionals.

Considerable research has gone into the field of mindfulness and its relation to cognitive performance – including both cognitive flexibility (the generation of new perspective taking and responding instead of reacting based on previous mental conditioning) and cognitive capacity (the fluid intelligence of individuals) [4]. Contrary to popular belief, Good, et al. [4] states that working memory and fluid intelligence is malleable, and that these qualities can be cultivated and improved within individuals through mindfulness training. Through improving cognitive flexibility and capacity, engineering professionals could benefit as it would enable them to develop new perspectives when solving problems. Additionally, the improved working memory and fluid intelligence would mean that professionals could recall information more quickly and may offer better insights through fluid intelligence.

3 METHODOLOGY

3.1 Research Approach

This research study aims to investigate topics that are personal to individuals, such as learning, mindfulness, and creativity. These states are subjective, and are experienced differently between individuals, each of whom possess differing mental constructs, beliefs, and understandings of the world. It was therefore deemed most applicable to adopt a constructivist- and interpretivist-based philosophical stance, which lends itself to subjectively experienced phenomena. This was more suited to the research study compared to an objectively rooted positivist philosophical standpoint.

A mixed methods case study approach was adopted for this research study, where the cases were engineering professionals in South Africa. This approach allowed for rich data and descriptions to be obtained from the participants.

The goal of this research study was to clearly understand the current situation in the engineering workplace context, in terms of mental health, mindfulness, job performance, and employee well-being. This was achieved with an in-depth study with individuals as cases. The perception of mindfulness as an effective practice to improve mental health among engineers was also explored.

This research study required an appropriate sampling design. A probability sampling design was used for the survey, and Simple Random Sampling was used for this part of the research. The population was identified as professionals working at an engineering firm in South Africa, as an engineer or otherwise. The important aspect was that the respondents were employed by an engineering company, as all employees working in this sector would be able to offer valuable insights into the nature of mental health and mindfulness within this context.

Purposive sampling was used for the structured interviews. Participants who were interviewed were not randomly selected from the sample, as they were selected based on their work experience, job position in the organisation, and their perceived contribution to the research study. To ensure that a suitable sample group was selected, a mixed purposive sampling approach was used.

3.2 Data Collection and Analysis

A 40-item self-report survey was used in conjunction with an open-questioned semi-structured interview, consisting of 16 questions. The survey consisted of five sections: Mindfulness, Fatigue, Stress Levels, Productivity, and Well-being in the workplace. The survey questions helped to elicit a score for each of the respondents in every one of the five sections. The survey provided clarity when addressing the aim of gaining insight into the mental health situation in the corporate engineering sector in South Africa, and assisted in answering the research questions pertaining to mindfulness. Additionally, relationships could be established between each of the sections in the survey through regression analysis, which helped gain valuable insights into the research aims and questions. The survey was a unique combination of existing survey questions dealing with mindfulness, fatigue, stress, wellbeing, and job satisfaction. The structured interview made up the qualitative aspect of the mixed methods approach. The interviews directly questioned the mental health situation in the engineering sector in South Africa, as well as the perceptions of mindfulness among engineers working in South Africa. In addition to this, the interview also helped in answering the research questions directly.

Statistical analysis was used to analyse the surveys. The numerical survey data was exported into *Statistica*, a statistical analysis software tool. This software was used to conduct regression analysis of the survey data, which would help establish relationships between the variables (different sections of the survey). A combination of both Linear and Multiple regression was used to establish relationships between the five main categories from the survey (Stress levels, fatigue, job satisfaction, mindfulness, and productivity), which offered insight as to how the variables related to one another, as well as the strength of the correlations.

Audio recordings of the interviews were transcribed and imported to *NVivo 12*, which was used to conduct the qualitative data analysis. Content analysis was used to analyse the data, which were coded using an inductive approach. Transcribed data was analysed for any emergent themes and categories, allowing the data to naturally unfold and tell their own story. The emergent codes from the transcribed interview data were then categorised into broader themes and categories. The same process was used to code relationships between categories. Whenever an interviewee related two or more themes/categories together in some way, a relationship emerged. Through coding the relationships, a clearer picture could be painted of what was being said by the interviewees, and how various categories related to one another.

Since the research study involved human participants, ethics approval was obtained from the Faculty of Engineering and the Built Environment at the University of Cape Town.

4 RESULTS AND CONCLUSION

The findings from the analysis of data from the 10 participants interviewed, and 65 survey responses are presented below. While 10 interviews may be too few to obtain true representativeness of the entire population being studied, the diverse range of individuals who were interviewed and each participants' insights into collective problems faced by engineers means that the data collected should be sufficiently generalisable. Furthermore, additional survey responses are required to obtain true statistical significance, the responses collected so far are proposed to represent trends that emerge from the sample population.

4.1 Perceptions of Mindfulness and its Effects on Job Performance Amongst Engineering Professionals in South Africa

Among the participants who were interviewed, 60% of them believed that mindfulness revolved around an aspect of awareness. A further 20% understood mindfulness as being aware of and absorbed in the present moment. Both of these beliefs are supported by existing literature on the topic of mindfulness (e.g. Kabat-Zinn [9], Brown and Ryan [17]). Other participants believed that mindfulness included aspects of gratitude, mental health, physical health, and finding a healthy balance to life.

When questioned about how mindfulness could be used to enhance job performance as an engineer, a wide range of responses were elicited from participants. A majority of participants (60%) claimed that mindfulness was an effective way of reducing stress, while 40% of participants believed that learning was an important aspect to being a successful engineer. The former statement suggests that mindfulness could enhance learning in engineers, as several participants believed that in order to learn effectively, it was important to have low stress levels. This is supported by Vogel and Schwabe [15], who found that high stress levels correlated to a lower rate of memory retrieval and effective learning in individuals. Through a reduction in stress, and therefore improvement in learning, an individual is predicted to be a more successful engineer professional.

Half of the participants believed that mindfulness practice would enhance productivity in individuals, meaning they would be more efficient when engaging with the task at hand, and therefore more efficient at their workplace. A further 20% of the participants suggested that mindfulness would result in an improvement in time management, which ties in to productivity. Regardless of what the task is, an improvement in productivity would mean that an individual can complete it more effectively with greater attention to detail and fewer errors being made – a sentiment that was reflected by a participant who was interviewed. This would apply to a task such as learning too, suggesting that through improving productivity in individuals, mindfulness can indirectly enhance an individual's ability to learn, and therefore function more effectively and successfully as an engineering employee.

30% of participants stated that mindfulness could lead to an improvement in interpersonal skills and emotional intelligence, which would be likely to lead to an employee's success in the engineering workplace. These skills tie in to effective collaboration and communication in an organisational context, and can enhance a team's ability to work together to find innovative and creative solutions to complex problems that present themselves through the advancement of technology and an evolving society. An additional 20% of participants suggested that mindfulness would lead to an improvement in one's self-confidence and self-perceived workplace identity. When an individual appears more self-confident in the workplace, they are more likely to elicit respect, come across as more trustworthy and reliable, and gain credibility in their organisation, thereby increasing their chances of success, promotion, and notable influence within their organisation [22]. Self-confidence relates to positive self-image, which suggests that individuals with higher self-confidence would be more adequately equipped to deal with setbacks, such as those experienced during the learning process when aiming to understand new concepts.

Other perceptions of mindfulness and its effects on job performance, which were proposed to a lesser extent by participants, included decreased burnout, less rumination, and fewer mental health issues. In contrast, participants believed that mindfulness could lead to an increase in quality of work, enhanced mental clarity and capacity (thus leading to improved job performance), better quality of life, increased focus, improved self-awareness, and enhanced intellect.

4.2 Learning, Job Performance, and Mindfulness

Of the participants interviewed, 40% of them indicated that learning was a key aspect to successful job performance as an engineering professional. Participant 3 suggested that learning and upskilling oneself, even when it was not part of the job description, could enhance an individual's job performance as an engineer and would enhance workplace identity and self-esteem as it would '*make your day-to-day life at the job easier, and with that, you get less depression, you get less resignation…'*. Participant 5 believed that learning was strongly linked to personal growth, and that as a junior engineer, learning was critically important to adapting to the working environment. This was reflected by participant 8 too, who stated that learning was paramount to job performance, particularly as an engineer who is new to the work environment, as it is expected that there is a lot that new employees would not know. Lastly, participant 9 believed that as new, more novel ways of completing tasks evolved with time, it was important for engineers to be dedicated to learning and adapting as technology progresses. This participant also indicated a concern that older engineers in the workplace were often unwilling to adapt and use newer, more efficient ways of doing things, which reflects a closed, narrow mindset. Mindfulness is a means to cultivating an open, receptive mindset that enhances creativity, innovation, and flexibility [3], which would likely assist senior engineers in opening themselves up to newer ways of doing things in a creative, innovative manner.

Participants believed that mindfulness could actively improve learning skills in individuals. Participant 3, who had had experience in mindfulness practice, believed that mindfulness could enhance mental clarity, which in turn, could improve one's rate of learning as one is able to engage more fully with the task at hand since there is less mental clutter and external thoughts. Participant 5 stated that *'when one is stressed and under a lot of pressure, learning falls out the window*'. The same participant went on to explain that they believed that mindfulness could improve ones quality of life, productivity, and time management, and that this could indirectly enhance an individual's learning ability. Participant 8 suggested that mindfulness could reduce the rate of errors when an engaging with a task, which could increase the rate at which learning could take place. Participant 9 believed that learning was made significantly harder when experiencing a state of stress, and that mindfulness could be used as a means to reduce stress. This was supported by Vogel and Schwabe [15]. In this way, it is believed that mindfulness could enhance learning.

4.3 Collaboration for Problem Solving and Mindfulness

A significant proportion of participants believed that interpersonal skills, including communication, teamwork, and emotional intelligence, was an indicator of successful job performance in the engineering sector. Participants 1 and 9 indicated that teamwork was a crucial trait to determine successful job performance, participants 3 and 10 cited communication, and participants 6 and 10 suggested emotional intelligence was an important trait. All of the aforementioned traits are conducive to effective collaboration in a team-based environment. Through improving interpersonal dynamics, and therefore enhancing effective communication and collaboration, engineering organisations would be more suitably equipped to working together to find solutions to increasingly complex challenges.

Participant 1 stated that being able to rely on and ask for help from others in a team was important when collaborating on finding a solution to a problem, and participant 9 believed that people skills and being able to effectively work in a team was paramount to successful job performance as an engineer. Participant 3 indicated that communication and responsiveness was important to succeeding in the workplace, and participant 10 claimed that being able to communicate '*large ideas in a simple and easy to understand way*' was a vital aspect to effective collaboration and job performance. Participant 5 explained that by being emotionally intelligent, and if *'you know yourself, you know what your capabilities are, capacities are, you don't have to… you won't overcommit yourself, you'll be able to say no, you'll be able to manage your relationships*', that individuals would be able to perform and collaborate more effectively in an organisational, team-based environment. Participant 5 went on to state that they believed that younger engineers coming in to the workplace were generally more eager to learn, as well as being more emotionally intelligent to senior engineers. In doing so, this participant believed that younger engineers were contributing to a more productive and collaborative workplace environment for engineers.

When questioned about how mindfulness could enhance teamwork, communication, or emotional intelligence, participants all believed that there existed a positive relationship between mindfulness and the abovementioned interpersonal skills. Participant 8 believed that engineers generally '*have a lot of IQ but not a lot of EQ*', and that mindfulness could be used as a means to enhance emotional intelligence (EQ) in engineering professionals. Participant 9 highlighted that '*Mindfulness is very important, especially with the people skills, especially if you're a manager'*, and that managers who were more mindful were more adequately equipped to managing teams and facilitating collaboration amongst employees. This agrees with existing research carried out by Shonin, et al. [23], who found that managers who had received mindfulness training showed significant improvements in job performance (as rated by supervisors) compared to a control group and their initial performance. Participant 10 claimed that in order to communicate effectively, individuals require a certain level of mental clarity and mindfulness. Without these states being active when communicating, the participant claimed that one is more likely to be closed off and consumed with one's own thoughts, and therefore more likely to miss cues and lack coherent emotional understanding.

Through effective collaboration, which requires coherent communication, teamwork, and emotional intelligence, engineering professionals are more likely to be able to develop creative and innovative solutions to complex problems that present themselves as technology continues to advance. Findings suggest that mindfulness can enhance communication, teamwork, and emotional intelligence, and therefore improve collaborative efforts within an engineering organisation.

4.4 Statistical Analysis of Survey

Statistical analysis of the survey revealed relationships between the five variables, namely Fatigue, Stress, Job Satisfaction, Productivity, and Mindfulness. The table below highlights the findings, which were obtained through linear and multiple statistical regression analysis:

Dependent Variable	Independent Variable(s)	Correlation (R)	p-value (statistical significance) [<0.05]	Correlation Type/Significance
Mindfulness	Fatigue	0.311	0.0116	Negative (significant)

Mindfulness	Stress	0.171	0.173	Negative (insignificant)
Mindfulness	Job Satisfaction	0.153	0.223	Positive (insignificant)
Mindfulness	Productivity	0.345	0.00486	Positive (significant)
Mindfulness	Stress and Fatigue	0.311	0.0424	Significant
Mindfulness	Productivity and Job Satisfaction	0.349	0.0178	Significant
Mindfulness	Stress, Fatigue, Productivity, and Job Satisfaction	0.400	0.0310	Significant

The statistical linear regression analysis revealed that there were statistically significant relationships between mindfulness and fatigue, and productivity. The relationship between mindfulness and fatigue, and productivity, showed that there were moderate correlations between mindfulness and the independent variables mentioned. This suggests that mindfulness can effectively be used as a practice to reduce fatigue while enhancing productivity amongst engineers. Statistically insignificant relationships ($p>0.05$) emerged between mindfulness and stress, and job satisfaction. A weak correlation existed between mindfulness and stress, and job satisfaction. These findings suggest that higher levels of mindfulness cannot be used to predict lower stress levels and higher incidences of job satisfaction among engineers. Based on the review of existing literature and the data obtained through the structured interviews, it can be concluded that the statistical relationship that emerged between mindfulness and stress in incorrect, and this may be due to the relatively low number of survey responses gathered at this point in the research study.

Multiple regression analysis revealed that statistically significant relationships emerged between mindfulness and stress/fatigue, mindfulness and productivity/job satisfaction, and mindfulness and stress/fatigue/ productivity/job satisfaction. All the aforementioned relationships between mindfulness and the respective independent variables demonstrated a moderate correlation between the variables. This suggests that higher levels of mindfulness can be used to predict lower rates of detrimental variables investigated (stress/fatigue) among engineering professionals, and that higher levels of mindfulness can be used to predict higher rates of beneficial variables investigated (job satisfaction and productivity) in the survey.

5 CONCLUSIONS AND RECOMMENDATIONS

Based on the findings presented, the following conclusions and recommendations can be made:

- Mindfulness can be used by engineering professionals to assist engineers in adequately coping with a challenging and changing workplace environment.
- Mindfulness can be used as an effective practice to enhance job performance and lifelong learning as an engineering professional.
- Mindfulness practice should be introduced to undergraduate engineering students to improve academic performance, reduce stress, and enhance learning ability.
- Mindfulness can be used as a practice to enhance individual well-being, productivity, and job satisfaction, while reducing stress, fatigue, and turnover intention.
- A higher number of interviews should be conducted to ensure representativeness, and a larger survey response is required to ensure that the sample data accurately represents the population.

6 APPENDIX

6.1 Interview Questions

1. How would you describe your own mental health in the workplace environment? 1.1. How would you describe the broad mental health situation in the engineering sector?

2. What do you consider the three most important indicators to determine job performance in the engineering sector?

3. What can you comment on stress and fatigue levels in this sector? 3.1. Do you think they are related to one another?
3.2. How would these states affect job performance in your opinion?

4. What can you say about employee well-being in the engineering sector? 4.1. Do you feel as if companies do enough to ensure the well-being on their employees?
4.2. Are you satisfied at your place of work? Do you expect to find new employment in the next 2 years?

5. How would you describe your own productivity in the workplace? 5.1. What do you understand by the term 'productivity'?
5.2. What is your general perception of productivity in the engineering sector in South Africa?

6. What does the term “mindfulness” mean to you? What do you understand by it?

7. How do you think mindfulness could affect the three most important job performance indicators mentioned above?

8. How do you think mindfulness could affect job performance in the engineering sector, if at all?

9. Please add any additional comments or reflections on the questions posed in this interview.

10. Would you be interested in partaking in a mindfulness intervention running over 8 weeks, to observe what effects it has on your job performance?

6.2 Survey Questions

Mindfulness Section

1. I am able to appreciate myself.
2. I see mistakes and difficulties without judging them.
3. I accept unpleasant experiences.
4. I am friendly to myself when things go wrong.
5. In difficult situations, I can pause without immediately reacting.
6. I am patient with myself and others.
7. I rarely break or spill things due to carelessness, not paying attention, or thinking of something else.
8. I find it easy to stay focused on what's happening in the present.
9. I always remember a person's name after I've been told it for the first time.
10. I am aware what I'm doing, and always feel in control.
11. I take time when engaging in activities, and am fully attentive to them.
12. I listen to someone fully, without doing anything else at the same time.

Fatigue Section

1. Work brings on fatigue.
2. Fatigue interferes with carrying out certain duties and responsibilities.
3. Stress brings on my fatigue.
4. My motivation is lower when I am fatigued.
5. Long periods of inactivity bring about my fatigue.
6. Resting does not reduce my fatigue.
7. Sleeping does not lessen my fatigue.
8. Positive experiences do not lessen my fatigue.
9. I am easily fatigued.
10. Fatigue causes frequent problems for me.
11. Fatigue interferes with carrying out certain duties and responsibilities.
12. Fatigue interferes with my work, family and social life.

Job Satisfaction and Turnover Intention Section

1. I am satisfied with my job.
2. I feel valued, and my contribution appreciated, at my place of work.
3. I look forward to going to work.
4. My managers always value my feedback and contributions.
5. I am likely to remain with the same employer for the next next 2 years.

Productivity Section

1. I am productive at my workplace.
2. My mood has little effect on my levels of productivity.
3. Others would describe me as being productive and hardworking.
4. Being at work increases my productivity.
5. Stress has little effect on my productivity levels.

Stress Section

1. I am frequently stressed at work.
2. I often find myself worrying about things that have not happened yet and are not likely to happen.
3. After a stressful situation arises, it takes me a long time to no longer feel stress.
4. I find it difficult to feel relaxed.
5. I struggle to find a healthy work-life balance.
6. I feel like I have little control over my life at work.

UNDERSTANDING OF DIFFERENTIAL EQUATIONS IN A HIGHLY HETEROGENEOUS STUDENT GROUP

ABSTRACT

Differential equations (DEs) are an important mathematical concept for a wide variety of disciplines in engineering. Hence, students need to develop a good understanding of the basic concepts of DEs. However, they encounter many difficulties when studying DEs and often exclusively focus on procedural knowledge. This study therefore investigates the difficulties concerning DEs encountered by engineering students at a university of applied sciences in Germany.

In contrast to previous studies on this topic our investigation differs in two aspects. First, the group of first-year engineering students at this university is highly heterogeneous; e.g. while some begin their studies immediately after secondary school, others have completed vocational training and joined the workforce for some time. Second, the engineering study programs considered here provide for only two semesters of mathematics and do not include specific courses on (ordinary) differential equations. The subject of DEs is dealt with in a three- to four-week period at the end of the second semester.

We conducted think-aloud interviews lasting about 45 min with 9 students after completion of the relevant course. We found that the main difficulties students

doi:10.5821/conference-9788412322262.1280

experience are connected to: substantial lack of prior knowledge, attempting (sometimes unsuccessfully) to apply memorized procedures, and a failure to understand both the difference between a DE and a function and what a solution to a DE is.

The results shall be used to design three to four collaborative-group worksheets that build on students' ways of thinking and aim at improving students' conceptual understanding.

1 INTRODUCTION

1.1 Importance of Differential Equations

Differential equations (DEs) are an important mathematical concept for a wide variety of disciplines in engineering (e.g. mechanical, electrical, chemical and green engineering, applied chemistry, and applied computer science at our university). Students need to develop a deep understanding of the basic concepts of differential equations so that they can assign meaning to DEs from their field later in their study programs and apply them correctly. Literature and our experiences show, that students encounter many difficulties when studying DEs [1-3] and often exclusively focus on procedural knowledge.

1.2 Distinction of Common Difficulties with DEs

The difficulties with DEs can roughly be divided into those with the equations themselves and those with respect to the solutions of DEs [2]. Distinctions of difficulties in literature are first according to different comprehension levels, e.g. action, process or object level understanding in APOS theory [5], and second according to different representations like graphical, verbal, numerical, symbolic or physical [6]. We refrain from a detailed listing of common difficulties and misunderstandings connected to DEs here, but include them in the results section.

1.3 Students' Background

Previous studies on students' understanding of DEs focused mainly on students enrolled at universities in mathematics, physics, teaching mathematics and teaching physics programmes. The students attended several mathematics modules before entering a (full) course on ordinary differential equations. In some cases, students had to fulfil certain requirements (e.g., minimum grade in other math courses, passed algebraic tests) to be considered within the studies.

In contrast, (1) the composition of the students at our university of applied sciences (Hochschule) is very heterogeneous and (2) hardly any prior knowledge can be assumed. Nevertheless, a basic understanding of differential equations should be imparted to all students.

(1) The group of first-year engineering students at our university is highly heterogeneous since more people are allowed to study here compared to regular universities. Not only "Abitur" (high school degree) but also work experience, a good

vocational degree, and others qualify for a study programme. Some students have (very) little knowledge of physics and mathematics. Difficulties to work / learn self-dependent, to organize themselves and to study continuously are also common. In addition to the large differences in prior knowledge and abilities among students, there are large differences in personal qualifications as well that can affect the studying itself: children, difficulties with the German language, financial problems and / or work which is not related to their studies.

(2) The engineering study programs considered here provide for only two semesters of mathematics (5 ECTS each) and do not include specific courses on (ordinary) differential equations. The subject of DEs is dealt with in a three- to four-week period at the end of the second semester where three weeks is the standard and four weeks is the exception.

1.4 Teaching Differential Equations

There are various approaches to increasing students' deep understanding. All have in common that activating methods are used. The methods range from guided task sheets [4] to computer-based, numerical approaches [7] to project work on topics chosen by students themselves [8]. Various approaches attempt to achieve at least a basic conceptual understanding and usually focus on specific representations, especially graphical and / or numerical understanding.

With this study, we want to find out what essential difficulties prevent (our) students from understanding what makes differential equations special, how to "read" or get an overview of them, and what a solution to a differential equation is. The step-by-step analysis of the students' thinking process is necessary to design collaborative-group worksheets (like the McDermott Tutorials in Introductory Physics [9]). The worksheets will be designed to build on students' ways of thinking allowing students to arrive at a (deeper) conceptual understanding of DEs.

2 METHODOLOGY

2.1 Semistructured Interviews

We conducted think-aloud interviews lasting about 45 min with 9 students after completion of the relevant course. The purpose of the interview was communicated to the interviewee, and it was thereby made clear that the research objects were their thinking processes and their difficulties, and not their performance in terms of a correct response to the questions asked. Students were asked to solve two tasks and to communicate their thoughts. The interviewer did not intervene to tell students whether a thought or an answer was correct or wrong. All she did was asking questions about the specific reasoning, how students gained certain answers or what they would do next, e.g. “How did you determine that graph xy is not a solution?”, “How did you realize that …”, “How would you proceed with that?”, or “Restate the task with your own words.”

The interviews were recorded and transcribed. To find out students' difficulties, the correctness of answers was assessed as well as their reasoning and the relevance and strengths of the argument's given.

2.2 Tasks of the Interviews

The interviews consisted of two tasks:

1.) Which graph could be a solution to the differential equation $y'(x) = -a \cdot x \cdot y(x)$? (Fig. 1)

2.) The number of fish[2] in a lake increases the faster the more fish there are in that lake. A certain number of fish is taken from the lake each year to sell.

Can this problem be described by a differential equation?

Set up the differential equation for the fish problem.

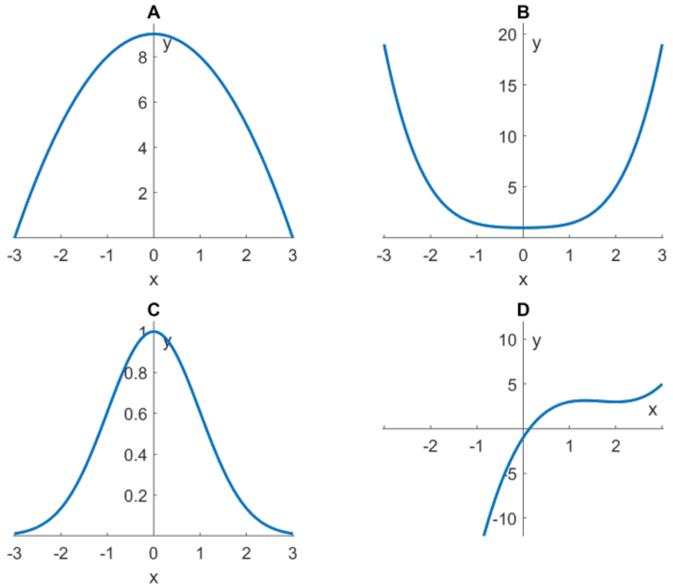

Fig. 1. Which graph could be a solution to the differential equation $y'(x) = -a \cdot x \cdot y(x)$? [10]

There are multiple ways to answer the first task. Some of them are:

First, the differential equation could be solved ($y(x) = a \cdot e^{-\frac{1}{2}x^2}$) by separation of variables. The graph that fits this function can only be C.
Second, y' is the slope, so "values" (the signs, the magnitudes and its courses) for x and y could be read from the graphs and put into the formula.
Or third, the algebraic functions for A to D could be set up and then be inserted into the DE. If a true statement is obtained, the graph is a solution.

The fish problem in the second task can be modelled by a DE since the growth rate of fish depends on the number of fish in the lake. The DE is $y'(x) = ay(x) - c$ with the constants a and c. y describes the number of fish, x the time passed and $y'(x)$ the growth rate of fish.

3 RESULTS

3.1 Categorization of Student Difficulties

We found that there are several substantial difficulties that students experience when dealing with the topic of differential equations. Those difficulties are connected to

i. substantial lack of basic knowledge from algebra and calculus,

---

[2] Initially, "fish population" was used instead of "number of fish", which caused language difficulties for some students.

ii. applying memorized procedures,
iii. understanding the difference between a differential equation (DE) and a function, and
iv. the understanding what a solution to a DE is.

Difficulties connected to other areas also exist e.g. with regard to homogeneous / inhomogeneous DEs, initial conditions or obtaining solutions of DEs.
We think, that many difficulties are associated with key concepts. Key concepts are concepts that have to be understood in order to be able to proceed within the field. To overcome difficulties related to DEs a good understanding of those key concepts, especially from the categories iii. and iv., would be necessary. Once those key concepts are understood and internalized, difficulties might not appear at all or can easily be overcome.

3.2 Subdivision of student difficulties

Students can understand key concepts as well as face difficulties on different levels and within different representations. We want to call those levels basic, advanced and comprehensive. They are inspired by, but not identical to the action, process and object levels in APOS theory [5]. Typical representations are graphical, verbal, numerical, symbolic or physical [6].

For this paper we use the levels in the following way:

Basic level understanding of a concept in a certain representation is more or less procedural knowledge that does not necessarily require a deeper understanding. In extreme cases mathematical procedures can be applied without any mathematical understanding at all. Students can perform the action e.g. on a sheet of paper (external) but need not to be able to perform it purely mentally. Students do not need to know why the procedures are applied nor need to make general statements nor switch representations.

Advanced level understanding of a concept in contrast is more comprehensive. Students can make generalisations within the same representation, work with different inputs (e.g. different numbers, variables, graphs, or physical contexts) and manipulate the concept. They recognize when and how the concept can be (properly) applied and make first connections to different representations. Students can perform the actions internally. For a particular concept and representation understanding can be complete at the advanced level.

Comprehensive level understanding means that students can deduce more comprehensive, general statements. They do this by encapsulating multiple (key) concepts and / or by combining different representations. Students switch appropriately between different representations, as needed. Comprehensive level understanding is very abstract and examples are not needed anymore for explanations.

In the next sections, the levels basic, advanced and comprehensive were assigned to the difficulties. The assignment is not yet final. It occurs that a difficulty is assigned to two levels. For example, an assignment to basic and advanced level may occur when certain aspects of these difficulties could also be worked through procedurally but in order to really use the key concepts behind that difficulty an advanced level understanding is necessary. If difficulties are assigned to the advanced as well as the comprehensive level, the actual classification of this difficulty depends on whether it is related to only one representation or to the interaction of several ones.

3.3 Basic knowledge from algebra and calculus

i. Difficulty rearranging equations (*basic level*)
Some students make serious mistakes when rearranging equations. For instance, one student rearranged $y'(x) = -xy(x)$ to $y'(x) - y(x) = -x$ and another one did not know how to transform $-\ln(10)$ $(= \ln\frac{1}{10})$.

ii. Difficulty remembering and applying differentiation rules (*basic level*)
Some students struggle to remember differentiation rules. Some could not remember how to differentiate x^n, one student wrote $(a^{-x})' = -xa^{-x-1}$ (correct would be $a^x \cdot \ln(a)$ for positive a), and one student did not remember how to differentiate e^{-ax}. When students realise that they cannot remember the rules, they feel very uncertain, get stuck with the whole problem and cannot concentrate on continuing with the problem anymore.

iii. Difficulties in dealing with diagrams (*basic level, advanced level*)
Some students do not know what exactly is shown in a diagram or how to get the relevant data like x, y, or y' from it. For instance, one student said in task 1 where graphs A to D were given (Fig. 1) "… because I don't know, A to D, are they $y(x)$ or $y'(x)$?" and another one said "… but I don't know, what $y(x)$ looks like; it could have any sign." A third student put $x = 2$ into the equation from task 1, got $y'(2) = -2 \cdot y(2)$ but then did not know how to get information about $y(2)$ and $y'(2)$ from the graphs.

iv. Difficulties with infinitesimal quantities (*advanced level, comprehensive level*)
The difficulties relate to the understanding of infinitesimals and can occur in different representations (e.g. symbolic, graphical or verbal). Some students do not seem to know the difference between a variable y and an infinitesimal small change of that variable dy, as well as the difference between $\frac{dy}{dt}$ and $\frac{y}{t}$. dy is sometimes considered to be the same as y and sometimes to be $d \cdot y$. E.g. one student put the wrong equation $y'(x) = \frac{y(x)}{dx} + c$ (correct is $y'(x) = \frac{dy}{dx}$) into $y'(x) = -a \cdot x \cdot y(x)$, (omitted c) and obtained $\frac{y(x)}{dx \cdot y(x)} = -x$. He rearranged this to $\frac{1}{dx} = -x$ and to $\frac{1}{d} = -x^2$. Another one said for the fish problem: "The number of fish is growing per time, so it is $\frac{y}{t}$." Then he compared it to the velocity of a car which he said would be $v = \frac{s}{t}$ (correct is $v = \frac{ds}{dt}$).

v. Difficulties in dealing with mathematical problems
Many students think, a given problem must be solvable in an easy and quick way

with one correct solution. They cannot imagine that there are multiple very different correct solutions or that a problem requires quite some effort. If they do not find an answer in one way, most cannot stop at that point and try to find a different way of solving the initial problem. It seems, that many students do not have a basic confidence in their mathematical abilities.

3.4 What is a differential equation?

vi. Difficulty in characterising a differential equation correctly (*basic level*)
Many students forget very quickly after the mathematics course how to characterise a DE that is given in an algebraic form, e.g. linear – nonlinear, homogeneous – inhomogeneous (and correctly naming the disturbing function), and constant – non-constant coefficients.

vii. Difficulties with text-based problems (*basic level, advanced level*)
Many students do not recognize whether a given text-based problem describes a DE or not or think it is a DE for the wrong reasons. They cannot correctly assign variables (e.g. independent variable, dependent variable, derivative) to physical quantities nor assign the correct meaning to terms and variables in the DE.
E.g. for the fish problem (task 2) at least one student thought it was a linear problem because the growth in the number of fish was not recognized as the first derivative of the number of fish. ("[When I say the number of fish doubles every year] then I would already have [writes y=2x+50].") One student thought he would need specific values and only then it would be a DE (which would correspond to the initial value problem).

viii. Difficulty seeing how functions and DEs are related to each other (*comprehensive level*)
DEs are a (for students new) way to describe functions compared to the explicit form they are familiar with from school or preceding mathematics courses. For some students, however, DEs and functions are fundamentally different. If something can be described as or be graphically displayed as a function known to them (e.g. a parabola or straight line in a diagram) it is no longer associated with a DE. For instance, they think that there is "no need" for a DE if something can be described by a "regular" function. Students said "With a parabola, the slope is not dependent on the function itself, so a normal parabola does not form a DE.", or "The slope is always the same for a straight line. I would not need to work with a differential equation."

ix. Difficulties regarding the dependencies of variables (*comprehensive level*)
Many students, intentionally or unintentionally, consider independent or dependent variables as (positive) constants.
E.g. in the DE $y'(x) = -a \cdot x \cdot y(x)$ either x or $y(x)$ are considered to be constant (one student said "y must be negative so that the sign on the left is correct." and thereby kept x and y' as positive constants). Students are not clear about the serious implications of the dependence of y' on y. Sometimes the function is associated with symmetry solely because y' is dependent on y (which is a wrong

argument).
Some students also do not understand, that the dependence on the independent variable, e.g. on time, is implemented into a DE already by $y(x)$ and need not appear explicitly. Therefore, students often explicitly took the time into their DEs (not realizing what this actually would mean).

x. Difficulty setting up the differential equation for a certain problem and checking its validity (*comprehensive level*)
Students do not explicitly think about variables and assign them consciously before setting up a differential equation. They set up wrong equations that, in the fish problem, e.g. explicitly include the time ("Of course I need the time in my equation because I want to know, how many fish there are at a certain time.").
Students e.g. wrote $y'(x) = e^{y(x)}$, $y' = y^x$ or $y' = e^x$ since they "knew" the number of fish is growing exponentially with time. One student thought, a DE must be differentiated in some way.

3.5 What is a solution to a differential equation?

xi. Difficulty using memorized procedures to solve a DE (*basic level*)
Some students cannot remember the rules to solve a DE. This is because they did not understand them but only learned the procedures by heart. Soon after the exam this knowledge is forgotten. E.g. no student remembered how to solve the DE in task 1.

xii. Difficulty verifying that a given (or found) algebraic function is a solution to a DE. (*basic level, advanced level*)
Some students do not know the goal of putting $y(x)$ into the DE (results in true or false statement). One student got the (correct) result $-2x = x^3 - 9x$ in task 1 when putting the squared function $y(x) = -x^2 + 9$ into the DE and said "Now I have a cubic function. That's a new context and I would need to interpret that." He did not realize that the equation is a false statement. Another one said at that point "I can rearrange this any way I like. So how would I know if this is a solution?"

xiii. Difficulty understanding that functions are the solutions to differential equations. (*advanced level*)
Many students make a fundamental distinction between a solution of a DE and a function as they know them. Some students cannot imagine that the solution of a DE is represented in a diagram and looks like a "normal" function. Some students do not know at all, what a solution to a DE is – neither in an algebraical, graphical nor physical representation. The difficulties regarding this concept overlap with those in item viii.

Note that we concentrated on the most basic concepts and most fundamental difficulties that could realistically be covered in an introductory mathematics course in the second semester. There are many more difficulties connected to solutions of differential equations and difficulties in all representations. Examples are the concept that an algebraic function can be solution to multiple differential equations, that one

DE will have multiple solutions (and therefore multiple graphs in a diagram), and the concepts behind different characterisations of DEs.

4 OUTLOOK

Through interviews we revealed major difficulties students face when dealing with differential equations and solutions of differential equations. Those insights shall be used to design three to four collaborative-group worksheets (tutorials) that build on students' ways of thinking. The tutorials will aim at improving students' conceptual understanding. The learning goals for the tutorials are that students understand

- what the difference between a function and a differential equation is,
- what the terms and variables in a differential equation mean and do (mathematically),
- how to set up a differential equation from a given problem, and
- what a solution to a differential equation is and how it differs from the DE.

The tutorials shall use as little recourse to (memorized) prior basic knowledge from calculus and algebra, as possible, but students shall learn this necessary knowledge along the way. Classroom observations as students work through the tutorials will indicate whether difficulties are addressed and lead to fruitful discussions. In a future publication we hope to go more into the details about creating and presenting the tutorials.

ABSTRACT

A large-scale correlational analysis was conducted on the grades of the students who completed their studies in the 1994 curriculum in the Barcelona School of Architecture. The study included the passing grades of a total of 3910 students corresponding to all 47 compulsory subjects, as elective courses were excluded. The objective of the research was to explore whether courses with related content were associated with the corresponding grades at an aggregate level, and identify similarities and dissimilarities in their clustering. The correlation between the grades in all courses was computed pairwise, and used as a distance measure to quantify the grade of affinity between them. Using this distance metric, the results were processed using hierarchical cluster analysis producing a tree structure according to this similarity/dissimilarity measure. The clustering results were visualized in a phylogenic tree, identifying the optimal number of clusters and coloring the results accordingly. The visualization of this tree matched very closely the grouping of

courses according to departmental divisions, indicating a strong association between the grades obtained and specific areas of knowledge. The lowest marks were also found to be concentrated in the first years and among the graphic and design subjects. These results reinforce previous studies that have investigated the relationship between academic performance during the degree course and the entry grade. The great discontinuity between them and the fact that PBL is characteristic of the degree course and less common in secondary school could be the reasons for these results.

1 INTRODUCTION

Architecture studies have as their backbone the active methodology of Project Based Learning (PBL). “Learning by doing projects” connects with the methodology that is being implemented in the learning environments of early childhood and primary education cycles, and which is less frequently applied in secondary and higher education. Architecture studies are a prime example of how training is based, precisely, on practical workshops where designs are developed and integrate other disciplines such as construction, structural engineering, history or representation, and which involve skills such as teamwork, creativity, communication or social commitment. These design workshop courses do not have a parallel in secondary education, which causes a discontinuity between university admission scores and the grades obtained during university studies [1].

More specifically, the 1994 curriculum, which we analyze, was the first that include the course of Architectural Design in the first academic year. Unlike other schools, at the Barcelona School of Architecture (ETSAB-UPC) it was included from the first semester and was present until the capstone project in the fifth year. The course of “design” and its characteristic “architecture workshop” –understood as both the setting and teaching modality– becomes the most distinctive teaching practice within the studies, both in the beauxartian and the polytechnic traditions that began in the 19th century. Learning is not only "by projects", but "making projects", an aspect that defines the teaching-learning dynamics of the degree. However, this study is not restricted to the group of design courses, but contextualizes them within the framework of other technical and theory subjects, more related of humanistic studies, as well as science and polytechnic studies.

Therefore, based on previous studies that analyzed the low correlation between the university admission score and the grades throughout the career, we now focus on the relationship between the 47 compulsory subjects in the degree, which as explained before were very diverse. Specifically, the research questions are:

1. Is there any relationship between the different courses and the academic year in which they are taught? It could be assumed that the discontinuity between the learning methodologies prior to entering the degree and the different skills and abilities that are valued in Architecture (creative thinking, and design of

forms and spaces) should have an impact on the quantitative academic performance of the first years.

2. Is there any correlation between the courses that make up the 7 areas of knowledge in the curriculum: Construction, Composition, Physics, Mathematics, Urban and Territorial Planning, Architectural Design and Graphic Representation? It should be noted that, despite the fact that this plan was developed prior to Bologna and the process of homogenization of all university studies (which became degrees), the very polytechnic structure of the university in which the ETSAB is included already entails the inclusion of training activities and assessment systems common to all degrees, regardless of their particularities. This circumstance, in the field of Architecture and such heterogeneous curriculum, makes it especially relevant to analyze to what extent the diverse nature of the areas of knowledge correlates with the quantitative results of learning. A learning that also responds to PBL in some subjects, while others work with more classical, behavioral and passive approaches.

2 METHODOLOGY

2.1 Data processing

All data was processed using the R programming language [1] because of its wide availability of packages for data analysis [2], and following the principles of reproducible research [3].

Source data was stored as a Microsoft Excel file that contained 3910 records corresponding to the grades of the students that graduated within the 1994 Plan of Study in the Barcelona School of Architecture, excluding the elective courses. For each record, the passing grades of each of the 47 compulsory courses were stored as columns.

This data structure was not suitable for analysis, and following the principles of tidy data [4] where each variable should form a column and each observation should form a row, was converted from this “wide” format to a “long” format table structure, resulting in a table with 183,770 rows for each pair of student-course, and a column with their corresponding passing grades.

Because the collected data corresponded to compulsory courses that were a requirement to graduate, by definition there was not any missing data in the dataset. There were, however some grades that were below the passing grade of 5, because some grades above or equal to 4 could be “compensated” with higher grades in other courses.

2.2 Grade distribution

The mean of all the grades was 6.22, and the standard deviation was 1.12 grade points. The distribution was right-skewed with a moderately positive skew of 0.73. Since the normality could not be computed using the Shapiro–Wilk test because the sample size was larger than 500, the Kolmogorov–Smirnov test was used to check the grade distribution against the normal distribution, resulting in a D value of almost 1 with a p-value very close to zero, rejecting the hypothesis that the grades were normally distributed.

The density of each of the 47 courses in the degree were plotted in a single chart to visualize their distributions, using the overall density plot corresponding to the combined grades in the whole degree as a reference (Fig. 1, left). The bandwidth of the smoothing kernel was 0.5, about half the standard deviation of the population, which was considered an adequate value of the uncertainty of the grades, as most grades clustered in increments of half a grade point in a 0 to 10 scale.

The results showed that the distribution of the grades in the degree does not follow a normal distribution, and that almost none of the grades obtained in the courses appear to be normally distributed. There is a large variation in the grade distributions per course, with some courses having a peak near the passing mark, and others almost symmetrically and normally distributed around the 6 to 7 marks.

To investigate this variation in the distributions, the courses were grouped according to the academic year where they belonged within the five years of the architecture degree, using the global distribution as a reference (Fig. 1, right), using the same bandwidth parameter as the previous figure. The results showed that the grades become progressively more normal in the later years, while the initial years concentrate most of their grades near the passing grade.

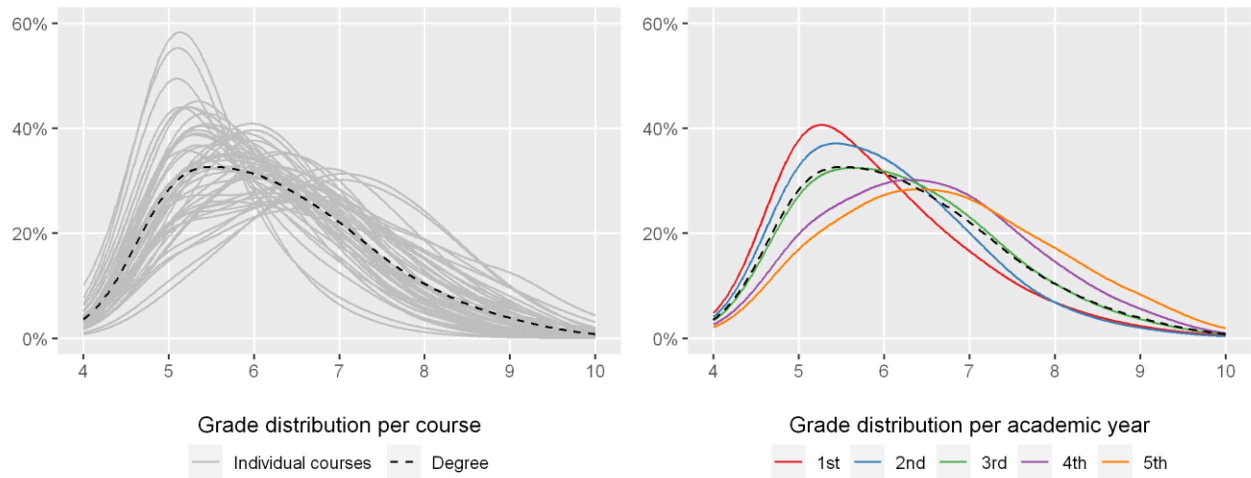

Fig. 1. Density plots for all 47 individual courses analyzed (left) and grouped according to their academic year (right), compared to the density plot of all the grades in the degree (overlaid as a dotted black line)

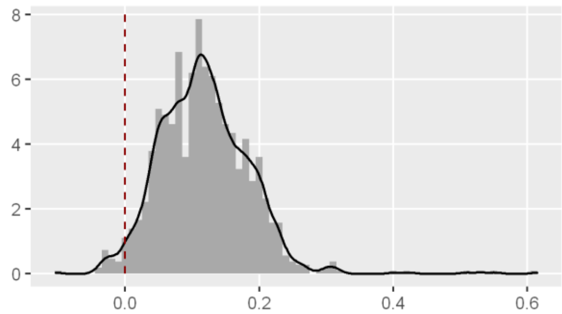
2.3 Correlations

The table of all grades was converted to a matrix, where each student was assigned to a row and the corresponding passing grades of each course were assigned to the columns, resulting in a 3910x47 matrix. The pairwise Pearson's correlation coefficient was computed for all pairs of columns using the *rcorr* function in the *Hmisc* R package. The function returned a symmetrical 47x47 matrix with the pairwise correlation coefficients, with ones in the diagonal as the grades in every course were perfectly correlated with themselves. In addition to the correlation matrix, the function also returned a matrix with the asymptotic p-values required to compute the statistical significance for each pair of correlations.

The correlation values corresponding to a single triangle and excluding the diagonal were extracted and plotted as a combined histogram and density plot (Fig. 2, left), with the same value of 0.1 for both binwidth and bandwidth. The result show that almost all courses are positively correlated, but also that most of the correlations are very weak, with a range of -0.10 to 0.61, and a peak near the 0.1 value.

In addition, the correlations below the statistical significance threshold ($p < 0.05$) were overlaid with a cross. Interestingly the courses of “Structures II” (E I) and “Descriptive Geometry I” (GD I) showed a much higher number of non-statistically significative correlations than expected (Fig. 2, right), with 27 and 16 respectively, followed by “Sketching I” (D I) with 12. The mean number of non-significant correlations per course was 3.2.



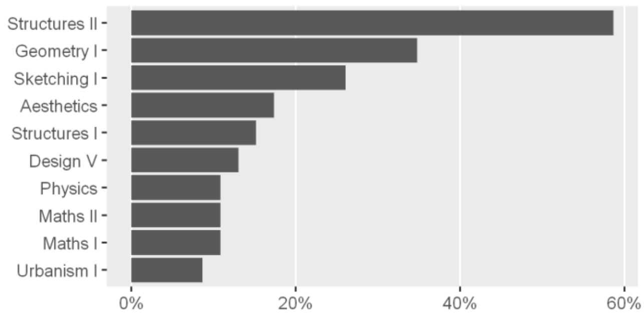


Fig. 2. Combined histogram and density plot of the pairwise correlation between courses (left). Outstanding courses with more than 3 non-statistically significant correlations (p > 0.05) with any other courses in the degree (right)

2.4 Heatmap

Since the correlation matrix was difficult to interpret visually, the results were plotted as a heatmap using the *corrplot* R package (Fig. 3). The heatmap colors used diverging color scale using a cold-hot representation (red for lower values, gray for near-zero values, and blue for higher values), with most of the values appearing in light orange colors. This heatmap revealed that some course correlations exhibit clustering, which is directly observable in blocks of courses that share a similar name when sorted in alphabetical order, and is discussed in the following subsections.

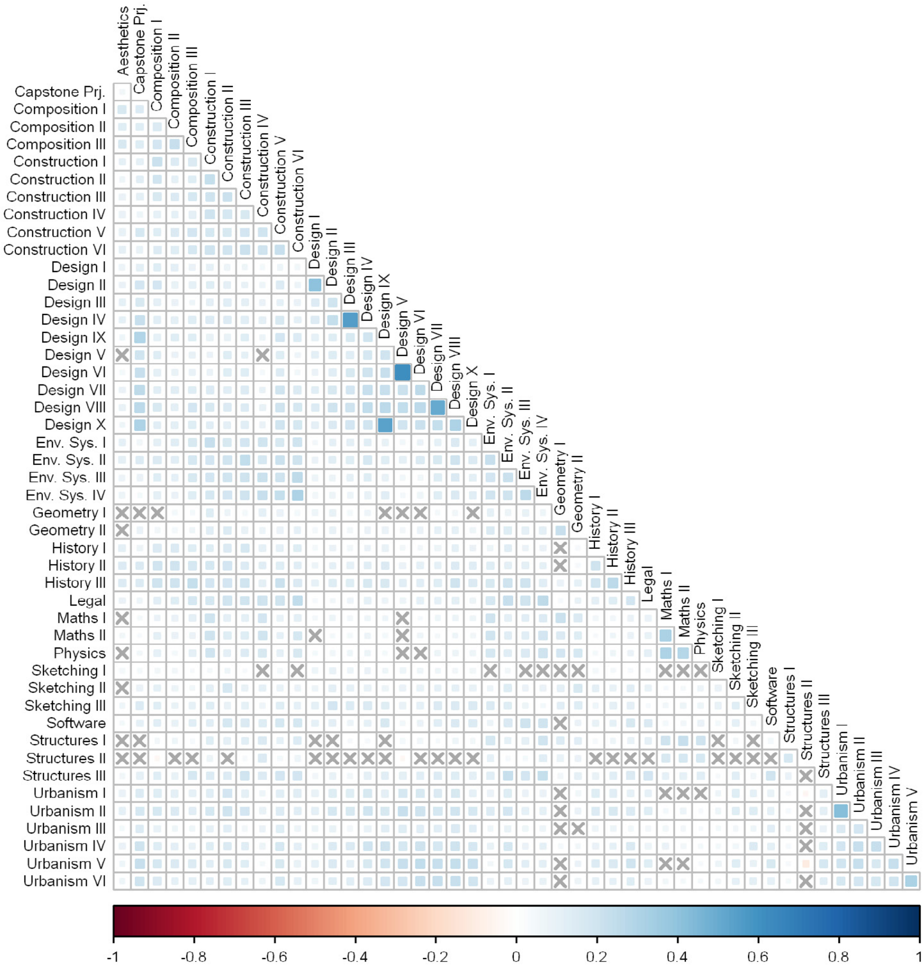

Fig. 3. Pairwise correlations between courses from the passing grades of all 3910 students. Results below statistical significance (p > 0.05) are shown with a black cross overlaid

2.5 Distance metrics

The matrix of Pearson's correlations was interpreted as distances using the *distanceMatrix* function in the *ClassDiscovery* R package, using the "pearson" metric with the following formula of distance between course *i* and course *j*.

$$distance(i,j) = \frac{1 - correlation(course_i, course_j)}{2}$$

Since the Pearson's correlation has values in the [-1, 1] range, this distance metric can only have values in the [0, 1] range. The distances were stored in a 47x47 distance matrix, symmetric because $d_{ij} = d_{ji}$ and the diagonal was populated with null values to replace zero distances for the cases when *i=j*.

The representation of this distance matrix was produced with the *pheatmap* R package, reordering the rows and columns according to the distance metric to place more affine courses together, separating clusters into rectangular partitions of the heatmap (Fig. 4), and placing a dendrogram at the margins of the heatmap.

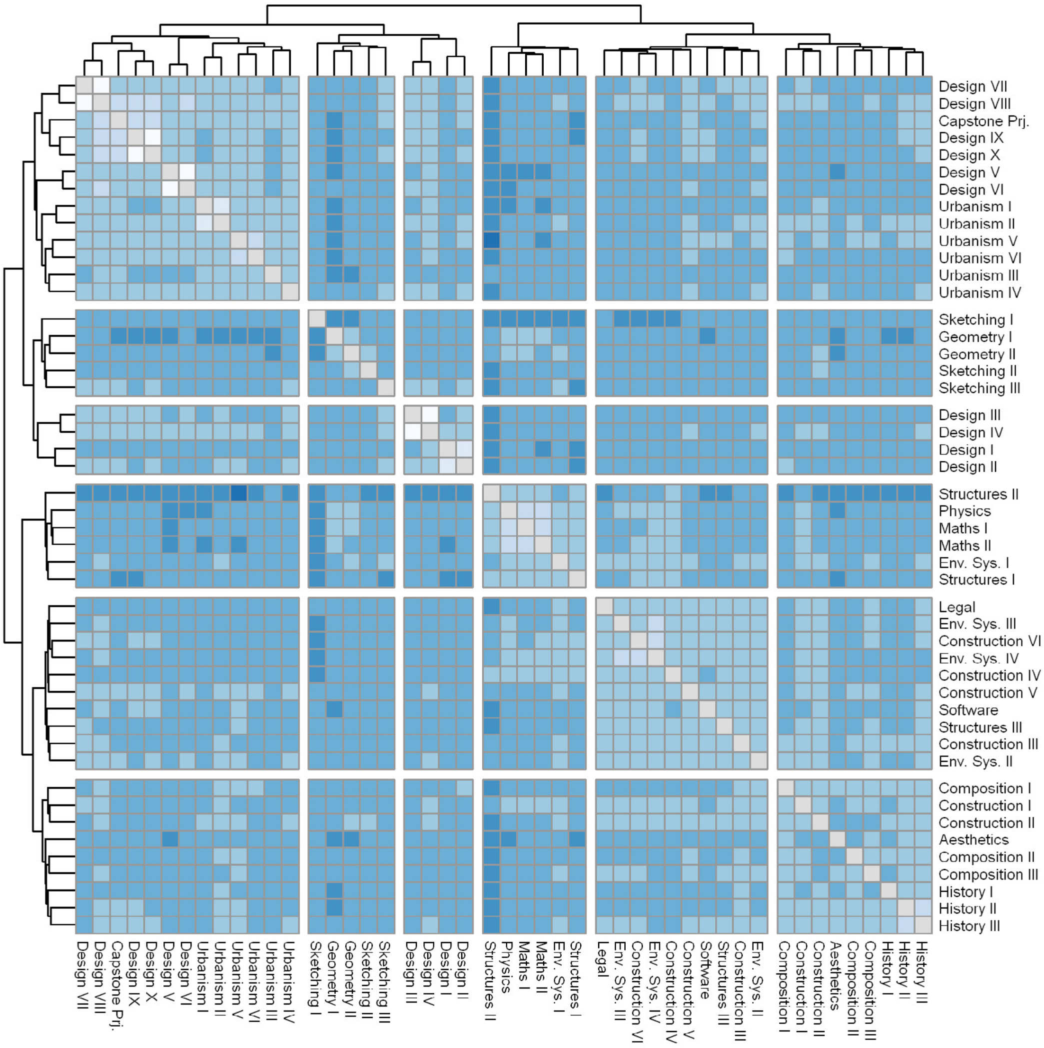

Fig. 4. Distances computed from the Parson's correlation with the cluster separation

2.6 Clusters

The distances in the matrix were clustered using agglomerative hierarchical clustering with the *hclust* function in the *stats* R package using the “ward.D” method. The results were visualized using the *fviz_dend* function in the *factoextra* R package (Fig. 5).

This tree-like representation allows partitioning the dendrogram into clusters according to their distance (height) to the “trunk”, summarizing multiple possible clustering results into a single diagram. In the case of the degree of architecture, the number of clusters chosen were 6, but from the figure it is clear that there is another possible partition around height=1 into two clusters, and around height=0.7 into four clusters. The distribution of the grades within the identified clusters was also plotted (Fig. 6) for comparison.

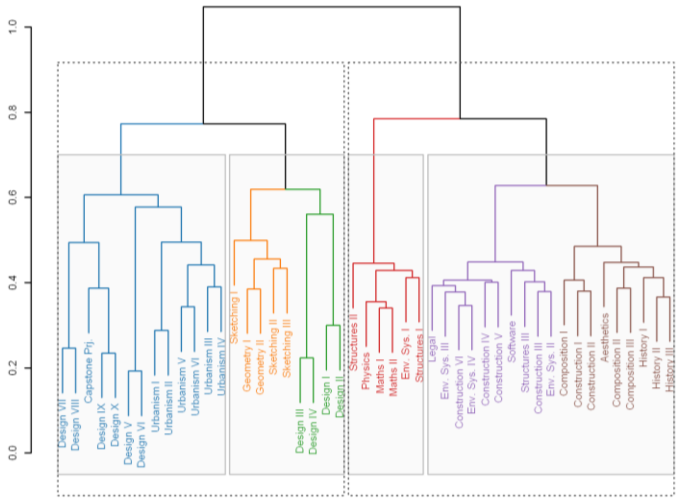

Fig. 5. Dendrogram representation of the results of the hierarchical clustering, depicting partitions into 2 clusters (dotted rectangles), 4 clusters (shaded rectangles), and 6 clusters (color labels)

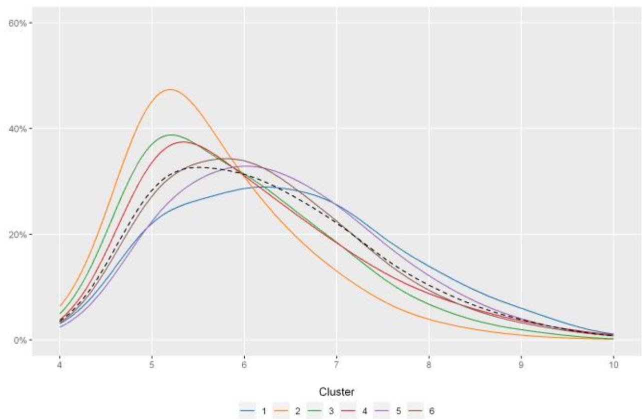

Fig. 6. Distribution of the grades within the identified clusters

3 RESULTS

The results obtained through the discussed methodologies, point to three very specific conclusions:

First, as Fig. 1 shows, the correlation of grades across the degree shows a quantitative increase in the average grades as the years advance. Therefore, the discontinuity with prior pre-university training is confirmed, which may imply that adaptation to studies structurally based on PBL and with a great emphasis on creative abilities entails greater difficulty in passing the initial courses, despite that many of them are propaedeutic.

Second, the correlation between the 47 courses shows a grouping (dendrogram in Fig. 5) that practically reproduces the organization in the different areas of knowledge of the curriculum. Moreover, an analysis at a more global level allows us to organize them into two large groups: the graphic and propositional subjects (design, urban planning and drawing) and the non-graphic ones (the rest). This distinction has been the classic way of organizing the degree in the different curriculums since the 19th century, and it seems to be ratified at the level of quantitative results, despite the rigid polytechnic structures in which the ETSAB has been circumscribed since the 1970s. Therefore, the PBL associated with workshop subjects condition not only the learning-teaching methodology, but also the type of grades.

Third, we can also observe in Fig. 6 that if we analyze the distribution of grades of the 6 clusters, and more specifically in the graphic-propositional block, the projects and drawings subjects of the first and second years (Design I-IV, Geometry I-II, Sketching I-III) have the lowest grades. From the second year onwards, the grades are not always lower in the workshop subjects, as is the case at the beginning. The process of adapting to the PBL of the students can explain this progression and suggests the necessity to reinforce university orientation that previous studies also pointed out, and even the possibility of establishing a specific admission test that assesses the competencies of the degree and the methodologies of active work developed in design subjects, present in all semesters.

Finally, one might wonder about the hypothetical results that a parallel study would generate in post-Bologna ETSAB study plans, such as the 2010 and 2014 curriculums. The research question would focus on whether the implementation of ECTS credits has had an impact on the correlation of grades between the different core subjects of the degree (which continue to have a very diverse nature); or if the pre-university training and the new pre-entrance models of recent years have led to greater preparation to enter Architecture, and therefore the first and second grades are no longer the lowest of all studies.

4 SUMMARY AND ACKNOWLEDGMENTS

The authors would like to express their gratitude to the Management of the ETSAB for providing the data to carry out this study, and especially to the Head of Academic Management, Elisa Capellades, and to the computer scientist Lluís Ferrer, for their help in management and organisation of all data. Likewise, the support of the UPC's *Institut de Ciències de l'Educació* (ICE-UPC) has been crucial for this study, which has financed the initiative as an educational innovation project.

ABSTRACT

A venture creation programme (VCP) is an academic programme in which students' creation of a new entrepreneurial venture is a central vehicle for learning. A VCP puts students in the role of entrepreneurs with real opportunities and challenges. The entrepreneurial journey is a bumpy ride, and COVID-19 has added significant challenges for entrepreneurs, including students in VCPs. Previous research emphasises how entrepreneurial learning occurs through handling entrepreneurial challenges. The purpose of the present paper is to investigate the role of COVID-19-induced challenges in VCP students' learning. We applied fuzzy-set qualitative comparative analysis (fsQCA) to data from students in a technology-oriented VCP in Scandinavia, collected in April 2021. FsQCA offers the opportunity to investigate complex logic combinations of factors that explain an outcome and is particularly suited for small samples. Multi-item measures assessed (1) the progress of students' ventures, (2) entrepreneurial learning and (3) perceived challenges from COVID-19. We also asked whether students had entered or exited an entrepreneurial project and whether these projects were run by a team or only the individual student. We found that COVID-19-induced challenges impeded VCP students' learning and that students' individual progress was important for learning during crisis situations. Thus,

entrepreneurship educators should help students get ‘back on the horse—which means being involved in new entrepreneurial projects—if their challenges lead them into stagnation and inactivity. Progress, both in students’ ventures and for students as individuals, should be nurtured by entrepreneurship educators.

1 INTRODUCTION

Liguori and Winkler [1] emphasised the impact of the pandemic on teaching practices in entrepreneurship education, as entrepreneurship educators worldwide are transitioning from physical ‘offline’ to virtual ‘online’ teaching practices. However, developments in entrepreneurship education have also moved towards not only facilitating students’ learning about entrepreneurship in the classroom but also learning through actually undertaking entrepreneurship [2], feeding the growth and interest in practices for experiential entrepreneurial learning [2,3], action-based entrepreneurship education [4] and courses and programmes in which students create their own ventures as an integrated part of their education [5,6].

A venture creation programme (VCP) is an academic programme in which students’ creation of a new entrepreneurial venture is a central vehicle for learning. A VCP puts students in the role of entrepreneurs with real opportunities and challenges. The entrepreneurial journey is a bumpy ride, and COVID-19 has added significant challenges for entrepreneurs, including students in VCPs. Previous research emphasises how entrepreneurial learning occurs through handling entrepreneurial challenges [7] and even failures [8]. In this respect, COVID-19 could be expected to foster significant learning for student entrepreneurs in a VCP, and recent research has found that entrepreneurs learn from crisis experiences during the pandemic [9].

However, the adversity presented by COVID-19 may also lead entrepreneurs to pursue reactive and protectionist strategies [10], meaning that activities may halt, which may negatively impact entrepreneurs’ learning processes. Therefore, the present paper argues that when ‘real-world’ entrepreneurial activity [3] is introduced as an essential part of the educational process, the potential impact of crises such as the COVID-19 pandemic is likely to go far beyond the transition from offline to online education. Being part of local, regional and even global business life, student entrepreneurs are direct subjects of abrupt restrictions put on their businesses, customers, partners, financers and stakeholders. The purpose of the present paper is thus to investigate the role of COVID-19-induced challenges in VCP students’ learning.

The next section develops a research model for the present paper, outlining factors that are expected to influence students’ learning in VCPs. The research model is empirically investigated using questionnaire data from students in a technology-oriented VCP in Scandinavia. Fuzzy-set qualitative comparative analysis (fsQCA) is applied for data analysis. The present paper contributes to entrepreneurship education research by suggesting that learning from failure should be followed by new entrepreneurial endeavours [8] and by pinpointing that learning through being active in a new venture is essential for entrepreneurial learning [5]. Moreover, the present paper relates to developments in challenge- and problem-based engineering education [11].

2 FRAME OF REFERENCE: LEARNING IN STUDENT VENTURES

Learning is central to all entrepreneurship [12], and entrepreneurial learning has emerged as a core concept in entrepreneurship research over the last few decades. In essence, entrepreneurial learning can be understood as the process through which experiences from entrepreneurship are transformed into knowledge that informs future entrepreneurial actions [13]. Entrepreneurial learning builds on experiential learning theory [14]; hence, being involved and active in a new venture is a key factor for entrepreneurial learning [7]. Learning also occurs in situations that are detrimental or even fatal to a new venture, such as different degrees of failure [8]. Thus, the event of entering or exiting a new venture is considered relevant for explaining entrepreneurial learning.

Since entrepreneurial learning is seen as the process informing new entrepreneurial action that is developed or improved over time [14], progress in a new venture is also relevant for entrepreneurial learning. The new venture's progress is a sign that entrepreneurial learning has occurred in the past and that new situations, tasks and challenges are presented to the entrepreneur, which, as mentioned, is key to entrepreneurial learning |7]. Hence, new venture progress is to be considered relevant for explaining entrepreneurial learning. Experiences of challenges in the entrepreneurial process, such as the crisis situation represented by COVID-19 [9], are also relevant for entrepreneurial learning, and challenges from COVID-19 are therefore considered relevant for explaining entrepreneurial learning alongside new venture progress.

The four factors found to be relevant in explaining entrepreneurial learning—challenges from COVID-19, new venture progress, entrepreneurial entry and entrepreneurial exit—may be combined in a research model, as presented in Eq. (1). The research model states that entrepreneurial learning can be expressed as a function of the four abovementioned factors.

$$entr.learning = f(challenge, venture\ progress, entr.entry, entr.exit) \quad (1).$$

The next section explains the research methods applied to empirically investigate the research model presented in Eq. (1).

3 METHODOLOGY

3.1 Research context and data collection

This research builds on empirical data collected from a cohort of students in a technology-oriented VCP in Scandinavia. The VCP is a two-year MSc programme and includes courses in strategy, business management, engineering and social sciences, alongside the facilitation of students' venture creation processes. In April 2021, we collected our research data through an online questionnaire administered to students in the VCP. Twenty-seven students responded to the survey, representing a 73% response rate. The following paragraphs explain the measures we used in the survey and how we proceeded with the data analysis.

3.2 Sample and measures

Multi-item measures assessed (1) entrepreneurial learning, (2) challenges experienced from COVID-19 and (3) progress of students' ventures. We also asked whether students had entered or exited an entrepreneurial project and whether these projects were run by a team or only the individual student.

Entrepreneurial learning was measured using four items adapted from Funken et al. [15] and rated using a seven-point Likert scale, where 1 = Not at all and 7 = To a very large extent. The questionnaire items were: 'In the last year, I have…' (a) '…learned to develop and implement business strategies', (b) '…developed my capability to make a great deal of progress towards building a viable business venture', (c) '…learned to run the new venture more effectively' and (d) '…learned to read the signs of whether the new venture has difficulties'.

Challenge from COVID-19 was measured using a custom-made scale for the present paper, since the COVID-19 pandemic represents a unique and novel situation. For each item, the respondent was asked to answer using a seven-point Likert scale, where 1 = Not at all and 7 = To a very large extent. The questionnaire items were: 'In the last year, the pandemic has given me problems in relation to…' (a) '...discussing with others in the study programme', (b) '…participating in lectures', (c) '…communicating with my new venture team' and (d) '...getting/keeping in touch with customers and partners'.

New venture progress was measured using three items adapted from Funken et al. [15] and rated using a seven-point Likert scale, where 1 = Not at all and 7 = To a very large extent. The questionnaire items were: 'In the last year…' (a) '...the new venture has made good progress', (b) '…the likelihood for new venture success has been enhanced' and (c) '...the new venture has developed substantially'.

Entrepreneurial entry was measured with yes/no (yes = 1) alternatives to the question, 'In the last year, I have started or involved myself in at least one new venture'. Entrepreneurial exit was measured with yes/no (yes = 1) alternatives to the question 'In the last year, I have exited at least one new venture'. Table 1 presents the descriptive statistics for the variables.

Table 1. Descriptive statistics

Measure	Chro.a	Mean	SD	Min.	Max.	FNT	CP	FMT
Entrepreneurial learning	0.91	4.78	1.56	2	7	2.75	4.60	6.25
Challenge from COVID-19	0.83	4.14	1.32	2	7	2.75	4.00	5.25
New venture progress	0.96	4.35	2.05	1	7	1.33	4.66	6.33
Entrepreneurial entry	–	0.79	0.41	0	1	–	–	–
Entrepreneurial exit	–	0.42	0.50	0	1	–	–	–

SD=standard deviation, FNT=full non-membership threshold, CP=crossover point, FMT=full membership threshold [19]

3.3 Fuzzy-set qualitative comparative analysis

To be consistent with the research model, we included only students who were involved in a start-up, and three responses were thus removed from the sample. We applied fuzzy-set qualitative comparative analysis (fsQCA) to analyse our data. FsQCA offers the opportunity to investigate complex logic combinations of factors that explain an outcome and is particularly suited for small samples [17]. The package 'fuzzy' by Longest and Vaisey [18] was used in STATA/MP version 17.

FsQCA requires that values of all variables range from 0 to 1, where 1 represents 'full membership', meaning that a condition is fully in place, and 0 the opposite. While already dichotomous variables are ready for fsQCA, Likert-scale variables need calibration before analysis. We used the direct approach described by Ragin [18]. The values for full non-membership thresholds, crossover points and full membership thresholds are presented in Table 1. Solution consistencies indicate a well-fit model (solution consistency > 0.9).

4 RESULTS AND DISCUSSION

The results from the fsQCA are presented in Table 2, which reveals three sets of how the included factors combined explain students' entrepreneurial learning or the absence thereof. One set (Set 1) explains entrepreneurial learning (Entr.learn = 1) and two sets (Sets 2 and 3) explain the absence of entrepreneurial learning (Entr.learn = 0).

Table 2. Truth table from the fsQCA

Set	Chall.	Vent.prog.	Entr.ent.	Entr.exit	Entr.learn.	R.Cov.	U.Cov.	S.Con.
1	0	1	1	1	1	0.192	0.192	0.901
2	1	0	0	–	0	0.149	0.094	0.916
3	1	–	0	1	0	0.055	0.000	0.982

R.Cov.=raw coverage, U.Cov.=unique coverage, S.Con.=solution consistency. '1' means that a factor is present, '0' means that a factor is absent and '–' means that the factor is not relevant in the set.

Using the notation from the research model in Eq. (1), the solution leading to entrepreneurial learning in Set 1 (in Table 2) may therefore be expressed as in Eq. (2). '~' denotes the inverse of a condition, which is the absence of a factor.

$$entr.learning = {\sim}challenge * venture\ progress * entr.entry * entr.exit \quad (2).$$

Similarly, the solutions leading to the absence of entrepreneurial learning in Sets 2 and 3 (in Table 2) may be simplified to Eq. (3).

$${\sim}entr.learning = challenge * {\sim}entr.entry * ({\sim}venture\ progress + entr.exit) \quad (3).$$

Eq. (2) shows that new venture progress and entrepreneurial entry and exit, as well as an absence of pandemic-induced challenges, were necessary for entrepreneurial learning. Using Eq. (3), we found that pandemic-induced challenges and the absence of entrepreneurial entry were necessary for the absence of entrepreneurial learning. Entrepreneurial exit during the pandemic hindered entrepreneurial learning. Additionally, either the absence of new venture progress or entrepreneurial exit completes the two pathways that explain the absence of entrepreneurial learning. Thus, one finding of the present paper is that all four factors in the research model in Eq. (1) were relevant for explaining entrepreneurial learning.

Even though fsQCA operates with the existence or non-existence of an outcome, entrepreneurial learning is, in practice, not either-or but rather relatively more or less learning. Thus, the results suggest that the combination of factors on the right side of Eq. (2) facilitates entrepreneurial learning, while the combination of factors on the right side of Eq. (3) prevents entrepreneurial learning. Challenges from COVID-19 are therefore found to counteract entrepreneurial learning to some degree, while new venture progress, as expected, facilitates entrepreneurial learning. Interestingly, the combination of entrepreneurial exit and entrepreneurial entry, in addition to progress in the new venture, was found to be necessary for entrepreneurial learning. Assuming that the progress is in the new venture that was entered, this finding points to some interesting dynamics. For instance, some ventures may be severely impacted by COVID-19, to the point that a student entrepreneur chooses to exit that venture. However, the process of experiencing and handling that process could potentially facilitate the student's learning. In contrast, a lack of new venture progress or entrepreneurial exit without entrepreneurial entry (see Eq. (2) and Eq. (3)) did not facilitate learning to the same degree, given that the student had experienced high levels of COVID-19-induced challenges.

The present paper cannot prove causality between, for instance, new venture progress and entrepreneurial exit or entry, between COVID-19-induced challenges and new venture progress, or between COVID-19-induced challenges and entrepreneurial exit. Thus, there may be processual dynamics that can provide clearer models and conceptualisations of how crisis-induced challenges influence the entrepreneurial learning of students in VCPs. However, the results of the present paper suggest that while challenging events such as exiting and entering a venture facilitate learning as long as there is progression in the new venture, challenges combined with stagnation prevent learning. Not only is new venture progress important for entrepreneurial learning in VCPs, but also progression for individual students. In other words, it is important that VCP students get ‘back on the horse’ during a challenging situation to avoid passiveness and stagnation. For action-based entrepreneurship education in which students learn through entrepreneurship, faculty should be aware of how active progression for the individual student is important for learning and ensure that students who experience difficulties handle those difficulties within their current venture or choose to become part of another venture in which progress can be made and experienced. Faculty providing challenge- and problem-based engineering education should balance the levels of challenges that students are exposed to, strive for some degree of progression and help students avoid too much stagnation in the activities and projects they are involved in [11].

5 SUMMARY

The purpose of the present paper was to investigate the role of COVID-19-induced challenges in VCP students’ learning. Through an empirical study of students in a technology-oriented VCP in Scandinavia, the present paper found that COVID-19-induced challenges prevented VCP students’ learning. Interestingly, the findings of the present paper further suggest that students’ individual progress was important for learning during crisis situations. An implication for entrepreneurship educators is to help students get ‘back on the horse’—involved in new entrepreneurial projects—if challenges in the current venture lead to stagnation and inactivity. The adversity presented by COVID-19 is an example of what could present too much of a challenge for VCP students. The present paper therefore contributes to entrepreneurship education research by suggesting that learning from failure should be followed by new entrepreneurial endeavours [8] and by pinpointing that learning through being active in a new venture is essential for entrepreneurial learning regardless [5].

ABSTRACT

Integration of entrepreneurship in current engineering education emphasises the need for engineers to initiate and drive innovation processes that transform ideas into societal value. Learnings from the history of engineering and the at times unsustainable impact of technology on society have drawn attention to user

[1] *Corresponding Author: J.E. Holgaard, jeh@plan.aau.dk*

doi:10.5821/conference-9788412322262.1266

requirements and the societal context of technological innovations. In addition to this view, entrepreneurial education underlines the need to move beyond reactively addressing user requirements and societal developments to proactively creating opportunities and realising their potential to change societal patterns and trajectories. Grand challenges, such as climate change and the recent COVID-19 pandemic, have indeed confirmed the need for such abilities. This paper argues that when integrating entrepreneurship in engineering education, the pedagogical approach to how we teach entrepreneurial engineering will inevitably have to be revisited. The study aims to explore the facilitation of entrepreneurial projects in a problem-based learning (PBL) environment. Design-based research (DBR) was conducted to co-develop and test guidelines and models for entrepreneurial PBL based on existing PBL approaches. In this process, ten facilitators of entrepreneurial PBL projects were continuously challenged to change their perspective from being facilitators to students and from being practitioners to reflective practitioners. In this paper, we especially report on the part of the study investigating the following question: What challenges do students experience when PBL becomes entrepreneurial? The paper concludes with insights into the nuances of entrepreneurial PBL and closes with a short discussion on the need for more research to ensure integration and not the addition of entrepreneurship in engineering education.

1 INTRODUCTION

“We live in a rapidly changing society where it is essential that everyone has the capacity to act upon opportunities and ideas, to work with others, to manage dynamic carriers and shape the future for the common good. To achieve these goals we need people, teams and organisations with an entrepreneurial mindset, in every aspect of life.” [1, p. 3]

On this note, the European Commission presented the European Entrepreneurship Competence Framework (EntreComp), distinguishing between three pillars of entrepreneurial competencies in the following way [1]:

1. ideas and opportunities, including the competencies related to spotting opportunities, creativity, vision, valuing ideas and ethical and sustainable thinking;
2. resources, including competencies related to motivation and perseverance, self-awareness and self-efficacy, financial and economic literacy, mobilising others and mobilising resources;
3. into action, including learning through experience, working with others, planning and management, taking the initiative and coping with ambiguity, uncertainty and risk.

This framework for competencies relates to the whole entrepreneurial process from idea to value creation, and the focus on going “into action” captures both the learning “about”, “for” and “through” entrepreneurship [2]. Thrane et al. [3] argue for a learning ”through” strategy, where the learning experience is seen as a co-evolutionary process. Mäkimurto-Koivuma and Belt [4] suggest adding learning “in” entrepreneurship to underline the importance of experiencing entrepreneurship in a real-life context. Aligned with this approach, Mäkimurto-Koivuma and Belt [4] highlight active learning methods for learning “in” and “through” entrepreneurship, with reference to Graaff and Kolmos [5].

Problem-based learning (PBL) is one of the approaches which makes use of active learning methods. A PBL curriculum combines specific cognitive, collaborative and content-related strategies [6]. From a cognitive point of view, learning is based on experiences with real-life problems, and learning is collaboratively organised in participant-directed teams working on projects. Content-wise, learning is interdisciplinary and exemplary and emphasises theory as well as practice.

The focus on real-life problems as the starting point in PBL will offer students the opportunity to experience entrepreneurship in a real-life context, and the focus on collaborative learning embedded in PBL is aligned with the view of entrepreneurship as a co-evolutionary process. However, as with any other pedagogical model, there is, and should be, sensitivity towards the context of use, and in this case we are specifically interested in distinguishing PBL and entrepreneurial PBL to address specific concerns for the entrepreneurial project. More specifically, we work from the following research question:

What challenges do students experience when PBL becomes entrepreneurial?

2 METHODOLOGY

Challenges for students in entrepreneurial PBL are addressed as a part of a longitudinal design-based study. This study has as its primary purpose to clarify principles for facilitating students who want to pursue an idea by initiating a start-up project with a view to creating value and business, or at least a business plan, based on an idea. In the following, the overall research design of this longitudinal design-based study is presented together with the more specific context and methods used to study students’ challenges in entrepreneurial PBL.

2.1 Research design – a longitudinal design-based study

This study follows the conduct design-based research (DBR) presented by Reimann [7] including the following three phases:

1. preparing the experiment, including clarifying instructional goals and starting points, envisioning a learning trajectory and placing the experiment in a theoretical context;
2. experimenting to support learning, including collecting data in cycles of design and analysis, applying interpretive frameworks and formulating and testing domain-specific instructional theories;
3. conducting retrospective analysis, including argumentative grammar, establishing trust in the findings and ensuring repeatability and generalisability.

Specific for DBR are multiple iterations, the development of learning theories along with innovative real-life practices, development of design principles and, last but not least, collaborative partnerships between researchers and practitioners [8].

This longitudinal DBR has as its main purpose to improve the facilitation of entrepreneurial PBL by an improved awareness of the distinct types of competences, problem design and project organisation needed for entrepreneurship as well as the following implications for teaching practice. An overview of the first part of the study (co-creating the guides) is pictured in figure 1.

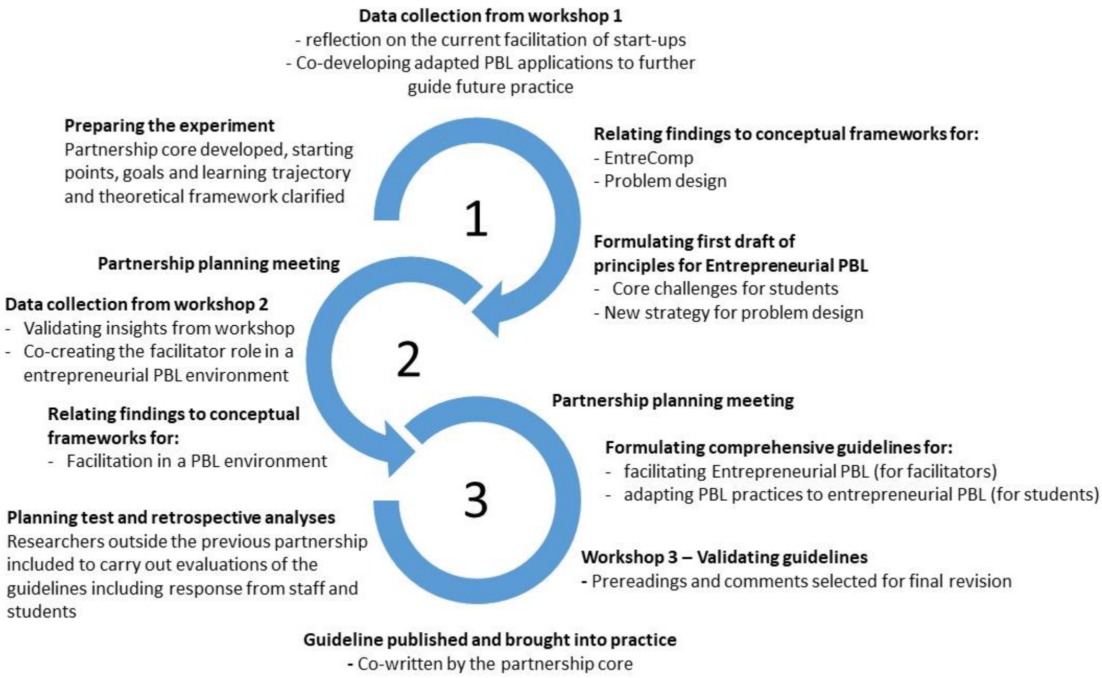

Fig. 1. Overview of the first part of the longitudinal design-based study; the second part of the third iteration includes evaluation and revision of the guides to be carried out in 2022/2023.

A guide for staff to facilitate entrepreneurial PBL and a guide to support students in carrying out a problem-based and entrepreneurial project have served as the main boundary objects to formulate actual design principles for the facilitation process. The ambition has been to co-construct the guide in a partnership between PBL researchers and facilitators.

From 2019 to 2020, ten facilitators of entrepreneurial PBL projects were continuously challenged to change their perspective from being facilitators to students and from being practitioners to reflective practitioners. They were introduced to cases and asked to reflect on the challenges students typically face in different phases of a project and the themes, questions and advice in which this would likely result. They were challenged to put themselves in the role of the students making a problem design and thereby to identify, analyse and formulate the problem using PBL methodology and to provide input to matches and mismatches, which informed new adapted instructional models. They were challenged to reflect on their own role as a facilitator in the entrepreneurial project and to reflect on their own learning style and differences in the way they (to their surprise) advised students during the different phases of the entrepreneurial project. Furthermore, they were challenged to view facilitation as an impact on organisational learning and to consider the importance of collective interpretations and shared-meaning structures in entrepreneurial project groups.

Data were primarily collected by feedback sheets, on which groups of participants as well as individuals were asked to provide short written statements summarising their main concerns and reflections. These feedback sheets followed a previously fixed structure with themes and overall questions for the groups/individuals to fill out. After the workshops, the data were collected and summarised to be presented at the subsequent workshops. Furthermore, when writing up the guides [9,10], the insights from participants were supplemented with other sources.

In this paper, we report in particular on the part of the study investigating the challenges students experience when PBL becomes entrepreneurial. The empirical base for this part was created during the first iteration at workshop 1. The group was working from a fictive case, picturing a group of media technology students having the idea of creating an intelligent walker to assist walking-impaired persons in new ways. The start-up was integrated in a half-year problem-based project of 15 european credits according to the european credit transfer system (approx. 450 working hours per student). In three groups, the participants were asked to decide on the core challenges that students would most likely experience at the beginning, middle and end of the semester project. All participants were experienced facilitators of entrepreneurial projects. The findings were validated in the second iteration at workshop 2 and were further used to guide facilitation practices in the third iteration.

3 RESULTS

Table 1 presents the key challenges that facilitators noted as common for students working on entrepreneurial projects. Based on these insights as well as the follow-up questions related to the themes, questions and advice in which such challenges would most likely result, the challenges where grouped according to three themes. One theme centres around the power of the idea, another around the need to cross traditional borders and, last but not least, a final theme relates to the resilience needed on the part of students to work on insecure ground.

3.1 Challenge 1: Tunnel vision – the power of the idea

This first challenge centres around one of the more fundamental barriers to entrepreneurship, that is reluctance to “kill you darlings”. The idea is, as such a darling, it holds an embedded promise and perceived greatness that make students risk actually engaging in a start-up. As can be seen from Table 1, unrealistic expectations about the potential of the idea and blind spots related to already similar solutions are symptoms of an idea-generated tunnel vision.

Table 1. Key challenges at the beginning, mid and final stage of the start-up project. The challenges are presented directly as noted by facilitators (translated into English).

Beginning	Mid-term	Final stage
- Unsure about what it takes and where to start – need help to proceed - Unrealistic expectations about the potential of the idea - Insecure about a lot of things – resources, competencies, benefit/potential, impact on personal life - Too far in the process considering what they actually need (they lack insight) - Having a hard time approaching users/customers (validation)	- Having a hard time understanding what they have signed up for - Having a hard time defining the business model - Lack of professional competencies - Lacking an overview of how to present their idea to external panels - Are blind to knowledge suggesting that the idea “exists” and no further iteration is possible - Having a hard time making a time schedule and setting up targets - There is (still) a typical lack of validation	- Motivation to do enough and the right things (move into execution mode) - Developing a prototype - Prove concept and test business model - Access to user groups - Lack of resources - Lack of funding in general and for prototyping - Lack of “squid” competences - Having a lot of excuses why it was not possible (for me) including personal/private circumstances - They are stuck – no progress

The impact of not questioning the idea can furthermore have a negative spin-off effect on the motivation to validate the market potential of the idea. Why validate what is already perfect, and why question potential consumers when it is just a matter of convincing them about the brilliant prospects of this idea? The facilitators experienced that such an attitude, although caricatured in this context, can be a barrier, can bypass or slow down the process of validating market potentials and outlining value propositions in the business modelling process. However, as competence frameworks like EntreComp [1] do not specifically highlight the importance of critical thinking, it can also be argued that this is a more general blind spot in the outline of an entrepreneurial mindset.

3.2 Challenge 2: Intensified boundary work

The overview of student challenges provided by facilitators show that students have to cross different boundaries during their entrepreneurial project.

First of all, the process of entrepreneurial PBL is different from more traditional PBL processes due to the central focus on the idea in the problem-design process. Facilitators experience the problem-design process as challenging for students, as they have a hard time planning the process and getting an overview of expected deliveries. This challenge for students to transfer planning experiences from a PBL project to entrepreneurial PBL was, nevertheless, also considered a challenge for the facilitators. In the guideline [9,10], a specific focus was therefore on providing a road map of the problem-design process in entrepreneurial PBL, not as a matter of fact but as a frame of reference to guide student-directed entrepreneurial projects.

Secondly, the increased focus on business modelling in entrepreneurial PBL outlines a process that calls for interdisciplinary interaction; as in any business, different professions are needed to generate value out of ideas. Furthermore, there is an intensified need for transdisciplinary collaboration as interaction with potential user groups is considered a necessity in the entrepreneurial mindset. Facilitators reported the need to push students out of their comfort zone of the university. The challenges in the last phase of the process (see Table 1) indicate that such a lack of drive can result in some rather extensive and comprehensive challenges in the last phase of the project. Stakeholder interaction is needed in order to validate assumptions of user needs, provide proof of a concept, make a prototype and test the business model, etc. The iterative nature of entrepreneurship calls for not just one but continuous interaction with key stakeholders.

3.3 Challenge 3: Lacking resilience

Finally, Table 1 also illustrates the personal dimension of entrepreneurship. These identified challenges relate very much to competences stressed in the EntreComp framework, such as self-awareness and self-efficacy, motivation and perseverance as well as coping with ambiguity, uncertainty and risk. It should be noted that in this case these challenges are observed among students who are experienced with self-directed learning and open-ended problem-based projects involving a high degree of uncertainty. This fact puts the insecurity level for an entrepreneurial newcomer into perspective. As noted in Table 1, students in start-ups feel insecure about a lot of things – resources, competencies, benefit/potential of the idea and even about how this will impact their personal life. Facilitators therefore stressed the importance of questioning students to find out what the uncertainty is about, how they feel about it and why. In other words, although entrepreneurship is a co-constructing endeavour, it is also a very personal matter.

With respect to this, it is worth noticing that even though learning outcomes are stated on the individual level and what could be called resilience competence is recognised as important for an entrepreneurial mindset, it is typically not an integrated part of the curriculum. Facilitators reported that when students gave up on their idea, they had a hard time acknowledging the learning outcome of the start-up project. This underlines the importance of increased attention to affective learning outcomes in the curricula of entrepreneurship education and the need for taxonomies to assess students' abilities to establish and uphold resilience.

4 SUMMARY

In this paper, we have argued for the differences between students' challenges in project-based PBL and entrepreneurial PBL, and we have pointed out key differences in entrepreneurial PBL due to the power of the idea, the intensified need for boundary work and the ambiguity and uncertainty of the entrepreneurial problem-based project. From the outset, we have also argued for the need for more research on curricula design for entrepreneurship, and we have highlighted critical thinking, adapted models for problem design and affective learning outcomes as potential areas of research. As entrepreneurship is a fundamental element of technological innovation, our engineering education research communities are, in our view, central players.

5 ACKNOWLEDGMENTS

This research has been made possible by the project "Start-up in praxis" (SIP), a 3-year project that seeks to develop and integrate internships in start-ups. The project is a collaboration between Aalborg University, Copenhagen Business School, Copenhagen University, Aarhus University and the Danish Foundation for Entrepreneurship. The project is funded by the European Social and Regional Development Fund.

the newly acquired skills and experience with remote teaching and digital learning media? Here, we present the findings of the first European-Union-wide survey on the potential long-term impacts of COVID-19 on higher education, evaluating over 800 responses from students and faculty members of higher education institutions located in 17 different European countries. Our survey – developed in the context of the ide3a university alliance (http://ide3a.net/) highlights possible differences between students and instructors in their attitude toward retaining digital teaching formats and media, examines which formats have increased in use over the course of the pandemic, and investigates which of them are intended to be kept and consolidated post-pandemic. The tools and formats examined in this survey include tools for communication and collaboration, formats of didactic activity, as well as assessment formats. Survey responses reveal that all evaluated tools and format have significantly increased in use during the pandemic and most of them are intended to be used at lower frequency in the future, while still at significantly higher frequency than before the pandemic. Moreover, attitudes toward long-term use of remote teaching and digital learning media seems to be comparable between students and faculty members, except regarding some tools.

1 INTRODUCTION

1.1 Background

Over the course of the COVID-19 pandemic, remote teaching and various digital learning media ensured that higher education could continue. Two years after the initial shift to ‘Emergency Remote Teaching’, institutions all over Europe are either returning to presence formats or converging towards hybrid formats. As many tools and formats were new to many students and instructors, the pandemic may have provided a glimpse into an entirely transformed educational system [1]. However, the transition to remote teaching was not strategically planned and occurred as an emergency shift in most cases. Thus, the question whether digital education formats will persist in post-pandemic scenarios and, if so, which tools and formats students and instructors will want to use remains unsolved. Other studies to date have evaluated the reception of the shift to emergency remote teaching and pandemic experiences [2],[3]. Yet, to the authors knowledge, none of them examined the attitude of students and instructors toward long-term changes. Their focus on (early) pandemic experiences and limited, sector-specific, samples make it difficult to evaluate whether the pandemic has the potential to cause an overall lasting paradigm shift in higher education in Europe [3],[4].

1.2 Research Objectives and Hypotheses

This paper examines in how far students and instructors alike intend to utilize remote teaching and digital learning media within higher education across Europe in the long-term. Given that the weight of additional effort related to remote teaching and digital learning is distributed differently between the two groups [5], we also investigate whether there is a difference in attitudes toward teaching formats between students and instructors. The two hypotheses tested in this paper are as follows: H1) a large majority of formats used during emergency remote teaching will be kept long-term, post-pandemic (by both students and faculty members); H2) attitudes towards using e-learning formats post-pandemic differ between instructors and students. To test these two hypotheses, we conducted an online survey between August 2021 and January 2022 investigating the attitudes and intended frequencies of use of remote teaching and digital learning media with students and instructors from different universities in Europe.

2 METHODS

2.1 Participants

The sample of survey respondents (after data cleaning) consisted of 658 students from 14 different European countries and 121 faculty members from 13 different European countries. Figure 1 summarizes the geographical distribution of respondents (A and B), as well as participating students' age (C), faculty members' years of teaching experience (D), and faculty members' role in their institution (E).

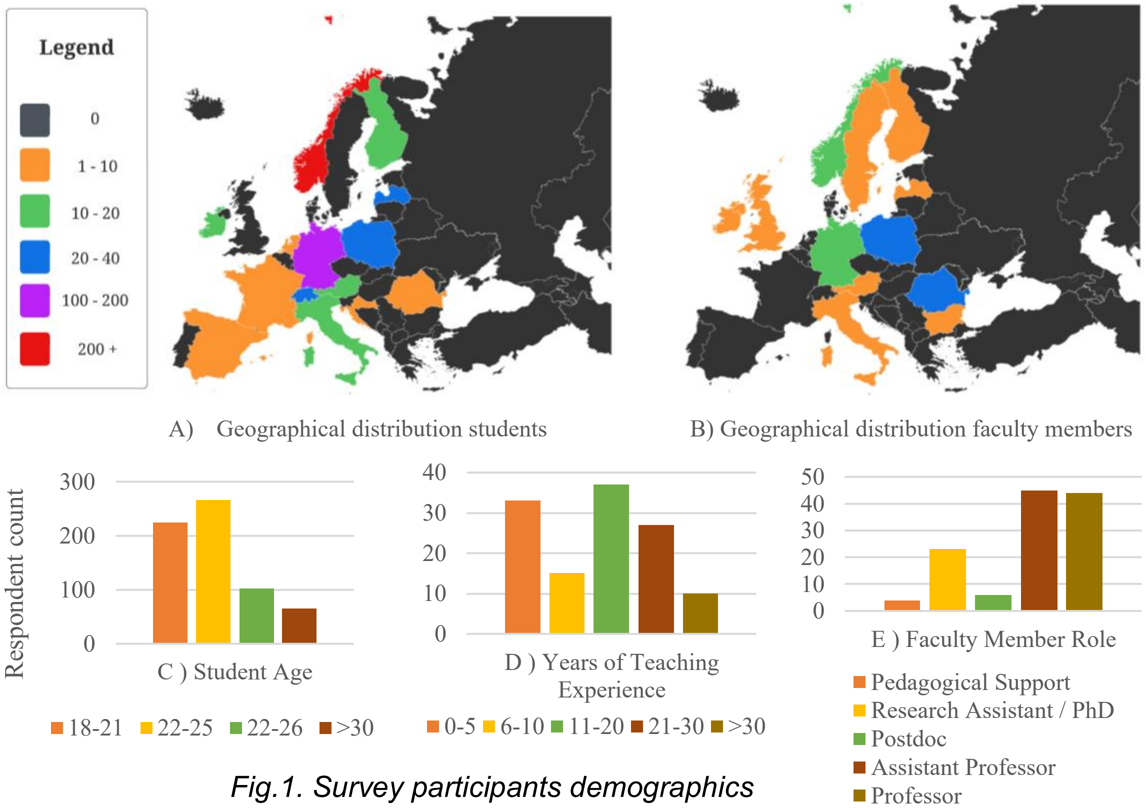

Fig.1. Survey participants demographics

2.2 Survey Design

Our online survey consisted of two sections: (i) one section on demographic data and categorical attitude evaluation and (ii) one section evaluating the frequency of use of remote teaching and digital learning media. Tartavulea et al. [6] investigated how the frequency of use changed for a limited list of tools and formats at the beginning of the pandemic. Our survey builds on that list to compare results. Additionally, given that their study only captured a brief influence of the pandemic as it was conducted in April 2020, we extend its scope to include late-pandemic aspects and post-pandemic intentions.

Participants were asked to indicate their frequency of use for 21 tools and instructional methods, before and during the pandemic, as well as their intended frequency of use after the pandemic. Tools were categorised into those used for communication (6 tools), collaboration (3 tools), formats of didactic activity (6 formats), and assessment formats (6 formats and tools). Tool use frequency was determined on a 4-point Likert Scale (1 = not at all, 2 = rarely, 3 = sometimes, 4 = frequently), while also allowing participants to select that they were 'Unsure' [7].

Within the categorical section, questions were either of 'yes/no' nature or prompted participants to indicate the extent to which a statement was true, out of a given set of options. Participants who were located outside of Europe or were neither a student nor a faculty member at the time of the survey were automatically exempted from continuing the survey.

2.3 Statistical Analysis

To test H1, a two-way repeated measures ANOVA on actual and intended frequency of tool use was carried out using SPSS, comparing both students and faculty members groups. H2 was tested using a one-way between subjects ANOVA on various separate categorical variables [8], [9].

3 RESULTS

3.1 Pre-pandemic, Present, and Intended Post-pandemic Frequency of Use

All evaluated tools and formats increased in frequency of use during the pandemic across both students and faculty members, except from e-mailing, which was equal to pre-pandemic times for faculty members. The intended frequency of use after the pandemic indicates that most tools (16 of the total 21) are intended to be used at lower frequency than during the pandemic, but all 21 tools will be retained with significantly higher frequency than before the pandemic, both by students and instructors (again except for e-mailing, which remained relatively constant across all three time-points for faculty members). The evaluated tools and formats can be categorised into different clusters according to the intended post-pandemic frequency of use by the participant groups. Table 1 summarizes all findings on tool and format frequency use before, during and intended use after the pandemic, reporting the mean and standard deviation (Std. Dev.). It further indicates the different clusters by colour. The clusters are described in the following.

The tools and formats that both groups want to continue using at the same level of frequency as during the pandemic are indicated in pale yellow in Table 1 and consist of crowd questioning tools, asynchronous digital group work, and media production for assessment. These tools and formats show no significant frequency change to during the pandemic. Forum and collaborative text editors also want to be kept at the same level of frequency as during the pandemic, but students want to retain them with significantly higher frequency than faculty members.

Tools which students want to use even more frequently than during the pandemic, while instructors intend to keep it at the same level as during, are indicated in pale blue and contain virtual brainstorming tools (such as miro [10]) and asynchronous interaction with digital tools or plug-ins (such as H5P [11]). Interestingly, these tools are also among those with the lowest intended frequency for instructors (together with online ice-breaking sessions). An evaluation of whether familiarity of these tools and willingness to try new formats correlates with intended frequency of use might be useful to explain difference between students and instructors. Asynchronous plug-ins such as H5P were also the least frequently used tool during the pandemic, suggesting low familiarity across both groups.

Tools that students want to use at significantly higher frequency than instructors, although still at lower levels than during the pandemic are indicated in orange in Table 1 and include chat functions, Learning Management Systems (LMS, e.g., Moodle), online quizzes, and digitally supervised exams.

Likewise, tools that instructors want to use at higher frequency than students, although at still lower levels than during the pandemic, are indicated in pale green and include online office hours and online oral examinations (e.g., virtual presentations).

Lastly, tools that both groups would like to use at lower frequency than during the pandemic are indicated in pink and include video conferences for lectures, virtual whiteboards, synchronous digital group work (such as break-out rooms), media production for knowledge transfer, online icebreakers, online submission of assignments, and online projects.

For some of the tools and formats there are also significant differences between students and instructors for frequency of use during the pandemic, which could be explained by the fact that some tools are more aimed to be used across groups and some are for in-group collaboration or communication. The 'collaborative text editor' for example, would be one tool that students use amongst each other, as well as faculty members with each other, but apparently at different frequency. How relevant and useful a certain tool is to a group might also influence their intended frequency of use.

Pre-pandemic, present, and intended post-pandemic frequency of use for several tools and didactic formats was reported in the survey on a 4-point Likert scale (1= not at all, 2 = rarely, 3= sometimes, 4 = frequently). Answers indicating 'Unsure' have been excluded from analysis. N for each tool/format therefore varies. The significant statistical differences at 0.05 level between during vs. before, and after vs. during pandemic are reported as ***. Significant differences at 0.05 level between students and instructors are indicated by 'Yes' or 'No'.

3.2 Attitude towards use of e-learning tools long-term

None of the one-way between subjects ANOVAs conducted on the three questions relating to the analysis of H2 yielded significant differences between students or faculty members. Attitude towards the long-term post-pandemic use of remote teaching and digital learning media therefore appears to be similar.

In response to the question whether participants see the pandemic as an accelerator for the modernization of higher education, response patterns are very similar ($F(1,778) = [.112]$, $p = .738$). The majority (65.8%) of students and faculty members (66.4%) believe the pandemic to be an accelerator for modernization, while 16.1% and 16.4%, respectively do not. 16.1% of students and 13.9% faculty members are unsure, and the remaining 2% and 3.3% are not interested.

Similarly, 62.5% of students and 69.7% of faculty members wish to continue to use remote teaching and digital learning media complementarily to presence teaching, another non-significant difference ($F(1,778) = [.256]$, $p = .613$). Only 12.5% and 8.2% would be glad if teaching stayed mainly remote, also after the pandemic. Also, only

20.2% of students and 19.7% of faculty members believe that these tools are something only to be used in emergencies. A minority of 3.8% students and 0.8% instructors do not want to use remote teaching or digital learning media again. Only 1% and 1.6% respectively are unsure.

Lastly, as for the quality of personal interaction with each other, both groups almost equally agreed that it was worse than before the pandemic (55.7% of students and 60.7% of faculty members). About 26.3% and 31.1% respectively thought it was of adequate quality, and 9% of students and 4.9% of faculty members evaluated it to be even better than before. 9% and 3.3% respectively are unsure. Again, these percentages indicate non-significant differences in attitude between the two groups of interest ($F(1,778) = [.110]$, $p = .740$).

Notably, even though the majorities of both groups indicate the quality of their interaction to have worsened, indicating that certain elements of presence teaching are irreplaceable by its digital counterpart, they both wish to continue using remote teaching elements long-term. The answers to these categorical questions also reflect the desire to decrease entirely digital formats such as video conferences, online projects, and media production for knowledge transfer. While attitude toward long-term use of remote teaching and digital learning media appears to be similar between students and faculty members overall, the results from Section 3.1 indicate that there are differences when it comes to specific tools and formats and how frequently they should be applied.

3.3 Additional Analyses on Respondents' Experience

Analysis of additional categorical questions to account for any prior experience with remote teaching and digital learning media yielded interesting results as well. In response to the question whether participants had knowledge of remote teaching and digital learning media before the pandemic, students indicated significantly more prior knowledge than faculty members, as evaluated using a one-way ANOVA ($F(1,778) = [31.37]$, $p = <.001$). Nonetheless, both groups indicated equally low prior experience with remote teaching or digital learning media.

Faculty members also attended trainings for further education significantly more often than students both before and during the pandemic (($F(1,778) = [14.383]$, $p = <.001$) and ($F(1,778) = [9.919]$, $p = <.001$)) and acquired significantly higher levels of new skills during the shift to emergency remote teaching ($F(1,778) = [50.703]$, $p = <.001$).

4 DISCUSSION AND CONCLUSION

4.1 Discussion and implications

Overall, as evaluated in this Europe-wide online survey, attitudes toward long-term use of remote teaching and digital learning media seems to be comparable between students and faculty members. The majority of students and faculty members would like to use them complementary to presence formats, likely to compensate for the decreased quality of interaction with each other during virtual classes. Evaluating different tools and formats however does reveal differences in preference for frequency of use for certain tools. While the use of remote teaching and digital media increased significantly during the pandemic, almost all evaluated tools and formats want to be used at lower frequency after the pandemic, yet all still more frequently than before the pandemic. This stands in contrast to Tartavulea et al. [6], who, in the beginning of the pandemic, found that certain tools (e.g., virtual whiteboard, pre-recorded videos) would be used at an even higher frequency than during the pandemic.

For a few tools, such as virtual brainstorming software and plug-ins such as H5P, students would even like to use them more frequently than during the pandemic, indicating that instructors should not necessarily follow only their own preferences, but also continue to experiment with tools to cater to their students' needs [12]. The 'winners' of the pandemic tools, which want to be kept at the same frequency of use as during the pandemic, suggest having offered additional pedagogic benefits. These tools were crowd questioning tools, asynchronous digital group work and media production for assessment, as well as the forum function and collaborative text editors. In the context of the ide3a project [13], we have used all of these with great success and believe these tools to be of additional benefit in compensating missing social interaction especially in entirely virtual, international, and collaborative courses.

4.3 Limitations

This study aimed to provide a pan-European perspective on the intended frequency of long-term use of remote teaching and digital learning media. While participants were recruited from 17 different countries, the sample representativity remains somewhat poor. The number of participants per country was neither evenly distributed, nor representative for each country, which is why this study, and its results can only be understood as a glimpse into a European overview, but do not capture country-specific differences or those between different types of study programs (e.g., humanities vs technical). We encourage additional, national, or even local inquiries into the preference of specific tools and teaching formats to complement our aggregated results.

4.4 Recommendations for Further Analyses

Possible interesting additional analyses could include one-way ANOVAs of tools comparing different age groups or different levels of teaching experience to see whether they influence intended frequency of use. It is plausible that especially younger students might be less keen on continuing to use remote teaching, as they are most affected by the lowered social interaction, having never attended presence formats. Additionally, further insights into the psychodynamics of the attitude toward remote teaching and digital learning media could be derived by further quantitative analysis, e.g., using a Technology Acceptance Model (see [14]).

ABSTRACT

Student projects have been widely adopted in software engineering education. Project teams are composed of students in the same institution, and students can meet and communicate face-to-face regularly. The Covid-19 pandemic, however, forced the student projects to rapidly transition to remote mode and adapt to the virtual team. Virtual teams in distributed environments face challenges due to distance factors that separate collaborators from each other. This study aims at investigating the communication challenges student teams encountered and managed to overcome. We report on an analysis of data collected from reports and interviews in the software project course delivered in fall 2020. There were 57 participants, forming 10 project teams in the study. The results show that remote work negatively affects the social aspects of project teams, especially early communication difficulties in a project. The teams were able to handle most identified challenges but had less interest in tackling those that they did not see as a risk to project completion, which would have most likely caused problems in real-world projects. This study improves understanding of communication challenges in student project teams and the findings serve as a resource for course teachers to design student project courses in the context of virtual teams.

1 INTRODUCTION

The recent COVID-19 pandemic has forced many software development teams and developers to remote work instead of working in the traditional office environment. For many software development teams, this sudden shift has changed how team members communicate their work [1]. Similar changes happened also to students' software development projects in universities. Lectures were given remotely, groups had their internal meetings virtually, intensive usage of collaboration and communication tools was forced, and customers and course staff participated remotely in review meetings and other project activities.

The goal of this study is to identify challenges, especially the communication challenges in student projects in which students are forced to rapidly transition to a remote mode and adapt to the virtual team in software development projects. The research questions that guided our study are as follows: *What are the communication-related challenges identified in the students' virtual teams for software development?* and *How are the challenges tackled in virtual teams?*

The rest of the paper is organized as follows. In Section 2 we give an overview of communication in virtual teams. Section 3 covers background information of the case study and describes how data was collected and analyzed. Findings are given in Section 4. The last section concludes the work. This paper is based on a master's thesis [2] of the first author.

2 COMMUNICATION IN VIRTUAL TEAMS

Software development is highly collaborative work. To be successful, adequate communication is needed. Lack of communication or poor communication practices can be a significant factor in project failure. Especially in distributed environments where face-to-face communication is limited, effective communication practices become even more important.

In distributed software development, software products are developed by teams with members from different sites [3]. Virtual teams can be defined as geographically distributed collaborations that rely on technology to communicate and cooperate [4]. Based on the definition, virtual teams can be the opposite of collocated teams. Members of a virtual team are distributed across separate sites, but they work on the same tasks as a team [5]. In distributed projects, there can be one or more virtual teams with distributed members [6].

Communication challenges are constraints that decrease the efficiency and effectiveness of communication, and consequently, they can negatively affect the project's success [7]. Alzoubi and others [7] conducted a systematic literature review on communication challenges in globally distributed agile software development to identify communication challenges and solutions to them. They identified a total of 17 communication challenges and categorized them into six distinct categories: distance differences, team configuration, project characteristics, customer communication, organizational factors, and human factors.

Distance differences refer to geographical and temporal distances between team members. Team configuration is related to team size, team structure, and member changes in the team. Project characteristics cover project domain, project architecture, and project type. Customer communication refers to communication between the team and the customer's representatives. Organizational culture, project management processes, communication tools, and infrastructure characterize organizational factors. Human factors refer to personal differences like language, national culture norms, values, and style of communication, and personal attitudes and skills.

Agile software development can be understood as software development that follows the values and principles defined in the Agile Manifesto [8]. Software development projects in industry and university education are nowadays mainly done using some agile software development model or framework, like Scrum [9]. Calefato and Ebert [10] give an overview of collaboration tools used in agile distributed projects, and Ahmad and others [11] give a systematic mapping study on communication channels and practices in agile software development.

3 CASE STUDY: VIRTUAL STUDENT PROJECTS FOR SOFTWARE DEVELOPMENT

3.1 Study context

To answer the research questions, we studied the software project courses implemented at Tampere University in Finland in fall 2020. The course aims at training students the basic skills and competence for software development. Although the study was done with the computer science students, the content of the course was essentially the same as described by Sten and others [12]. The course forms an essential part of the bachelor's degree studies in computer science and computing. In the course, students worked in a team of approximately six members to develop a software system or improve an existing application for real clients. Students typically take the course during the 3rd year of their studies, and therefore, have at least basic skills and knowledge of the techniques and process of software development. For some students, the course also serves as their first experience in solving a real problem in teams. Besides, each team has a master's degree student who acts as a project manager. Project managers have gained a basic understanding of software product and process management in the software project course and other prerequisite studies. The project course lasts 4 months. The development process applied by the project teams can be generally considered agile [8] and iterative.

3.2 Data collection and analysis

There were 57 participants in the course, and 10 teams were formed. Seven teams had six members and the rest had five members. Two of the teams were international and their working language was English, and the rest teams had only Finnish speaking students. The primary channel for data collection was reports required in the course. A final report was for each team to summarize the project performance and the retrospective. Ideally, the entire team participated in preparing the report. In addition, personal reports were required for every individual to report his/her personal discoveries about the learning and the process of the teamwork in the middle of the project and at the end of it. Open-ended questions such as communication challenges the project teams or individuals encountered and how they reacted were used to elicit feedback from the course participants in both types of reports. The final reports were returned by all 10 teams and the personal reports by 56 out of 57 participants.

All project managers of the teams were invited to participate in voluntary interviews. At the end of the course in January and February 2021, semi-structured interviews were conducted with four project managers. The interview lasted between 45 minutes to 75 minutes. Our purpose was to identify challenges that were not necessarily noticed by the project teams. Besides the questions asked in the reports, challenges identified from the literature were also discussed to determine whether the project team has faced such problems or not.

The course participants were informed that the questions would be used for research purposes, and that it is voluntary to answer the questions. The projects were anonymized using an alphabetical identifier. The course participants were referred to as team members or project managers. The course teacher collected and pre-processed the reports by making only the relevant data accessible for analysis. The open coding technique [13] was applied to interpret and analyze the answers based on the perceived similarity and the common challenge categories identified by Alzoubi and others [7].

4 RESULTS AND DISCUSSION

The COVID-19 pandemic has forced teachers and students to rush into the virtual events of teaching and learning, with inadequate preparation for the unique demands the virtual events post. When the software project course was implemented in fall 2020, students still have limited experience in working in a virtual team. The teams were able to decide their communication practices. They managed to organize regular virtual meetings with team members, project clients, and the course teacher. Most meetings last 30-60 minutes, while others reported that sometimes weekly meetings lasted for several hours. Besides, four teams also arranged coding sessions for members to work on tasks together or at least have a possibility to communicate with others while working on individual tasks. The teams relied on text-based communication tools for daily communication. Synchronous communication was possible but often limited because students often had different schedules and were online at different times.

The teams managed to communicate during the project and experienced different challenges. When 44 out of 56 students seemed to agree that there was enough communication in their teams, as shown in Fig. 1, more than half of the students still would have preferred more face-to-face communication, as shown in Fig. 2.

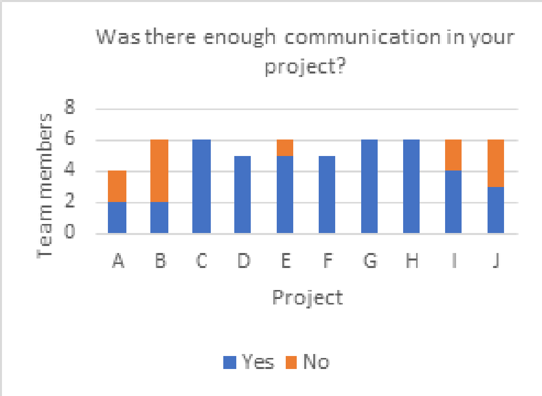

Fig. 1. Sufficiency of communication during the project.

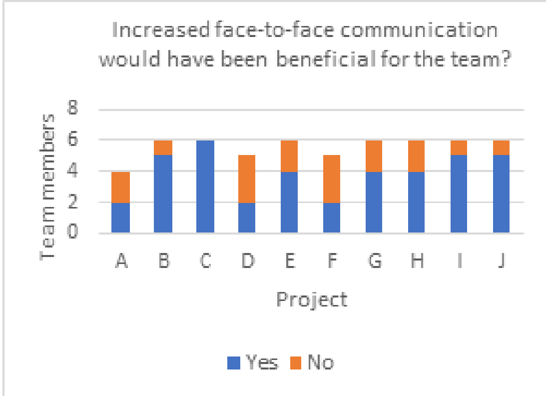

Fig. 2. Would face-to-face communication has been beneficial for the team?

All teams found appropriate communication tools according to their needs and prior experience. The most used communication tool was Slack (used by four teams). Discord and Telegram were used by three teams, and WhatsApp by two teams. The online meetings were held on Zoom (used by four teams), Google Meet (by three teams), Microsoft Teams (by two teams), or Discord (by two teams). Most teams used more than one tool. Some teams used different tools for team meetings and client meetings. For instance, Team C used Zoom for client meetings and Discord for team meetings, while Team J used Zoom for team meetings and Google Meet for client meetings. In the report, it is unclear which tool Team A used for organizing meetings. This may be a signal of insufficient communication within Team A, as reflected in Fig. 1. In addition, some teams used an instant messager, e.g. WhatsApp or Telegram as a reliable way of reaching their team member before they got used to the use of Slack, their primary communication tool.

4.1 Challenges in students' virtual team projects

There were 91 challenges reported in the 56 personal reports. Fig. 3 illustrates the challenges and their distribution in projects.

The most identified challenges are related to team members' skills, reported by 25 students in 9 project teams. They were related to the team's familiarity with the tools or technologies used in the project. Some students also reported skill differences between team members and a steep learning curve of knowledge or skills, especially at the beginning of a project. In addition, 13 members from three teams reported technical problems in project implementation; however, these are related to a particular domain and implementation technologies of the given project.

Time management and scheduling form the next common challenge, reported by 14 students in 8 teams. They were described as procrastination issues such as leaving too much work to the end of a project, inadequate time to finish all features, etc. Many projects had a slow start which led to an unbalanced workload at the later stage. In addition, challenges for team members in different time zones were reported by Project I, and members in Projects D, G, I, and J faced challenges in balancing their studies or full-time work with the project schedule.

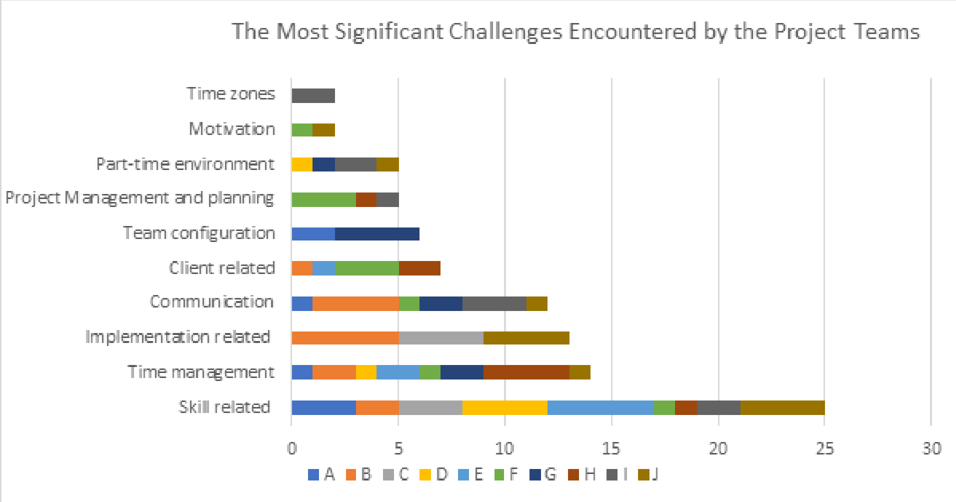

Fig. 3. Challenges identified in personal reports. The chart shows the challenges on the Y-axis and the no. of answers on the X-axis. The color represents the respective team, as indicated in the chart's legend.

Communication challenges were reported by 12 students in 6 teams, among which two teams (B and I) had significant communication challenges, as they were reported by most of the team members. The other four teams have only one or two members reporting such challenges. On the other hand, students in Projects A and G reported team configuration challenges, such as members quitting the project, teams being merged, and the project manager missing at the beginning of a project. These may partly cause communication difficulties. Also, some students reported the issue of misunderstanding project requirements, which implies the challenge of communicating with the clients and understanding their needs.

Besides, three teams have difficulties with project planning, scope management, and project management. These are related to the project managers' competence and skills and are also affected by how smoothly the team communicated with the client above the project objectives and requirements.

4.2 Tackling the challenges

Communication challenges were identified by synthesizing findings in the project team's final reports, personal reports, and interviews with project managers. We adopted the communication challenges and categories presented by Alzoubi and other [7] to summarize the identified challenges, their causes, recognized consequences, and the project teams' solutions in Table 1. The findings show that remote work decreased the feelings of social connection and team cohesion. Even though every team reported they had regular meetings, there are questions regarding the quality and ease of communications. Herein, differences in schedules and differences in skills were the most common challenges.

The difference in team members' schedules was reported in eight teams. It was one typical distance factor causing challenges like delays in communication and difficulties in arranging meetings, as one team mentioned in the final report, "*the main problem was: agile projects need frequent communication. Meanwhile, students do not like to be bothered frequently*". Even though the temporal distance was a common challenge, the teams managed to handle it in various ways, e.g. introducing the 24-hour rule of reading and responding to the posted messages, suggesting members turn on the new message notification in communication tools, being aware of team members' availability to schedule regular meetings in advance, sharing meeting notes, etc.

Table 1. Communication challenges reported by project teams and their solutions. The parentheses include teams that recognized the challenges but did not mention solutions.
(env. – environment, comm. – communication, TM – team member, PJM – project manager)

Category	Cause	Consequence	Solutions	Teams Affected
Geographical distance	Lack face-to-face meetings	Eliminates spontaneous interaction in demo or development env. setting	screen sharing and other tools in online meetings	E, (A)
	Lack of informal comm.	Lack of team cohesion	Improved over time	B, C
	Limited access to project-specific tools	Lack of shared knowledge	Tool demo using videos or shared screen	C
Temporal distance	Different schedules	Delays in communication	24-hour rule, message notification	A, B, E, G, J
		Difficulties in scheduling meetings	scheduling regular meetings in advance	B, C, D, E, F
		TMs absent in meetings	Meeting notes	B
	Different time zones	Difficulties in scheduling meetings	-	I
Comm. tools	Unfamiliarity with tools	Passive/inefficient use of tools	Using alternatives	B, C, E, J
	No use of webcams	Less social cues	-	B, H, J
	Prefer text over voice comm.	More difficult to comm.	-	H, J
	Inefficient use of task boards	Reduced comm. and awareness	Increasing TM's involvement with task board	E, F, (B, H)
	Using multiple tools	Difficult to keep track of all comm. channels	-	F
Customer comm.	Insufficient/miscomm. with the client	Assumptions about requirements or goals	Regular meetings with clients	B, F, (A, H)
Team comm.	TMs were unfamiliar with each other	Early comm. problems	Improved over time, PJM as a role model of active communication	B, C, E
	TMs quit & teams merge	Early comm. problems	Addressing problems in meetings	G, (A)
	Lack of task-related communication	Lack of task awareness, assumptions have to be made	Task boards (e.g. Trello), task dependency model, more meetings for project progress	C, F, A
	Lack of meeting agenda	Inefficient meetings	Adding agenda	C
Human factors	Different learning goals	Not following comm. protocol	-	B, J
	Different skills	Poor understanding or explaining technical concepts	Giving TMs tasks matching their skills	B, C, E, (F)
		Dominated/passive TMs	Involving less active TMs by asking their opinions	C, J, A
	Different language skills	Misunderstandings, passive comm.	-	(H, I A)

Besides, human factors related challenges were identified almost in all projects and were caused by factors such as language differences, the passiveness of team members, skill differences, and the members' motivations or goals. Among which skill differences were the most common ones leading to problems such as difficulties in explaining or understanding technical concepts, experienced team members dominating communication, and misunderstandings. Encouraging communication was the common strategy used by the teams. Specifically, two teams mentioned their strategies such as assigning tasks that match the member's skills and always asking for everyone's opinions during the meeting. However, most teams did not mention any specific solutions to the problems related to skill differences, implying the difficulties and low motivation for the teams to overcome such challenges.

It is remarkable how the virtual teams have adapted so quickly to remote working on the project and that the virtual team setting and limited face-to-face communication did not cause significant communication challenges for most teams. The availability of face-to-face interaction would have made communication smooth and mitigated the difficulties brought at the beginning of a project when team members were not familiar with each other and the team-building efforts had to take place virtually. Face-to-face interaction would have eased the demonstration of code and tools and avoided some technical problems brought by the communication tools. However, most of the communication challenges would have likely remained even if face-to-face interaction was possible. Some teams even seemed to prefer the remote setting due to its benefits, such as, saving time commuting to face-to-face meetings.

The teams solved the encountered challenges reactively. Also, the agile practices adopted by every team, like review meetings, regular team meetings, task boards, etc. helped to communicate and manage project tasks. Typically, the recognized problems were addressed in meetings and the team would decide how to deal with them; while some others were only recognized retrospectively and mentioned in the reports, like those presented in the parentheses in Table 1. The teams were able to handle the most crucial challenges to complete their project. However, the less significant communication problems were often ignored, if they did not see them as a threat to the project's success. For instance, none of the teams used webcams actively, although visual cues can help team members better read each other's emotions in a meeting. The decision of no use of webcam may be related to the team members' personal preferences or technical problems like the webcam not working, poor internet connection, etc. but the teams did not initiate any actions to improve the social cues in communication.

5 CONCLUSIONS

Software development projects are often complex, and they require sufficient communication which is not always easy to achieve. Communication becomes even more difficult in virtual teams in which face-to-face interaction is limited. This study identified communication challenges and their solutions based on software projects worked by university students. Our findings show that remote work negatively affects the social aspects of project teams, especially early communication difficulties in the project. The teams were able to handle most of the recognized challenges in one way or another. The common agile practices like review meetings, regular team meetings, task boards, etc. helped communicate tasks within the team and between the team and the customer. For these teams, communication was mostly a minor challenge, and challenges related to individual's knowledge and skills, project time management, implementation techniques, etc. impacted more on project conducting. The unsolved communication problems were mainly related to human factors. Considering that students might have different motivations to take the project course, we see that the project teams have less interest in tackling challenges that they did see as a risk to project completion. This might have been sufficient for a student project, but in real-world settings, their practices would have potentially caused more significant problems.

In virtual student projects, although most teams found ways to meet regularly, the quality and ease of communication remain challenging. Effective communication helps build trust and enhance understanding. When designing a student project course, it is importance to emphasize the learning objectives and provide sufficient guidance to help project managers and their teams organize meetings at the beginning of the project and discuss with team members not only the tasks and roles of team members but also the recommended practices and tools in communication, and expectations such as use of cameras by remote participants, trust, prompt responses, regular meeting hours, etc.

This study identified many communication challenges that are relevant to university student projects. However, not all the possible challenges could be identified. Students with limited experience may not be aware of all the problems that affect their projects. Our next step is to further investigate the challenges with data collected using different methods from similar projects. This will certainly enrich the understanding of the communication challenges and provide effective guidance for designing student project courses in the context of virtual teams.

ABSTRACT

Doctoral teaching assistants (TAs) provide key support for learning in STEM fields because they are present during exercises, labs and projects when students are actively engaging with course material. While some institutions provide training for TAs, their effect on teaching activities is rarely assessed. We use the lens of Social Cognitive Theory (SCT) to analyse data on the pre and post course teaching priorities of 20 doctoral TAs who followed a 5 day practice-intensive course on STEM HE. Course time was split between instructors modelling interactive teaching strategies to engage TAs in a data-driven reevaluation of their beliefs about teaching and having each TA teach a lesson everyday using a structured feedback loop to promote

doi:10.5821/conference-9788412322262.1148

reflection. TAs reported self efficacy gains for designing instruction, addressing disruptive behaviour and managing student attention spans after the course. Their priorities also appear to shift away from 'teaching' and towards 'learning'. TAs' affective reactions and utility judgements after the course indicated that they thought the course was useful and they intended to use the strategies that they had learnt. This practice and reflection intensive course model, able to accommodate up to 40 TAs, is relevant for institutions seeking to improve the quality of undergraduate education or doctoral candidates' preparation for academic roles.

1 INTRODUCTION

Doctoral programs primarily prepare doctoral students for research, and may not sufficiently prepare them for other aspects of academic life including teaching [1, 2]. Additionally, doctoral candidates often play a key role as teaching assistants (TAs) in undergraduate courses and can contribute significantly to the quality of the learning. In engineering, TAs are present during exercises, labs and projects - i.e. when students are actively engaging with course material [3] and developing key disciplinary thinking skills. The importance of ongoing training is underlined by the high turn-over rate, with approximately half the TAs being new to teaching every year [3]. Investing in TA training is therefore not only relevant to prepare them for their future academic careers (presumably at a different institution) but also for maintaining excellence of the education offered to undergraduates at their current institution.

1.1 Theoretical framework

We use the framework of Social Cognitive Theory (SCT) to explore the effect of a practice-intensive course on the evolution of TAs' teaching priorities. The SCT [4] has been used in multiple fields, including education, to describe how behaviours can be learnt and maintained. One of the key features of the theory is the social dimension of learning, i.e. behaviours are learnt and/or reinforced by observing and interacting with the environment. A very important dimension of the SCT is the importance it places on the role of self-efficacy. Bandura [4] describes self efficacy as "*people's judgement of their capabilities to organize and execute courses of action required to attain designated types of performances*" (p.395). High self-efficacy is a good predictor for higher performance on tasks. However, self-efficacy can be influenced by other social dimensions such as ethnicity and culture [5].

1.2 SCT and self-efficacy in teaching

Prior research has shown that the social dimension of learning is very important for developing teaching behaviours. Teachers draw from the way they were taught and as well as their experiences in research and non-academic roles [6]. Connolly et al. [1] and DeChenne et al. [7] summarise prior work showing a correlation between high self-efficacy and teachers' characteristics of good teaching (learning focus, classroom management skills, willingness to experiment with teaching methods), as well as in TAs (persistence, student achievement). Since self- efficacy develops with experience on task, less experienced teachers tend to focus on their own behaviour (teaching v learning) and worry about student misbehaviour, potentially decreasing implementation of evidence-informed teaching strategies [8]. Bitting et al. [2] collate a series of studies that further link novice faculty's reluctance to implement evidence-informed teaching strategies to low self efficacy and concerns about the effect of negative student feedback on tenure decisions. Therefore, providing opportunities that allow TAs to practice their instructional skills and to develop self-efficacy in lower stakes environments are important dimensions for the pedagogical development of doctoral students.

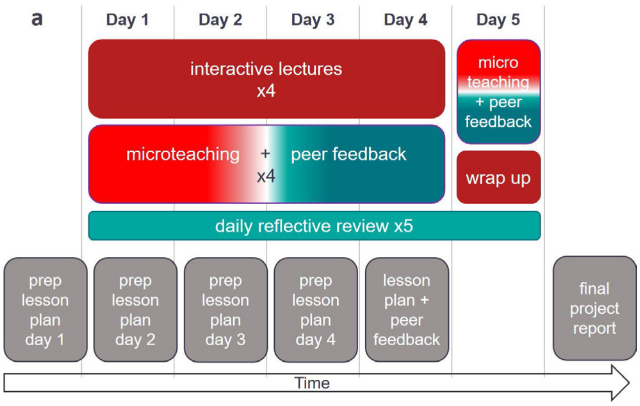
Despite broad agreement about what constitutes good teaching in higher education, (see [8] Ch. 8 for a review), traditional teaching methods persist in STEM labs, exercises and projects. Bitting et al.'s review [2] identifies TAs' tendency to reproduce their own educational experiences (which rarely include interactive courses or inquiry labs) and low self-efficacy for 'novel' pedagogical strategies as barriers to the adoption of evidence-informed approaches. Their review also highlights that "*changes in practice without supporting changes in beliefs are often short lived, inconsistent, or ineffective*" (p.520).

Tormey et al. [9] argue that STEM TAs need "*training which is informed by evidence, which addresses the needs of engineering disciplines and which is short enough so that doctoral assistants will not be discouraged from participation*" (p.379). While rigorous evaluations of STEM TA training programs are scarce [2, 7], three Canadian studies particularly interested us. White et al. [10] found that participants in a two day workshop for STEM TAs did not hold different ideas about teaching than non-participants, however attendees reported they would allocate more class time for student-to-student discussions and lecture less than non-attendees. They conclude that their workshop assisted TAs to identify effective pedagogical strategies. Meadows et al. [11] report that their training with aspects of intercultural communication designed to assist a diverse TA cohort to understand the local teaching and learning culture had better outcomes on teaching self-efficacy, observed teaching effectiveness, and adoption of student-centred approaches to teaching compared to their standard training. Hughes and Ellefson [12] report that biology students whose TAs trained them to ask good questions (*vs.* trained to provide good answers) performed better on the exam.

Our approach has been significantly informed by Tormey et. al.'s nine recommendations for TA training [9, p.383] resulting from their review of teacher education and STEM literature. For example, opportunities to confront their own ideas about good teaching, practising and getting feedback on teaching skills, and addressing the concerns of novice teachers, such as classroom management.

1.3 Description of the course

The format of this course, offered to doctoral TAs at a research-intensive public engineering school, is shown in Figure 1a. The course content focuses on strategies for inteactive teaching informed research evidence from higher education in general with a specific focus on the disciplinary skills and epistemologies of STEM.[2] The key pedagogical innovations are the course activities designed to leverage the principles for developing expertise identified by Tormey and Isaac (2022, p.257). Course time was split between instructors modelling interactive teaching strategies to engage TAs in a data-driven reevaluation of their beliefs about teaching and having each TA teach a lesson everyday. This peer microteaching occured in stable 4-5 person groups and employed a structured feedback loop (Fig. 1b) [13]. The five days of the course spanned 4 weeks to allow participants time to develop their next lesson plan and to complete additional readings. The first two days were entirely on campus and the final three days were hybrid. Daily reflective reviews, where TAs write about what they had learnt, their experience in the microteaching and the implications for their practice, are an integral part of the course. These daily reviews enable instructors to follow TAs' evolving thinking about STEM pedagogy and to provide feedback. Asssessment takes the form of a project report where TAs summarise their teaching evolution through three of Brookfield's lenses: self-reflection, peer-feedback and the literature [14]. TAs' teaching skills did not contribute to course grades.



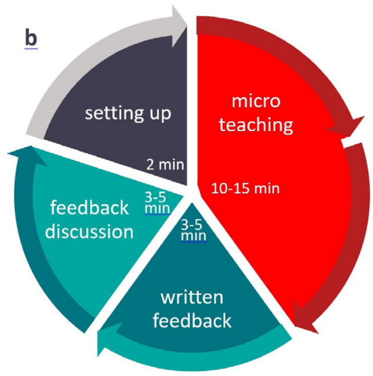


Fig 1. Schematic of (a) the course plan and (b) the microteaching cycle. *The course included daily interactive sessions with the instructors (deep red) as well as an opportunity for each student to teach and get peer feedback (red + teal). Students submit several deliverables (grey + deep teal) before, during, and after the course for teacher feedback.*

The four key components of increasing self-efficacy [15] have been addressed by various aspects of this course:

1. Mastery experience: TAs taught five lessons to their peers during the course. They were advised to use the feedback to design every subsequent lesson.
2. Social modelling: TAs observed their peers teaching and were able to analyse and learn from the strategies they chose to use.
3. Improving physical and emotional states: Since they were teaching their peers TAs were able to gain mastery in a low stress environment. Additionally, they were able

[2] More details available in the course description: https://edu.epfl.ch/coursebook/en/lecturing-and-presenting-in-engineering-ENG-629

to deal with the positive and negative emotions that come from receiving feedback in a supportive environment.

4. Verbal persuasion: TAs got a lot of feedback from their peers as well as from the instructors.

1.4 Research question

While many universities offer some TA training, the impacts are rarely assessed because it is resource intensive. This is unfortunate given the important role TAs play for STEM undergraduate programmes. In our study, we were interested in assessing the impact of a practice-intensive course on the self-efficacy and teaching priorities of doctoral teaching assistants. Specifically, does this course have a measurable impact on TAs' intention and self efficacy to teach in evidence-informed ways?

2 METHODOLOGY

2.1 Participants

2022 represents the 6th edition of this course and its first hybrid iteration. The 20 doctoral TAs came from 12 programmes including Robotics, Photonics, Electrical Engineering, Chemical engineering, and Computational biology. Roughly ¼ of the TAs were in their first 18 months of their PhD and ¼ were in the final phases of completing their doctoral work. All TAs reported that they had some prior teaching experience; 85% reported being a TA for a university level course and 50% had done private academic tutoring. Before starting the course, ⅓ of TAs had read advice about teaching well (n = 7), ⅕ had read at least one educational research paper (n = 4), and ¼ had previously attended one of the various half day pedagogical development workshop offered by our teaching support centre (n = 5).

2.2 Data collection and treatment

To generate relevant observations for our research question, we identified a series of behaviours and strategies that we anticipated course participants would use during their TA duties, such as organising group work or managing disruptions. Course participants' teaching self-efficacy assessments for teaching strategies (4 level agreement Likert scale) and teaching behaviour intentions (temporal scale, ie 5-10 minutes per hour) were collected at two time points: on the first day of the course and on the final day of the course. The final questionnaire had items oriented towards evaluating the course, including utility judgements. Both questionnaires concluded with a free text question. A set of anonymous unique identifying codes was circulated among the students to allow the pre and post data sets to be linked, ensuring that the instructors were unable to link responses to individual students. Given the nature of the study design, it was exempt from a full review of the institutional ethics review board for research involving human participants and was conducted in accordance with our institution guidelines.

This approach generated 21 responses to the pre survey and 19 responses to the post survey. Qualitative analysis and descriptive statistics used the entire data set; however only the 16 data sets which could be paired were used for statistical tests. While the non-normality of our data suggested that a Wilcoxian signed-rank test would be most appropriate to assess pre and post treatment effects, we ultimately employed a paired t-test due to constraints of the Wilcoxian signed-rank test that make it an inapporiate statistical test when ⅓ of participants report only small changes. Pre and post treatment differences for items on the ordinal temporal data scale were determined via a mixed effects ordinal logistic regression (with unique identifier as random intercept).

3 ANALYSIS AND RESULTS

We evaluated TAs' self efficacy assessments for teaching behaviours (Fig. 2). While their responses before the course show that they were already relatively confident about their teaching skills before the course, TAs' reported statistically significant improvements (paired t-test; $p < 0.05$) for 3 behaviours: Directly address students' disruptive behaviour in the moment to allow other students to work efficiently, Manage students' limits in working memory and attention span, and Design instruction using complementary modes of communication and representation. There was no increase in participants' self-assessment of their ability to 'proactively minimise disruptive behaviour'; this is useful feedback for us as instructors. While we did employ some of the proactive strategies for fostering a constructive class climate and avoiding disruptions in the current course, we did not step outside our immediate teaching role to reveal our behind-the-scenes thinking that informed our instructional choices. Nor, given the brevity of their microteaching slots, were TAs able to employ such practices in their own microteaching.

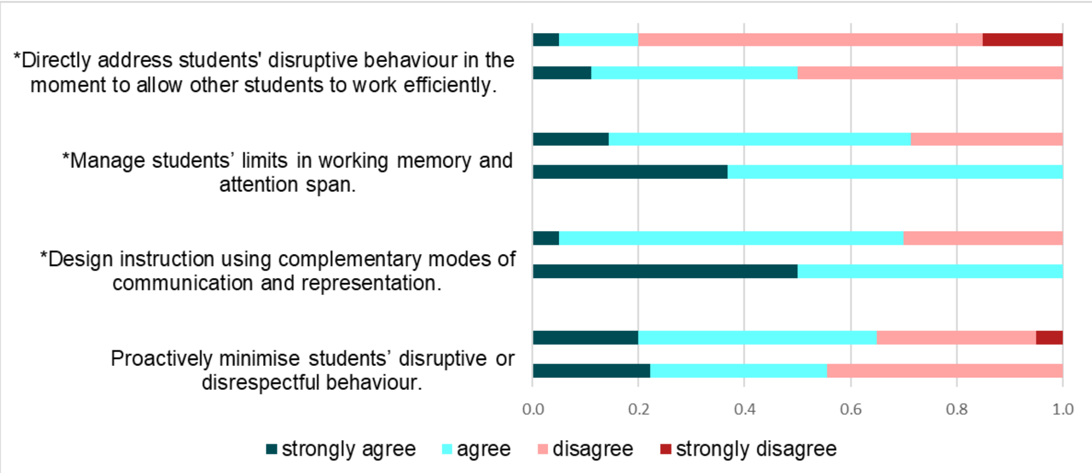

Fig 2. Comparison of TAs' self efficacy assessments for teaching behaviours. *For each item, responses on the first day appear on the upper line and post data on the lower line. Total n= 20 for the chart; missing values are excluded. Paired t-test performed only on the 16 matched questionnaires; * designates items with statistically significant differences at $p < 0.05$.*

TAs' intentions in terms of the number of minutes they would anticipate using various teaching behaviours are shown in Fig. 3. TAs' pre survey responses indicate that when teaching, they devote most of their time to presenting material and modelling their thinking for students. TAs' responses in terms of the time they would spend asking questions to their students, providing students with feedback on their learning or using small group activities spanned the entire spectrum (never to as much as possible). ⅔ of respondents stated that they would spend less than 5 minutes being silent to allow students to think during class.

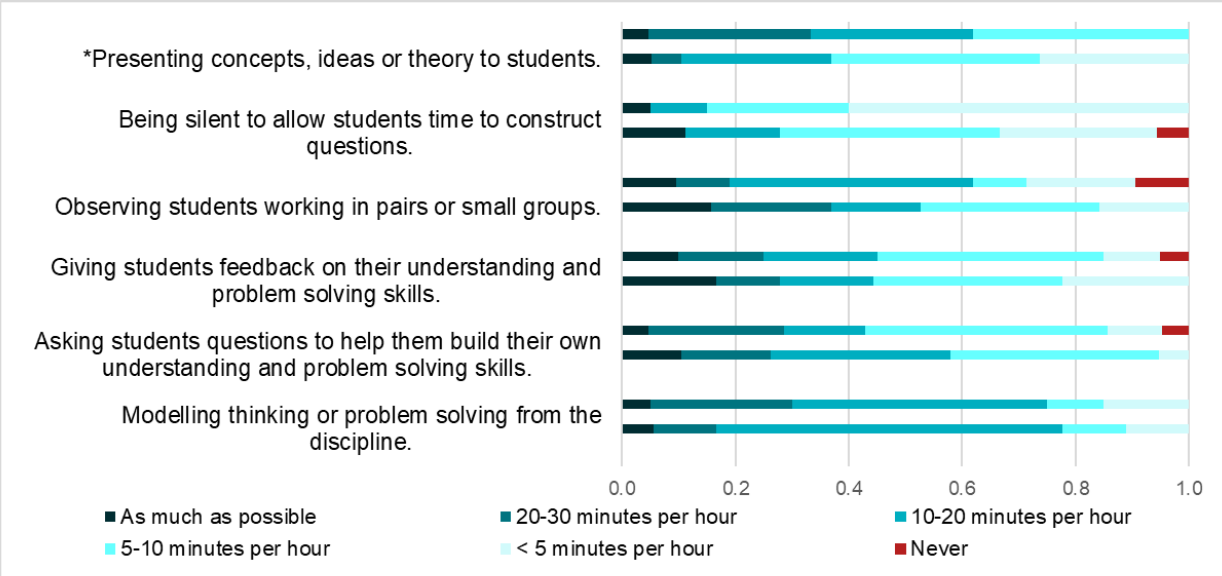

Fig 3. Comparison of TAs' intentions for teaching behaviour *. For each item, responses on the first day appear on the upper line and post data on the lower line. *designates items with statistically significant differences at $p < 0.05$ using a mixed effects ordinal logistic regression (with student code as random intercept) to analyse the data.*

Comparing the pre and post course data from a descriptive approach, TAs report small increases in the time they intend to spend on learning-focused behaviours such as 'Asking students questions to help them build their own understanding and problem solving skills' and 'Observing students working in pairs or small groups'. However these observations were (unsurprisingly given the small sample size) not statistically significant. The one item that had a statistically significant increase was a decrease in the time that TAs intended to spend 'Presenting concepts, ideas or theory to students.' There was not an appreciable difference in the time TAs intended to spend giving students feedback, making the material relevant, being silent and modelling thinking or problem solving. It is interesting to note that, after the course, TAs intended to spend less time presenting to students but to maintain their modelling of thinking or problem solving. This seems to be a pedagogically sound priority.

We also evaluated the TAs' affective reactions and utility judgements [16] following the course (Fig. 4). This allowed us to go beyond simply quantifying their satisfaction and to assessing the utility of the course as well as intentions to put learnt skills into

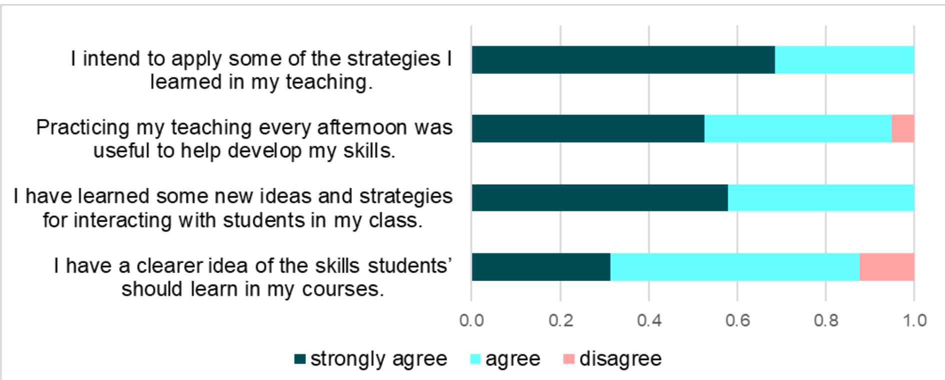

Fig 4. TAs' affective reactions and utility judgements of their experience in the course.

practice. In addition to the TAs thinking that this course was good, and useful in terms of learning and developing new teaching skills, all of them indicated that they intend to apply some of the strategies they learnt in their teaching.

We analysed the free response questions, using qualitative content analysis, to determine the key concepts that emerged. Similar concepts were then grouped together into main themes wherever possible.

Before the course, TAs' responses to the question "What are the three things you would like to improve to be a better teacher?" prioritised the 'teaching' aspect of the teaching and learning process (Fig. 5a).TAs focused on what they, as teachers, would be doing. This included structuring presentations/classes (n = 13), explaining concepts (n = 6), and attracting student attention (n = 4). Some TAs did mention wanting to learn about ways to enhance student engagement (n = 6), pedagogical research that underpins teaching methodologies (n = 4), and how to tailor the material to suit the audience (n = 3).

After the course, TAs' responses to the question "What are the three strategies you found most useful and will be using in your teaching?" indicated a shift in their priorities towards the 'learning' aspect of the teaching and learning process (Fig. 5b). While they still included teacher actions such as lesson planning (n = 16), the main focus was on enhancing student learning by using active learning (n = 16) and various active learning strategies (n = 18). Additionally they spoke about the importance of creating a classroom culture (n = 5) and giving/getting feedback (n = 5) in order to enhance learning.

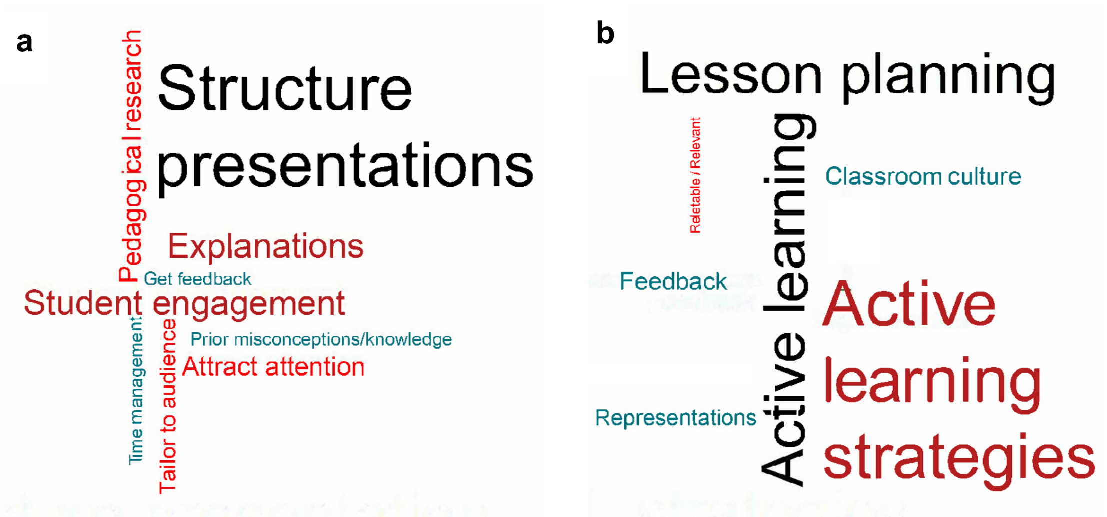

Fig. 5. Main themes from TAs' comments on (a) pre-course and (b) post-course questionnaires. *Size and colour of the font corresponds to the frequency with which these concepts appeared in student responses.*

4 CONCLUSION

This study investigated what TAs thought that they should prioritise in their teaching (a pragmatic approach to teaching philosophy) and how well prepared they feel to realise their prioroties in their teaching (self-efficacy). Our study showed that the course was effective in shifting TAs’ priorities and focus away from teaching and towards learning, including using pedagogical strategies with higher cognitive engagement. TAs also reported increased teaching self-efficacy for the skills which they practiced during the course. Similar effects of TA training programs have been documented in other studies [1, 7, 10, 11]. As Connolly et al. [1] postulated, it is possible that courses such as ours increase TAs' self-efficacy by providing students opportunities to engage in the four key activities for increasing self-efficacy.

At the end of the course, TAs reported positive affective reactions (they liked the course) and utility judgements (they intend to use concepts and strategies from the course). A meta analysis by Alliger et al. [16] identified that intention to use material from a training was more strongly correlated with implementation than direct measures of learning. So while we did not directly observe the impact of the course on TAs’ actual in class teaching behaviours, the shift in their priorities and increased self efficacy is expected to increase their use of evidence-informed teaching strategies. While we are planning a more robust evaluation of this course, the current findings support our practice and reflection intensive model. Further, the course format can accommodate up to 40 TAs without requiring significantly more resources while maintaining all the microteaching and reflection opportunities. This is relevant both within our institution, and potentially for colleagues, in light of institutional priorities around the quality of undergraduate education and doctoral candidates' preparation for academic roles.

ACKNOWLEDGEMENTS

Dr. Mridul Thomas for statistical advice and Dr. Cécile Hardebolle for contributions to developing the course material in previous editions of this course.

ABSTRACT

On the basis of the current state of research, this study identifies and validates future-oriented competencies. Using quantitative social research methods, it then investigates demands in industry. This involved, first, an evaluation of literature and the identification of competencies for research and innovation (R&I) activities. Next, from clusters of the identified competencies I derived 14 different types. On this basis, I generated a competency profile that informs the development of a tool for R&I, the *Wheel of Competencies*. With this newly developed tool specific competency profiles can be generated and analysed.

Second, I operationalized and implemented the competence components in a questionnaire. On this basis, 200 CEOs and heads of research and development (R&D) departments of medium-sized and large enterprises in Germany were surveyed in November and December 2021 using computer-assisted telephone interviews (CATI). All enterprises have at least 50 employees and an in-house R&D department. In addition, enterprises have to belong to one of the following industry sectors: automotive, chemical, electrical or mechanical engineering.

The results show that certain competencies are in very high demand across all industries, while others are more specific to an industry sector. Overall, the results indicate that the competencies in demand address the dynamic complexity in collaborative R&I processes. The results presented here make an important evidence-based contribution to curriculum development in engineering education based on future-oriented competencies and illustrates which transfer activities and collaborative formats are increasingly relevant.

1 INTRODUCTION

To conceptualize Research and Innovation (R&I) activities, the quadruple-helix model is the state of the art to understand the generation and impact of academic knowledge [1]. It explains how collaborations between the sectors academia, industry, politics and society enable sustainable innovations that can drive socio-technical transformations [2].

A means to this end is Knowledge and Technology Transfer (KTT). Here, KTT is not understood as transfer in the sense of its Latin origin from *transferre*, but as exchange and joint generation of knowledge, i.e. a broader understanding.

This generation of knowledge is described as inter- and transdisciplinary as well as application-oriented, so-called mode 2, and is characterized by being "socially accountable and reflexive" [3]. Such knowledge provides answers to grand societal challenges and ‘wicked problems’, because it takes into account their complexity and systemic nature, and also because solutions are developed jointly by actors from different sectors. Currently, this is being discussed under the term ‘new mission-orientation’, in which politically negotiated missions divide complex challenges into manageable problems [4]. An example of this are the Sustainable Development Goals (SDGs) that in turn inform research policies such as EU's Horizon Europe framework program.

However, to collaboratively generate new knowledge and find future-oriented solutions to pressing challenges is no easy task. It makes certain demands of those involved. In particular, activities in innovation ecosystems, i.e. collaborating stakeholders from academia, industry, politics, and society, require competencies and skills that go beyond domain-specific knowledge and abilities. Such competencies are complementary to disciplinary hard skills and socio-communicative soft skills. Which competencies and skills will become more important in the future is the subject of various debates that are conducted under the labels ‘professional skills’, ‘future skills’, ‘transversal or general skills’, ‘transfer skills’, ‘future-oriented competencies’ and ‘emerging skills’.

This study pursues two goals:

> First, it explores the question which (professional) competencies should be developed by actors in R&I collaborations, and,
>
> second, it seeks to validate a profile of such competencies by industry.

To this end, I first reviewed the state of research to identify relevant competencies for R&I activities and KTT in the literature. In a second step, the results were analysed, typologysed, and transferred into a tool. These results were then, in a third step, validated in a quantitative survey of 200 medium-sized and large enterprises. The results complement our understanding of practice-oriented competencies and is relevant for curriculum development in engineering education.

2 METHODOLOGY

2.1 State of Research, Typology and Tool Development

Which competencies will become (more) relevant for collaborative R&I activities in the future (within the German innovation landscape) is the subject of various specialized discourses. My work is based on a broad concept of transfer, i.e. the concept of KTT referring to a dynamic process of generating knowledge in mission-oriented research collaborations [5]. I claim that pertaining to this understanding, works from the fields of transformative sciences, transdisciplinarity, education for sustainable development, key competencies, (future-, professional-, emerging-, 21st century-) skills are relevant. For each of these fields, I surveyed contemporary literature, and evaluated the state of research with a special focus on key literature and mission statements by national academies and advisory bodies, such as German Academy of Science and Engineering, German Advisory Council on Global Change, and Donors' Association for the Promotion of Humanities and Sciences in Germany. To this end, I identified professional skills and competencies for innovation activities.[2]

I build on Weinert's conception of competency [6]. Thus, competencies are more than knowledge and its application. It is a knowledge-based disposition to meet complex demands by drawing on and mobilizing psycho-social resources in varying contexts to solve a given problem [7,8].[3] On this basis, I created a pool of all competencies relevant to R&I and KTT that are not strictly disciplinary, e.g. engineering mathematics like applied analysis. Next, as illustrated by α in Figure 2, I clustered the surveyed competencies and, following Kluge, developed fourteen types that are characterised by internal homogeneity and external heterogeneity [10]. For each type a definition was derived based on concepts in literature:

Table 1 - Competencies for R&I and KTT

1	*Agility* characterizes individuals who can adapt their behaviour and expectations as well as processes and structures flexibly and promptly to new framework conditions. They can react proactively, anticipatively, and proactively to changes by utilizing distributed knowledge and by continuously adapting to varying (social) situations [11,12].
2	*Agency in systems* refers to the ability to plan and realize actions and processes within complex personal, social and technical systems. The necessary prerequisites for this are the recognition and understanding of interdependencies between elements or parts of the system as well its boundaries. Specifically, this describes the ability to consider one's own actions

[2] I describe my methodology in more detail in 'Innovation Emloyability" (forthcoming).

[3] In Chomsky's sense, I understand dispositions as the components of a competence that are expressed in observable actions [9]. Unlike Chomsky, however, I do not assume that these dispositions are essentially fixed but rather that they may be developed.

	in a larger context in order to identify necessities and assess potential consequences [13].
3	*Handling complexity* describes the ability to recognize and understand relevant relationships and patterns in situations with an unknown multitude of factors that interact dynamically. On that basis one's own actions and behaviour can then be adjusted accordingly [14–16].
4	*Process analysis and design* describes the ability to recognize opportunities and obstacles to achieving personal or professional objectives. It includes identifying limits of the scope of action, deriving steps for an effective and purposeful intervention, and managing processes [13,17,18].
5	*Teamwork* is the ability to work with others from different backgrounds, organizations, and disciplines. Working in teams requires building trust and communicating effectively face to face as well as using media services [13,19].
6	*Attitude towards challenges* describes the mindset that individuals exhibit towards cognitively demanding tasks and situations with no apparent strategy for dealing with them. Specifically, this refers to whether situations and tasks that are perceived as challenging tend to be avoided or whether they are seen as an opportunity to learn or try something new [20].
7	*Acting according to ethical principles* refers to knowledge and understanding of ethical positions including the ability to identify relevant ethical questions. It, then, refers to the ability to act in accordance with such ethical principles in order to realize an individual or societal value by considering ethical dimensions of conditions of application, norms, interests, and consequences. Specifically, this competency describes the ability to recognize and evaluate values and norms and to direct one's own actions toward values and norms, taking into account the respective context, and to be able to justify a chosen course of action [21–23].
8	*Agency despite uncertainties and contradictions* refers to the ability to recognize and understand ambiguity and heterogeneity, as well as to be able to set priorities independently in situations in which feelings of uncertainty or excessive demands arise, and to align one's own actions accordingly. Specifically, such agency describes the ability to assess situations with contradictory or unclear information and to prioritize information in order to direct personal or professional actions towards a given objective [13,14].
9	*Motivation to learn* describes the individual attitude toward acquiring new or deepening existing knowledge, skills or attitudes. The focus is on the willingness to control one's own learning process and to activate the necessary resources and social processes. Specifically, motivation to learn refers to the individual willingness to intentionally acquire new knowledge or skills and to develop one's existing portfolio which can also mean that an initiative is undertaken to create the prerequisites for doing so [13,24,25].

10	*Critical thinking* describes the ability to (reasonably) assess facts on the basis of their essential components against the background of given sources and possible alternatives by applying general standards of rationality. Critical thinking involves questioning and evaluating what is supposedly self-evident [26].
11	*Recognizing emotions and taking other perspectives* is the ability to perceive and assess emotions both in oneself and in others. Within a professional context it refers to management and control of emotions on the basis of different behaviours and incentives. This also includes the ability to place oneself in the shoes of other people or organizations. In practical terms, this involves assessing emotional states or attitudes of others and considering them when addressing these others [27–29].
12	*Reflection of own actions* describes the willingness and ability to critically analyse oneself along with personal actions. It includes the ability to manage the utilization of personal resources. In addition, it includes the ability to recognize and relate to underlying systems of behaviour, thinking and values. By extension, the ability to reflect also includes actions of other people. Practically, this describes the ability to contextualize actions by recognizing and evaluating the relevant influencing parameters. The opposite is routine action or acting according to instructions [30,31].
13	*Handling diversity* refers to an appreciative approach to diversity and the ability to recognize commonalities in professional, cultural, or personal diversity (e.g., goals or values) that form the basis for joint action in a communicative-social process. This involves the ability to direct diverse impulses towards a common objective by fostering commonality in a sensitive process of exchange and communication [19,32,33].
14	*Creativity* is the ability to generate, shape, and implement ideas in order to find unconventional, novel, and appropriate solutions to a given challenge. Creativity allows to generate original solutions to emerging, complex, and unconventional challenges. Finding such solutions requires an open-mindedness toward unconventional methods and approaches as well as the ability to develop ideas exploratorily [11,25].

Illustrated by β in Figure 2, I then developed the *Wheel of Competencies* from these fourteen competencies. It is a tool to illustrate competency profile for collaborative R&I activities and KTT formats in the context of the new mission orientation:

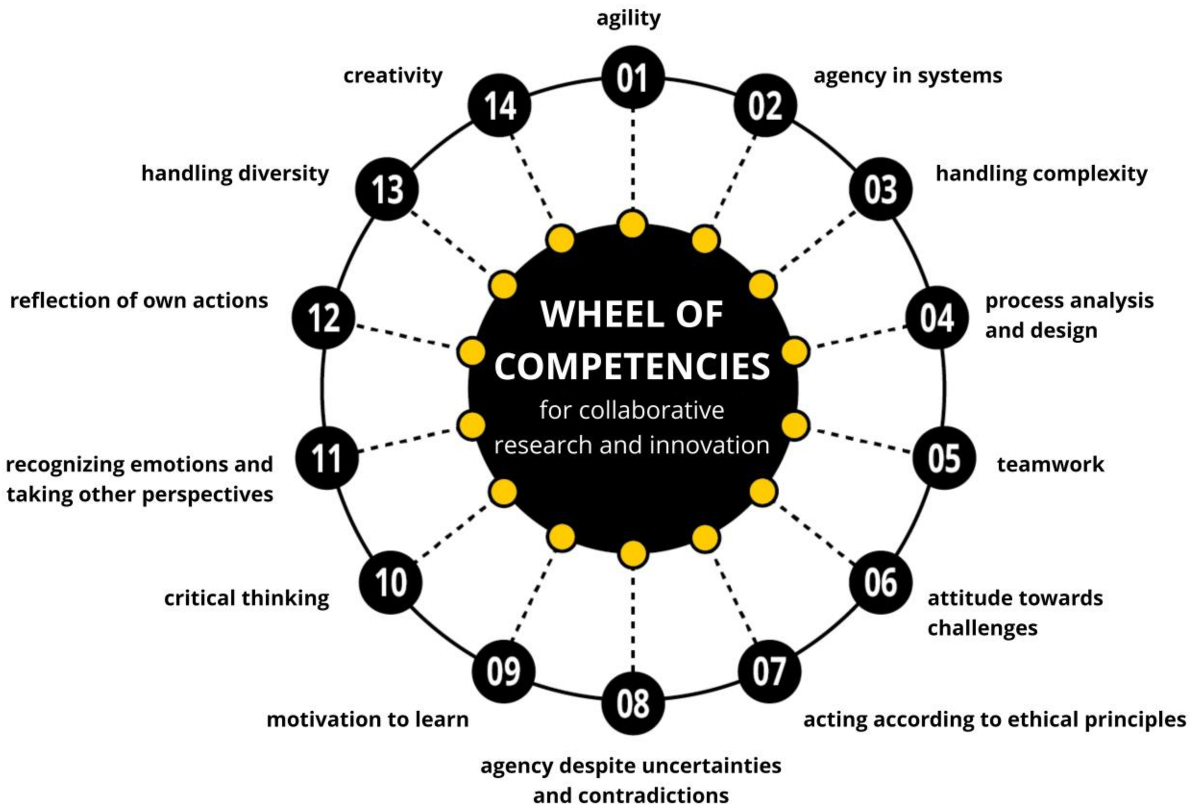

Fig. 1: Wheel of Competencies for Collaborative Research and Innovation

As a tool, the *Wheel of Competencies* may be used to compare different profiles, to identify potentials and to develop tailor-made training offers and teaching formats. Thus, it provides support for educators in engineering education to come to an understanding about desired results and outcomes of curriculum development processes. In order to validate the results and to survey such profiles, I subsequently conducted a quantitative study.

2.2 Survey

The study was designed as a quantitative survey of industry needs. Its intended to, first, validate the competencies and, second, to substantiate profiles that are needed by industry to collaborate in R&I. The survey was conducted in the form of structured computer-assisted telephone interviews [34]. In the fourth quarter of 2021, 200 managing directors or heads of R&D departments of medium-sized and large enterprises from the four largest industry sectors automotive engineering, electrical engineering, chemical engineering and mechanical engineering sectors were surveyed [35]. For each industry sector, I calculated the weighted values according to the relative size of the industry sector and size of the company in order to create a representative and accurate set of data to include in the analysis. In total, I was able to realize the following cases:

Table 2. Sample by industry sector and size of the compony

Industry sector	Staff headcount 50-249	Staff headcount ≥250
Automotive engineering	31	16
Chemical engineering	31	16
Electrical engineering	34	22
Mechanical engineering	30	20

For the purpose of the present study, I operationalized the 14 competencies and converted these into questionnaire items with a 5-point Likert scale (γ). Each item inquired: "How relevant are the following factors for your company among your R&D employees: very relevant (=1), relevant (=2), neither relevant nor irrelevant (=3), rather irrelevant (=4) or not relevant at all (=5)?" Incomplete answers were excluded. For research pragmatic reasons, the questionnaire was limited to two items for each competency. Every item covers an essential part of each definition given in Table 1. I used validated items from empirical research and, if necessary, adjusted the wording of individual items [36]. Before the start of the study, I conducted a pretest, then conducted the semi-structured interviews (δ). In order to analyse and interpret the data gathered, I used the software PSPP for analysis of statistical data. For the visualization I utilized Microsoft Excel (ε).

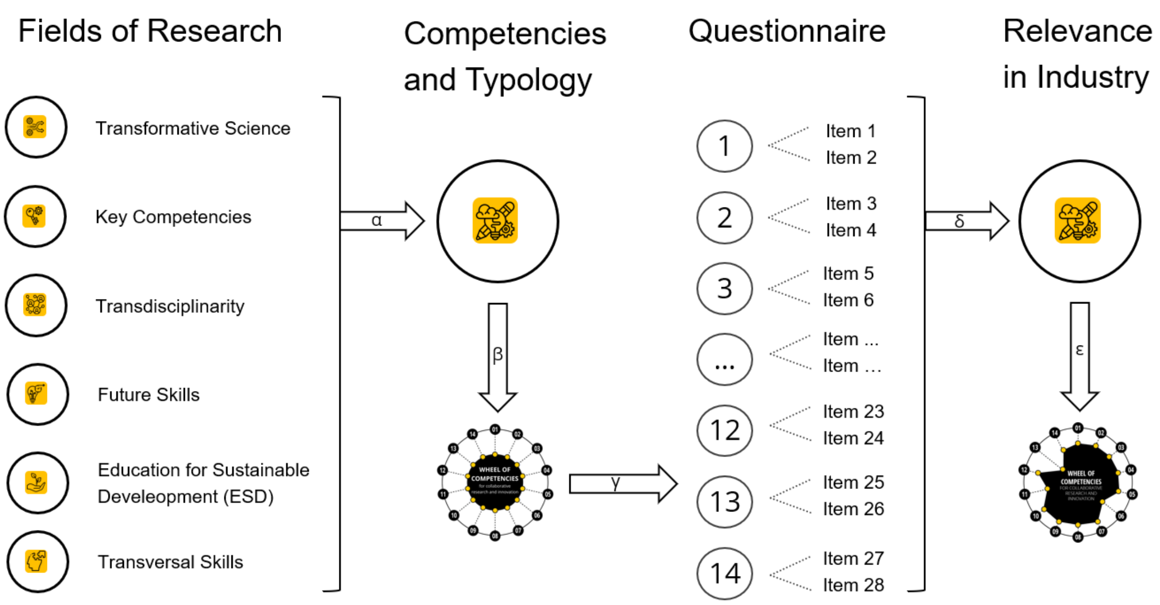

Figure 2 - Research Process

For the analysis, all data were considered that were coherent with regard to a competency. To achieve coherence, those items were excluded that varied on a 5-point Likert scale with a value larger than 1 in regard to a single competency, i.e.

Δ (item a; item b)>1 . For example, the answer to Item 1 is “very relevant” (=1) and the answer to Item 2 is “rather irrelevant” (=4) on a 5-point Likert scale. Thus, a delta follows that is 4-1=3>1. Because it is larger than 1, the answers were disregarded on the assumption that here “very relevant” and “rather irrelevant” are not coherent in respect to the competency in question. Applying this rule, the average number of cases considered per competency is 170 with a standard deviation of 19.28 among all fourteen competencies. The maximum is n=194 for *handling complexity* and the minimum is n=122 for *teamwork*.

While the *Wheel of Competency* as illustrated in Figure 3 is descriptive in regard to the relevance of the fourteen competencies, an ANOVA was conducted for the internal differentiation by competency and industry sectors.

3 RESULTS

3.1 Competencies for Research and Innovation

The results of the survey of R&D enterprises in engineering professions confirm in principle the competencies derived from literature. Figure 1 illustrates these findings. As this is a typologised summary of the latest research and debates, the data can essentially be interpreted as validation. However, the results also show that the relevance of individual competencies for collaborative R&D varies among competencies as well as among industry sectors.

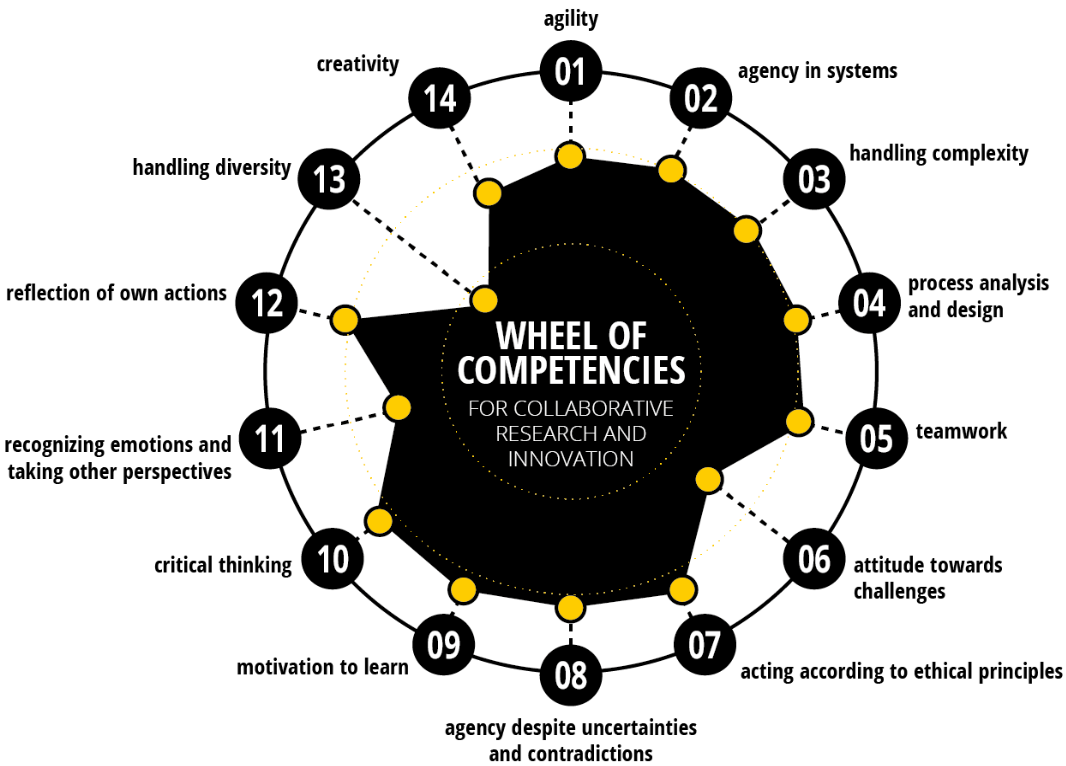

Fig. 3. Wheel of Competencies with adjusted values for all competencies (scale 1-3)

Initially, when evaluating the data collected for all industry sectors, it shows that the enterprises rank the importance of the competencies surveyed as at least "rather important" on average. With one exception, they have a mean value of <2 which translates into something between "rather important" and "very important". It is noticeable that *dealing with diversity*, *emotional competence* and, to a lesser extent, *creativity* rank behind the other competencies. Notably, *dealing with diversity* is the only competency with a value >2. The interviewed managers find it less important that their employees have these competencies. It is also striking that *agility* is less in demand than its presence in the discourse on forward-looking and innovative forms of work - particularly in the area of R&I - would lead one to expect [37].

Table 3. Competencies listed by mean value (possible max. = 1, min. = 5)

Competency	**Mean value**
motivation to learn	1,32
handling complexity	1,36
teamwork	1,41
process analysis and design	1,42
reflection of own actions	1,44
critical thinking	1,48
agency despite uncertainties and contradictions	1,49
acting according to ethical principles	1,52
agency in systems	1,53
agility	1,62
attitude towards challenges	1,63
creativity	1,77
recognizing emotions and taking other perspectives	1,85
handling diversity	2,10

Although the data cannot be interpreted unambiguously, the results nevertheless point to a scalable relevance of competencies for R&I collaborations in engineering industries. The fact that *learning* of new content and the ability to *handle complexity* stand out can be understood against this background as confirmation of the hypothesis that professional profiles are becoming increasingly dynamic - as summarized by the term employability in the interplay between person, organization and policy [38]. It is noticeable that *diversity* and *dealing with emotions*, which can also be described as *empathy*, together with *creativity* play a significantly less important role for R&I processes if the self-assessment of industry is to be believed.

3.2 Competencies by Sectors Industry

Looking at industry sectors individually, it becomes apparent that *creativity* is in conspicuously low demand in mechanical engineering. The same applies to *dealing with diversity* in chemical engineering, while *teamwork* on the other hand seems to be particularly important here. There are hardly any differences between the sectors with regard to the importance of *dealing with complexity* and only minor differences in the importance of *teamwork* and *motivation to learn*. Hence, a cross-sector consensus with regard to the three most relevant competencies exists.

Table 4 - Competencies listed by industry sector (possible max. =1, min. = 5)

Competency	Automotive engineering	Chemical engineering	Electrical engineering	Mechanical engineering
agility	1,68	1,62	1,57	1,63
agency in systems	1,61	1,40	1,48	1,63
handling complexity	1,38	1,34	1,36	1,38
process analysis and design	1,45	1,43	1,31	1,52
teamwork	1,46	1,29	1,40	1,48
attitude towards challenges	1,57	1,67	1,52	1,79
acting according to ethical principles	1,58	1,27	1,56	1,65
agency despite uncertainties and contradictions	1,53	1,39	1,47	1,55
motivation to learn	1,35	1,28	1,28	1,37
critical thinking	1,51	1,35	1,48	1,55
recognizing emotions and taking other perspectives	1,83	1,83	1,82	1,91
reflection of own actions	1,51	1,48	1,34	1,44
handling diversity	1,94	2,37	2,05	2,11
creativity	1,64	1,76	1,70	1,95

The interviewed managers reported that most of the competencies have similar relevance in all considered industry sectors. Analyses of variance (ANOVA) show that the differences in competency values in individual industries are not significant. With *acting according to ethical principles*, there is, however, a single exception.[4] Considering the descriptive level of mean values, there are notable results of the

[4] The relevance of the competency *acting according to ethical principles* differs with statistical significance for the four industry sectors: $F(3,174)=4.02$, $p<.01$.

survey. Among these is that *attitude toward challenges* in mechanical engineering is rated by interviewees as comparatively low in relevance, and represents a negative deviation from the mean value. The same applies to *handling diversity* in chemical engineering and *creativity* in mechanical engineering. The latter is particularly noteworthy because the design process, as part of mechanical engineering, would lead one to expect a different level of importance. In addition, there are also positive deviations. For example, mangers from chemical engineering state that *acting according to ethical principles* is of particular importance with the best sector-specific value of all, while the other industrial sectors only achieve a medium value.

4 DISCUSSION

4.1 Results

The results of the survey support the typology of important competencies for collaborative R&I derived from literature and show that these competencies are in demand in research-oriented industries. However, it was found that R&I managers regard these competencies to be relevant to varying degrees.

Of particular relevance are *motivation to learn* and *handling complexity*. *Motivation to learn* addresses the individual attitude towards acquiring new or deepening existing knowledge, capabilities, or attitudes. The emphasis lies on the willingness to control one's own learning process and to activate necessary resources and engage in adequate social interactions [13,24,25]. *Handling complexity* refers to the ability to recognize and understand relevant interrelations and patterns in situations with an unknown number of different variables and dynamic interactions between these variables, in order to align one's own actions in an impact-oriented manner [14,39].

With the competencies *teamwork* and *process analysis and design*, which are also considered highly relevant, the results support the observation that cross-organizational and cross-sector innovation activities are becoming increasingly important and require new competencies from those involved in order to successfully shape highly dynamic and complex collaboration processes.

The *Wheel of Competencies* can be used to generate distinct competency profiles based on context-specific parameters and individual needs. Thus, the *Wheel of Competencies* can be used to identify and depict the requirements for individual sectors or transfer activities and collaboration formats. By illustrating the requirements in this way, needed qualifications can be addressed in a second step with customized training programs or curricula respectively. This provides opportunities for professional education programs, further and executive education, but likewise for academic higher education.

4.2 Implications

In engineering education, these results help to identify not only subject-specific and disciplinary educational content, but also those competencies that are becoming increasingly important in professional careers and that enable inter- and transdisciplinary collaboration in R&I networks. In this context, competency profiles can be identified that derive specifically from the perspective of an academic discipline. For example, the relevance of the *ethical dimension* is particularly evident in chemical engineering. This should be reflected in appropriate courses of study and continuing education programs.

On this basis, firstly, curricula can be revised and supplemented with respective content. More importantly, however, this emphasizes the need to focus engineering education on competencies by implementing appropriate teaching and learning methods and didactic concepts that address these competencies. This will not have to come at the expense of the disciplinary content, but can be accomplished as an integrated approach, as I demonstrate elsewhere [40]. However, it requires a mindset change with respect to teaching and learning formats, which are too often designed traditionally in a frontal way and thus forfeit considerable potential. Which teaching and learning methods are suitable cannot be answered in general terms and must be explored in the context of the respective study programs and courses. Generally speaking, however, the focus on competency development can be a means to prepare for both changing job descriptions as well as those jobs that are currently emerging or will emerge in the near future [41]. The competencies studied here refer to underlying dispositions and, hence, are most likely to be understood as transversal competencies, but at the same time they form a foundation for acquiring new and developing existing professional competencies. The results can then also inform professional (further) education. The *Wheel of Competencies* may serve as a tool for the development of tailor-made training programs, enabling providers and recipients of trainings to identify specific focal points and to agree on desired outcomes. The typology of competencies illustrated in the *Wheel of Competencies* does not claim to be complete or exhaustive and can therefore be individually adapted to the requirements in the respective application.

4.3 Limits

The results of the study should be interpreted considering its limitations. First, the competencies considered in the study cannot claim to be exhaustive because collaborations in specific research fields or innovation ecosystems may require different competency profiles. Second, only four industry sectors were surveyed. While the comparison of results across sectors suggests generalizability, it cannot demonstrate it conclusively. Third, despite the sample size of 200 enterprises, it cannot be ruled out that there is a common method bias [42].

***Conference Key Areas**: Global Ethics*
***Keywords**: Engineering Ethics, Accreditation, Global Analysis*

ABSTRACT

Ethics in engineering has long been an important element in engineering programmes, however these subjects are often taught at a basic learning level with little attempt to connect to demonstrative learning outcomes. In recent years there has been a step change in the importance of ethics as an integral part of engineering programmes and is reflected in the text of accreditation documents. In this paper we expand our analysis from an earlier study, which focused on four European countries, to understand the role of ethics on a more global scale. We conducted a multi-country analysis on how and where ethics features in accreditation documents in twelve countries across five continents (Belgium, Canada, Colombia, France/Switzerland, Ireland, Japan, Romania, South Africa, Sweden, UK and USA). We identified explicit or implicit references to ethics education, extracted verbs relating to learning outcomes, and compared definitions of key terms. A comparison to Bloom's taxonomy showed considerably higher frequency of verbs linked to ethics teaching associated to lower levels of cognitive learning. Definitions of terms relating to the process of accreditation were often lacking in documents, highlighting a need for setting terms of reference. This study highlights differences in how ethics is described in accreditation documents. However, more needs to be done to explicitly highlight ethics as an integral part of engineering education. Relying on implicit links to ethics leaves the role of ethics open to interpretation, resulting in uneven emphasis in the translation of ethics within programme designs.

1 INTRODUCTION

1.1 Background

Globally, engineering accreditation programmes identify specific areas of knowledge and skills that need to be addressed in order for students to qualify as engineering graduates. Historically, the main focus has been on specific areas of scientific, mathematics and engineering knowledge with little detail with regards to ethics. In recent years there has been a step change in highlighting the importance of ethics as an integral part of engineering programmes, which often is reflected in accreditation documents. Examples of this renewed focus include the significant change in UK Engineering accredition by the Engineering Council launched in 2020 [1], as well as shifts in the Australian accreditation documents[2]. While this is a positive step, our previous research[3] indicates that more work is needed at the policy level to explicitly integrate ethics across engineering programmes, particularly in the way learning outcomes are written and demonstrated.

1.2 Study Aim and Research Questions

The aim of this study is to explore how engineering ethics is portrayed in engineering accreditation documents and observe trends or differences in a multi-country global analysis. We address three research questions:

1) What key terms are defined and how do they compare across documents?
2) What learning outcomes are specified implicitly and explicitly that refer to ethics?
3) What verbs are used in learning outcomes that refer to ethics and which levels of cognitive learning do they represent according to Bloom's taxonomy?

2 METHODOLOGY

A multi-country analysis was carried out on the accreditation documents of twelve countries: Belgium, Canada[4], Colombia[5], France/Switzerland[6,7], Ireland[8], Japan[9], Romania[10], South Africa[11], Sweden[12], UK [1] and USA[13]. For Switzerland, only the French Swiss region was reviewed, where the same accreditation document is used as in France, thus covering both countries. Belgium does not have national, discipline-specific engineering accreditation therefore the engineering programmes can be accredited via the procedure in other countries, such as the French speaking region aligning with the CTI French accredication document. Therefore, ten accreditation documents were analysed for the study. The competencies, learning outcomes and program outcomes where appropriate were reviewed and the analysis was divided into 3 sub-sections that align to the 3 research questions outlined below.

2.1 Classification of key terms

We identified and extracted all definitions of key terms in the accreditation documents that are related to programme content or content delivery, such as "learning outcomes", "higher education" and "accreditation". Where terms were defined in two documents or more, we performed a qualitative comparison of the different definitions. This analysis was done to help identify any contextual or interpretive differences in definitions, which may influence how ethics is viewed, taught and evaluated from the learning outcomes that were evaluated in this study.

2.2 Explicit and implicit references to ethics education

Although the general method was consistent, due to the large variety in scope and structure between different accreditation documents, the method applied was adapted on a case by case basis to accommodate different documentation formats as outlined in the appendix. To analyze *explicit references to ethics education*, we first counted how many times the terms "ethics" and "ethical" were used in the respective documents. We then extracted all the learning outcomes in relation to these terms for verb analysis (next section). To analyze *implicit references to ethics education*, we first developed a set of reference terms that are used in engineering ethics education. For this purpose, we extracted key words and topics related to ethics from the table of contents of 5 textbooks (Fig. 1) as described in the previous study[3]. A quantitative word analysis was carried out in order to identify the use of these common terms in the accreditation documents.

2.3 Analysis of verbs used in ethics-related learning outcomes

Verb usage was analysed in three steps: First, we identified all verbs in learning outcomes that are related to the terms "ethics" or "ethical". For example, in the phrase "demonstrate awareness of ethical aspects", we identified "demonstrate awareness" as a verb related to ethics learning. Second, we categorized all identified verbs as either *action verbs* (doing), *cognitive verbs* (thinking) or both. Third, a comparison was carried out on the use of these verbs according to the hierarchical learning levels from Bloom's taxonomy of learning.

3 RESULTS

3.1 Classification of key terms

A total of 22 terms were defined across 10 documents. Only five terms were found defined in three or more documents: "Accreditation" and "Learning Outcomes" (both terms in 6 documents), "Graduate Attributes", "Knowledge" and "Understanding" (each term in 3 documents). The remaining terms occurred only once or twice as shown in Table 1.

What is not clear from the frequency of the use of specific terms across documents is how the use of terms can vary across contexts. For example, the term "accreditation" can refer to processes of quality assurance for engineering programmes that include formal assessment of compliance to existing standards, peer review by stakeholders regarding program quality, or both. Similarly, "learning outcomes" are defined in relation to different contexts, such as the programme of study (Colombia/UK AHEP4) or the process (France/Bel CTi/Switzerland). Furthermore, “learning outcomes” can include “knowledge” and “skills” (UK, USA, Colombia), “competence” (France), “values” (UK), and “approach” (Sweden) or they can be used to specify “graduate attributes” (South Africa).

Table 1. Word list highlighting most common terms of reference in 10 documents from 12 countries showing the most commonly defined in red.

Terms Defined	No. of documents	Terms Defined	No. of documents
Accreditation	6	Learning outcomes	6
Assessment	1	Module	1
Competence	1	Pathway	1
Delivery	1	Programme educational objectives/ Programme Outcomes	1
Engineering design	2	Programme/Program	1
Evaluation	1	Responsibilities of engineering practice	2
Graduate attributes	3	Skill	2
Higher Education	2	Societal context	2
Higher Education Institution	1	Student	1
Know-how	1	Transferable skills/ Complimentary skills	2
Knowledge	3	Understanding	3

3.2 Explicit and implicit references to ethics education

The terms “ethics” or “ethical” were only *explicitly* mentioned in learning outcomes or programme outcomes between 2 and 10 times across documents (average 4.5 $\pm$ 2.2 SD). In contrast the *implicit* terms were found between 6 and 187 times (average 77.5 $\pm$ 62.1 SD). The explicit terms will be expanded in section 3.3 on verb-usage.

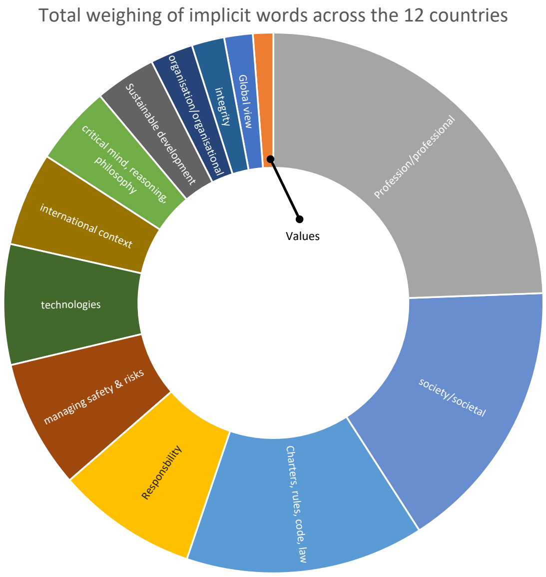

Fig. 1. Weighted frequency with which implicit reference terms are used, showing high representation of terms such as “professional” and low represention of terms such as “integrity” and “values”.

Our analysis of terms associated with *implicit* references to ethics showed that the frequency with which the top five terms were used corresponds to more than 70 % of all implicit terms were used (Fig. 1), these were: “Profession”, “Society”, “Codes/Laws”, “Technologies” and “Responsibility”. Conversely, four of the five least used terms constitute less than 6 % of all occasions of term usage: “Global views”, “Organisation”, “Integrity” and “Values”. Finally, “Justice” was not used in any of the analyzed documents.

3.3 Verbs used in ethics-related learning outcomes

Among verbs *explicitly* related to ethics learning, we found a strong emphasis on *cognition* and less on *action* verbs (Fig. 2).

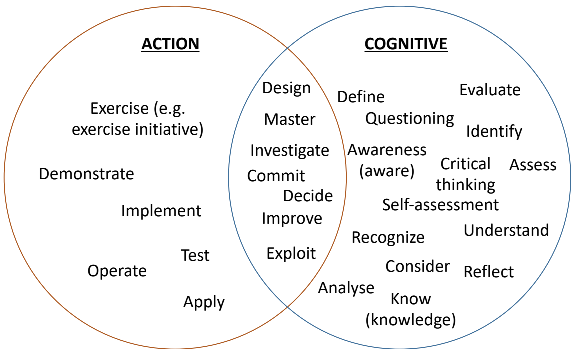

Fig. 2. Verbs related to explicit references to ethics learning that are used in the included accreditation documents.

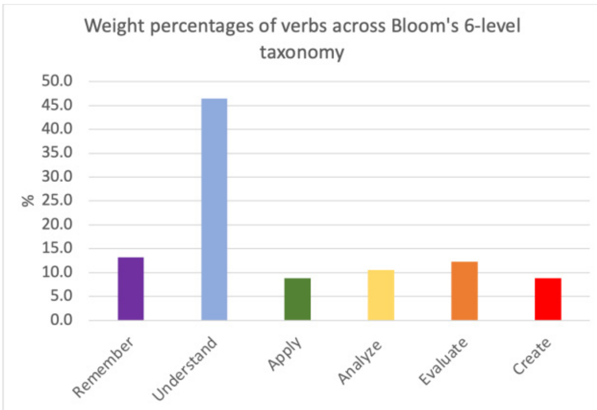

Fig. 3. Weighted percentage of verbs in learning outcomes relating explicitly to ethics shows high representation in the lower levels of learning according to the Bloom’s taxonomy model.

Comparing the verbs (including both action and cognition) to Bloom’s six levels of cognitive learning, we found that verbs relating to learning outcomes at all levels are included, however, verbs related to the second level (“understand”) clearly dominate in all documents (Fig. 3). While a peak is expected at the lower levels of learning, there was no trend showing a gradual transition to higher levels of cognition from “Understand” to “Create” (Fig. 3).

4 DISCUSSION

The aim of this study was to explore how engineering ethics is portrayed in engineering accreditation documents and observe trends or differences in a multi-country global analysis. The definition of terms provides context to the terms used in the documents. Currently the lack of common definitions potentially leaves room for ethics to be differently defined, perceived and actualised in the engineering programmes of the different participating countries. The most common terms that were found across 6 documents were “Accreditation” and “Learning Outcomes” allowing some comparative analysis. However, the remaining terms were either found once, twice or thrice across all 10 documents reviewed. This made a comparison of terms not always possible for terms such as “assessment” (USA and South Africa) and “competence” (France, UK, Ireland, Colombia). Furthermore, in the case of South Africa, there was an emphasis on definitions for technical, rather than educational terms. For Canada, the definition of terms were removed in 2021 and made accessible elsewhere. In this instance, they were not relevant to programme development but rather to the accountability of roles in the accreditation process. The implications of differences in the definitions of terms is that some national accreditation documents have international reach and have been used as a benchmark for other countries, such as ABET (US), which accredits programmes in 41 countries, using an identical process for all. This wider reach makes these terms open to varied, and perhaps unintended, interpretations and affects how the terms are applied in programme development. With this in mind, accreditation bodies could bring into focus the terms they use and what they mean as part of their ethical due diligence in the construction of engineering programmes across a range of countries where the context or intended meaning of the learning outcomes as stated might otherwise be missed.

The explicit and implicit analysis of terms reflects that ethics is still marginal to the curriculum compared to other subjects. A more common language in other technical areas of the curriculum where terms and context are well-defined and understood. This is in contrast to the varied vocabulary found in the implicit terms identified in this analysis. Making this transnational comparison is important as student are mobile when they graduate and may be required to undergo legal processes for their degrees to be formally recognised. The implicit terms identified demonstrated a lack of pattern between countries or even between regions, other than the observation that the better represented ethical topics are ones that directly impact technical instruction such as “technology”, “profession” and “responsibility”. This lack of commonality is of interest and perhaps suggests no rigorous discussion on ethics from a regional level as compared to the technical subjects in engineering. This raises the question as to whether there should be a transition to a more common agreed language for ethics education in engineering.

The low profile of non-demonstrable aspects of ethics education is shown by the low emphasis on terms such as “Values”, “Integrity” and “Justice”. A focus on these terms may require a specific framework as a benchmark for the analysis of ethics education, such as that provided by the Rest Model[13], which identifies the four areas of ethical decision-making as Moral Awareness, Moral Reasoning/Judgment, Moral Intent and Moral Behaviour/Action. The Rest Model can be used to capture the non-actionable aspects that are a pre-requisite to demonstratable skills and behaviours. For example, ethical motivation and ethical character links to integrity and values, which are largely missing from accreditation requirements. This suggests that ethical competence and a stepwise progression through ethical development may be missing and perhaps could be included at a policy level. This will be explored in the next phase of the study.

There are several limitations to the study. For practical reasons, we had to rely on a convenience sample, including countries based on the nationalities and associations of the participating authors. We focused primarily on differences in the linguistic formulation of policy across the included countries. As we do not aim to *explain* these differences, we did not engage in in-depth analysis of the different social, cultural, political and technological challenges across borders. Therefore, our analysis may indicate differences in how the responsibilities of the engineering professionals are represented in the accreditation documents, but these differences are not the focus of the analysis. We further assume that the inclusion of definitions of certain key terms in accreditation documents to some degree reflects what is considered relevant by the respective accreditation agencies.

Another limitation is the nuanced differences between methodological approaches, which was captured in the appendix. With such an overview the next stage is for quality control measures such as cross-checking the methodologies with a second reviewer to assess the true variation in approaches. The second limitation is the representation of regions. Europe is well represented (6 countries), whereas the remaining regions have very limited representation with only one document analysied in Africa (South Africa), Asia (Japan) and South America (Colombia). However, this is a preliminary study where our observations will feed into further inclusion of countries to be expected for the next stage in this study.

Further work will look to ensure a wider coverage of ethical topics in common use is considered, which may have been excluded from the list derived from text references, where a further exploration of alternative terms of association is planned. The authors also take this opportunity to invite researchers to join this study, particularly from countries in less represented regions (South America, Africa and Asia or Australasia) and encourage any interested parties to contact the corresponding author.

ABSTRACT

Capacity building is a corner stone for having well prepared and effective teaching staff in engineering education. Despite the importance of capacity building in engineering education, there is relatively little research on this topic. In this paper, we address this gap by reporting on an international comparative study on capacity building practices in university-level engineering education. We examine how capacity building is organised in seven European institutions (in Belgium, Finland, France, Germany, Hungary, Sweden, UK) and Australia, based on institutional education policies and practices. We compare the preparation of teaching staff, their initial training, and continuing capacity building activities throughout their careers. To do this, we applied a qualitative approach, collecting data through (1) a structured questionnaire answered by the members of the SEFI SIG on Capacity building and (2) written notes produced during an international workshop on capacity building at the 2021 SEFI conference. We then conducted a comparative case study, exploring similarities and differences between incentives for permanent academic staff to engage in capacity building, how capacity building is organised, and at what point in their careers staff engage in it. Our findings indicate very diverse approaches, rules and practices as well as different obstacles and challenges for engineering education. The outcomes of our study can be used by policy makers to inform capacity building practices and engineering education in HEIs (Higher Education Institutions), and our questionnaire provides a tool for monitoring and reporting practices throughout the sector.

1 INTRODUCTION

Accelerated technological development, population growth and environmental change lead to constant changes in the sociotechnical landscapes in which engineers operate. These changes necessitate responsiveness in engineering education to prepare students for the shifting realities of the workforce and society at large. As the purveyors of technical content and professional socialization, engineering educators play a key role. Changing expectations for engineering graduates and developments in cognitive science have emphasized the need for educators and institutions to engage in capacity building [1]. Capacity building, also known as pedagogical training or professional development, is an important mechanism for improving engineering education [2]. Academic staff who participate in capacity building are more likely to use active learning pedagogies and student-centered approaches [3], and the adoption of such evidence-based practices improves learning and student outcomes [4].

In this study, we collected and analysed data regarding the ways in which capacity building (pedagogical training) is organised for permanent academic staff at nine institutions that offer engineering programs. Employing an exploratory, comparative approach, we address the following research questions (RQs):

RQ1 What are the incentives for permanent academic staff to engage in pedagogical training?

RQ2 How is this pedagogical training organised (who designs and delivers the provision, and how tailored to a specific discipline is the training)?

RQ3 At what point in their careers, and how frequently, do permanent academic staff engage in pedagogical training?

2 LITERATURE REVIEW

The notion of *capacity building* has been defined as ‘the process through which individuals, organizations and societies obtain, strengthen and maintain the capabilities to set and achieve their own development objectives over time’ [5:5].

Even though capacity building has been shown to benefit staff development and student learning, research in the United States has shown that participation is generally low and that most engineering educators continue to learn by trial and error [6]. Further, most capacity building opportunities in the United States are organised by social scientists (having no, or little, engineering background and teaching expertise) for a campus-wide audience and without discipline-specific examples and practices [7]. Consequently, ‘there is generally neither a meaningful incentive for engineering faculty members to participate in instructional development nor meaningful reward for any improvements in teaching that may result from their participation’ [7:90-91]. Perceptions of incentives and barriers can vary depending on the different roles academic staff have in their institutions; According to Sabagh and Saroyan’s [8] comparative study, there are significant differences between permanent and non-permanent (tenured and non-tenured) academic staff’s continuous engagement in capacity building for pedagogical improvement. In particular, non-permanent academic staff are more influenced by institutional cultures, which are often perceived as unsupportive of teaching excellence compared to research due to, for example, perceptions of a lack of appreciation, professional rewards and support for teaching activities and development. Permanent academic staff identified high workload and lack of time as the main barriers to engage in capacity building. However, in their study, Felder et al. [7:90] identified several incentives for engaging in capacity development, including institutions placing high value on teaching, teaching improvement activities, self-motivation, efficiencies of time, and teaching evaluation [see also 12].

Another challenge in capacity building is the lack of time and incentives for sharing results and effective practices, unlike in research where there are clear and relevant incentives for sharing results [9]. Furthermore, even when staff have an individual interest in teaching improvement activities, high requirements for research productivity can prevent academic staff from dedicating effort and time for it.

The challenges for academic staff to engage in capacity building are different during early-, mid- and late-career stages [7]. Therefore capacity building programmes need to ensure relevance throughout academics' entire careers. Provision of capacity-building opportunities for early-career academic staff is crucial for an institution's education performance as these educators often provide the majority of undergraduate and practical courses, thus playing a significant role in students' education [10]. Contrarily, if there is no required initial training (e.g., teaching certificates) for new academic staff – or only limited opportunities for participating in adequate professional development programmes –, early-career staff are forced to resort to developing their teaching skills through trial and error, based on their personal experience and with limited efficiency.

3 METHODOLOGY

To explore similarities and differences in capacity building practices across institutions, we developed and distributed a survey among the members of the Special Interest Group of SEFI focusing on Capacity Building (https://www.sefi.be/activities/special-interest-groups/capacity-building/). The following 9 institutions are considered in this study: (1) Budapest University of Technology and Economics (Hungary), (2) ENSTA Bretagne (France), (3) Hamburg University of Technology (Germany), (4) KU Leuven (Belgium), (5) LAB University of Applied Sciences (Finland), (6) University College London (UK), (7) University of Technology Sydney (Australia), (8) Umeå University (Sweden) and (9) Vrije Universiteit Brussel (Belgium).

The survey was designed based around qualitative data and arising themes from a preliminary discussion in the SIG meeting at the 2021 SEFI conference covering capacity building approaches at 7 of the included institutions. We developed four multiple-choice questions with response alternatives that covered all scenarios we identified during the preliminary discussion. For each question, we also included two open-ended alternatives (“other”, “comments”) to allow participants to enter responses that had not previously emerged. Finally, we added an additional open-ended question (“comments”) at the end of the survey. Participants were required to respond to all multiple-choice questions, but open-ended questions were optional. For each question, it was possible to select multiple answers. The survey (See Appendix) was administered through a web survey tool.

4 RESULTS

The findings of the study are presented in the following three sub-sections, directly related to the three research questions (see above).

4.1 Incentives

To gather information regarding the reasons why staff engage in pedagogical training, we asked: “What incentives do permanent academic staff at your institution have to engage in pedagogical training?” Response items are related to three types of incentives: (1) formal requirements (mandatory for all/part of the permanent academic staff or required for promotion), (2) formal incentives (wage setting or non-economic incentives, such as diploma or awards) and (3) informal incentives (valued by colleagues, students or others outside of the institution). The exact wording of the response items can be found in the Appendix.

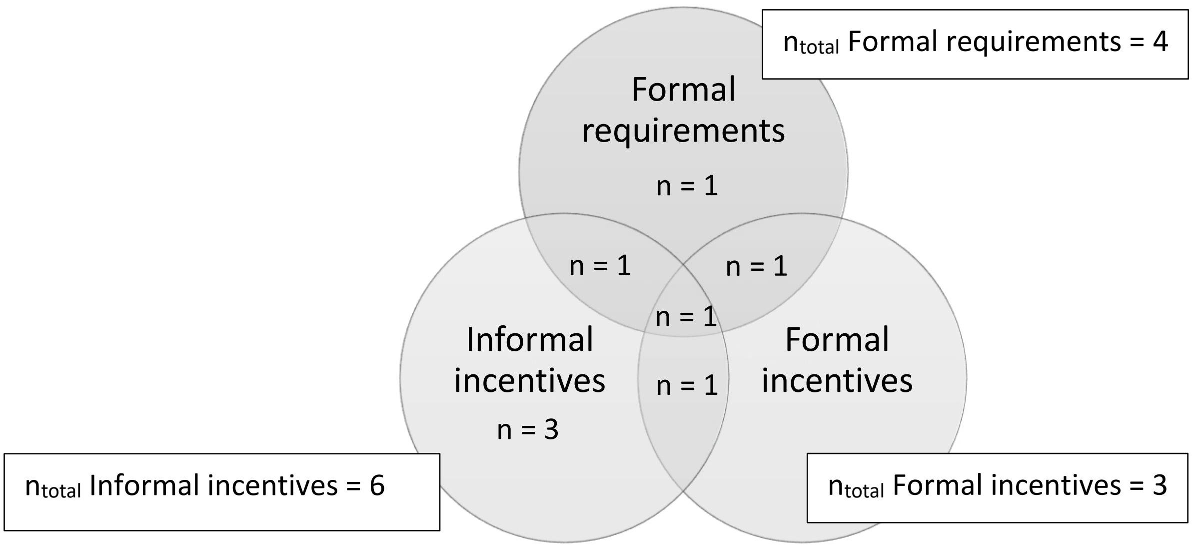

Figure 1. Overview of responses concerning incentives

The responses to this question indicate that all three types of incentives are used at the included institutions, but that informal incentives may occur slightly more often than formal requirements or formal incentives (Figure 1). For only one institution, no incentives or requirements were reported. More specifically, the results indicate that *formal* requirements are in place at only 4 of the included institutions. *Formal incentives* were identified for 3 institutions, two of which also have formal requirements. Examples of formal incentives are: (1) including criteria related to pedagogical training for wage setting or promotion, or (2) pedagogical awards and diploma. In total, formal requirements and/or formal incentives were identified for five institutions.

Six institutions provide *informal* incentives, such as (1) opportunities for teachers to meet for stimulating pedagogical discussions, supportive networks, opportunities to meet pedagogical experts, (2) support for dealing with teaching challenges and saving time, (3) recognition by colleagues and university leadership, and (4) intrinsic motivation. 3 institutions provide only informal incentives and only one respondent indicated that their institution has both formal requirements, formal incentives, and informal incentives.

4.2 Organisation

Participants were asked about the ways in which pedagogical training is organised at their institutions. We asked two separate questions to explore this aspect of pedagogical training. The first aimed to explore the level within the institution where pedagogical training is designed and delivered. Response items for this question included organisation at the national/regional, institutional, faculty, or departmental level (see Appendix). 7 of the 9 participants indicated that pedagogical training at their institutions is organised in a top-down manner, by a pedagogical development centre or other entity at their institution (Figure 2). 3 of these participants also indicated that faculties organise additional training for their teachers. Free text answers related to this item further indicate that training at the faculty level tends to be organised in a bottom-up manner – as a response to pedagogical challenges experienced by the faculties' staff. One participant indicated that pedagogical training at their institution is organised at a national level. Thus, 3 of the included institutions appear to combine top-down and bottom-up approaches to pedagogical development, while 5 institutions only employ top-down approaches. One participant indicated that no pedagogical training is offered at their institution at any level.

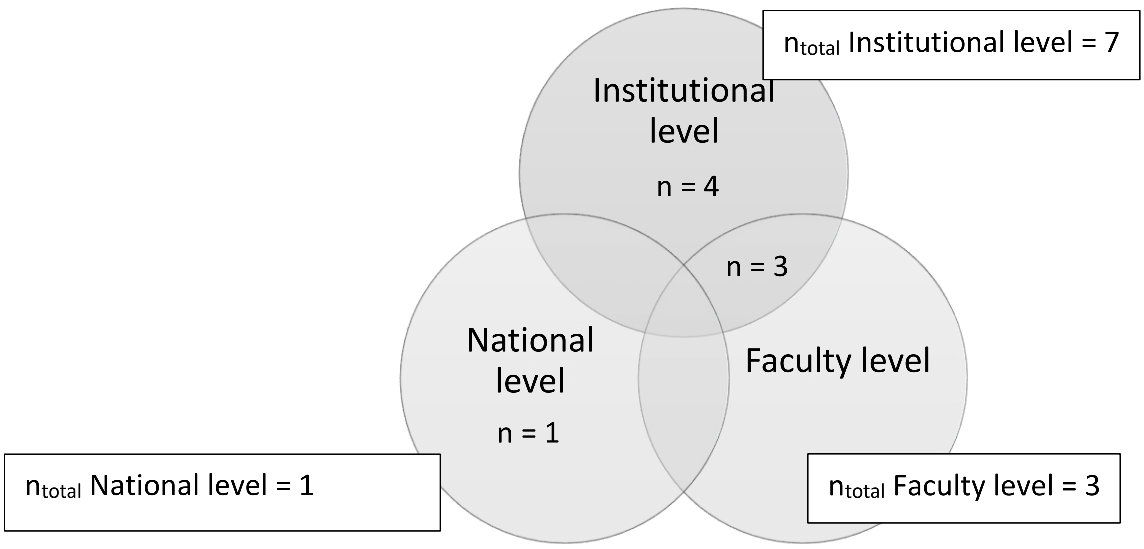

Figure 2. Overview of responses concerning organizational levels

The second question focused on the level of discipline specificity with which pedagogical training is organised: "How is pedagogical training organised across different faculties/disciplines at your institution?". Response items for this question included options indicating (1) multidisciplinary (open to staff from all faculties/disciplines), (2) disciplinary (tailored to staff from a specific faculty/discipline), and (3) generic monodisciplinary (offered to staff from one faculty/discipline, but not tailored to their disciplines) approaches.

Participants' responses indicate that the majority of the included institutions (n=8) employ multidisciplinary approaches, often combined with monodisciplinary or generic monodisciplinary approaches. One institution was categorized as not offering any pedagogical training.

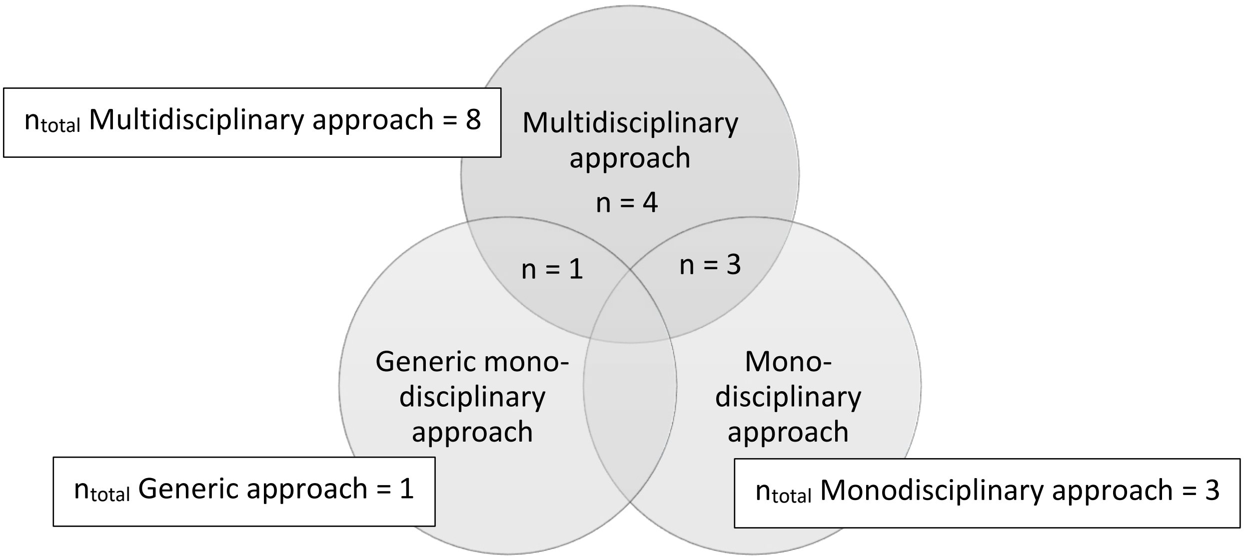

Figure 3. Overview of responses concerning organizational approaches

4.3 Participation

To gather information about participation in pedagogical training, we asked: "At what point(s) in their careers (after obtaining a permanent academic position) do staff at your institution engage in pedagogical training?". Response items for this question included options indicating whether staff primarily participate in pedagogical training early (first five years after obtaining a permanent position) or later (after more than five years after obtaining a permanent position) in their careers. Most of the responses (n=7) indicated that training typically occurs early in academics' careers. Just one institution indicated that pedagogical training is more common during later career stages and one institution was, again, categorized as not offering any pedagogical training.

Finally, we asked about the frequency with which staff members engage in pedagogical training. Only three of the participants indicated that staff members at their institution), on average, engage in pedagogical training at least once a year.

5 DISCUSSION

Our results indicate a diversity of approaches, rules, policies and practices related to capacity building. This is in line with findings from other studies: even research focusing on just research-intensive institutions within a single country (UK) have found that “job titles, expectations, development opportunities, reward systems and careers structures of educators vary widely across institutions” [11]. It would be valuable to explore possible reasons for, and effects of, this diversity, as it may indicate both strengths (e.g., that many capacity building programmes are developed in context-sensitive approaches) and weaknesses (e.g., that many capacity building programmes are developed ad hoc and without clear aims and strategies).

Our analysis of *incentives for engaging in capacity building activities* shows that no institution in our study solely offers formal incentives; these are always coupled with either formal requirements, which may indicate commitment from senior leadership, or with informal incentives such as peer esteem and networks, which may indicate an environment where good practice and engagement with pedagogical development is valued locally. We have also observed a relatively low overlap between formal requirements and informal incentives, which raises questions about whether and how they are related. Are there any systematic differences in how formal requirements and informal incentives are organised across contexts? Could formal requirements decrease rather than strengthen a culture in which pedagogical training is valued by students and colleagues? Or do institutions that lack a strong tradition of valuing pedagogical training resort to formal requirements to increase participation and the perceived value of training activities?

In our analysis of *how pedagogical training is organised*, we noted that some institutions combine top-down and bottom-up approaches, while others only seem to employ top-down approaches. It would be interesting to explore opportunities and challenges that may arise when institutions in different contexts employ either or both of these approaches and the reasons for their decisions to do so. This may be related to Felder et al.’s [7] conclusion that there is no meaningful perceived incentive for engineering educators to participate in capacity building organised at institutional level where there is a lack of discipline-specific examples.

Further, our results indicate that permanent academic staff, on average, *engage in pedagogical training less than once a year.* We also found that staff at most of the included institutions primarily engage in pedagogical training during their first five years of employment. These findings suggest that continuous pedagogical development may not be adequately valued or prioritised at some of the included institutions. More specifically, it appears that pedagogical training is often deemed necessary/desirable for junior academics, but that senior staff do not need to continue developing their pedagogical skills.

Finally, we observed the following *potential relationships between dimensions* explored in this study*:* (1) If pedagogical training is not valued throughout the organisation and as part of permanent academic staff members' careers, informal incentives will likely be weaker. It may also be that the relationship with the incentives on offer may change over an individual's career or that the opportunities for engagement with relevant capacity building decrease as careers progress. (2) In our sample, we noticed that institutions with monodisciplinary approaches have 'formal' requirements and institutions with frequent engagement in pedagogical training have 'formal' incentives or requirements. We therefore suggest that future research should explore any potential relationships between the ways in which pedagogical training is enforced or valued through different forms of incentives, how pedagogical training is organised in terms of disciplinary approaches and levels of organisation, the frequency with which permanent academic staff engage in it, and at what stages in their careers they do so. We expect that both large-scale, quantitative analyses and in-depth qualitative studies will be needed to better understand the role of capacity building for improving engineering education practice.

Limitations

Due to the complexity and large variety in institutional organisation of capacity building, interpreting the results has been challenging. More in-depth research will be needed to explore nuances, for example regarding different groups of academic staff. It should also be noted that all participating institutions are active members of SEFI, with staff who engage in the Capacity Building SIG, which may have influenced their experiences of and knowledge about how capacity building is organised at their institutions.

Also, in a written comment, one participant added an option we had not included in our survey: pedagogical training is also regularly organised in a *decentralized* manner, for example by the institution's digital learning team. This is likely the case in other institutions as well and should be taken into account in future studies.

Finally, participants may have relied on different interpretations of "permanent academic staff". For example, "permanent" can be interpreted more narrowly – as staff who have obtained tenure, or more broadly – as staff with other types of long-term contracts. There are also distinctions to be made around academic staff on research and teaching tracks and those on teaching and scholarship tracks.

6 CONCLUSION

In conclusion, our study has taken a snapshot of capacity building for engineering educators at nine institutions across seven European countries and Australia. It offers preliminary data and a framework for studying and monitoring capacity building across institutions which can be used to inform policy makers and create a common understanding of activity across the sector. This is particularly important at this time, since the expectations of staff at all levels in organisations related to their own and colleagues' future engagement with education are changing. The international Teaching Cultures Survey [12], for example, indicates an expectation from university staff at all levels that reward and recognition for quality teaching will increase.

We intend to follow up on this study with a larger, explanatory mixed methods study, including more institutions and an in-depth investigation of incentives and motivation related to participation in capacity building. We welcome other engineering education scholars to join our group and projects.

APPENDIX

Question: What incentives do permanent academic staff at your institution have to engage in pedagogical training?
Response items for incentives

A. Pedagogical training is mandatory for all permanent academic staff.
B. Pedagogical training is mandatory for part of the permanent academic staff.
C. Pedagogical training is required for promotion.
D. Pedagogical training automatically leads to salary increase.
E. Pedagogical training is one of several aspects considered in salary setting.
F. Pedagogical training is rewarded through non-economic incentives
G. Pedagogical training is valued by colleagues.
H. Pedagogical training is valued by students.
I. Pedagogical training is not acknowledged or valued at the institution, but at a national/regional level.
J. Pedagogical training is not acknowledged or valued at the institution, nor at a national/regional level.
K. No pedagogical training programs are offered for permanent academic staff.
L. Other

Question: What type(s) of entity/ies organize pedagogical training for permanent academic staff at your institution?
Response items for organizational levels

A. Pedagogical training is organised by national/regional entities.
B. Pedagogical training is organised by a pedagogical development center/entity at the institution.
C. Pedagogical training is organised separately by each of the institution's faculties.
D. Pedagogical training is organised separately by each of the institution's departments.
E. No pedagogical training is organised for permanent academic staff at the institution, but staff are encouraged to engage in pedagogical training on their own.
F. No pedagogical training is organised for permanent academic staff.
G. Other

Question: How is pedagogical training organized across different faculties/disciplines at your institution?
Response items for organizational approaches

A. Pedagogical training programs are tailored to each faculty's/discipline's specific needs.
B. Pedagogical training programs are offered separately for each faculty/discipline, but they are generic and not tailored for each faculty's/discipline's specific needs.
C. Pedagogical training programs are open for staff from all faculties/disciplines, but they are often dominated by participants from one or a few faculties/disciplines.
D. Pedagogical training programs are open for staff from all faculties/disciplines and participants typically come from various faculties/disciplines.
E. Pedagogical training programs are organised to guarantee that participants come from various faculties/disciplines.
F. No pedagogical training programs are offered for permanent academic staff.
G. Other

Question: At what point(s) in their careers (after obtaining a permanent academic position) do staff at your institution engage in pedagogical training?
Response items for participation

A. Permanent academic staff engage in pedagogical training primarily during the first five years after obtaining a permanent position.
B. Permanent academic staff engage in pedagogical training throughout their careers, but they engage more often during the first five years after obtaining a permanent position.
C. Permanent academic staff engage in pedagogical training throughout their careers, but they engage more often during later stages in their careers (more than five years after obtaining a permanent academic position).

Keywords: *Engineering curriculum, mathematics, double integrals, misconceptions*

ABSTRACT

Mathematics plays a significant role in engineering students' education. To undergraduate engineering students, calculus concepts are foundational to their engineering courses. One such concept is the double integral. It is thus important to ensure that students not only learn this concept but also engage to understand it and are able to apply this knowledge in relevant engineering courses. This research paper focuses on the following two components: Firstly, the relevance of double integrals to the engineering curriculum. And secondly, students' understanding of the double integral concept.

We present the relevance of double integrals in the engineering curriculum by looking at the use of this concept in different engineering fields. We explored students' understanding of double integrals and administered a test to 35 second year engineering students enrolled in an undergraduate Calculus III course. In a qualitative study, the performance of students was used to analyse the type of misconceptions they have in double integration. The findings reveal that the students encounter difficulties with graphical representation of surfaces and region of integration. In addition, students struggle with changing the order of integration and performing the integration process. While some of these errors are conceptual, others are really due to carelessness in the procedure.

Further analysis indicate that some misconceptions are a result of misunderstandings in prerequisite courses. The results will be useful to Mathematics educators who are keen in finding sources of misconceptions. The research may be used in designing functional teaching and learning instruments to rectify misconceptions in double integrals.

1 INTRODUCTION

1.1 Background

Undergraduate engineering students taking mathematics courses in the first and second years of their programmes are introduced to calculus concepts as a foundation for other engineering courses. Thus, for their success in professional engineering programmes and their future practice, the understanding of such mathematical concepts and the ability to interpret and apply them in future courses is essential for engineering students.

In South Africa, engineering students enrolled in a four-year programme encounter mathematics courses, of which calculus is a large part, in their first two years of study. Students are introduced to differential and integral calculus and their related applications during their first-year calculus courses [1] and this concept is further expanded on in the second-year vector calculus course. At the University of Cape Town, it is mandatory for engineering students to complete three semesters of calculus.

Integral calculus consists of the study of fundamental concepts useful in engineering. It also has various applications in fields such as physics and engineering [2] and is used widely in courses such as thermodynamics, mechanics, and hydraulics. For example, in thermodynamics, energy is a function of pressure, temperature, volume, and entropy; in engineering, density may be a function of $x, y,$ and z [3].The significance of calculus in engineering is highlighted in a study [4] where the correlation between students' understanding of derivative and integral calculus with thermodynamics is researched. The aforementioned study reports that results of the thermodynamics subject were affected by students' comprehension of derivatives and integrals and makes a convincing argument to improve calculus learning in order to increase the quality of achievements in thermodynamics and moreover other topics that involve integrals. It stresses the importance of monitoring engineering students' understanding and experience of calculus concepts.

The body of research on calculus topics show that students have difficulties in limits, derivatives, and integrals. Their difficulties are a result of various errors and certain misconceptions in the calculus concepts [5]. Common errors, persistent misconceptions and misunderstandings should be identified to inform and improve the teaching and learning of mathematics to facilitate student success. While researchers have documented students' understanding of various concepts in single variable calculus such as on difficulties and errors made by students in the topic of limits and integration [5,6], fewer studies exist about their understanding of multivariable calculus concepts making a case for this research study[3].

Double integration is a fundamental concept in many engineering applications and widely used in courses across the engineering disciplines. Integral calculus is a prerequisite for further coursework as it consists of important concepts such as the fundamental theorem of calculus and integral-area relationships. The focus of this research is to investigate the misconceptions in double integration in vector calculus among undergraduate engineering students.

1.2 Relevance of double integrals to Engineering

In the Mechanical engineering curriculum, vector calculus is a prerequisite course for the two third year courses namely control systems, and stress analysis and materials. In the latter, the course content covers topics such as theories of failure due to different loading conditions and material processes.

In theories of failure, finding beam deflections by double integration is one of the basic calculations students should know. They have to use boundary conditions and integrate twice; firstly, to find the slope and secondly the deflection. At this point, students apply double integration knowledge from their vector calculus course to calculate beam deflections.

For a cantilever beam in Figure 1 subjected to a combination of loading, the method of double integration is used to determine the deflection at the free end by integrating this deflection equation $EI\frac{d^2y}{dx^2} = 5 - \frac{20x^2}{2}$ twice.

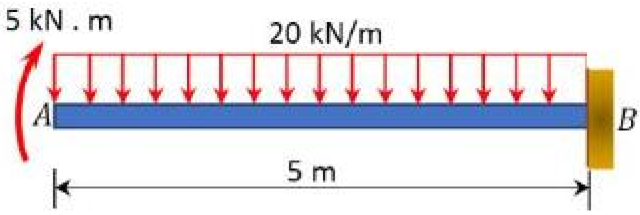

Fig. 1. Beam deflection calculation

With this example, it is clear that students have to understand the concept of double integration to minimise carrying misconceptions to future courses like the stress analysis and materials. Civil engineering students also apply the same concept in calculating beam and column deflections.

2 METHODOLOGY

2.1 Introduction

A mixed method approach was used drawing on quantitative and qualitative research data. Statistical data analysis was used to describe students' performance in the test on double integrals. The qualitative data was in the form of document analysis of the test, including their reflective notes and conducting interviews with students.

2.2 Participants

The research participants were second-year undergraduate engineering students at the University of Cape Town taking vector calculus. All participants had completed two first year calculus courses. Students in the class were invited to participate in the study, with all students agreeing that their class test could be used. Seven students agreed to be interviewed. They had given written consent and allowed the researcher to use their responses in the study.

2.3 Research method

The researcher designed the double integrals test to investigate students' understanding of and their reflections on the concept. Five questions were prepared for the test, discussed with the second researcher, and refined thereafter. The test included a reflection question at the end of each of the five questions, added to allow students to make sense of the material or experiences and the conditions that shaped those experiences. In the research study, the reflection questions help identify how the student perceived their response to the question.

Students wrote the test in 75 minutes. After the test marking was completed, an interview schedule was developed to learn about students' perspectives, experiences, and mathematics knowledge that shaped their understanding of double integrals. Amidst the circumstances presented by the pandemic, and students' unavailability for a physical meeting, the interviews were conducted and recorded using video conferencing technology. The qualitative data collected were thematically analysed through comparing and contrasting students' responses and interview results. These themes were students' misconceptions.

3 RESULTS

3.1 Performance statistics

The quantitative data analysis is presented as performance statistics of the test. This is followed by the analysis of the test responses, students' reflections and interviews culminating in the identification of the double integral misconceptions students displayed.

Overall statistical analysis on the test is presented below. Figure 2 shows the distribution of marks. The minimum mark obtained in the test was 2 and the maximum marks obtained were 28. The mean and the standard deviation were 16.06 ± 6.86 marks. Eighteen students (51%) achieved a passing grade in the test. In as much as a fair performance is observed, the overall test performance, looking at misconceptions students have and the errors they made, was not satisfactory.

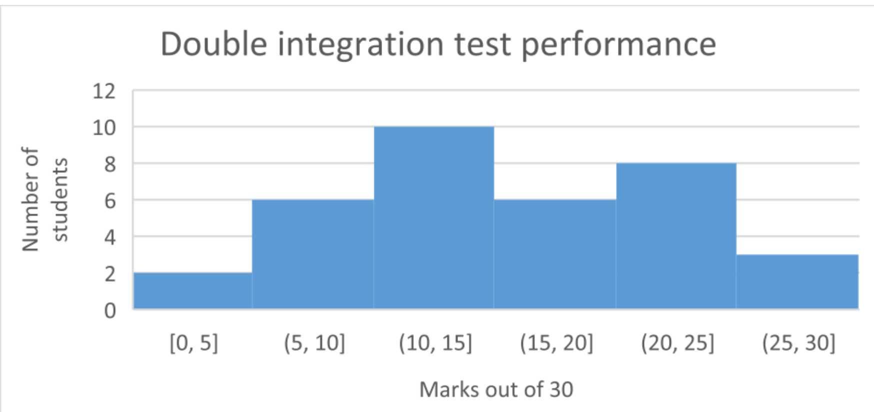

Fig. 2. Test performance

3.2 Misconceptions

Misconceptions are recognised as conceptual difficulties that students have. These may delay the learning process and hinder mathematical conceptual understanding. In this research, the following seven misconceptions were identified: Graphical representation of surfaces and the region of integration, difficulty with changing the order of integration, difficulty in setting up the integral, algebraic difficulties, treating a double integral as a triple integral, and changing the coordinate system from cartesian to polar coordinates. The first two prominent misconceptions will be discussed in the following sections.

3.2.1 Misconception 1: Graphical representation of surfaces and the region of integration

Graphical representation of the region of integration and of the three-dimensional surfaces was the primary misconception identified from the test analysis. This misconception is prevalent in all test questions. Sketching the region of integration is fundamental to setting up an integral to be evaluated. Despite students' knowledge of integration and integration techniques, incorrect double integrals setups will result in incorrect results. To this end, students' prior knowledge of curve sketching is necessary.

Curve sketching is a large focus in first-year calculus and with students sketching planes and intersecting planes. This prior knowledge would have been extended to include an introduction to 3D surfaces in second year vector calculus where students are required to recognise the equations and names of the typical surfaces (cylinders and quadric surfaces) and be able to sketch them. Sketching the region of integration requires the students' ability to draw curves and lines.

As an example, in question 1, students were required to sketch a plane $z = 5$ above the rectangle R = {x, y: 0 ≤ x ≤ 2, 1 ≤ y ≤ 4}. It is common practice to sketch the region of integration before setting up the Integral. Figure 3 shows Mary's correct response

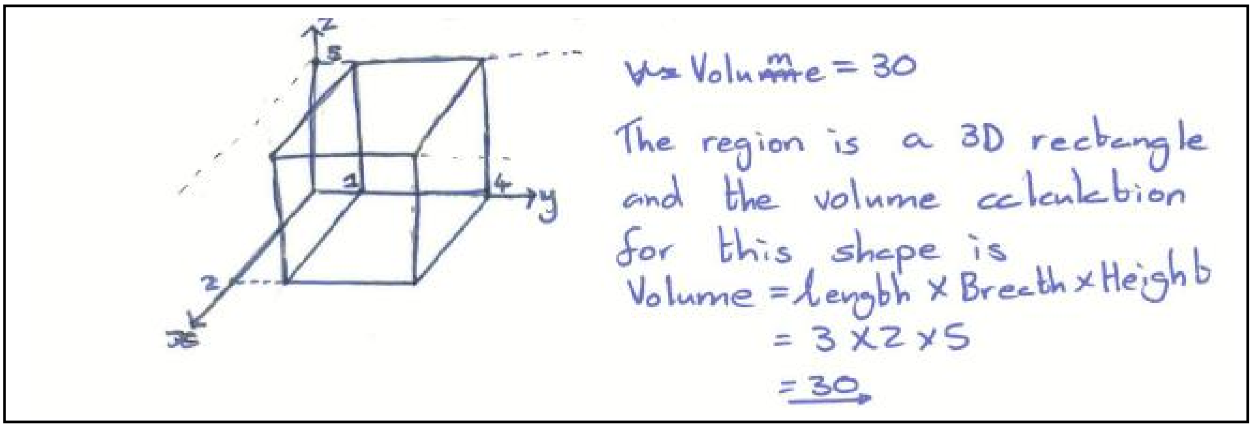

Fig. 3. Mary's correct response to sketching z=5 above the given region

In figure 3, part of the plane $z = 5$ above the region of integration is drawn. The region of integration lies in the xy plane and is defined by the rectangle. Five students were not able to draw the plane and the region of integration at all. When interviewed, some students mentioned that they knew that they had to draw a plane but were not able to draw it in three dimensions. Jessica drew a line to represent a plane in three dimensions and later during an interview said that although she knew that $z = 5$ represented a plane ,it was difficult to represent a plane in three dimensions on paper.

Figure 4a shows Jessica's region of integration. The region shows that the limits in the x and y axes were swapped and emphasises a further issue of plotting intervals incorrectly. When interviewed, the student demonstrated that they understood the required region. Figure 4b shows the plane $z = 5$. The student could tell that this particular plane lies flat at a value of $z = 5$ but could not represent it in three dimensions. Instead of a plane, a line was drawn above an unknown region of integration. Since this misconception is fundamental, it is important to ensure that first year calculus equips students with necessary curve sketching skills and revision of this should be done at the beginning of vector calculus.

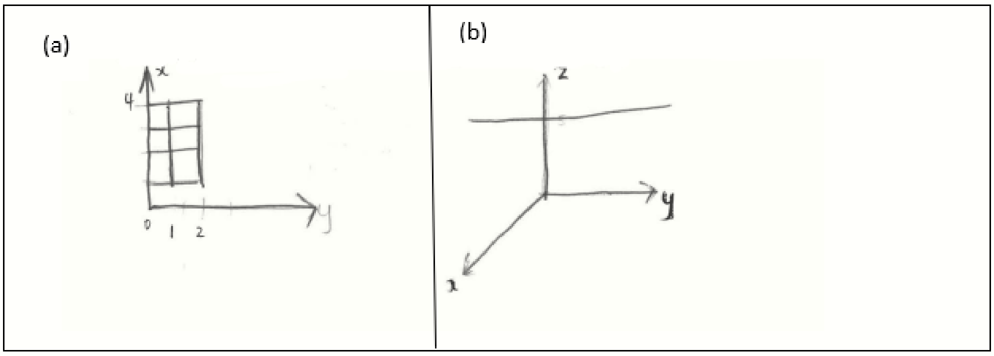

Fig. 4. Jessica's region of integration and plane sketches

Some students could not interpret the plane $z = 5$ as a function $f(x, y)$ with a value of 5 for all values of x and y. They were used to the plane with the following equation $ax + by + cz = k$, yet they could not tell in the case of $z = 5$ that $a, b \;=\; 0, c = 1$ and $k = 5$. The understanding of what a double integral represents was also crucial in interpreting the sketch. Students with ability to interpret a double integral as being used to calculate volume under a surface could have drawn the cuboid in figure 3.

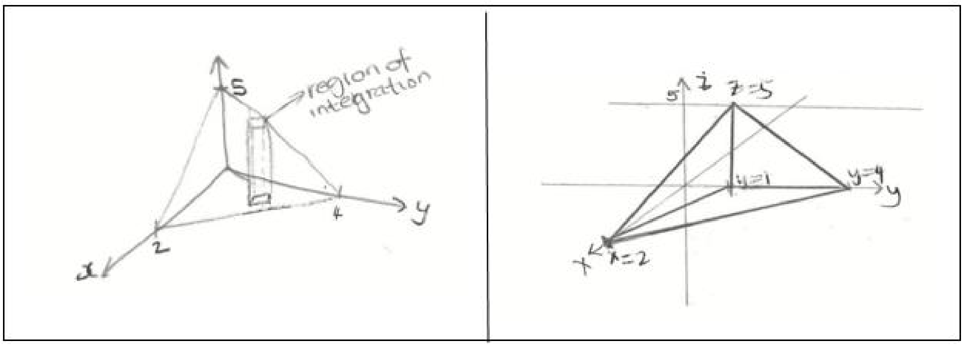

Fig. 5. Incorrect sketches from two students

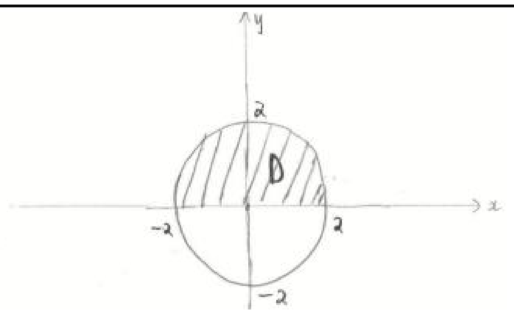
One way of understanding double integrals is by relating them to the Riemann sum. Thus, students can set up the integral $\iint_R 5dA$ by thinking about $\sum\sum f(x_i y_j)\Delta A$ as an area (determined by the region of integration in the xy plane) multiplied by the height function z=5. Interpreting double integrals this way can be helpful in sketching the three-dimensional surfaces.

In some cases, students' interpretation and understanding of the limits of integration can be a determining factor in sketching the region of integration. In question 1 for example, students were given that $0 \leq x \leq 2$ *and* $1 \leq y \leq 4$. To draw the rectangular region in the xy plane, the limits can be interpreted as the area enclosed by the following straight lines $x = 0, x = 2, y = 1\ and\ y = 4$. This rectangle can be extended upwards to have a cuboid representative of the plane $z = 5$ above the region of integration. Figure 5 reveals, that the two students could not interpret the limits of integration and hence their sketches were not representative of a rectangular region of integration even though this was indicated in the question.

In addition, it is important for students to distinguish a rectangular region from non-rectangular regions. Students with non-rectangular regions ended up with limits of integration representative of a rectangular region. John's region of integration shown in the double integral in figure 6 represents a rectangle not a circle as in the picture on the left. When interviewed, students expressed that they often struggle identifying the upper and lower limits of integration even with the correct sketch. This, they say it is because they want simpler limits to work with when integrating. Students should understand that the limits of integration describe an area and they should express bounds of this area. Taken in the x direction first the bounds are $f_1(y) \leq x \leq f_2(y)$ and the limits in the y direction will range from $a \leq y \leq b$, a,b are elements of real numbers.



$$\iint_D (x^2+y^2)\,dx\,dy$$
$$\int_0^2 \int_{-2}^2 (x^2+y^2)\,dx\,dy$$

Fig. 6. John's limits of integration representative of a rectangle

3.2.2 Misconception 2 : Difficulty in Changing the Order of Integration

The change of the order of integration is important in cases where the given integrand is complicated and results in the integration being difficult or not possible to compute.

The integral $\int_c^d \int_a^b dx\,dy$ is written in a way that the integration with respect to x is carried out before the integration with respect to y. Assuming that the limits of integration were constants, changing the order of integration will result in simply $\int_a^b \int_c^d dy\,dx$. The difficulty is experienced when the region of integration is not rectangular. To achieve changing the order of integration in this context, students are required to sketch the region of integration before determining new limits of integration.

This misconception arose in response to question 4 of the test. Students were required to change the order of integration of the following double integral $\int_0^2 \int_{y^2}^4 ye^{x^2}\,dx\,dy$. They were to begin by drawing the region of integration with the resultant expected integral of this form ; $\int_0^4 \int_0^{\sqrt{x}} ye^{x^2}\,dy\,dx$. When asked if they were able to evaluate this integral, twenty-six students responded with "No", mostly citing that the integrand ye^{x^2} is too complex to integrate with respect to x. Nine students however commented that it was possible to evaluate the integral since the limits of integration were given. Two of the nine students highlighted incorrectly that knowledge of integration by parts could be employed to solve the question.

Confirming misconception 1, 30% of the class presented incorrect sketches and therefore were not successful in changing the order of integration. Even though this cohort of students had difficulties with sketching the region of integration, they acknowledged its importance in identifying limits of integration. Some students' responses revealed that they did not understand the limits of integration and what these represented. With the given integral $\int_0^2 \int_{y^2}^4 ye^{x^2}\,dx\,dy$, it is expected that students interpret the inner integral limits as $y^2 \leq x \leq 4$. The outer limits will therefore be $0 \leq y \leq 2$. The four inequalities culminate to produce the region of integration on the xy-plane. Jeffry's region of integration and the integral setup revealed this misconception. In figure 7, Jeffry represented the parabola $x = y^2$ as a straight line. Furthermore, the student did not understand that, when setting up the integral, changing the order of integration requires the limits to also change to first in the y direction and followed by the x direction. With the current limits, Jeffry suggests that the boundaries are $4 \leq y \leq y^2$ and $0 \leq x \leq 4$. The equation $y = y^2$ is the case for the two points $y = 0$ and $y = 1$.

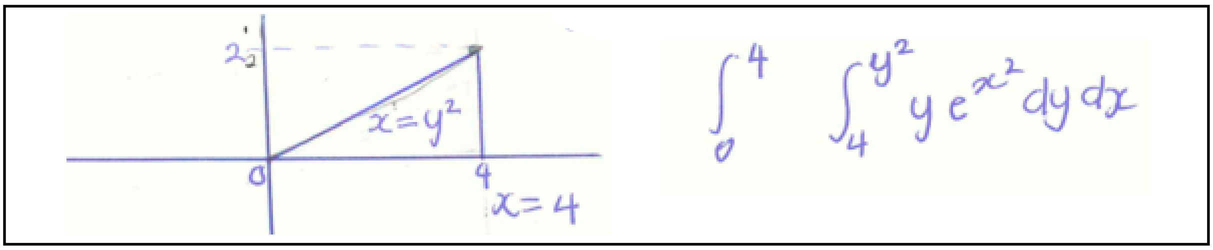


Fig. 7. Jeffry's change of order of integration

A few students did not understand that changing the order of integration involves changing the limits of integration accordingly. They simply changed the $dxdy$ to $dydx$ without altering the corresponding limits of integration. This is a serious misconception and, it was impossible for such students to succeed in effectively changing the order of integration.

In the question, three students not only denoted the incorrect region of integration but also an incorrect integrand. This is demonstrated through Jordan's response in figure 8. The integrand in question is the function $f(x, y) = ye^{x^2}$. In changing the integrand to $yln(x^2)$, Jordan effectively changed the question. It is not clear how the student arrived at this integrand. Because Jordan did not change the order and the limits, it is concluded that the student did not understand what it entailed to perform the change of order of integration.

$$\int_0^2 \int_{y^2}^4 y \ln x^2 \, dx \, dy$$

Fig. 8. Jordan's change of order of integration

4 SUMMARY

This study highlights the relevance of double integrals to the engineering curriculum. Therefore, students' understanding of the double integral concept is non-negotiable if they are to avoid difficulties in engineering courses. To identify and address misconception in double integration, difficulties experienced by vector calculus students in double integrals were studied. The prominent misconceptions included difficulty with graphical representation of surfaces and regions of integration, setting up of the double integral and changing the order of integration. It is recommended that the software application for the visualization of multivariate functions should be explored further in the teaching of this course to better students' achievements in determining the domain of integration and the integration bounds in order to solve double integrals.

Misconceptions in double integration also affect students' performance in other sections in vector calculus such as line integrals, surface integrals and Stokes' Theorem, making it equally important for teaching to focus on these misconceptions to improve performance in vector calculus

Researching students' difficulties help educators design appropriate teaching and learning activities. It is suggested that vector calculus educators liaise with first year calculus educators to discuss misconceptions resulting from prerequisite knowledge.

Conference Key Areas: Building Communities and Coordination, Fostering Engineering Education Research

Keywords: Teaching collaboration, networking activities, software engineering teachers, motivation to collaborate.

ABSTRACT

Teaching collaboration between universities is becoming increasingly important. Student intakes are increasing, and students are including MOOC courses from other universities to their studies. In Finland, there has been a long tradition in national teaching collaboration in computing education field. Our main research question is what motivates software engineering teachers to collaborate among universities. In this paper, we first give a short overview of national teaching collaboration from 1990's to the present day. Then, we present findings from a questionnaire that had respondents from active network participants. Main factors and practices that motivated teachers to participate in networking activities were existing project funding, active leaders and enough participants, interesting topics such as new innovations in learning technology, regular meetings and remote participation.

doi:10.5821/conference-9788412322262.1199

1 INTRODUCTION

Finland has long traditions in national teaching and research collaboration in the fields of computing education (CE) and computing education research (CER). Typically, active Computer Science (CS) teachers have also done controlled experiments related to their courses to study different teaching methods, developing new tools and software, and doing learning analytics, just to mention a couple of research activities. These early adopters have also collaborated among teachers from other universities to share the new innovations and practices with other pioneering stakeholders.

Currently, Computer Science is taught in almost every Finnish university. Most of the university level teachers in Finland have a PhD degree. First year basic programming courses are large and typically each course has hundreds of students. This is one of the motivations to develop novel learning tools and methods, but also to share the best practices with colleagues. It is not surprising that the teachers giving these first bachelor's level courses are the most active in the Finnish teacher networks as well.

As our theoretical lens, we use Lave and Wenger's communities of practice [1], as reviewed by Li et al. [2]. The communities of practice are a type of learning community that are characterised by "the support for formal and informal interaction between novices and experts, the emphasis on learning and sharing knowledge, and the investment to foster the sense of belonging among members" [2, 7]. These communities of practice are often informal networks, where learning occurs in social interactions between professionals rather than in a formal classroom settings. Experts mentor novices and eventually a professional identity forms for these communities. The informal interactions between the professionals are eventually systematized as means for professionals to improve practice and generate new ways to address recurrent problems [2]. In an previous study, Ryoo et al. [3] found that learning communities helped computer science teachers at high school level to transition to an inquiry-based classroom culture and break professional isolation.

In this paper, we study the history of established networks to recognise the enablers and blockers of the collaboration in Finnish context. We describe three past *network projects*, which institute the current collaboration among Finnish university teachers giving software engineering education (see Table 1). By a network project, we refer to a granted project that has a principal investigator, and limited time frame after which it is reported to the funding agency. In addition, we analyse four latest thematic *teacher networks* (Data Structures and Algorithms, Databases, B.Sc level programming, and Web Software Development), which might be project spin-offs, but attract enough participants to make the collaboration continue also after the original project has ended. In these networks, there is some fluctuation in the collaboration intensity throughout the years. In addition, the latest undertakings to run teacher networks seem to have different levels of activity, thus we do not dare to call them Special Interest Groups (SIGs), which we consider to be more established organizations possibly under some legal entity such as an association.

Our main research question is what motivates software engineering teachers to collaborate among universities. We present findings from a literature study as well as from a questionnaire that had respondents from active network participants. The results show that the main cohesive factor is project funding. However, having an active leader and participants is what keeps the network running. Moreover, shared interesting topics, regular meetings and remote participation seem to be important factors as well.

The rest of the paper is structured as follows. In Chapter 2, we first give a short overview of national teaching collaboration from 1990's to the present day. Chapter 3 gives an overview of the current situation. In Chapter 4, we report the results from a survey we conducted between

2 TEACHER NETWORKS IN FINLAND

Table 1 gives an overview of the network projects conducted between 2001 and 2020. The table indicates the year each university has attended the network.[1] The year is boldfaced and underlined in case of founding universities.

2.1 OSCu Network – Open Source Courseware Network

In 2001, three universities (UTA, TUT, UO) founded the Open Source Courseware (OSCu) network [4]. The philosophy behind OSCu was to be able to share courses and improve cooperation between universities. Courses given through the OSCu network were expected exceptionally high quality documentation following common guidelines and practices, and teachers were given training on how to give online lectures for remotely participating universities. The network grew quickly and in 2007 it already involved eight universities (TUT, UTA, UTU, UWA, UH, UO, HUT, UKU), with two more universities joining in 2009 (JYU, LUT). The network activities were at their peak in year 2007, when 8 course implementations were offered across universities, after which the offering started to diminish, as only 2-4 courses were arranged each year 2008-2010, and from 2011 onwards only one course was offered. OSCu's way of providing the courses was such that a course lectured on one of the participating universities was streamed to all other participating universities via a video bridge and Virtual Network Computing (VNC). In other shared sessions Adobe Connect Pro was used for communication. Each university had local arrangements for handling the stream, organizing exercise sessions, and so on. The most popular course was "Software Architectures", lectured at TUT, which

[1]Records from OSCu are incomplete between years 2001-2007. While universities have joined the network at different stages between 2001-2007, we only have access to data on who were part of the network at the end of 2007.

was given yearly while other offered courses varied every year. The course became such a staple that other universities in the network began to rely on receiving lectures from TUT, even after the OSCu network itself was discontinued. Software Architectures was shared to other universities until 2015, while other OSCu activities quietly faded away in the turn of 2010-2011, due to little enthusiasm to share other courses, critical changes in university representatives in the network (mainly, the surprising death of the founding member), and ending of ministry funding for virtual teaching networks.

2.2 NBEP – The Network for Basic Education in Programming

The Network for Teaching Basic Programming (NTBP) (Ohjelmoinnin perusopetuksen verkosto) was funded by Ministry of Education, and founded by three universities (HUT, UTU, TUT) in 2006 [5]. It was operating in the fields of engineering and computer science to coordinate national and international activities. These activities included seminars, which were organized in the participating universities and had also international keynote speakers from Europe, Australia, and USA. Many participating teachers were also active researchers in the field of Computing Education Research. The goal was to research, develop, disseminate, and maintain tools and systems for teaching basic computer science courses. The tools included software for automatic grading and feedback [6–9], style checkers [10], visualizations and animations [11], as well as learning management systems [7, 8]. Many researchers and research groups in the network still collaborate and attend many international conferences such as those organized by ACM/SIGCSE (Association for Computing Machinery / Special Interest Group on Computer Science Education). The SIGCSE provides an international discussion forum for teachers and researchers in the field to exchange ideas on software and training development, courses, training programs, and other elements related to the teaching and pedagogy of computer science.

The network worked in close co-operation with the Computer Science Teaching SIG, a thematic group still active within the Finnish Society for Computer Science. The aim of the theme group is to bring together teachers in the field of computing education and researchers interested in teaching technology. The purpose is to promote e.g. cooperation between teachers, the exchange of teaching and learning materials, the introduction of novel tools to support teaching, and taking a stand on current societal issues in the field of teaching programming.

3 CURRENT NETWORKS

Universities that were active in OSCU and NBEP projects started to prepare a funding application together with Arcada University of Applied Sciences, Metropolia University of Applied Sciences and Tampere University of Applied Sciences in early 2018. Aalto University coordinated the application preparation. The Ministry of Education and Culture gave funding for this project called Intelligent Systems and Content Creation project (Älykkäät oppimisympäristöt ja niiden sisällöntuotanto in Finnish, shortly ÄlyOppi) for years 2018-2021 [ÄlyOppi, 2022]. In addition of funding the development of smart learning environments, part of the funding was targeted to establish teacher networks where teachers can demonstrate new developed systems, give support to take systems in use in other universities, create course materials together and then to share teaching and learning materials.

First teacher network meeting was held in December 2019. There were about 40 participants coming from eight Finnish universities. Initially it was planned to divide participants into five groups: i) Bachelor level programming, ii) Data structures and algorithms, iii) Databases, iv) Web-programming, and v) other special areas, like machine learning and data security. First three of the groups got most of the pre-registrations, last two groups only a few. The three most popular groups began their networking activities, and last two are still waiting for active leader and participants. These three groups also relate to topics lectured in all universities in the fields of engineering or information and communication technologies. Data structures and algorithms also has very active international teacher networks.

3.1 Data Structures and Algorithms

ÄlyOppi established The Teacher Network for Data Structures and Algorithms (TN-DSA) to enable call for participation for Finnish stakeholders that are interested in developing such courses in collaboration with instructors, teachers, researchers, and developers from other institutions. The different implementations of these courses range from pure lecture courses to realisations that heavily rely on automatically assessed assignments (AAA). The assignments can include simple multiple choice questions, but also smart content such as automatically assessed programming exercies [6, 9, 12] and algorithm simulation exercises [11, 13]. TN-DSA offers a forum to exchange ideas and materials among the teachers and other stakeholders. Due to COVID-19, TN-DSA has convened in Zoom. The meetings took place about every other month in 2020 (6 times), and almost every month in 2021 (11 times). Several interesting themes have emerged from the discussions, which are discussed in the following paragraphs.

Textbooks. The current trend in higher education is towards open courses and free learning materials including textbooks. This is also the case in DSA courses. There are several freely available textbooks that have gained a lot of interest in the DSA community. For example, Shaffer's OpenDSA [14] is a textbook developed further in collaboration with many researchers and instructors worldwide to include also interactive exercises and smart content [15]. Another example of freely downloadable material is the textbook written in Finnish by Laaksonen [16]. Both of these textbooks are examples of freely available materials to be shared among teachers and students, and which have introduced and discussed in the TN-DSA meetings.

Course arrangements. Many DSA courses were well prepared to COVID-19 as they already had a lot of automation and many students were already able to pass the courses almost without attending the campus teaching at all. For instance, the first automated assignments were introduced in Aalto University as early as 1991 [17]. In the corresponding DSA course, the development of novel automated exercises have continued ever since. For example, visual algorithm simulation exercises (VAS) [7, 13] were developed during the millennium changeover period. Nowadays, the course consists of multiple choice exercises, VAS exercises, and programming assignments that are all assessed automatically and the students can get immediate feedback on their submissions. This kind of assignments and learning management systems capable of hosting automatically assessed exercises are examples of demonstrations in the TN-DSA meetings. However, the idea is not only to exchange software, but also to learn from each other to maintain and develop courses further and discuss, for example, how to produce online learning materials or how to create innovative lecture videos.

New assignments. One of the issues with assignments is that they need to be varied once in awhile to prevent the students passing and sharing the solutions. Finding good new assignment topics can be laborious process. Thus, even though the assignments do not have any kind of automatic assessment, sharing the topics could be a valuable aid for teachers. Especially topics that have been tested with students and maybe elaborated based on the feedback can be very beneficial. This is also one of the frequent discussion points in the meetings.

Term Bank. New terms in computer science appear typically first in English. However, many universities in Finland teach DSA also in Finnish and Swedish. This has the consequence that different universities might have translated the terminology a little bit differently. It is a constant debate how to translate and try to harmonise the terminology. The developed

Term Bank includes definitions of the terms, links to external material (such as Wikipedia, Wiktionary or The Helsinki Term Bank for the Arts and Sciences [18]), and the local and most common translations among different universities in Finland. This is an ongoing project, which aims at expanding to other teacher networks than TN-DSA as well.

3.2 Databases

As a part of the ÄlyOppi project efforts to establish teacher networks, databases was identified as one of the networks due to SQL databases being an established concept with fundamentals changing only slowly. For this reason, it was thought that database fundamentals courses would have a potential to share.

The full establishment of the databases network (TN-DB) was slowed down due to COVID-19 and has convened few times per year over Zoom. During these introductory meetings, shared network interests were identified. Initially, these were: Sharing and listing open educational resources such as textbooks or query practise tools, showcasing course structures that use these resources, and comparing degree programs' course structures, to see how they implement the curriculum.

Although it has not been under the network umbrella, there has been some deeper one-to-one collaboration among TN-DB partners. For example, LUT has previously used JYU's openly available web-based coursebook for databases with embedded exercise tasks. Currently the databases network is in the process of mapping course units and has plans to reconvene to review the outcomes in 2022.

3.3 Bachelor level programming

Bachelor level programming lays the basis of computing curricula through higher education (HE). The teacher network for bachelor level programming (TN-BLP) was established in Äly-Oppi to support collaboration and information sharing. TN-BLP can be seen as a direct successor of NBEP.

Bachelor level programming is such a staple of computing curricula that it is a natural as well as a challenging topic for the network. Each HE provider offers teaching that covers the same learning outcomes while each have organized the teaching to meet the learning expectations of their specific degree programme. This means that the courses under the umbrella of TN-BLP vary in size, organization and programming language used.

TN-BLP included all universities participating in ÄlyOppi. The network initially met face to face but due to the COVID-19 pandemic, the meetings were held over Zoom. The network met based on availability and need. The topics discussed:

Courses included. At start the network collected the names and learning outcomes of courses that make the bachelor level programming in each participating university. This work covered also the programming languages used by each university. It is worth to note that while most commonly, all universities use Python, Java or Scala or C++ for learning, there are several different approaches to the order of the languages and the frequency of moving to a new language.

Course arrangements. The teaching of bachelor level programming has relied on automated grading and the use of flexible learning allowing for off-campus participation even before the COVID-19 pandemic hit. Still, how to organize teaching and especially assessment in remote teaching was a much discussed topic at the beginning of the pandemic. Experiences on the learning management systems and ways to automatically grade assignments and exam answers have also been shared.

Bridge Courses. As the student intake in computing has increased the backgrounds of students on the courses has become more heterogeneous. Furthermore, students' mobility between HE providers has increased. Hence one goal set by TN-BLP was to create a collection of small course modules coineed bridge courses to make collecting the necessary learning from several HE providers even though the programming languages are not compatible from the learning point of view directly. The pandemic brought this work to a halt.

Shared Courses. The idea of sharing course material and programming tasks has been discussed. There has also been sharing of full courses between two network participants. However, a wider sharing of course content has not been established. As a topic, this has increased interest to participate in the network among the Universities of Applied Sciences.

4 SURVEY ON WHAT MOTIVATES TEACHERS TO COLLABORATE?

Teacher communities are claimed to contribute to the improvement of teaching and schooling practices [19], where learning occurs in a social system through a dual process of meaning making. In addition to building and sharing profession-related artefacts (courses), these communities learn through activities and store the outcomes of learning as a body of knowledge in the form of words, tools, concepts, methods, stories, documents, and links to resources [20]. The participation and sharing has been reported to motivate newcomers [19].

This section describes the data collection and analysis in the context of Finnish teacher networks, a type of teacher community. In addition, findings on what themes the communities worked on and what factors supported participation in the communities are presented.

4.1 Data gathering

Data was collected during December 2021 and January 2022 using a web form. The form link with a brief description of the research was first sent to all teacher network participants, and later further distributed via the Finnish Society for Computer Science. The form had three background questions. First question asked consent (yes / no) to use respondent's answers in this research. Second question asked respondent's university, and third question asked respondent's teaching experience (0-4 years, 5-9 years, 10-14 years, 15-19 years, and 20 or more). Second and third questions were voluntary.

After the background questions, the fourth question was on which teacher network the respondent was involved in or whether they were answering to teacher network activities in general and not related to any specific network. The fifth question asked what themes the network has dealt with so far, and the sixth question asked what themes should be considered in future. The seventh question asked factors that support participation in networking activities. The last question was for free comments and future development ideas.

4.2 Findings

The questionnaire was answered by 13 respondents from 7 universities, all of which gave permission to use the data in the research. All the respondents were experienced teachers: nine had 20 years or more teaching experience, one 15-19 years, and three 10-14 years. The answers were spread over the teacher networks so that 5 were for TN-DSA, 2 for TN-DB, 1 for TN-BLP, 1 for Web Programming and 4 for network activities in general. Responses to question on themes covered in meetings match with the actual content of the network meetings according to the network leaders as described in Sub-chapters 3.1-3.3.

The following themes for future network meetings were mentioned in answers to the question six: common transition courses (between programming languages), more teachers should be involved in networking activities, electronic exams and evaluation in general, what kind of advanced level database courses are in universities, tools and methods related to distance learning, university level collaboration, developing open access course materials and exercise banks, and developing and sharing knowledge on learning management systems. Some themes that require new networks were also mentioned: data security, platform economy, information systems, operating systems, and programming larger scale applications.

Answers of questions 7 and 8 were classified by keywords into different topics. The seventh question surveyed the factors that supported participation in the networking activities. Most of the answers were related to meeting arrangements. Possibility to participate remotely was mentioned by 9 respondents. A few respondents mentioned that occasional face to face meetings would also be good. Many of the respondents mentioned factors that were related to the meeting practices: regular and enough meetings to keep connected (mentioned by 2 respondents), one hour per meeting (1) and two hours is maximum (2), usually one main topic per meeting (1), champion who leads and organises the meetings (1) and updates shared memo (1), and meeting recordings (1). Another theme that clearly raised from the answers was content of the meetings. Possibility to discuss with colleagues, give or follow tool demos and share ideas that can be used in teaching were seen important (2). General level goal setting was also mentioned by a respondent. Teacher networks should agree common tasks or goals with responsible persons. Required effort of the tasks should be realistic especially when there is no funding. One of the respondents also mentioned concrete outcomes as a motivating factor.

5 DISCUSSION

From the questionnaire data, several collaboration enablers were detected. Our data is collected from Finnish University teachers and instructors. Most of the answers mentioned importance of the meeting practices and arrangements: regular meetings to keep teachers connected, remote participation possibility, length of the meeting from one hour to two hours, as well as, active champion who leads and organises the meetings. In addition, content of the meetings was seen important. A meeting should provide a place to discuss with the colleagues, see tool demos and share ideas, and ideate teaching collaboration and material creation. However, the same factors can be the blockers as well. The end of a project is a critical moment. The network might also lose the champion that brings the participants together if the continuation of the networking is not planned during the project.

Although information about the network and network activities was disseminated successfully and a significant portion of the relevant field of education was reached, it was found that uptake and reuse of the materials remains an open question despite project funding. Some successes have been found due to good relationships between individuals and build of trust, but no new widely applicable approaches have been found. To summarize the dichotomy, awareness about the materials has been increased, but increased uptake of shared resources requires ongoing work. Traditional textbooks are still the most popular way of disseminating content, but disseminating interactive smart content remains hard to achieve.

Fortunately, from the learner point of view, utilization of resources has taken other forms during the last 10–15 years. MOOCs (Massive Open Online Courses) seems to be the contemporary way of sharing educational content. In addition, open education movement is currently actively trying to broaden access to the learning traditionally offered through formal education systems. Automatic assessment is one of the enablers that makes it easy to allow participation in online learning even though the number of participants is very large. MOOC seems to be the new book.

Although our data is only from Finland, the ebb and flow in network activity is a common aspect of all networks. Depending on the current topics discussed in the network and on the very human aspect of how busy the core network participants are in their daily work, the networks go through active phases followed by a quieter or even inactive phase. COVID-19 pandemic can be seen as one outside factor both driving network activity seen in TN-DSA, but driving network activity down due to the needed major shift in how education is provided seen in TN-BLP. There is also an overlap in the themes of the networks; when one network is active the participants may be less active in the other networks they participate in. The size of the network is important here. For the networks to thrive both shared interests or future directions and a leader or core group of people is needed to keep the networks going.

6 ACKNOWLEDGEMENTS

We thank the Intelligent Systems and Content Creation project (ÄlyOppi) funded by the Ministry of Education and Culture, and Finnish Society for Computer Science for supporting this work.

Conference Key Areas: *Mathematics at the heart of Engineering, Co-creation with students*
Keywords: *Interdisciplinary engineering education, theory-based engineering course, practice-based learning concepts*

ABSTRACT

Is it possible to predict the future? How accurate is the prediction for the future? These questions are fascinating and intriguing ones in particular for young generations who look at their future with curiosity. For a long time, many have tried to quantitatively predict future behavior of systems more accurately with techniques such as time series analysis and derived dynamical models based on observed data. The paper proposes a lecture structure in which elements of chaos, which greatly impacts the predictive capabilities of dynamical models, are introduced through two classical examples of nonlinear dynamical systems, namely Lorenz attractor and Lotka-Volterra equations. In a possible lecture, these two structures are introduced in a basic and intuitive way, followed by equilibria analyses and Lyapunov control approaches. The paper intends to give a possible structure of an interdisciplinary lecture in chaotic systems, for all students in general and non-engineering students in particular, to kindle students' interest in challenging ideas and models. By presenting an intuitive learning-based approach and the results of the implementation, the paper contributes to the discourse on interdisciplinary education. The lecture is a part of a course within a Complementary Study at Leuphana Unversity of Lüneburg. The material which inspired the proposed lecture structure is taken from the scripts of the Master Complementary Course titled Modelling and Control of Dynamical Systems using Linear and Nonlinear Differential Equations held at Leuphana University of Lüneburg.

1 INTRODUCTION

The presented lecture can be used in different contexts: in Bachelors courses for engineers as well as for Masters courses dedicated to non-engineers (non-engineering minor programs,

complementary study). In this way, the paper provides important insights into how to teach the first and only control course in non-control engineering programs. In fact, an important point of the complementary study at Leuphana University in Lüneburg, Germany, is a holistic vision of the culture in which also non-engineers can profit from knowledge which typically is just for engineers. Therefore, such liberal education demands and encourages the intellectual and personal development of each and every specific student profile, in which new ideas to teach and to connect naturally or technically with human sciences represent a prerequisite.

In this paper, a modified Lotka-Volterra model with fixed initial condition has been employed to examine whether there is a pattern in chaos situations and where equilibrium points are that do not change over time, see [1]. It is important that the course starts recalling basic knowledge of differential equations and, before starting with a lecture dedicated to sliding mode control, the course should introduce elements of nonlinear differential equations considering the fundamental direct method of Lyapunov [2] related to the stability of a solution of a differential equation.

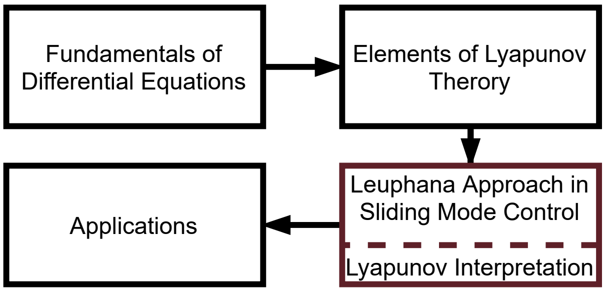

Fig. 1. Structure of the proposed course

Figure 1 shows the structure of the proposed course of this lecture in which the control of chaotic systems using Lyapunov control is proposed as an application. There are theoretical backgrounds about Lorenz's chaos theory and Lotka-Volterra model along with the explanation of forced Lotka-Volterra equations in Section 2. In Section 3, differential equations of Lorenz attractor of chaos theory as well as forced Lotka-Volterra equations in chaos scenarios with Jacobian matrix are computed manually in order to find equilibrium points and then they are followed by manual computation of Lyapunov equation for controllers. In Section 4, the simulations in Matlab/Simulink regarding Section 3 has been described. Later, conclusion and some remarks are devoted in Section 5.

2 MODELLING

Several kinds of dynamical systems from nature, and also synthetic ones, can be chaotic in their solutions. Two important ones are Lorenz attractors and forced Lotka-Volterra models.

2.1 Lorenz attractor

In the context of meteorology and fluid dynamics, Edward Lorenz came up with the simplest equation to explain the observed chaotic phenomena in the Earth atmosphere [3]. The result are three nonlinear differential equations $\dot{x}$, $\dot{y}$ and $\dot{z}$,

$$\frac{\mathrm{d}x(t)}{\mathrm{d}t} = \sigma\left(y(t) - x(t)\right), \quad (1)$$
$$\frac{\mathrm{d}y(t)}{\mathrm{d}t} = px(t) - y(t) - x(t)z(t), \quad (2)$$
$$\frac{\mathrm{d}z(t)}{\mathrm{d}t} = x(t)y(t) - \beta z(t), \quad (3)$$

where x is the rate of convective motion, for instance how fast the rolls are rotating, y is the temperature difference between the ascending and descending currents, and z is the distortion (from linearity) of the vertical temperature profile, see [3] for details on the practical interpretation of the parameters and variables of this example system. Parameters σ, p, and β depend on condition of the fluid, the heat input, etc., but they are assumed to be constant throughout experiments. So, in the simulations from Lorenz, $\sigma = 10$, $p = 28$, and $\beta = \frac{8}{3}$, see [4]. When the aspect of movement is transferred to the coordinate planes of the x, y, and z axes, a 'strange butterfly' shape can be seen. It is also called Lorenz's Butterfly Attractor because its shape resembles a butterfly. Here, the characteristic of chaos shows that it is sensitive to initial conditions but at the same time it is still possible to find the underlying pattern. Another, structurally simpler class of dynamical systems that can exhibit chaotic behavior under certain conditions is the dynamics of predator and prey populations in nature.

2.2 Lotka-Volterra models and their control

When there are preys, there are predators. It can also be applied to the other way around. When there are predators, there are preys. From this phenomenon, one can see that there must be a pattern or trend of prey and predator population over time. This pattern has been formed into equations by Alfred J. Lotka in 1910, analyzing prey-predator interactions as known as Lotka-Volterra model and predicting the population rate of change over time, see [5]. So the original Lotka-Volterra model is described by the following pair of equations, see [1]:

$$\frac{\mathrm{d}N_1(t)}{\mathrm{d}t} = \alpha_1 N_1(t) - \beta_1 N_1(t)N_2(t), \quad (4)$$
$$\frac{\mathrm{d}N_2(t)}{\mathrm{d}t} = -\alpha_2 N_2(t) + \beta_2 N_1(t)N_2(t), \quad (5)$$

where $N_1(t)$ and $N_2(t)$ are the population of prey and predator respectively, α_1 is the growth rate of prey and α_2 is the die out rate of predator. The term - $\beta_1 N_1(t)N_2(t)$ represents the loss rate of prey due to collisions with predator and $\beta_2 N_1(t)N_2(t)$ represents the growth rate of the population of predator due to collisions with prey. The equations have periodic solutions under the assumptions that none of parameters α_1, α_2, β_1, β_2 are negative, see [1]. From the model, the population of predator seemingly follow the pattern of the population of prey putting both populations into loop of increase and decrease. In this paper, the modified Lotka-Volterra (forced Lotka-Volterra) model which has been introduced by Gause, see [6], has been employed in order to obtain chaotic behaviour

$$\frac{\mathrm{d}N_1(t)}{\mathrm{d}t} = \alpha_1 N_1(t) - \beta_1 \sqrt{N_1(t)}N_2(t) - \gamma_1 (N_1(t))^2, \quad (6)$$
$$\frac{\mathrm{d}N_2(t)}{\mathrm{d}t} = -\alpha_2 N_2(t) + \beta_2 \sqrt{N_1(t)}N_2(t), \quad (7)$$

where $\gamma_1(N_1(t))^2$ is a logistic term and also a penalty due to lack of room for prey as its number grows and the terms - $\beta_1\sqrt{N_1(t)}N_2(t)$ and $\beta_2\sqrt{N_1(t)}N_2(t)$ are now not proportional to $N_1(t)$

but to $\sqrt{N_1(t)}$. In other words, the original Lotka-Volterras collision terms are proportional to $N_1(t)$ while Gauses collision is obtained when it is proportional to $\sqrt{N_1(t)}$ of the prey community which contributes to collision and provides saturation effect for the collision. The saturation effect causes a population explosion of prey when the logistic term is disregarded, see [6]. In this paper, time-variance will be considered since recovery of grass causes a periodic oscillation of the grass-eating prey's population. Then the growth rate of prey turns out to be as following, which according to [1] yields chaotic behavior:

$$\alpha_1(t) = 2\left[a - b\cos(\omega t)\right] \tag{8}$$

where a is the positive constant and b and ω are the amplitude and angular frequency of the oscillating part of the growth rate respectively. Furthermore, these two forced Lotka-Volterra equation will be extended again using control inputs which are $\mu_1(t)$ and $\mu_2(t)$. It is possible to control the population of both species by intervening in their interaction. In other words, population dynamics can be affected by controlling amount of food provided, or controlling the population of species by introducing or withdrawing individuals from the habitat.

$$\frac{\mathrm{d}N_1(t)}{\mathrm{d}t} = \alpha_1 N_1(t) - \beta_1\sqrt{N_1(t)}N_2(t) - \gamma_1 N_1(t)^2 + \mu_1(t), \tag{9}$$

$$\frac{\mathrm{d}N_2(t)}{\mathrm{d}t} = -\alpha_2 N_2(t) + \beta_2\sqrt{N_1(t)}N_2(t) + \mu_2(t). \tag{10}$$

Here, $\mu_{1,2}(t)$ will be regarded as controlling the population of two species by introducing or withdrawing individuals since time-variance for the amount of food has been already considered in form of $\alpha_1(t)$. Even in the presence of chaotic behavior in the populations, a controller can help to stabilize the populations from the outside at an arbitrary level.

3 SYSTEM ANALYSIS AND CONTROL

3.1 Equilibrium points of Lorenz attractor

With Lorenz equations (1-3), equilibrium points fulfil the conditions $\dot{x} = 0$, $\dot{y} = 0$, $\dot{z} = 0$

$$0 = \sigma\left(y(t) - x(t)\right), \tag{11}$$

$$0 = px(t) - y(t) - x(t)z(t), \tag{12}$$

$$0 = x(t)y(t) - \beta z(t), \tag{13}$$

Since parameters σ, p, β are given as constants, the solutions are $x = 0$ or $x = \pm\sqrt{\beta(p-1)}$, $y = x$, and $z = p - 1$. Therefore, the equilibrium points of x, y, z including the origin are [4]

$$C^{\pm} = (\pm\sqrt{\beta(p-1)}, \pm\sqrt{\beta(p-1)}, p-1). \tag{14}$$

Using parameters $\sigma = 10$, $p = 28$, and $\beta = \frac{8}{3}$ as fixed by Lorenz, computing equilibrium points by hand results in $C^+ = (8.5, 8.5, 27)$, $C^- = (-8.5, -8.5, 27)$, which corresponds with Fig. 2.

3.2 Limited equilibrium of Forced Lotka Volterra using Jacobian Matrix

Using the forced Lotka-Volterra model in Section 2.2, limited equilibrium points can be reached Solving these two conditions,

$$0 = \alpha_1 N_1(t) - \beta_1\sqrt{N_1(t)}N_2(t) - \gamma_1(N_1(t))^2, \tag{15}$$

$$0 = -\alpha_2 N_2(t) + \beta_2\sqrt{N_1(t)}N_2(t), \tag{16}$$

apart from the trivial solution $N_{1,2}(t) = 0$ yields the following two equilibria:

$$N_1(t) = \frac{\alpha_1}{\gamma_1},\ N_2(t) = 0 \text{ or } N_1(t) = \frac{\alpha_2^2}{\beta_2^2},\ N_2(t) = \frac{\alpha_1\alpha_2\beta_2^2 - \alpha_2^3\gamma_1}{\beta_1\beta_2^3}. \tag{17}$$

For sake of brevity, we will consider just the first two equilibrium points in terms of local stability using the Lyaponov criterium which concerns the local stability. We can see that these two equilibrium points are locally unstable. Point 1 gives trivial solution because when there is no prey ($N_1(t) = 0$), there will be no predator as well ($N_2(t) = 0$). In other words, when one species will go extinct, the existence of the other species will also be endangered. When it comes to determining whether equilibrium points in both Point 1 and 2 are stable, the eigenvalues of the Jacobian Matrix J should be examined. Assuming that $f_1(t) = \frac{\mathrm{d}N_1(t)}{\mathrm{d}t}$ and $f_2(t) = \frac{\mathrm{d}N_2(t)}{\mathrm{d}t}$, Jacobian matrix of forced Lotka-Volterra can be described as following.

$$J = \begin{bmatrix} \frac{\partial f_1(t)}{\partial N_1(t)} & \frac{\partial f_1(t)}{\partial N_2(t)}, \\ \frac{\partial f_2(t)}{\partial N_1(t)} & \frac{\partial f_2(t)}{\partial N_2(t)} \end{bmatrix} = \begin{bmatrix} \alpha_1 - 2\gamma_1 N_1(t) - \frac{\beta_1 N_2(t)}{2\sqrt{N_1(t)}} & -\beta_1\sqrt{N_1(t)} \\ \frac{\beta_2 N_2(t)}{2\sqrt{N_1(t)}} & -\alpha_2 + \beta_2\sqrt{N_1(t)} \end{bmatrix}. \tag{18}$$

In order to analyze the equilibria stability, Lyapunov stability theory for time-variant systems states that the eigenvalues of $J_p^T + J_p$ must have a negative real part [7]. Two points are investigated. First, when point 1 is used,

$$J_{p_1} = \begin{bmatrix} \alpha_1 & 0 \\ 0 & -\alpha_2 \end{bmatrix}, \tag{19}$$

where we have two eigenvalues λ_1: $2\alpha_1$ and $-2\alpha_2$.

$$\det(\lambda_1 I - J_{p_1}^T - J_{p_1}) = 0 \Rightarrow \det \begin{bmatrix} \lambda_1 - 2\alpha_1 & 0 \\ 0 & \lambda_1 + 2\alpha_2 \end{bmatrix} = 0. \tag{20}$$

The determinant formula shows that λ_1 equals $2\alpha_1$ which has a positive value, thus making the system locally unstable around this equilibrium point. On the other hand when using point 2, the result is as follows

$$J_{p_2} = \begin{bmatrix} -\alpha_1 & -\beta_1\sqrt{\frac{\alpha_1}{\gamma_1}} \\ 0 & -\alpha_2 + \beta_2\sqrt{\frac{\alpha_1}{\gamma_1}} \end{bmatrix}, \tag{21}$$

and so

$$J_{p_2}^T + J_{p_2} = \begin{bmatrix} -2\alpha_1 & -\beta_1\sqrt{\frac{\alpha_1}{\gamma_1}} \\ -\beta_1\sqrt{\frac{\alpha_1}{\gamma_1}} & -2\alpha_2 + 2\beta_2\sqrt{\frac{\alpha_1}{\gamma_1}} \end{bmatrix}, \tag{22}$$

where we have two values for λ_2:

$$\det(\lambda_2 I - J_{p_2}^T - J_{p_2}) = 0 \Rightarrow \det \begin{bmatrix} \lambda_2 + 2\alpha_1 & \beta_1\sqrt{\frac{\alpha_1}{\gamma_1}} \\ \beta_1\sqrt{\frac{\alpha_1}{\gamma_1}} & \lambda_2 + 2\alpha_2 - 2\beta_2\sqrt{\frac{\alpha_1}{\gamma_1}} \end{bmatrix} = 0. \tag{23}$$

The two solutions for λ_2 are complicated, with the same real (and non-zero imaginary) part

$$\mathrm{Re}(\lambda_2) = -\alpha_1 - \alpha_2 + \beta_2\sqrt{\frac{\alpha_1}{\gamma_1}}, \tag{24}$$

so in order to investigate stability, it is enough to consider the real part of the two solutions of λ_2 and the stability condition (depending on the system model parameters) becomes:

$$-\alpha_1 - \alpha_2 + \beta_2\sqrt{\frac{\alpha_1}{\gamma_1}} < 0. \tag{25}$$

3.3 Controllers using Lyapunov equation

With controllers $\mu_{1,2}(t)$ which allows for convergence to an arbitrary level, a Lyapunov equation is used to make sure that the arbitrarily desired population size combination is stable. According to the Lyapunov theory, it can be described as

$$v(N_1(t), N_2(t)) = \frac{1}{2}[(N_1(t) - N_{1d}(t))^2 + (N_2(t) - N_{2d}(t))^2], \tag{26}$$

where $N_{1d}(t)$ is desired population of prey and $N_{2d}(t)$ is desired population of predator. In this paper, the desired population of prey and predator have been set for 200 and 300 respectively. Assuming that $(N_1(t) - N_{1d}(t))$ is $S_1(t)$ and $(N_2(t) - N_{2d}(t))$ is $S_2(t)$, the result of computing $\dot{v}(N_1(t), N_2(t))$ is as following.

$$\begin{aligned}\dot{v}(N_1(t), N_2(t)) &= (N_1(t) - N_{1d}(t))\frac{\mathrm{d}N_1(t)}{\mathrm{d}t} + (N_2(t) - N_{2d}(t))\frac{\mathrm{d}N_2(t)}{\mathrm{d}t} && (27)\\ &= S_1(t)\frac{\mathrm{d}N_1(t)}{\mathrm{d}t} + S_2(t)\frac{\mathrm{d}N_2(t)}{\mathrm{d}t}. && (28)\end{aligned}$$

Substituting equations $\frac{\mathrm{d}N_1(t)}{\mathrm{d}t}$ and $\frac{\mathrm{d}N_2(t)}{\mathrm{d}t}$ with forced Lotka-Volterra equations, $\dot{v}(N_1(t), N_2(t))$ can also be described as

$$\begin{aligned}\dot{v}(N_1(t), N_2(t)) = S_1(t)[\alpha_1 N_1(t) - \beta_1\sqrt{N_1(t)}N_2(t) - \gamma_1(N_1(t))^2 + \mu_1(t)]\\ + S_2(t)[-\alpha_2 N_2(t) + \beta_2\sqrt{N_1(t)}N_2(t) + \mu_2(t)]\end{aligned} \tag{29}$$

The input terms $\mu_1(t)$ and $\mu_2(t)$ which both consist of an equivalent and a corrective control term, can then be derived considering requirement $\dot{v} \leq 0$ of the sliding mode control approach

$$\begin{aligned}\mu_1(t) &= \mu_{1eq}(t) + \mu_{1corr}(t), && (30)\\ \mu_{1eq}(t) &= -\alpha_1 N_1(t) + \beta_1\sqrt{N_1(t)}N_2(t) + \gamma_1(N_1(t))^2, && (31)\\ \mu_{1corr}(t) &= -\eta_1 \tanh(S_1(t)), && (32)\\ \mu_2(t) &= \mu_{2eq}(t) + \mu_{2corr}(t), && (33)\\ \mu_{2eq}(t) &= \alpha_2 N_2(t) - \beta_2\sqrt{N_1(t)}N_2(t), && (34)\\ \mu_{2corr}(t) &= -\eta_2 \tanh(S_2(t)). && (35)\end{aligned}$$

Here, $\eta_{1,2}$ determines how strong the input term will affect the equation to which it is applied, which means in this case, how strong it controls the population of prey and predator in order to stabilize a population combination, where it naturally would not be possible. In simulation for the convergence under the control, η_1 and η_2 have been set to 1 so that the desired population of prey and predator can be reached. Furthermore, the corrective term contains the hyperbolic tangent function as a substition of sign function $\mathrm{sign}(\mathrm{S}_{1,2})$ for leading to a smoother graph with less oscillations in the simulink model.

4 SIMULINK MODEL IN MATLAB

The simulation of Lorenz attractor has been implemented in Matlab/Simulink to check whether it is possible to find pattern in chaotic situations. Instead plots of the considered Lorenz attractor have been visualized to describe the state evolutions of variables x, y, and z with Fig. 2. The Simulink implementation to see how the population dynamics of prey and predator converges using chaotic methods and controllers shows the following. Without connecting controller parts, both of the population of prey and predator show chaotic, unpredictable patterns in the respective scope blocks individually.

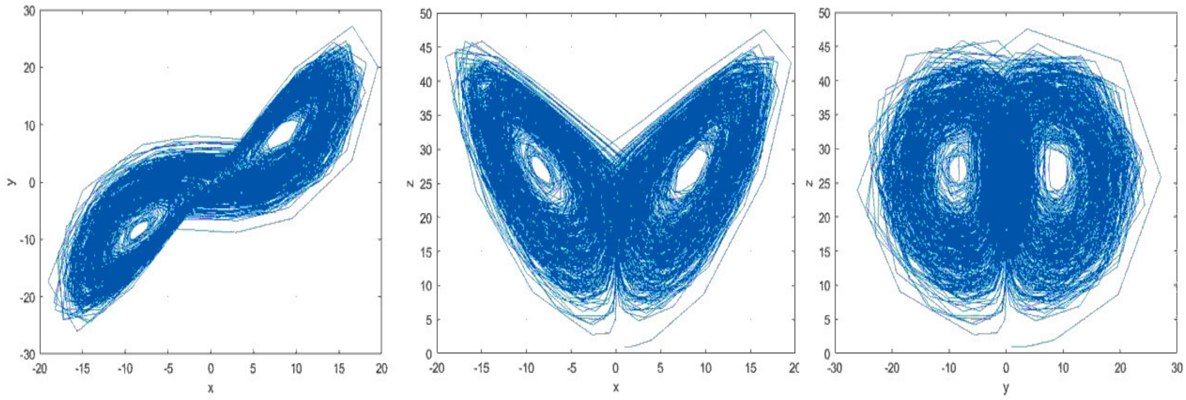

Fig. 2. 2D visualization of the three states of the Lorenz attractor

(1).png

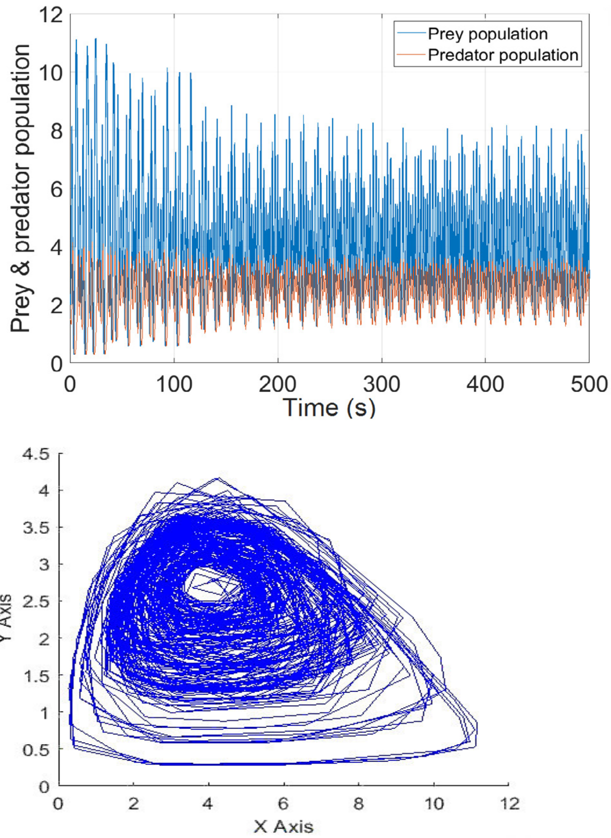

Fig. 3. Population evolution (left) of prey and predator without controllers and phase plot (right)

In Fig. 3, it can be observed that the population of prey ($N_1(t)$) fluctuates between 0 and 12 over time and the population of predator ($N_2(t)$) fluctuates between 0 and 4.5. Nevertheless, the XY graph shows that the population of prey and predator still converges into the center of the circle-like figure predicting that there will be approx. 4 preys (X axis) and 3 predators (Y axis) as time goes. With the controller part, the results show that the population of prey (X axis) and predator(Y axis) eventually reaches the desired population size which is 200 and 300, respectively, see Fig. 4.

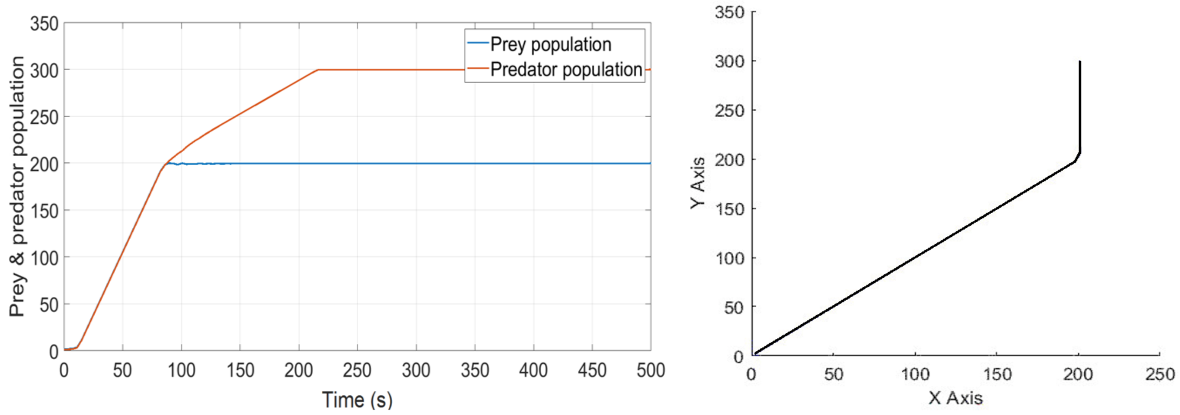

Fig. 4. Population evolution (left) of prey and predator with controllers and phase plot (right)

5 CONCLUSION

The real world is full of uncertain and chaotic phenomena. Therefore, employing simple linear prediction models with some assumptions is often not enough to enhance the accuracy of model-based predictions. Lorenz attractor from chaos theory and the forced Lotka-Volterra model are introduced as examples for systems that impede such predictions, due to extreme sensitivity w.r.t. the initial conditions. In case the initial conditions (and the model) are known with certainty, the chaotic behavior is deterministic and, hence, also predictable, with or without controller, yet more difficult. The presence of multiple equilibrium points implies that it is hard to predict real-life phenomena but thanks to simulation studies, it is still possible to make analyze convergence of the states. Furthermore, it is possible to deal with chaotic phenomena of fields other than meteorology using Lorenz attractor model and forced Lotka-Volterra equations. Promising applications can be found in economics (market shares of complementary and substitute goods), immunology of infectious diseases (populations of infected COVID-19 patients and susceptibles, etc.) or electronic devices (Chua's circuit). In execution of the course, the students' progress of learning was extensive.

ABSTRACT

This paper discusses the role popular science and science dissemination texts can have in learning physics in higher education for physics students and technical physics engineering students. In a mixed-methods study, students' attitudes, experienced motivation, and learning is mapped through a quantitative survey (N=155) and two qualitative surveys with in-depth interviews, one with six master level students and one with four 1st year students. The interview data shed light on two aspects of popular science's role in learning physics. Students report that reading popular science is highly motivating, but they do not have the perception of having learned physics from it. This converges with a division between calculations and conceptual understanding among the students. The paper then questions whether this gap could be closed or made smaller with greater emphasis on conceptual understanding in physics classes.

1 INTRODUCTION

In this study, we will examine the role of popular physics in motivation and learning in university-level physics education. We will try to answer the research question:

What contribution can popular science have as a learning tool, and how can it be employed as one in university-level physics?

Literature and experiences with popular science and physics education describe several tensions and dualities when it comes to the view of popular science from an academic perspective. We will particularly look at the literature regarding popular physics, but also use some considerations from the wider field of popular science.

1.1 The societal function of popular science

The first question we should apply is to define popular science. There is no common definition of what popular science is. A simple demarcation could be that it should be both “popular” - directed at a mass audience without strict demands on pre-knowledge, and “science” - it should be based on scientific knowledge, not fiction (or science fiction). As such it will have a large overlap with science dissemination texts, with one main difference being the latter having the stated objective of scientific dissemination.

However, one seminal text on the topic proclaims that ”If we are then to think of popular science as part of a conceptual ecosystem, we might then also have to conclude that there is no such thing as popular science.” [1] On the other hand, the author continues to argue that ”for popular science: it is not a thing, nor a category but a historical phenomenon that happens in human relationships.” In other words, do not ask what popular science *is*, but what popular science *does*.

We will firstly look at discussions on the role of popular science in society. This is not our primary objective - that is the effect on students - however, as little as physicists might like it, we too exist in society [2] and for our students, society is the primordial ooze they crawl out of on their way into the domain of physics.

In this area, the literature on popular physics mainly revolves around the role of popular science in domain conflicts, with common references to C.P. Snow’s “Two cultures” [3] and the United States’ “Science Wars” of the 1990s [4].

As an example, Felicity Mellor describes how ”The intertextuality of popular science books causes images of science which are supportive of scientists’ interests to continue to circulate in public discourse despite the alternative images thrown up by public scientific controversies reported in the news.” [5] Popular physics books are here thus seen as a tool for scientists to dominate not only science but also the public discourse on science in a process similar to a Gramscian struggle for hegemony [6].

In science, there has been a general concern about “public understanding of science“ and hence science has the responsibility to inform. “Scientists must learn to communicate to the public, be willing to do so, and indeed consider it their duty to do so” [7]. This will also to a large part be through science dissemination texts which will fall within popular science.

1.2 The effect of popular science on students

Drawing on a wide range of literature Christidou proclaims that «Popular science, communicated by the mass media, the internet, comics, films etc., pervades information sources widely used by young students -and the public in general- and is therefore considered as greatly influencing students’ conceptions, interests, and attitudes towards science.” [8].

We here, however, also find a duality, because even though it is important in forming and shaping students’ views of science, ”These information sources often promote intense, outdated, controversial, stereotypic and gender-biased images of science and its people.” [8]

This duality is about motivation and the view of science, but also of its practitioners, which popular science promotes. Similar dualities can also be found in the views on the effects popular science can have on learning physics. There does not seem to be a lot of literature on this topic, but there are a few more experience-based accounts that can give us an impression of the views on popular science from scholars in the relevant fields.

Lam [9] holds that «The use of popular science (PS) books is a long-neglected tool in teaching. [...] The idea is to help the students to broaden their scientific knowledge base as demanded by the real world out there, to foster a lifelong habit of buying and reading PS books, and become a science-informed citizen.” In such a perspective popular science can be a contribution to Bildung, in the sense of the German/North European tradition of education of popular enlightenment and connecting one’s education to one’s role as a citizen [10].

However, there are some worries about whether popular science might be more popular than it is scientific. Henry [11], e.g. observes that “However what sometimes happens is I see candidates who can regurgitate a lot of facts they have read in popular science books or New Scientist, but are then unable to relate this to the physics they have learned at school. They tell me about the Large Hadron Collider and the Higgs Boson, but get stuck when asked to draw the trajectory of a particle in an electric or magnetic field.” In this context, research on physics cultures sometimes one-sided focus on calculations should be mentioned as a possible partial explanation of the latter [12].

Leane also questions the scientific rigor of popular physics books. She e.g. points out that her “analysis of the use of metaphor in Zukav's The Dancing Wu Li Masters identifies the slippage of meaning that renders this text more of a hindrance than a help to cross-disciplinary communication.” [4]. There is thus a fear of simplifications that can hinder learning instead of strengthening it.

There thus seems to be a gap between the physics they read in popular science books and "real physics", i.e. the physics they learn in school or college, and the students cannot connect the two.

1.3 The effect of popular science on students

In reviewing the relationship between popular science and motivation we will employ self-determination theory (SDT) as described by Deci and Ryan [13]. SDT's describes three basic psychological needs, essential for motivation; autonomy, competence, and relatedness.

The first one, autonomy - the experience of being self-regulated in one's actions and experiences. Life as a student will always have the volitional aspects of being a student, feeling congruent and integrated, and not controlled by others, but at the same time, controlled by deadlines, a defined curriculum, and the final exam.

A second element is belonging - the experience of belonging and feeling socially connected. In this sense, it could be relevant to connect this to the discussions of popular science as a tool in domain struggles [4]. A university department will have a strong role in managing and controlling the professional domain of physics. In the sense that popular physics, perhaps written by a seasoned physicist, can give a student the feeling of access to this domain, it can be highly motivating. However, the skepticism towards aspects of popular science found within the same professional domain [4, 11], will also affect students' attitudes in the process of entering the domain of physics.

The third element, competence, is more contentious. How can students experience mastery and effectance from popular science if they struggle to connect it to their "school physics" [11]? One possibility is the overview popular science can give you [9]. If they do manage to connect it to the physics they learn in lecture halls, it can help the students to position it within a wider framework of knowledge.

When students enter the field of science, they are motivated to start studying and have a goal to finish, but, arrive with various knowledge about the path into the domain. Goals are representations of future scenarios that remain in memory, stored as knowledge structures. A goal can be defined as a "cognitive representation of a desired endpoint that impacts evaluations, emotions, and behaviors." [14]. Parts of this domain knowledge may be created by popular science.

2 METHODOLOGY

2.1 Section 1

The quantitative analysis is based on the Interactive Engagement and Motivation in Physics Learning (IMPEL) survey [15], which again is based on the Eccles-model within motivational theory [16]. The respondents are 157 first-year students from a physics class, composed of students where roughly one third are part of a bachelor physics program and two-thirds belong to an applied physics and mathematics 5-year engineering program. The students are asked about their motivations and perceived learning from different activities on a 5-point Likert scale.

We do a simple quantitative comparison of these IMPEL data on questions of perceived learning and motivation.

The 6 Master level physics students have gone through semi-structured individual interviews of approximately an hour length each. The data have been transcribed and are interpreted through a Phenomenological analysis looking for larger recurring meaning-units, using a process of meaning condensation from Giorgi [17-19].

We have also included elements from interviews of 4 first-year physics students. These interviews were mainly focusing on how students viewed their learning process facing the first course of mechanics but are included as there were elements from the interviews relevant to this current topic as well. The interviews were conducted by Martine Strand, a Master's student of Thorseth**.** These data were analyzed using thematic analysis as developed by Braun and Clarke [20].

We do not claim these qualitative data sets give reason to generalize to all physics students, not least as they are all from one Norwegian university, but also because it is a qualitative survey of a few students. We however believe these results may shed light on the quantitative results, and direct further research into whether and how popular science can be employed to increase student learning.

3 RESULTS

The quantitative results from this study show a huge gap between the perceived learning and motivation from popular science in physics. The qualitative data give us some suggestions for the mechanisms behind this gap and how it can be reduced.

3.1 Popular physics as motivation

The scores from the IMPEL-survey are presented in Table 1. If we first consider the responses on motivation, we see that all the popular science activities enter the top half, and 2 out of the top three most motivating activities are related to popular science. Only direct human interaction with peers tops popular science. When asked about perceived learning the popular science activities however drop dramatically. Watching popular science videos now get a medium score, while reading and lectures are placed in the bottom half. This difference between perceived learning and motivation can not be seen in any other activities. To clarify this we can look at the difference between the scores and see that apart from programming (which was not yet integrated well into physics for this student group) popular science are the only activities that motivate more than supply experienced learning, but also that the difference on a 5 point scale, between - 0,58 and - 0,82, is of a different magnitude than any other activities.

In examining the responses from the 6 master students we can confirm the motivating role of popular science. In describing their path to physics five of the six mention either popular science or fascination with the "big questions" about the universe as a key factor in their path to physics, often in connection. The same students, however, also reproduce the duality found in literature when it comes to perceived learning.

Table 1. Student responses to whether they experience learning and motivation from a range of learning activities on a 5-point Likert scale. The difference in mean score between learning and motivation is presented in the final column. The number of respondents, N, on the different questions ranged from 154-157 respondents.

	I learn physics well by…		I am motivated by…		Learn well minus motivated
	Mean	Std.dev	Mean	Std.dev	Mean
listening to the teacher talking in lectures	3,26	1,139	3,06	1,172	0,2
watching the teacher doing a demonstration	3,89	0,898	3,75	1,004	0,14
doing experiments	3,31	1,122	3,1	1,172	0,21
discussing subject matter with fellow students	4,5	0,799	4,32	0,843	0,18
solving problems with fellow students	4,46	0,83	4,23	0,944	0,23
solving problems alone	4,45	0,73	4,02	0,886	0,43
receiving help from a learning assistant	4,16	0,94	3,84	0,951	0,32
reading in textbooks	3,63	0,985	3,28	1,144	0,35
programming	2,55	1,024	2,81	1,127	-0,26
finding information I need by searching	3,61	0,918	3,4	1,033	0,21
watching podcast of lectures	3,03	0,872	3	0,95	0,03
popular science talks about physics	3,24	1,012	4,06	0,969	**-0,82**
reading popular science about physics	3,22	0,972	3,95	1,002	**-0,73**
watching popular science videos about physics	3,64	1,053	4,22	0,906	**-0,58**

Student 2 e.g., shows how she has made an autonomous choice of going to popular science to keep her motivation for physics up: "*I have in a way, parallel with my studies, to keep the spark, had to read popular science and sort of getting some* *input on that side parallel to my studies.*" We can see that this activity supplies motivation she needs for her studies. At the same time, it is considered as something separate from them. She also separates the two with the following description of her studies: "It's not like it's popular science we are doing".

Similarly, we can see from Student 3. "*I read about it, about physics on quite a popular science level, but… it was something I found quite interesting*", while at the same time describing his knowledge in one field: "*When we start talking about quantum field, because I haven't had that, it still becomes for me, like, popular science, because I don't know anything about that.*" We see here that popular science becomes a description om "not knowing anything about" something.

Student 6 brings in the same skeptical view: "*I always felt that when you read popular science, you become a little insecure - do you understand this? To understand physics, you sort of have to work intensively with it over a long period of time and the understanding comes gradually. If you read a popular science book, it's interesting, but the you think: 'Do I really understand this now?'*"

3.2 Conceptual understanding vs. calculations

Understanding how the world works is a central motivational point for physics students, most of the interviewed Master's students regard conceptual understanding as important for choosing physics. All students stress the importance of conceptual understanding in physics. Two students without being asked explicitly, point to the use of math to describe physical reality rather than just math itself, as the reason they chose physics over math.

The reality in physics education is however that many of these students believe there is too little room for the conceptual understanding within university physics. Student 2 points out that "*at times it becomes a bit like you learn what's in the books, learn to calculate and solve exercises, but you perhaps don't get to attach it to physical phenomena you can observe*". S3 continues: "*You sit there at the quantum lecture, and go through an hour of calculations, and you get something, and then - you got, the math is ok, you understood every step, but pfff - what happened here, like? What did we figure out?*"

Student 4 sums the sentiment up with "*you have to understand it up against nature. If it's just symbols on a paper and you don't even know what it means, what the result is for the world around it, then I actually don't have much interest anymore.*"

The Master level students thus share the dual view on popular science seen in literature: Motivating, yes - learning, more doubtful. At the same time, they experience a lack of conceptual discussions in calculation-dominated physics classes.

3.3 A possible connection

From one of the interviewed first-year students, we however get an example of how popular science perhaps could have a positive role in learning physics, at a university level. Here we see students having an aha moment when they link learning to previous knowledge, given by popular science:

"*At upper secondary… Yes, I had some aha-moments. They're not as big as here at university, I feel. But my aha-moments are often that I think something is very cool or that I have heard about something, and then I finally learn about it.*" He then goes on to explain how popular science can give these aha-experiences in later education: "*For example, this relativity with Einstein, not that I understand it completely, but that I have gotten to hear something about it, learn something about it, then I think it's very exciting and I get that aha-experience.*"

Being primed by popular science and then learning (more) about something can thus create motivating effects. If the perceived gap between popular and "school" physics can be overcome; this then discloses a role in learning popular science. By priming the students and giving an overview of a field of research, students can connect what they learn in classrooms to a wider map of knowledge.

4 SUMMARY

Physics students have self-driven motivation to read popular science beyond what is communicated in media and movies. Our physics students repeatedly turn to popular science for motivation, as an active way of regulating motivation. In this sense, popular science will fit well as it is usually not a part of a curriculum and will be something students autonomously choose to pursue on their own. They find popular science and popular science lectures motivating. A motivating part might be that it might reactivate the goals of becoming a physicist.

We have seen that both academics and students have a dual view of popular science. While it is highly motivating, its' learning effects are doubted. Both earlier research and students interviewed in this paper, often describes a calculation-driven university physics education. They call for increased attention to conceptual understanding, which connects the mathematical physics to the world it's meant to describe. One of the questions we thus would like to put forward based on these data is whether the gap between the mathematical and conceptual is an important reason for the perceived gap between "popular physics" and "school physics".

Conceptual understanding is an important part of physics, and in cases where this is being neglected, it should be given more room. This should diminish the gap between calculation-oriented university physics and conceptually oriented popular physics. If this is successful, could popular physics then be a tool for increased conceptual understanding and a better overview of the field in university physics?

We believe the results from these different surveys prompt the idea that this question should be taken more seriously and suggest that there is a possibility of more conscious use of popular science even at the university level. We believe there are possible paths for popular science to contribute to learning, and in addition, popular science brings forth a motivational factor sorely needed by some students when facing a perhaps solely calculation-oriented university physics education.

Abstract
In this paper we studied the student's perception of the acquisition of professional capabilities in Challenge based learning environments with a strong reflective component. The results show students feel the relevance of personnel development from the very moment the enter their master studies. However, they only truly acquire all the relevant professional capabilities when working in interdisciplinary teams on real life problems in interaction with stakeholders.

Introduction

Current trends in education, such as embedding challenge-based education and reflective activities, presume that professional skills training in these contexts strengthens students' professional capabilities. Moreover, it should prepare them for a better professional life after their higher Engineering Education. However, the variety in curricular design, the moment of measurements, and students' profiles will likely impact the students' perceptions of their capabilities. This paper investigates three types of challenge-based education offered on critical parameters. Successively, we will assess the impact of students' reflective journey in CBE on their perceived professional capabilities. The central questions is: **"What are the professional capabilities students feel they have acquired during courses including elements of challenge based education and reflection on personal, professional, disciplinary aspects?"**

The three CBE contexts concern (1) an MSc Programme in Robotics, (2) a fundamentals course in Bio-Medical Engineering and (3) a Second-year master course focused on interdisciplinary R&D development with external stakeholders. Each of these programmes/courses includes challenge-based elements; it consists of real-life cases, multi/interdisciplinary learning, stakeholder involvement, self-directed learning of students, collaboration, (transversal) skills development and last but certainly not least reflective learning. Together with the opportunities of a challenge-based learning environment, the reflection should expose students to learning that improves their professional capabilities. Professional capabilities consist of different elements based on the concept of the "deliberate professional" of Trede; the elements are:
personal development, collaboration, critical evaluation skills and contextualisation.

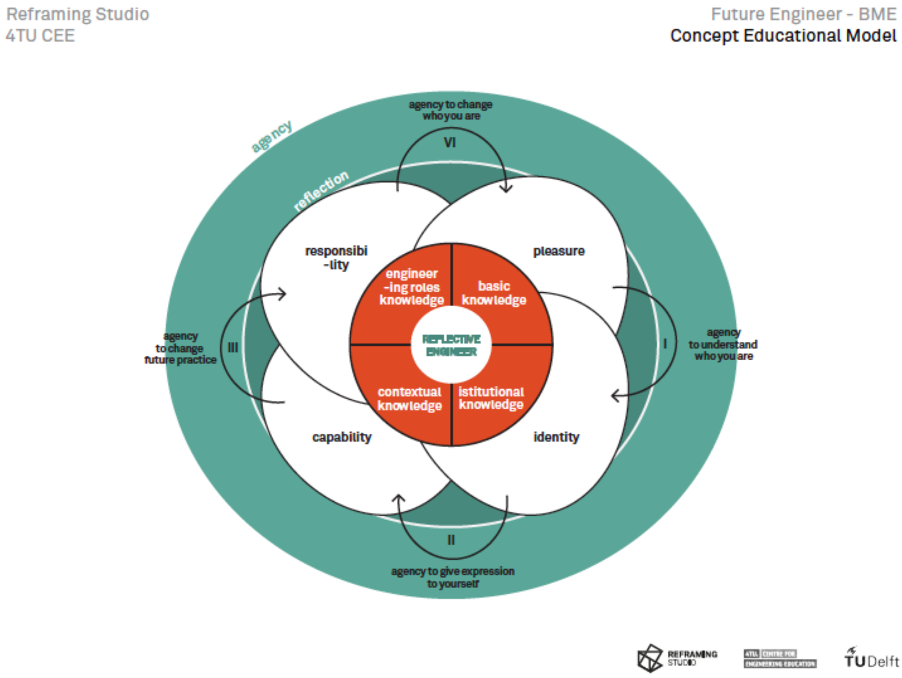
A survey has been administered to investigate the perceived professional capabilities. We will examine the curricular difference, moments of measurements, and to some extent, students' profiles related to the perceived differences. Finally, we will consider the implications for the curricular design of CBE and reflective activities.

THEORETICAL BACKGROUND

Nowadays, there is less congruence between scientific discipline and the occupational structure. New occupations and professions often emerge at the frontiers of disciplines, thus requiring a different kind of knowledge, skills and attitude (van Damme, 2022 (dies Natalis lecture wur). Biesta (2017) call this new purpose of education the task of qualification, socialisation and subjectification. The function of acquiring knowledge, skills and attitude for a job, the socialisation into a particular culture and the growing of identity as each individual are unique. Professional capabilities are representative of **the missing gap between** the more traditional disciplinary degrees towards the occupational structure, which also requires skills relating to socialisation and subjectification. According to Biesta, we need to balance these three educational functions and not over-emphasise one over the other. Trede (2016, 2022) has identified these additional capabilities, besides qualifications, as actions of the deliberate professional. She holds that reflexivity, action and dialogue will ultimately lead to purpose and values, decision making as supportive of choice and gaining change agency. The characteristics of the deliberate professional are expressed in fig. 1

Focusing on:

- Being aware of the complexity of the workplace practice, cultures and environments
- Being realistic about what can be done concerning existing and changing practices
- Positioning oneself in the field as well as making technical decisions
- Being aware of the consequences of doing and acting in relation to a particular practice.



In this" new model" (fig. 2), we have translated these principles into a cycle of Metamorphosis, wherein the kernel, the Qualifications and Socialisation are addressed at the level of basic disciplinary knowledge, the institutional knowledge of methods, tools and approaches and the accompanying skills, the contextual knowledge of authentic real-life situations of a company, institution or other stakeholder party and the finally, the individual engineering role or deliberate professional that emerges from the knowledge and skills accrued on the way, while centre-staging reflection on each of these (iterative) phases of growth. Where one first has to establish; who am I? How to express myself in a professional/academic context, have the insight and foresight to change future practices and eventually have the Agency to enact my role and change who I am. These translate into criteria that need to be met within the curriculum and are likely to be emboldened in challenging learning environments.

The three CBE contexts concern (1) an MSc Programme in Robotics, (2) a foundational course in Bio-Medical Engineering and (3) a Second-year master course focused on interdisciplinary R&D development with external stakeholders. These three courses have been chosen because they include reflection (on socialisation/subjectification) and are, to a greater or lesser extent, to offer a challenge-based environment (addressing qualification and socialisation) and in interaction and iteratively reinforce subjectification. Each of these programmes/ courses includes challenge-based elements; it consists of real-life cases, multi/interdisciplinary learning, stakeholder involvement, self-directed learning of students, Collaboration, (transversal) skills development and last but certainly not least reflective learning. These elements have been identified in scientific research from the 4TU Centre for Engineering education[1]. Together the opportunities of a challenge-based learning environment and reflection should expose students to learning that improves students' professional capabilities. Professional capabilities consist of different elements based on the concept of the "deliberate professional" of Trede.

In a recent review study by (Garcia-Alvarez et al., 2022), it is emphasised that higher education institutions are responsible for educating students to be relevant to the labour market and the need to adapt pedagogies of employability, where students learn to operate adequately across different contextual situations. They have investigated transversal skills in the literature and how oft these are mentioned by the industry as necessary skills to be learning in higher education to respond to and be aware of unpredictable environments. In contrast to this view, we would rather like to emphasise another stance, where it is not the industry that should or might determine what students need. Instead, it should be the students who have the tools and capabilities to shape and make sense of their personal lifelong learning trajectories. Despite this different viewpoint, there is a significant overlap in the knowledge and skills being addressed. However, it emphasises the individual's Agency to act with reason and decision in diverse situations. Thus, as Trede (2016) defined, professional capabilities have been operationalised in the elements; personal development, Collaboration, critical evaluation skills, and contextualisation, which are tooled to realise daily practices within a coherent model. (Higgs, figure 13.3, p……) see below fig. 3.

Fig. 13.1 Deliberate practice and deliberate education

We have further defined these elements in table 1 as;

Table 1 Constructs used to measure Professional Capabilities

Part 1 – Personal Development	
Self	Discovering who I am
Emotional Reflexivity	Dealing with emotions
Resilience	Bouncing back from set backs
Part II Agency	

Evaluating Information	Judgement against professional quality criteria/standards also known as evaluative judgement (Adawi)
Critical Stance	Critical thinking and taking a position concerning professional topics
Part III Collaboration	
Communication	Being able to collaborate with peers, within the community (team/groupwork) (Picard et. al)
Interprofessional Competence	Being able to communicate across domains/professional boundaries (Picard et. al)
Part 4 Contextual insight	
Informed Vision	Being aware of the wiser developments and one's (organisational) roles there in
Ethical Sensitivity	Ethical behaviour in complex sensitive situations. (Picard et. al)

In the table 2, we will show the elements of both the focus of reflection and the characteristic of challenge-based elements present in each course. Later on, we will reflect on these by combining them with professional capabilities.

Table 2. Characteristics of Challenge based education and the investigated courses.

Characteristics	**BME – 1st year MSc**	**1st entire year Robotics Programme, MSc level**	**Joint Interdisciplinary Course 2nd year MSc**
			Reflection (metamorphosis) Reframing/4TU- CEE based on Trede (2016)
Who am I	Personal reflection	Goalsetting	Establish personal learning goal at the beginning
Develop insight and foresight	Peer feedback from other teams	Continues feedback from staff and peers on reflection in portfolio assignment	Continuous feedback from peers, staff, stakeholders – during the course. Formalised reflection moments
How do I give expression to myself	X	Reflect on the received feedback in portfolio assignment	Reflect on feedback – write reflection doc.
Who I am and determine change	X	Feedback-cycle, setting new learning goals and making choices in that direction.	Growth feedback moments and reflection writing as a team and individual as part of the final assessment.
			CBE- based on
Learning Students work with teachers, in order to develop a deeper knowledge of the subjects they are studying. It is the challenge itself that triggers the generation of new knowledge, necessary tools and resources	Students follow lectures, workshops and at the end do a project with "real life" case. No external stakeholders are involved	Students design learning path, formulate learning goals (20 EC electives), follow multidisciplinary (5 EC) and integrated programme with focus on individual choices in the context of challenges in society. Transversal skills development /reflection portfolio (together 11 EC)	Students independently tackle and R&D project either with a societal or phenomenal problem.

Product It requires students to create a solution resulting in a concrete action	Results focus on solving the project assignment and passing the exam for their own learning	In the multi-disciplinary project students work with companies on real life cases by finding a robot integrated solution. A reflection portfolio is continuous.	Project report, including a concept design, prototype, model or research report
Focus it faces students with an open, relevant, problematic situation, which requires a real solution	It faces students with a relevant situation and pre-defined problematic for which a solution needs to be found	Students have to define the problem in teams and have to take the company's expectations into account, when generating ideas and creating solution findings for the multidisciplinary project.	it faces students with an open, relevant, problematic situation, which requires a real solution
Process students analyse, design, research and develop and execute the best solution in order to tackle the challenge in a way they and other people see and measure.	Students work with the assigned project in teams and generate products for their own learning	Students work during the whole programme on their development in skills in the (project) courses by reflecting in a portfolio and the guidance of mentors in mentor groups. As a final assignment the have to present their portfolio.	Students work in teams in collaboration with company staff and academics to come to a desired solution for a real-life problem
Students in the lead of the process, and from interdisciplinary backgrounds	Students (with narrow interdisciplinary backgrounds) coached on predefined problems space.	Students (with narrow Interdisciplinary backgrounds), work in teams, create an individual portfolio are coached by a mentor and partly define the problem space.	Interdisciplinary and intercultural students' teams are in the lead of the entire process
Teachers' role coach, co- research and designer	Instructing/ coaching students as expert.	Mentoring groups, mentors focus on student's personal development	Everyone (students, company staff/academic experts/IIP) is looking for answers.
Evaluation of the activities	Quality assurance and additional surveys + interviews	students reflect on the (technical) experiences. Instructing, coaching, guiding, advising.	Testimonials, surveys, interviews etc.

METHODOLOGY

In this mixed-method study, we have questioned whether students, through reflectional activities and course activities, felt better able to perform particular behaviour related to professional capabilities. The questionnaire has been developed to measure these professional capabilities across various contexts in two Master's programmes of an Engineering School, besides the interfaculty course referred to in this article. All of the Sample contexts include Reflective activities on personnel and skills development, some challenges – ranging in openness of the design briefs and "real" life cases, involvement of stakeholders, a level of flexibility in students' choice and a Master's level.

Professional capabilities are measured at four levels:
1st: Personal Development: Knowing oneself (Self), Emotional reflexivity and Resilience
2nd: Agency: skills to critically think about the problem at hand and take a stance; evaluate information at a professional level, such as evaluative judgements
3rd: Collaboration, consisting of interprofessional competencies and teamwork.
4th: Contextual Insight concerns contextualisation and ethical sensitivity.
.

The overall model components are derived from Trede's model on professional capabilities explained in her book the Deliberate Professionals (Trede, 2009). Such as having an informed vision, emotional reflexivity, resilience, and taking a stance. Questionnaire questions have been taken from existing and validated questionnaires or qualitative studies, amongst others from the IMPQ (Picard et al. 2021), which investigated professional teamwork skills. Furthermore, the critical thinking white paper from Davies & Stevens (2019) Pearson's talent management offers evaluative judgement and critical thinking items as a construct.

Table 3. Cronbach's alpha of each construct

	items	Cronbachs' alpha	Source
Part 1 – Personal Development		**.90**	
Self	N = 4	.75	Trede
Emotional Reflexivity	N = 6	.79	Trede
Resilience	N = 8	.79	Trede
Part II Agency		**.85**	
Evaluating Information	N = 5	.78	Critical
Critical Stance	N = 4	.77	Critical
Part III Collaboration		**.86**	
Communication	N = 5	.69	IMPQ
Interprofessional Competence	N = 5	.81	IMPQ
Part 4 Contextual insight		**.80**	
Informed Vision	N = 7	.67	Trede
Ethical Sensitivity	N = 4	.83	IMPQ

Response Rate
The sample population consisted of voluntary participants in a survey of those students who followed the course/programme. For BME, the response rate was N = 28 out of 100. For the Robotics, N= 47 out of 200, and for IiP, N = 54 out of 150, amounting to around 20 to 30% of the sample population. As the subgroups were not big enough for major comparative statistical procedures, we are reporting the aggregate average and (SD) on a construct (continuous variable) for each group. The ideal sample size with 95 confidence interval would be 177 in total. However we only have 126, which means we can interpret the data at a 85% confidence level, taking an error margin of around 5% into account, while at the same time not discarding relevant findings (Bacchetti, 2013)

As most of the Cronbachs' alphas were moderately high, we have been able to include all of the constructs. Hopefully, we'll be able to do a CFA when we have collected additional data in the next academic year. We do emphasise, however, that the question items have been taken from validated questionnaire scales, and we, therefore, assume they, together with the reliability measure, meet the quality criteria.

Focused Group Interview

After the survey, a focused group interview was held with students of the BME course N= 5, mentors of the BME- course N = 4, and Robotics N= 2 students. The JIP students have left testimonials. We have organised the group interviews around a journey map on which students could indicate their highs and lows within the course on specific key issues, such as engineering roles or organisation. After which, a conversation ensued about their likes, dislikes and recommendations for improvement. Equally, they indicated what they learned the most. No guiding comments were made apart from the engineering roles on aspects of the questionnaire. Here we will report on the Miro documented journey map and learnings. And possibly some quotes, as a systemic analysis has yet to happen on the transcripts of the group interview recordings.

RESULTS

In this part, we will 1st report on the survey results. Successively, we will proceed to the focused group interviews. In the conclusions, the results will be summarised..

Survey

We are comparing three different groups here. The constructs have been aggregated for a continuous variable. As almost all the assumptions for a One way ANOVA are met, no outliers, normal distribution (Shapiro Wilkes,05), apart from the Levine's test of homogeneity of variance, we have used the WELCH ANOVA to correct for differences in homogeneity and have used a post- hoc Games- Howell test and have found sig difference between all the groups. The following paragraphs will look at the levels and separate sub-constructs.

Table 4 Welch Anova test

Robust Tests of Equality of Means

		Statistic[a]	df1	df2	Sig.
Self	Welch	17.596	2	58.154	<.001
EmotionalReflexivity	Welch	21.694	2	62.087	<.001
Resilience	Welch	12.181	2	60.746	<.001
informedvision	Welch	11.938	2	63.925	<.001
EvaluatingInformation	Welch	19.469	2	55.782	<.001
CriticalStance	Welch	13.851	2	62.875	<.001
Communication	Welch	9.203	2	69.485	<.001
Interprofessionalcompetence	Welch	11.852	2	61.304	<.001
ethicalsensitivity	Welch	8.501	2	69.796	<.001

a. Asymptotically F distributed.

Personal development

In the personal development table one, we notice that the interfaculty interdisciplinary project (IIP) scores the highest average on personal development, closely followed by Robotics and the BME course, as shown in table 5.

Table 5. Personal Development (means /sd)

	SELF	EMOTIONAL REFLEXIVITY	RESILIENCE
IIP	M = 4.3 (SD.37),	M = 4.2 (SD. 44)	M = 4.15 (SD .40)
ROBOTICS	M= 4.1 (SD.51)	M = 3.8 (SD .48)	M= 3.9 (SD .46)
BME	M = 3.4 (SD.73)	M = 3.4 (SD .64)	M= 3.5 (SD .65)

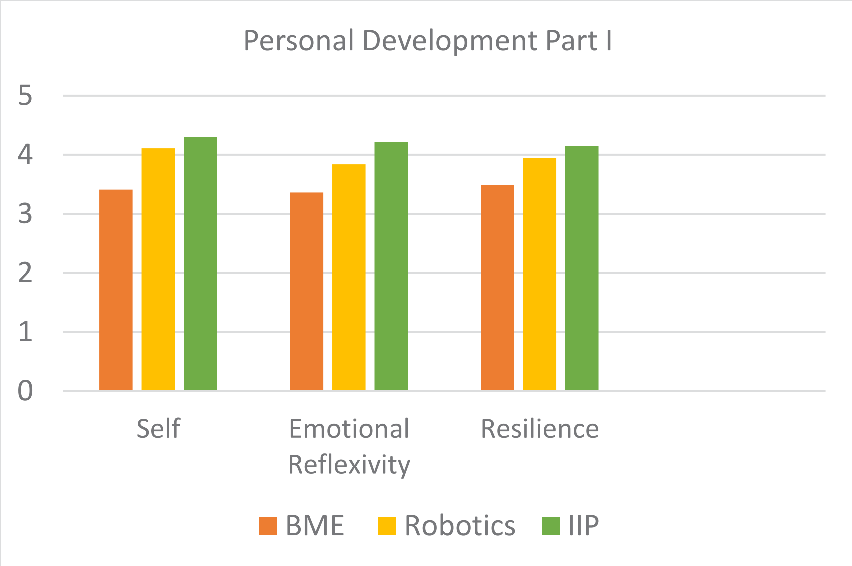
Despite the slight differences, there are significant differences for each sub-construct, Self, Emotional Reflexivity and Resilience smaller than < .001, between the IiP and BME groups. The IiP and Robotics group on the sub-construct Self do not score significantly .096. On the sub-construct Emotional Reflexivity, the Robotics/BME group scored significant (.005) differences. And on the sub-construct Resilience significance of .054 between Iip and Robotics and significance of .007 on Robotics BME. We are making the distance between IiP and Robotics more similar than the equation Robotics – BME.

The estimated medium effect sizes eta- squared are Self .30 Emotional Reflexivity .30, and Resilience .21. The numbers show a large effect size as their all higher than .14, meaning a larger proportion of the variance can be attributed to the personal development variable than what we can expect based on the standards of variance. Where Self and Emotional Reflexivity are vital aspects of knowing who one is. If we look at the course criteria, the BME course does not yet include all the reflection opportunities available, whereas the Robotics and IIP course does.
This finding suggests that going through the full circle of reflection is of importance; equally, the extent to which autonomy, interdisciplinarity and a real-life case is present may have impacted these results. Specifically, since Robotics is moving up to the fully challenge-based and interdisciplinary, autonomous shows results towards the IiP course. With items such as

- "I am aware of my engineering role."
- "I have become aware of my passions."
- "I have been able to make a choice that fits my personal value."
- "I feel more independent (in control)."
- "I am better able to make decisions."
- "I am better able to ask for help."

very close to the IiP course. Noteworthy is the item: I feel confident to share my ideas, which scores highest for Robotics average at 4.2 and an only average of 3.7 for IiP and BME. All the other items are scored close to BME.

Table 6. Visualisation average means Part I



Agency

The sub-construct Agency has the capability of giving expression to one Self. This Agency is supported through the creation of judgement and evaluation of professional standards in the survey evaluating information. Secondly, critical thinking helps to take a critical stance. Included in table x are the mean averages and SD.

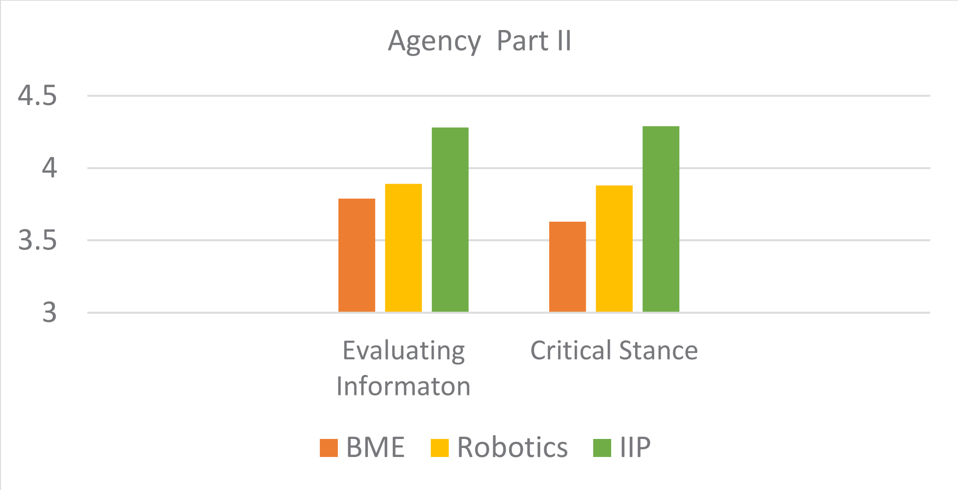
Table 7 averages part II

	EVALUATING INFORMATION	CRITICAL STANCE
IIP	M = 4.3 (.40)	4.3 (.49)
ROBOTICS	M = 3.9 (.42)	3.9 (.50)
BME	M= 3.8 (.65)	3.6 (.67)

Here we find a significant difference between IiP vs Robotics < .001 an IiP and BME .002 on Evaluating Information. The construct Critical Stance is significant <.001 between IiP vs Robotics and BME. Between Robotics and BME, we do not find a significant difference in Evaluating Information and Critical Stance.

Effect sizes being large again for Evaluating Information eta squared is .21, and for Critical Stance, the eta squared is .20. Albeit a little less than personal development, the impact still mainly shows the importance of evaluating information against professional standards with real stakeholders and learning to take a critical stance when dealing with peers, staff and stakeholders in real challenge situations. Although the Robotics group does have a slightly higher mean on individual items, they did not yet seem to have practised enough with these skills and remained close to the BME course, particularly on taking a critical stance.

Table 8 Visualisation Part II



Collaboration

The Construct Collaboration consists of the sub-constructs of Communication with peers and staff and Interprofessional Competence where the Communication with external stakeholders is emphasised and allows for reflection on the context of different disciplines, and provides insights and foresight to change these contexts. The means (rounded) averaged and standard deviations are reported below.

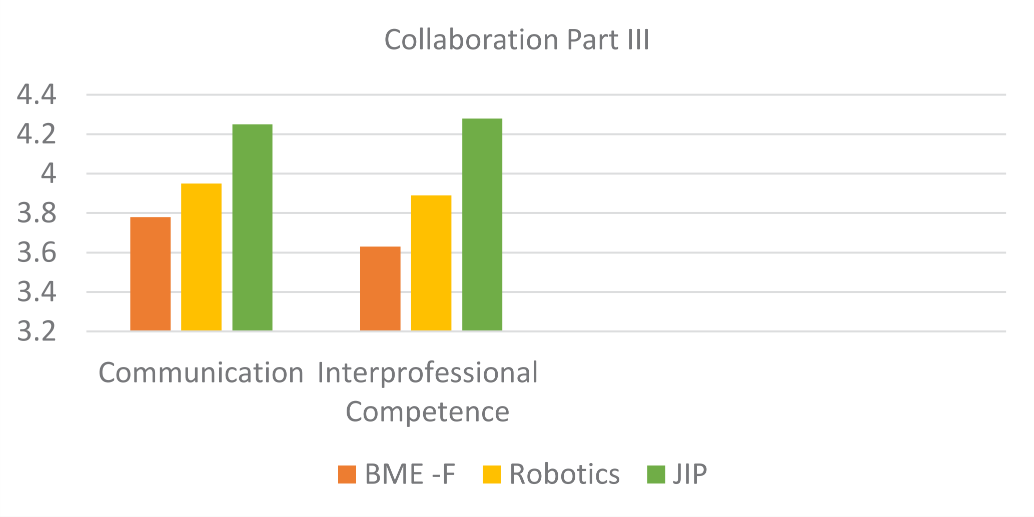
Table 9. Average Part III

	COMMUNICATION	INTERPROFESSIONAL COMPETENCE
IIP	M = 4.3 (.49)	4.3 (.49)
ROBOTICS	M = 3.9 (.56)	3.9 (.53)
BME	M = 3.8 (.48)	3.6 (.75)

The analysis of Communication shows significant differences between IiP and Robotics .017 and IiP and BME <.001. Robotics and BME do not significantly differ in Communication. For the interprofessional competence, we find both significant differences <001 for IIP vs Robotics/BME and non-significant differences between Robotics and BME.

Effect Size on Communication is moderate eta squared .12 and on interprofessional competence large .17. It shows that Communication within academia is at the end of the 1st year of normalised professional capability irrespective of the level of autonomy of students, the openness of the challenge brief and the reflection. However, for interprofessional competence, we again find that interactivity with external stakeholders and with peers and staff from other disciplines is of importance for the development of professional capability.

Table 10 Visualisation averages Part III



Contextual insight

Finally, contextual insight consists of having an Informed vision of the disciplinary context and ethical sensitivity. These skills should allow for contextualisation, determining one role and flexibly adapting based on individual values, responsible and moral judgement.

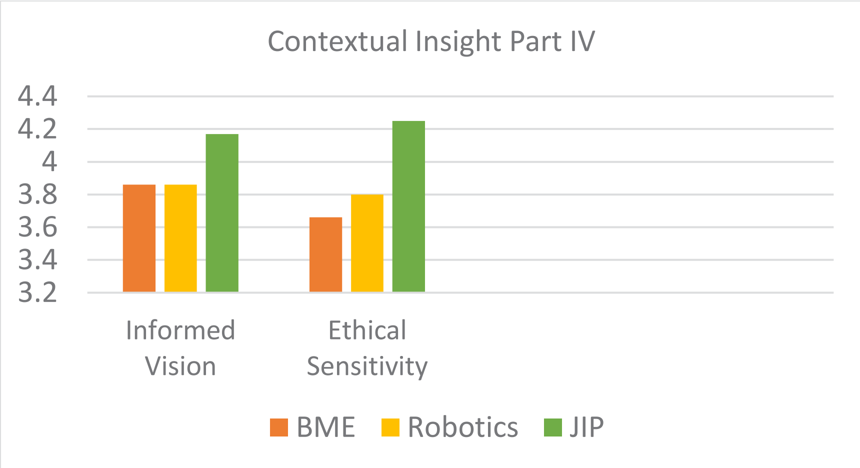
Table 11. average Part IV

	INFORMED VISION	ETHICAL SENSITIVITY
IIP	M = 4.1 (.40)	4.2 (.67)
ROBOTICS	M = 3.9 (.39)	3.8 (.70)
BME	M= 3.7 (.50)	3.7 (.63)

gain, significant differences at the <.001 level between IiP and Robotics/BME for informed vision and no significant differences between Robotics and BME. For Ethical Sensitivity, we find a significant difference at the .007 level between IiP and Robotics and .001 between IiP and Robotics, showing the Robotics group is much closer here to the IiP. For Robotics and BME, we did not find significant differences.

Effect sizes for informed vision are large .17 and for ethical sensitivity .12 moderate. Noteworthy on individual items is that the robotics students find it hard "to put themselves in the shoes of someone whose life could be affected by a project result". However, this fact may also be related to the fact that Robotics is focused on the artefact to a larger extent than the other two courses and possibly causes an indirect impact or no impact at all. Another Item is "I am aware of the historical development of my disciplinary field", in which Robotics scores (M = 3.6) are much lower than the BME (M= 3.8) /IiP (M= 4.0) courses. Possibly, as there is not much history yet. The item "I am aware of the wider (societal, academic, technical) system in which my discipline operates" is scored on par with the IiP at 4.0.

Table 12 Visualisation average Part IV



Focused Interview results

In this section, we include some of the major outcomes of the post-it notes (of the Miro board) on learning. One of the questions we have asked the student is what did you acquire in terms of professional skills during the BME and Robotics programme. Included below are the quotes.

Personal Development students mentioned;
BME – student; *"it is a good course to help the students understand their role as engineers and direct them to future choices*."
BME – Students: "*Looking back I can say that it was good to think about my role in society and I have learned a lot from the self-reflection assignments."*
BME – Mentor; *"Thought of role, they were never confronted with before, which may help them for the future."*
BME – Mentor; "*I liked that the course forced participants to think of engineering in a social context. It is an area often overlooked, or secondary to professional development, but ultimately it holds great importance and is key to the success of the individual."*
Robotics- students: *"Providing feedback and taking feedback in a constructive and valuable way."*
Robotics -student: "The portfolio was hard to set up in the beginning but helped me in my personal development, and I think it was very good to have, by design, spread out over the 1.5 years."

Professional skills:
BME- students: – "*Some workshops, e.g. on the debate, were really appreciated."*
Robotics students: - "*Communicating with many different backgrounds and being open-minded."*

Robotics students: "*I like the variety of the assignments and the connection to developments in the outside world; it always felt like we were working on contemporary topics.*"

Engineering knowledge:
Robotics students:
- *"it is always important to go back to the general question and not to get lost in details. "Breaking down the problem helps with developing a solution."*

Students in the BME course asked for more interaction with the stakeholder field and external professionals or involvement from the industry. Additionally, they asked for more professional skills training. And their wish for a stronger focus on personal development. Equally, better mentorship guidance would have been appreciated. Indeed, the Robotics students noted that the mentor's guidance was valuable in becoming more autonomous learners. In IiP, the continuous feedback from peers and external stakeholders, together with the reflections on content and personal development, forced them to work independently very quickly.

CONCLUSIONS AND SOME EXTRA OBSERVATIONS

In this study, we have learned that students value working on personal development from the very start of their Master's Programme. However, in the 1st course, students are not confronted yet with real-life cases; they are experimenting with a technical solution for a BME problem and focus on discovering who they are and their role—resulting practically in less pronounced development in professional capabilities. This result could either be due to the limited maturation of the students or the fact that they did not get challenged and autonomous enough during this course.

Furthermore, professional capabilities such as Agency, supporting how to give expression to myself, Collaboration: having insight and foresight to change future practice and contextualisation are particularly acquired in a situation where challenge-based education with real-life cases, external stakeholders and different academic disciplines are brought together. Although the maturation of students may also have affected these results, reflection at each level is one of the key tools to accomplish a greater mastery of professional capabilities. The portfolio reflection particularly helped students with their personal development and expression of their ideas, but only to a limited extent for the other professional capabilities. The CBE course for Robotics may have come too late in the process, as growth truly occurs when integration of the engineering knowledge, skills and personal development come together. An integration which the students highly appreciate. Equally, mentor coaching and InterVision in the robotics programme were highly appreciated and felt as if students were better prepared for their final thesis work.

DISCUSSION

In the introduction, we asked the central question: **What are the professional capabilities students feel they have acquired during courses, including elements of challenge-based education and reflection on personal, professional, disciplinary aspects?".**

We conclude that programmes where students work on real-life challenges with third party stakeholders, address personal learning goals, and critically reflect on their personal, professional development, and engineering knowledge seems to yield higher learning awareness levels. This increase in learning awareness levels can either be achieved through early integration in the programme or when students have a higher level of maturity. It might be more effective to offer students challenge-based education over a more extended period than to offer them internships, although this bold statement should be investigated.

When particularly looking at the course design, we note that:

- More attention should be given within the curriculum to evaluative judgement and critical thinking, and taking a stance
- Interprofessional skills informed visions, and ethical sensitivity is particularly learned when external stakeholders and a real-life challenge are available
- Personnel development can best be developed with goal setting, discovering who you are, beginning at a very early stage with the support of a portfolio, leading to more autonomy and maturity.
- Integrated curricula with self-management are likely to better prepare students for their master thesis work.
- Creating learning awareness should start early on through reflection and skills training, which may support motivation and autonomy.

In line with Biesta's observations, we feel that attention to Subjectification and Socialisation processes leads to better professional capabilities.

Limitation of study

This study has been realised with small numbers and should be replicated to substantiate the results. We intend to collect more data in the next academic year to get more data points and longitudinally analyse the impact of the intervention embedded in the programmes/courses. Also, more data points may allow for Confirmatory factor analysis of the theoretical framework to further validate the questionnaire. Nonetheless, we consider the results here as sufficiently validated as we worked both with validated questionnaire items and results showing despite the small group numbers, relatively large effect sizes, and a substantial impact across different course contexts. We equally felt the focused group interview substantiated the survey observations and gave them more depth.

Naturally, having said this, it should be noted that the issue requires additional study. In particular, a more detailed overview of the CBE elements that directly contribute to one of the four levels of reflection and learning awareness. This investigation should include teachers triangulating results and matching these results against the summative assessment results of students, in parallel with the study of the reflection portfolio across different contexts. However, as the embedding of these professional capabilities elements becomes more necessary today in higher engineering education to tackle the complexity of today's world, extended and continuous research seems the only answer.

Annex 1

Professional Capabilities Questionnaire

Measured on a 5 point likert scare from 1 strongly disagree to 5 strongly agree.

Personal- Part I Personal Development
Self

- Q1 I am aware of my engineering role(s)
- Q2 I have become aware of my passions
- Q3 I have been able to make choices that fit my personal values
- Q4 I can articulate what I need to personally grow

Emotional reflexivity

- Q5 I tend to reflect and discuss positive/negative experiences
- Q6 I feel more confident
- Q7 I feel more independent – in control
- Q8 I stay calm when under pressure
- Q9 I am better able to make decisions
- Q10 I can empathize better with people in different (professional) positions

Resilience

- Q 11 I am better able to ask for help
- Q 12 I ask more questions based on my reflective activities
- Q13 I feel confident to share my ideas
- Q14 I have learned from my own mistakes
- Q15 I feel engaged with the offered learning materials
- Q16 I am proactive in seeking new learning experiences
- Q 17 I recognize the need for professional boundaries
- Q 18 I persevere in difficult circumstances

Part II Agency

Evaluating Information
Q8 The ability to evaluate the quality of information presented
Q9 I am aware of the assumptions I make with respect to the problem at hand
Q10 I recognize assumptions others are making with respect to a problem discussed
Q11 I validate the inference I make from data (truths or falsification)
Q12 I am aware when certain conclusions are drawn following from information in given statements

Critical Stance
Q13 I interpret and weight evidence and decide if generalization or conclusions are warranted
Q14 I recognize relevant and irrelevant arguments given to solve a particular problem
Q15 I make judgement on the basis of accumulated evidence and reasoning
Q16 I find it easier to establish what to do or what strategies to adopt to the problems we are solving.

Part III Collaboration
Communication
Q17 I am good at trying to understand the perspective of other team members. D
Q18 I am good at making sure that all the necessary information is shared with other team members. D
Q19 I am good at explaining my ideas in ways that other people can understand. D
Q20 When someone disagrees with me, I am good at paying close attention to see if I can learn something from their alternative perspective. D
Q21 I can normally work productively with another team member even if I am angry or frustrated with them. D

Interprofessional Competence
Q22 I am good at recognizing the knowledge and skills of different professions involved in a project team. E
Q23 I am good at being sensitive to the way in which different professions may use the same word. E
Q24 I am good at clarifying with people from other professions how their knowledge and skills contribute to each stage of a project. E
Q25 I am good at identifying the skills or knowledge that other professions in the team have, which I should try to develop. E
Q26 I am good at sharing responsibility with the other professions in the team for the overall success of a project. E

Part IV Contextualisation

Informed vision
Q1 I feel committed to sustainable development goals such as; equitable economic opportunities, environmental awareness, sustainable production etc.
Q2 I am able to envision alternative futures for the improvement of my disciplinary field
Q3 I am aware of the historic development of my disciplinary field
Q4 I am aware of the wider (societal/academic/technical) system in which my discipline operates
Q5 I am aware of the political, national/global contexts
Q6 I am aware how these context shapes individual lives
Q7 I am aware of the different stakeholder perspectives

Ethical Sensitivity
Q27 When working on a project, I am good at asking myself if a project like this could have a positive impact on someone else's life. C
Q28 When working on a project, I am good at asking myself if a project like this could have a negative impact on someone else's life. C
Q29 I am good at putting myself in the shoes of someone whose life could be affected by a project's results. C
Q30 I am good at identifying all the people who could be impacted by a project, no matter how directly or indirectly. C

ENGINEERS' PERCEPTIONS OF THEIR ROLE IN SOCIETY: THE SOUTH AFRICAN CASE

ABSTRACT

Being sparked by interactions with students in the context of a course called 'Engineer in Society', this work-in-progress study explores how engineers conceived of their role during the period of apartheid in South Africa. The literature suggests that engineers consider their contribution to society in solely technical terms rather than in social or political terms. Using interviews with engineering academics, this paper examines how respondents' navigated engineering practice and academic work. The findings indicate significant complexity in terms of how engineers conceived of their role in relation to society, a relationship that was mediated by politicised academic institutions and differentiated cultural norms. This also has an impact on the notion of the culpability of engineers and the question of whether they resisted or complied with the pervasive and brutal regime of apartheid. Although the study revealed a variety of positions and dispositions taken on by engineers, an interesting stance was that of 'technical activism' which involved engineers resisting apartheid by exploiting the liberal spaces that were made available in the context of their engineering work.

1 INTRODUCTION

Given the nature of the engineering curriculum, it is not surprising that engineering students tend to view their contribution to society in solely technical terms [1] while being inattentive to the political dimensions of society. A new undergraduate course offered at the University of Cape Town in 2020 called 'Engineer in Society' aimed to bring the social aspects of engineering to the attention of students. Given that the first democratic elections in 1994 was such a singular moment in the history of South Africa, the course deals directly with apartheid – the infamous political regime that gripped South Africa for 48 years before democracy – and its impact on engineering activity.

Interactions with students in this course prompted the launch of a research project to investigate two things: (i) the transformational learning that was a specific intention of the course and; (ii) the role of engineers – both academics and practitioners – in South African society, focusing on how they negotiated apartheid. Some work has been done on the first part [2] and this paper is a work-in-progress for the second part of the project. While the intention is that these findings feed back into the course to provide the students with a more nuanced understanding of how engineers negotiated society under apartheid, this phase has not yet been initiated.

1.1 Background

To provide some background, it is worthwhile describing how the broader research project emerged from the Engineer in Society course. At the beginning of 2020, when the course was being offered for the first time, two lectures were set aside to introduce students to the role of engineering in South Africa. The first lecture was billed 'part 1' and it focused on the role of engineering during apartheid; the focus of part 2 was the role of engineering in society after the first democratic elections.

Part 1 sketched the history of engineering in South Africa, starting with the discovery of gold which caused a sudden influx of engineers in the late 1800s and marked the start of engineering education in that country. It also delved into the details of a few large engineering projects, pointing out the political dimensions of these projects and how they supported apartheid in one way or another. The intention was to then open the floor (this was about a month before the Covid-19 pandemic hit South Africa) for discussion. The question put to the students was whether engineers have 'blood on their hands' [3] for their role under apartheid. But before opening the floor, it dawned on the lecturer – who is one of the authors of this paper – that the political dimension of engineering is very seldom discussed.

As might be expected, the student discussion was lively. Most students were of the view that engineers who worked in South Africa during apartheid are guilty for not standing up to such an unjust system. Some empathised with the inaction of engineers, pointing out that engineers were probably weighing up the personal cost, and the cost to their families, if they spoke out against what was a very brutal regime. One student suggested that engineers were not liable because they were just doing their jobs but this was not a popular perspective.

It is important to point out that all of the students in the class were born after 1994 and therefore had not experienced first-hand what apartheid was like but were reflecting on the issue from what they had learned in school and heard from others. Given that the class was made up of a diverse cohort of students, ranging from those whose parents and families had been severely oppressed by apartheid laws, others with families who benefited from apartheid, and a few international students, a variety of perspectives was to be expected.

As mentioned above, this experience sparked the launch of a research project and this paper is a work-in-progress on the second part of the project which focuses on how engineers negotiated South African society, particularly under apartheid. It addresses the following research question:

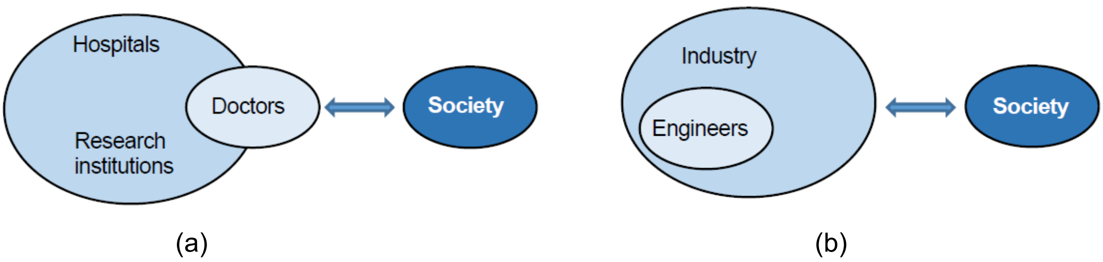
How did engineers conceive of their role in relation to society during the period of apartheid in South Africa?

What follows is a discussion of the role of engineering and engineers in society, as framed by [4] and [5], followed by the research approach. The initial findings are then discussed and conclusions are drawn that consider the particular dimensions of the South African case.

2 CONCEPTUAL FRAMING

Engineers play an important role in society. Definitions of engineering emphasise the technical aspect, but they also frequently include the social aspect of engineering. The national body for accreditation of engineering programmes and professional registration, the Engineering Council of South Africa (ECSA), defines engineering as 'the practice of science, engineering science and technology concerned with the solution of problems of economic importance and those essential to the progress of society' [6]. Other definitions point to the role of engineers in advancing or improving society for the benefit of humanity.

Exactly how engineering does this is complex. Unlike doctors who have a more direct relationship with society, Aslaksen [4] suggests that engineers are almost completely embedded within industry which mediates the relationship with society.



Illustrating the indirect interaction between engineers and society, in (b), as opposed to the direct interaction between doctors and society (their patients), in (a) [4].

The term 'industry' is used here in a broad sense to refer to the engineering enterprise as well as government entities and even educational institutions [4]. However, in the context of this work it is important to distinguish between engineers who work in industry and engineering academics who work at universities.

This framing has implications in terms of the potential benefits that engineering holds for society. The technical expertise of engineers is vital for the growth of industry and, through this means, has the capacity for improving humankind. As the world becomes increasingly globalised, engineering is adapting and remains important for the growth of industry in general. However, Cech [5] critiques the norms and values embedded in engineering, noting the narratives of heroism that the profession uses to present itself in relation to society. This is evident in the *Grand Challenges* [7] document produced by the US National Academy of Engineering that Cech [5] targets but can also be clearly seen in the centenary publication of the South African Institute for Mechanical Engineering (SAIMechE) [8] that was published in 1993, one year before the fall of apartheid. Such documents tend to valorise the technological aspects, narrowly conceiving of social change as technological change with scant regard for the ‘religious, political, environmental, and cultural factors that are interwoven in societal change’ [5].

This research paper contributes to Cech’s [5] call for increased reflexivity – that is, a ‘critical examination of engineers’ role in the past, present and future of societies’. It does this by drawing on the context of South Africa, a country with a history of a political system which discriminated on the basis of ‘race’[2], resulting in a legacy of social and economic injustice. In exploring how engineers understood their role under apartheid, in terms of valorising technological aspects , it provides a critical evaluation of the role of engineers in society more generally. Following this, it explores the extent to which engineers saw themselves, within the context of a pervasive and brutal regime, as contributing to, or resisting, apartheid.

3 METHODOLOGY

3.1 Research design

A qualitative research design [9] was developed for this study. Semi-structured interviews were the primary source of data with the intention to access the perceptions and experiences of the participants. This paper is a work-in-progress piece, reporting on the findings of the first five interviews with engineering educators.

3.2 Data collection and analysis

The interview schedule was developed by all the researchers at the start of the project, revisited before data collection took place and adjusted as themes emerged from the interviews. The interviews were conducted face-to-face or online via Zoom or MS Teams. Respondents were selected through purposive sampling with the aim of ensuring some representation of the sub-disciplines of engineering (mechanical, electrical and chemical). All of the respondents selected for this initial stage were white males who had worked in academia for between 22 and 43 years, thus having experienced the workplace during apartheid. The respondents had a mix of university and industry experience. One respondent had spent significant time in industry – 20 years – before joining the university but most combined industry work with university research in some way. One respondent – who saw himself more of an

[2] It is acknowledged here that ‘race’ was used as a construct to institutionalise oppression in South Africa. Such references are not intended to entrench racial classifications. However, given the history of South Africa and the nature of this study, it is impossible to avoid the use of these designators.

activist than anything else – left engineering during his undergraduate studies although he remained active in engineering education.

Ethics approval for the research was obtained through the Faculty Ethics Committee to ensure that issues such as protection of information and informed consent were addressed. Pseudonyms were used when storing the data and reporting the findings. Further permission was required from the UCT's Human Resources division since some of the respondents were employees of the university.

The table below provides a brief description of the trajectories and positions of the research participants. The interviews that were conducted in person were audio recorded; those conducted online were video recorded. In both cases the recordings were transcribed which formed the basis of the findings. A methodology of narrative inquiry in the mode of Polkinghorne [10] was employed for the data analysis. Narrative inquiry is particularly suited for the topic of this paper since a 'storied narrative… preserves the complexity of human action with its interrelationship of temporal sequence, human motivation, chance happenings, and changing personal and environmental contexts'. Polkinghorne [10] identifies two forms of analysis in his work but this paper draws on 'paradigmatic analysis' which analyses a set of narratives, the aim being to 'identify particulars as instances of general notions or concepts'.

Table 1: Research participants

Pseudonym	**Background**
Nikolai	Engineering academic involved in theoretical research around the deformation of materials at an English-language university during apartheid.
Gary	Grew up in Rhodesia (now Zimbabwe) to English-speaking parents, Worked in engineering consulting for 20 years before working part time at the university and consulting.
Zachery	Studied engineering but switched to a degree in applied mathematics. Took a university post as a way of being an activist in the higher education space.
Ryden	Born into an Afrikaans-speaking family and served two years in the military during apartheid. Worked for an engineering company that consulted for an arms procurement company under apartheid. Currently an academic at an English-language university.
Barry	Grew up in South West Africa (now Namibia) and studied in South Africa. Now an engineering academic at an English-language university.

4 FINDINGS AND DISCUSSION

Although this paper draws on only five interviews, the results demonstrate a complex interaction between institutions, engineering activity and the political complex that had an overbearing effect on social activity. This in turn affected how engineers understood their role in South African society during this time. Although the interviewees were all engineering *academics*, there was significant overlap in terms of their work for (private) industry and university work which involved academic research and associated activities such as publishing papers and attending conferences. Of course, successful technical research in the university context often leads to collaborations and contracts with industry. However, the findings suggest even more of an overlap through a close, symbiotic relationships between industry work and university research, as well as dual roles via part-time appointment arrangements.

This has implications for understanding the impact of engineering activity on society since a mutually beneficial relationship between the university and industry suggests even more embeddedness. For example, if an engineer working on a particular technology dedicates time to writing research papers for publication because of the prestige and reward this provides in the university space, this takes time away from the development of technology and its application which arguably has a greater chance of impacting society.

For this initial analysis, it is useful to focus on the armaments industry and the electricity industry although other industries, such as the synthetic fuels industry, were also mentioned. Nikolai was involved in theoretical research around the deformation of materials. This work was relevant to the arms industry but the English-language[3] university at which he was employed prohibited academics from associating with industry in any way, whether private arms companies or the arms procurement agency of the South African Department of Defence, Armscor. Nikolai relates how he found himself in a ‘lose-lose situation’ because, while he was prohibited from associating with any organisations that supported apartheid, he was treated as if he belonged to an apartheid state when travelling overseas for conferences.

In contrast, Ryden was born into an Afrikaans-speaking family, went to an Afrikaans high school and then served two years in the military which, at the time, was compulsory for all school-leaving white males. He then went to an Afrikaans university and studied engineering. Immediately after graduating, he started working for an engineering company which consulted for Armscor. During this time, he retained ties to the university in terms of lecturing and he also studied his Master’s:

> … I actually did my Master’s on the aerodynamics of a mortar bomb. And I remember at that time, I thought, ‘I don’t know… this is not ideal’ and so on but, you know, it's a cutting edge project, that's what do you think, you know, I do this cutting edge project and CFD modelling and wind tunnel work and all that. But… but the application, I guess I told myself, ‘Well, we’re protecting the country’. I mean, I was in the army for two years... I mean, you are dulled a little bit to this… you know, you don't think too deeply about all the other stuff.

What is interesting about these stories is the very circumscribed way in which engineering work impacted society. Nikolai was very much embedded in the English-language university at which he was employed. Its policies limited his interactions with industry so that he researched in a rather isolated way. Interestingly, the stand that the university took against apartheid (although whether it went far enough is contested) also meant that he identified with its struggle against apartheid. As well as setting limits on association with industry, the university partnered with progressive corporations that funded programmes for the admission and academic support of black students a decade before these students were officially allowed onto

---

[3] As a result of its colonial past, South Africa was divided into English- and Afrikaans-speaking universities under apartheid.. Afrikaans is a derivative of Dutch which was spoken by the first European settlers.

the campuses of 'white' institutions. In the case of Ryden, he was also very much embedded in industry, even working for a company that Nikolai was prohibited from interacting with. The difference was that his upbringing and army experience 'dulled' his conscience about the possible consequences or implications of his engineering work on society.

Another of the respondents, Gary, spoke at length about the embeddedness of engineering in industry. He worked for about 20 years in electrification before he joined an English-language university in 2000. This meant that much of his work occurred during the apartheid years which resulted in him building up tremendous experience in low-cost electrification. He put this to use in the strong drive for electrification after apartheid fell and became involved in work with the national utility, municipalities in South Africa, electricity entities across sub-Saharan Africa as well as becoming involved in electrification policy at various levels. He shared how he has even given comments twice to the Federal Energy Regulatory Commission in the USA. About embeddedness, he had this to say:

> The technical has no impact except through social, economic, and legal provisions. We kid ourselves that we're important as engineers. But it's not our engineering that's important, it's our *outputs* and our *outcomes*… through assimilation in society, [this] gives the *impact*, which is quality of life or economic activity or things like that. We are at the bottom end of this chain. And most engineers don't operate... don't even get into the assimilation areas, don't… don't even look at it.

The extent to which this embeddedness relates to the culpability of engineers in relation to apartheid is interesting. One might expect that, since engineers are so embedded in industry (broadly speaking), they see themselves as being less culpable or responsible for the injustices of apartheid. Interestingly, both Ryden and Nikolai acknowledged some guilt in terms of not standing up against apartheid, even though they were in very different social circumstances. Speaking about himself, Nikolai said:

> …my wife and I had a view that you are either against apartheid and you were an activist, or you basically just sat through the middle of it and allowed these things to happen around you. And you were – if you did that – you were just as guilty…

Ryden spoke about the difficulty of recognising that apartheid was wrong when you were raised in a system that supported – and was supported by – apartheid: '…it is very difficult. I mean, I would definitely say I have contributed to something that in the big picture is not right…'

Gary and another respondent, Zachery, both argued that one had to exercise as much agency as possible, in whatever position one found oneself, to challenge the system. Everyone was aware of the very serious consequences of becoming known to the Bureau of State Security (BOSS) who tapped phones, sorted to tactics of intimidation, and incarcerated – or worse – dissidents for transgressing apartheid laws. To avoid this meant trying to find ways to oppose the systematic injustice that pervaded society while 'keeping your nose' clean (in the words of Nikolai).

Since the areas that Gary's consulting firm were assigned to were designated 'black' by the government, he saw his electrification work as significantly improving the quality of life of the recipients of his efforts. Although he was not a supporter of the regime, and he recognised the social and political factors at play in engineering, he took this stance: ‘I made it clear that my contribution was technical.’ He related many instances of how he worked hard to ensure good access to electricity at a reasonable cost, even if his client was not supportive of this effort.

Zachery is an interesting case because he saw himself, firstly, as an activist and then as an educator. The English-language university at which he worked was simply the context he chose to push against the pervasive injustices of apartheid that he recognised, both before *and after 1994*. About the role of engineers under apartheid he made this comment:

> …whether you are an engineer, or whether… it didn't matter what you were, and, and, you know, because it was so tightly controlled… as long as they were pushing the boundaries, you know, as long as they were willing to push the boundaries. In other words, they can't just accept that in fact, the plan is that these people aren't going to have electricity… the issue was to push; push in the liberal spaces that were created. And to always have to keep your eyes open to look below the surface as to what's happening.

5 CONCLUSION

The emerging findings from this study suggests indicates, as expected, that the embeddedness of engineering activity mediates the engagement of engineers with society. However, the multiple dimensions of the relationship between engineers and society show that this process of mediation is extremely complex. The ways in which the participants navigated apartheid society was influenced by the academic institutions at which they were employed, and the ways in which academia interacted with the engineering industry. Furthermore, the differences between the cultural norms within society (in this case, between Afrikaans- and English-speaking segments of society) added another layer of complexity. These differences extended to the overlapping constituencies of academic institutions, engineering industry and the state.

This complexity plays out in terms of how engineering academics conceived of their culpability in relation to apartheid. The framing of the lecture given in the Engineer in Society course assumed inaction and complicity on the part of engineers, but this research indicates a range of reflexivity. Some respondents did conceive of their relative inaction as contributing to the systematic oppression of apartheid (Nikolai and Ryden) although this was couched in explanations about the difficulty of standing up the regime. Others saw themselves as alleviating the suffering of black people through their engineering work and associated technical prowess (Gary). While this does not equate to a narrative of engineering heroism in the sense of Cech [5], it can perhaps be understood as ‘technical activism’ on the part of South African engineers who saw themselves as resisting apartheid by exploiting ‘liberal spaces’. Others, such as Zachery, considered themselves as activists under apartheid, and emphasised the importance of ‘look[ing] below the surface as to what’s happening’ rather than allowing their conscience to be ‘dulled’ by the prevailing political system. Across the spectrum, these perspectives provide valuable insights and much-needed material for students to understand the South African case, the complexity of society and the role of engineers within it.

ABSTRACT

Although engineering education is often characterized as a principally rational activity, research suggests that emotions are vital for learning at all levels of education. In ethics education in particular, there is evidence that including mild emotional information in case studies can enhance learning. Evidence also suggests that specific emotions such as guilt and shame can impact on motivation to act in ethical scenarios. The place of emotions in ethics education remains controversial, however, since emotion can be perceived as a source of bias rather than as a valuable factor in learning and in motivating action. While some specific emotions have been explored in ethics research, there is a lack of empirical research addressing the relationship between ethical judgement and emotional empathy. In this research, therefore, we

[1] *Corresponding Author*

nihat.kotluk@epfl.ch

doi:10.5821/conference-9788412322262.1124

aimed to investigate the impact of mild emotional empathy on engineering students' ethical judgements. We conducted this study as an experimental design with 305 participants in two groups. Both groups took a modified version of the Engineering and Sciences Issues Test (ESIT) with an experimental group in which we induced a low level of emotional empathy and an emotionally neutral control group. Results show that a low level of emotional empathy does not impact participants' ethical decisions/judgments. Since the prior research evidence suggest that low level of emotional content improves learning, and given that it does not introduce biases in moral reasoning, we conclude it would make sense to include a low level of emotional content into ethics case studies.

1 INTRODUCTION

The role of emotions in engineering education has been the subject of increased research in recent years [1]. There is also a growing literature on the role of emotions in moral decisions in engineering and in ethical decision making more generally. Researchers even have latterly begun to focus on the various effects of some specific emotions which are called moral emotions such as empathy [2], shame [3], embarrassment, and guilt [4] in engineering and science education. However, given that emotions are vital for learning at all levels of education, the area is still under-researched.

In engineering ethics education, the importance and use of ethics cases, which are framed as a moral dilemma, is frequently highlighted [5, 6]. For example, Kerr, Brummel, and Daily stated that the use of case studies in engineering education is one of the most prominent methods of ethics training [7]. Some of this literature indicates that emotions can be important for the educational process related to using case studies to learn ethics. For example, Thiel et al., found that emotional case content stimulates the retention of cases and facilitates the transfer of ethical decision-making [6]. The researchers stated that emotions also make cases more realistic, an essential component for effective case-based instruction, and are an inherent part of ethical decision-making.

However, the place of emotions still remains controversial. There is evidence [8] that highly emotional cases can reduce student learning from case studies, and perhaps such cases should be avoided. This is an interesting finding given that many engineering ethics cases involve large scale death and destruction (Challenger and Columbia Space Shuttle disasters, Netherlands Flood Disaster of 1953, the Ford Pinto Case, Volkswagen emissions scandal, Hyatt Regency Walkway collapse, Chernobyl, the Bhopal Union Carbide disaster, and others). Indeed, it has frequently been argued that emotion may play a potentially harmful role in biasing rational judgement [9]. On the other hand, there is also evidence that experiencing no emotion during an ethical event may actually impede moral judgement [4] while some of the empirical literature also highlights emotion’s role in moral motivation [10]. This leads to our research question: If our goal is to enhance learning without biasing moral judgement, what is the appropriate degree of intensity of emotional content in engineering ethics case studies?

The literature thus far has explored some specific emotions. Johnson and Connelly, for example, found that feelings of guilt are positively related to making ethical decisions [11]. Higgs et al., supported the proposition that guilt, shame, and embarrassment exert differential effects when making ethical decisions [4].

Furthermore, Han et al., not only addressed the importance of moral emotions in all stages of the moral decision-making process but also indicated the effects of suppressing these emotions on ethical decisions. They argue that suppression of guilt and shame influences each of the three stages of the moral decision-making process; judgment, intention, and behavior differently [12].

While some specific emotions (guilt, shame, etc.) have been explored in ethics research, there is a need to look at emotional empathy. This provides a more focused research question: If our goal is to enhance learning without affecting moral judgement, what is the appropriate degree of intensity of emotional empathy in engineering ethics case studies? In this research, as a first step, therefore, we aimed to investigate the impact of mild emotional empathy on engineering students' ethical judgements by using the mild emotion-induced case studies.

2 METHODOLOGY

2.1 Method

We conducted this study as an experimental design with 305 participants in two groups. Both groups took a modified version of the Engineering and Sciences Issues Test (ESIT) with (a) an experimental group in which we induced a low level of emotional empathy and (b) an emotionally neutral control group.

2.2 The Engineering and Science Issues Test (ESIT)

In this study we used the ESIT test as a measure. In engineering ethics education, researchers have commonly used the Engineering and Science Test (ESIT), which is based on neo-Kohlbergian understandings of ethics [13]. The ESIT was developed by Borenstein et al., and includes six ethical dilemmas [14]. These dilemmas are related to engineering and science, in response to which participants are asked to make a choice. For each dilemma, participants rank the relevance of twelve considerations to their decisions. Then, they pick and rank the four most important considerations. Based on Kohlberg’s theory [15], to assess engineering students’ moral development, each of the twelve considerations corresponds to either the (a) pre-conventional, (b) conventional, or (c) post-conventional schema, or (d) a nonsense category, included as a check to ensure participants are considering and completing the ESIT in earnest. Rankings are analysed to determine the prevalence of post-conventional reasoning, measured by the P-score, and scores for conventional and pre-conventional moral reasoning can also be calculated. Another measure used is the N2 score which assesses the prevalence of post-conventional relative to pre-conventional reasoning [14].

2.3 Emotion Induction in the Case Studies

In this study, we induced emotional empathy into the six case studies of the ESIT to apply to the students. We have adapted these case studies to generate a mild feeling of emotional empathy. We did this by adding the following features to the experimental group’s cases: (i) an emotional target (people that could be empathized with), (ii) a similarity between decision-maker and target group (since empathy is typically enhanced by perceived similarity), and (iii) evidence of potential distress of target (which might give rise to empathy). In order to ensure comparability of control and experimental case studies, the emotional target was also added to the control case studies. For example, in the original version of the ESIT, the first case study is as follow:

Case 1 (Stock)

> Engineer Jameson owns stock in RJ Industries, which is a vendor for Jameson's employer, Modernity, Inc., a large manufacturing company. Jameson's division has been requested by management to cut one vendor: either RJ Industries or Pandora Products, Inc. Pandora Products makes a component that is slightly higher in quality and slightly more expensive than that made by RJ Industries. Management and the other engineers in her division do not know that Jameson has a financial interest in one of the two vendors.

Firstly, we only added an "emotional target" (added in red) to this case for the control group as follow:

> Engineer Jameson owns stock in RJ Industries, which is a vendor for Jameson's employer, Modernity, Inc., a large manufacturing company. [Jameson has a lot of interaction with the main sales representative for his company's products in both RJ Industries and Pandora Products], Jameson's division has been requested by management to cut one vendor: either RJ Industries or Pandora Products, Inc. Pandora Products makes a component that is slightly higher in quality and slightly more expensive than that made by RJ Industries. Management and the other engineers in her division do not know that Jameson has a financial interest in one of the two vendors.

Then, we added "similarity between decision-maker and target group" and "potential distress of target group" for the experimental group as well as an "emotional target" as follows:

> Engineer Jameson owns stock in RJ Industries, which is a vendor for Jameson's employer, Modernity, Inc., a large manufacturing company. [Jameson has a lot of interaction with the main sales representative for his company's products in both RJ Industries and Pandora Products], [both of whom are a similar age to Jameson and all three also graduated from the same university]. Jameson's division has been requested by management to cut one vendor: either RJ Industries or Pandora Products, Inc. Pandora Products makes a component that is slightly higher in quality and slightly more expensive than that made by RJ Industries. [Jameson knows that this decision could have a negative impact on the career of the sales representative affected]. Management and the other engineers in her division do not know that Jameson has a financial interest in one of the two vendors.

The 'Jameson has a lot of interaction with the main sales representative for his company's products in both RJ Industries and Pandora Products' here can be seen as an "emotional target". Being 'a similar age' and graduating from 'the same university' can be seen as a "similarity between decision-maker and target group". And, 'the decision could have a negative impact on the career of the sales representative affected' can be seen as an "emotional empathy of target group".

2.4 Participants and Data Collection Procedures

Participants were assigned to a control or experimental group randomly and they took either the standard (control) or modified (emotion induced-experimental) version of the ESIT. The tests were administered on-site in December 2021 at a large technical university in mainland Europe. The tests lasted 40 minutes. Participants were not asked for any identifiers (e.g. name or other ID). Basic demographic data were collected (e.g., age, gender, main field, work experiences in engineering or technical domains). An overview of the participants is included in Table 1.

2.5 Data Analysis

We excluded questionnaires from the analysis if they met one of several criteria below because they were either too nonsensical or had omitted too many questions to be considered reliable:

- Failed to complete 24 or more rating questions (equivalent to two dilemmas)
- Failed to complete 9 or more ranking questions (approximately two dilemmas)
- Received a “nonsense” score of 11 or more points.

After applying the above metrics to the participants' responses, we excluded 5 questionnaires out of 305 from the analysis. In total, we included 300 (150 control groups and 150 experimental groups) questionnaires in the analysis. In our study, first, we performed the descriptive statistics for all data. Then we computed participants’ post-conventional score (Post-S), pre-conventional score (Pre-S), conventional score (Con-S), and N2Score (N2-S). Post-S is based on a participant's ranking of prototypic items written for Kohlbergian Stages 5 and 6 (Post-conventional level). The Post-S is interpreted as the relative importance participants give to principled moral considerations (Stages 5 and 6) in making a moral decision. Similarly, while Pre-S is interpreted for Kohlbergian Stages 1 and 2 (Pre-conventional level), Con-S is interpreted for stages 3 and 4 (Conventional level) moral reasoning. Since it uses both rating and ranking data than the Post-S, the developers of the original test prefer to use the N2-S. The N2-S assesses the prevalence of post-conventional relative to pre-conventional reasoning [14].We used specific calculations that Borenstein et al., (2010) formulated in their study for calculating Post-S, Pre-S, Con-S and N2-S scores. Then, we conducted two-sample t-tests or ANOVA on the differences in each mean and score for the groups. The results of these tests are provided in Table 2 across several groupings. We marked the results in the Table 2 that are significant at the 5% level or better.

3 RESULTS

Table 1. Descriptive statistics and scores of the groups

		Post-S	Pre-S	Con-S	N2-S
Group	Control (N:150; 50%)	0.47	0.14	0.30	4.81
	Experimental (N:150; 50%)	0.47	0.13	0.32	4.84
Gender	Male (N:163; 54.3%)	0.46	0.15	0.30	4.57
	Female (N:133; 44.3%)	0.48	0.12	0.33	5.06
Age	18-20 years old (N:157; 42.3%)	0.47	0.14	0.31	4.59
	21-23 years old (N:113; 47.6%)	0.48	0.13	0.31	5.23
	24-35 years old (N:30; 9.2%)	0.45	0.15	0.32	4.60
Level of Study	First Year Student (N:140; 46.7%)	0.47	0.14	0.32	4.73
	Second- & Third-Year Bachelor (N:89; 29.7%)	0.46	0.13	0.32	4.64
	Post Bachelor (N:59; 19.7%)	0.49	0.14	0.31	5.31
Main Field	Engineering (N:97; 32.3%)	0.46	0.15	0.31	4.73
	Natural Sciences (N:49; 16.3%)	0.52	0.12	0.28	5.32
	Social Sciences (N:53; 17.7%)	0.46	0.13	0.33	4.71
	Computer Sciences (N:21; 7%)	0.44	0.14	0.34	4.17
	Other (N:80; 26.7%)	0.47	0.13	0.31	4.90

Note: To protect anonymity, we do not present data for groups with a small number of participants

Table 1 breaks down the participants' demographic statistics for the study. The number of participants in both the experimental and control groups was roughly equal; there were 165 males (54.3%) and 133 females (44.3%). The vast majority of participants were between either 18 and 20 years old (42.3%) or 21 and 23 years old (47.6%); whereas, only 9.2% of the participants were between 24 and 35 years old. Most participants were either first-year students (46.7%) or second- and third-year bachelor students; whereas, 19.7% of the participants were Post-Bachelor. The largest group of participants were those from the engineering faculty (32.3%); 17.7% of the participants were social sciences majors; 16.3% were natural sciences majors (most of these also graduate with an engineering degree); while 7% were computer sciences majors (again, these all also graduate with an engineering degree); whereas, 26.7% of the participants reported that their majors were as other.

Table 2. t-Test statistics of the experiment and control groups

	Scores		t-test for Equality of Means						
	Experiment	Control	t	df	Sig (2-tailed	Mean Difference	Std. Error Difference	95% Confidence	
								Lower	Upper
Post-S	.472	.479	-.44	298	.656	-.006	.014	-.035	.022
Pre-S	.132	.140	-.78	298	.434	-.008	.010	-.029	.012
Con-S	.320	.304	1.30	298	.192	.016	.012	-.008	.040
N2-S	4.84	4.81	.110	298	.912	.033	.299	-.556	.622

To analyze the effect of emotion-induced content on the participants' moral reasoning, we looked at the Post-S, Pre-S, Con-S, and N2-S scores for each of these measures (Table 2). Significant differences were not found between experiment and control groups scores; Post-Conventional Scores [Experiment (M=.472, SD=.12) and control (M=.479, SD=.12) groups; t(298)=.44, p=.656, d=.05)], Pre-Conventional Scores [Experiment (M=.132, SD=.08) and control (M=.140, SD=.09) groups; t(298)=.78, p=.434, d=.09)], Conventional Scores [Experiment (M=.320, SD=.11) and control (M=.304, SD= 10) groups; t(298)=1.30, p=.192, d=.15] and N2-Scores [Experiment (M= 4.84, SD=2.62) and control (M=4.81, SD=2.56) groups; t(298)=.11, p=.912, d= .01]. In other words, there is no evidence that including emotion content biases participants' moral reasoning.

Table 3. t-Test statistics of the males and females

	Scores		t-test for Equality of Means						
								95% Confidence Interval of the Difference	
	Females	Males	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference	Upper	Lower
Post-S	.489	.460	-1.9	294	.048*	-.02909	.01464	-.0579	-.00028
Pre-S	.117	.154	3.5	294	.000*	.03743	.01056	.0166	.05821
Con-S	.326	.302	-1.9	294	.052*	-.02415	.01235	-.0484	.00016
N2-S	5.06	4.57	-1.6	294	.098	-.49767	.30024	-1.088	.09323

Although some researchers [14] did not find significant difference in the scores between male and female participants, we found significant differences between the scores of males and females except for N2-scores (Table 3). Significant differences were found between females and males Post-Conventional Scores [Females (M=.489, SD=.11) and males (M=.460, SD=.13); t(294)=1.9, p=.048, d=.24)], Pre-Conventional Scores [Females (M=.117, SD=.07) and males (M=.154, SD=.09); t(294)=3.5, p=.000, d=.45)], Conventional Scores [Females (M=.326, SD=.10) and males (M=.302, SD= 10); t(294)=1.9, p=.005, d=.24]; while a significant difference was not found for N2-Scores [Females (M= 5.06, SD=2.49) and males (M=4.57, SD=2.62); t(294)=1.6, p=.098, d=.19]. However, the effect size was found to be small almost in all scores.

Table 4. ANOVA statistics in terms of participants' level of study for all participants

		Sum of Squares	df	Mean Square	F	Sig.
Post-S	Between Groups	.030	3	.010	.629	.59
	Within Groups	4.782	296	.016		
	Total	4.813	299			
Pre-S	Between Groups	.010	3	.003	.399	.75
	Within Groups	2.529	296	.009		
	Total	2.539	299			
Con-S	Between Groups	.078	3	.026	2.329	.07
	Within Groups	3.294	296	.011		
	Total	3.372	299			
N2-S	Between Groups	18.584	3	6.195	.923	.43
	Within Groups	1987.524	296	6.715		
	Total	2006.108	299			

Note: Levels of study are "first year", "second and third year", and "post-bachelor".

Some researchers have also found a relationship between measures of moral reasoning on the DIT-2 and other factors such as age, level of study, or main field. In our study, dividing the students into groups based on their age and level of study yielded no significant results with respect to the scores (Table 4). No significant differences were found between participants in scores for level of study; Post-Conventional Scores [F (3,296) = .629, p= .59], Pre-Conventional Scores [F (3,296) = .399, p=.75], Conventional Scores [F (3,296) = 2.329, p=.07] and N2-Scores [F (3,296) = .923, p=.43]. This suggests that age and level of study of the participants do not impact moral reasoning.

Table 5. ANOVA statistics for engineering programs' students only in terms of participants' level of study

	Groups	N	Mean		Sum of Squares	df	Mean Square	F	Sig.
Post-S	First Year Student	78	.462	Between Groups	.044	3	.015	.840	.474
	Second- & Third-Year Bachelor	45	.497	Within Groups	2.850	163	.017		
	Post Bachelor	39	.491	Total	2.894	166			
Pre-S	First Year Student	78	.140	Between Groups	.009	3	.003	.342	.795
	Second- & Third-Year Bachelor	45	.130	Within Groups	1.484	163	.009		
	Post Bachelor	39	.137	Total	1.494	166			
Con-S	First Year Student	78	.310	Between Groups	.016	3	.005	.441	.724
	Second- & Third-Year Bachelor	45	.300	Within Groups	2.004	163	.012		
	Post Bachelor	39	.305	Total	2.021	166			
N2-S	First Year Student	78	4.54	Between Groups	18.768	3	6.256	.846	.471
	Second- & Third-Year Bachelor	45	4.80	Within Groups	1205.305	163	7.395		
	Post Bachelor	39	5.36	Total	1224.073	166			

The literature thus far has also found that engineering education did not lead to increases in moral reasoning over years [16,17,18]. We wanted to check if we have a similar pattern in our data. For this purpose, considering our findings presented in Table 4., we also performed data analysis only looking at those who will graduate with an engineering qualification (those from the engineering faculty, natural science, or computer science) and excluded those from social sciences and others. The results did not show significant differences between the groups' scores in terms of their background; Post-Conventional Scores [F (3,163,166) = .840, p= .47], Pre-Conventional Scores [F (3,163,166) = .342, p=.79], Conventional Scores [F (3,163, 166) = .441, p=.72] and N2-Scores [F (3,163,166) = .836, p=.47]. (Table 5).

4 CONCLUSIONS

In this study we aimed to investigate the impact of mild emotional empathy on engineering students' ethical reasoning by using mild emotion-induced case studies. It is known that some emotional content can improve students learning from engineering and science ethics case studies, however it is also feared by some that including emotional content may give rise to bias. Our study found no evidence at all that including emotional evidence biases moral reasoning: the overall results showed very little differences between the experimental and control groups' scores–any differences were not statistically significant. In other words, a low level of emotional empathy in case studies does not impact participants' moral reasoning.

Engineering ethics case studies often involve large scale death and destruction. This represents a high level of emotional content (even if emotions are not made explicit). Evidence from prior studies [8] suggests this should be avoided as it can reduce student learning from case studies. Our study focused on mild level ‘emotional empahty’. We addressed this by (a) identifying people/a person who was potentially impacted by an ethical decision and (b) identifying a source of empathy for them. Since empathy is linked to in-group relationships, we also sought to (c) increase an in-group relationship within the case study. This method could be used by others who are seeking to enhance a mild level of emotional content in case studies. Other methods used in other studies include explicitly identifying an emotion felt (“X feels guilty…”).

Numerous studies have found that engineers are somewhat unusual in that they do not seem to show much growth in moral reasoning over the course of their engineering education – this is at odds with the normal pattern of development in other professional domains [16,17,18]. We found a similar pattern here – there is little evidence that our student moral reasoning improved over the course of their studies. Hence our data reconfirms an imperative need to improve the quality of engineering ethics education.

The results of this study showed no impact on students' moral reasoning as a result of the inclusion of low to moderate levels of emotional empathy in case studies. Since the evidence [6] suggests that emotion inclusion can facilitate retention and transfer of the case’s knowledge content it would make sense for case study designers to include emotional information. Since low to moderate emotion does improve learning, and since we now know it does not impact moral reasoning, we recommend the inclusion of mild to moderate emotional empathy in case studies.

5 ACKNOWLEDGMENTS

Our special thanks to the students who participated in the study.

ABSTRACT

Sustainability has become an integrative part of engineering education since it is not possible to discuss sustainable development without also talking about innovation capability. Political and environmental frameworks request for a drastic change in the industrial landscape and also in the way design is carried out. This paradigm change forces new approaches to education that align with the prospects of the industry and also embed considerations related to the Triple Bottom Line (i.e. economic, ecological, socio-cultural elements). Addressing the complexity of sustainability requires innovative practices for teaching and learning, leading to new methodologies that aim to develop the broad sets of competencies required from the students. In Engineering Design, theories and methods related to sustainability have been mainly focused on the Design for X elements, material circularity, and product lifecycle leaving behind the importance of contextualized knowledge of regulations, or human-related aspects that motivates the students to tackle these challenges. Therefore, this study proposes a holistic approach that encompasses a broader understanding of what educators can exploit for capacitating future engineers in sustainability-related complex problem-solving. The framework highlights three main areas to be considered when teaching sustainability for Design Engineers: i) Context & Resources, ii) Human factors & Competencies, and iii) The D4i design process. A simplified version of this framework in class as a lecture-workshop format are presented and discussed along with multiple directions for future research.

1 INTRODUCTION

Undoubtedly sustainability is an integral part of Engineering Education (EE) and vice versa. Learning and teaching frameworks are instrumental to guide and reflect on teaching practice and to engage in academic conversations as well as consider strategies that integrate sustainability concepts and applied industry cases into nearly all core teaching subjects as part of active learning.

Despite the inherent urgency and general knowledge about the importance of sustainability for all societal segments, engineering students and educators might find themselves struggling to understand how to tackle such complex topics within the educational timeframes and how to effectively embed methodologies that promote the development of competency and of a lasting mindset of sustainability.

UNESCO (2002) promotes that “Education for sustainability seeks to empower people of all ages to assume responsibility for creating a sustainable future”. Therefore, reformation of the educational systems and open dialogue became necessary to prepare future engineers and managers to have the readiness to lead sustainability policies [1]. There is a need for embracing the individual capability of the engineer into creating lasting positive impact as a byproduct of personal drive and professionalism, and for extolling sustainability as a core competency to be taught and developed during engineering education.

This study proposes the development of a human-centric framework for teaching and learning sustainability in engineering education that aims at catalysing dialog between faculty, students, and industry stakeholders in order to answer the following questions:

- How can we promote an open discussion on sustainability as a core competency in design education?
- How can we integrate a holistic human-approach to sustainable design?
- How can we empower the designer as the decision-maker towards a sustainable mindset?

Therefore, we present the Design for Impact (D4i) framework for integrating sustainability within the engineering design curricula, and present initial feedback from students after the introduction of this methodology to their studies. D4i builds upon Design for Sustainability (DfS) methodologies and looks into equipping the designer with the capabilities to assess and reflect on the impact of a given product, service, or system with a positive impact for businesses by deconstructing knowledge silos via systemic thinking. D4i looks into a transversal approach to the triple bottom line of sustainability, empowering the individual designer to develop solutions that provide positive or even regenerative impact with depth and scale in product development. This approach positions the designer as a decision-maker who is responsible for administering a systemic overview of the impact and value creation for their concept developments.

This article examines the development of this teaching framework and provides insights from a study case where a short version of the D4i methodology is tested in a lecture-workshop class.

2 THEORETICAL BACKGROUND

2.1 Design for Sustainability

Over the years, several theories provided the foundations for building an understanding of how design researchers could start linking design theory and practice with sustainability transitions, in what we know today as Design for Sustainability (DfS). Models, tools and methods can be found in the literature for sustainable product and service design, but the authors recognize limitations in their implementation and in generating sustainable solutions [2]. Therefore, DfS needs to develop towards being strongly linked to the conditions and characteristics of circular economies, overlooking digital business models [2][3], where producers and consumers are an active part of a paradigm change and are aware of subjects such as closed material loops, reuse, remanufacturing, waste reduction and recycling and even of biological cycles [5].

2.2 Sustainability education in Design Engineering

The concept of "Education for Sustainable Development" has been explored over the past three decades and many educational associations focusing on sustainability have been established. In engineering education, this concept not only develops and guides the engineering curriculum to cover sustainability issues but also requires the engineering process to meet current challenges [6]. In this way, most approaches used to integrate more practices in the engineering curricula are through capstone design courses and senior graduation projects. Engineering design courses can increase the sustainability practices of future engineers by creating and implementing their designs while considering the sustainability triple-bottom-line and measuring sustainable performance indicators or other metrics. Accreditation Board for Engineering and Technology (ABET) criteria for accrediting engineering programs [7] also emphasized the need for considering sustainability as one of the outcomes related to design ability.

More than a practical skill, Goekler [6] argues that students effectively learn about sustainability when they develop the ability to think in new ways and engage with different worldviews. For students to engage with the complex challenges involved in Design for Sustainability and towards creating impactful design they need to engage in a deep cultural critique on the present ways of production and consumption, and be equipped with a set of competencies that build on the pre-requisite abilities to think, do, analyze, plan and make decisions. This wholeness of the individual character brings the need for a human-centric understanding of the designer, moving away from the exclusively technical allusion of DfS, and reflecting on what we understand as a Sustainable Mindset [8] as an integrative part of the designer's professional identity [9] that is developed throughout their education.

2.3 The need for a new framework

Within design education, some competencies can be acquired through formal learning, while some are embedded in one's personality. It is the educator's role to identify these competencies and direct their pedagogical approach and curriculum towards nurturing these different aspects of competencies. There has been considerable previous research that looked at educational practices and desirable competencies in design

[10], at dedicated competencies for building assessment framework [10][1], and at various pedagogical approaches to improve the efficacy of sustainability education in engineering such as project-based learning [12], guided-discovery learning [13], and problem-based learning [14]. Research has also focused on identifying goals and strategies to consider while performing design activities that can be adapted to sustainable design. However, existing literature and training on sustainable design does not propose any specific activities [15] nor extensively explore the role of intrinsic motivations and mindsets in the development of policies in EE.

Learning and teaching frameworks are instruments that invite faculty to reflect on their teaching practice and to engage in conversations on the teaching values that define their work at an institutional level [16]. Therefore, there is need for a framework that includes human aspects of the design engineer in the equation of sustainability teaching and learning. The designer's personal drive and mindset and its reflection in terms of professional identity is an important element of agency and professionalism that dignifies sustainable solutions and entices decision-making and behavior towards sustainability. For this purpose, we have developed and assessed a new framework.

3 DESIGN FOR IMPACT (D4I) FRAMEWORK

Design for Impact (D4i) is an experimental educational framework that builds upon DfS and looks into equipping the designer with the capabilities to assess and reflect on the impact of a given product, service, or system. Sustainability is currently defined through the interconnected domains of environment, economy and society, which is defined as the triple bottom line (TBL). Much has been discussed about new ways of seeing the interrelation of the TBL approach for sustainable development, where sustainability lay in the cross-section of equal-sized components and is now understood as facets or even layers within each other. The argument for what is now described as a “strong sustainability” approach follows a logic flow where economy is a feature of human society, which is in itself embedded in the biosphere of the planet. To take it a step further, Stockholm Resilience Center [17] introduced the concept of transversality with the “wedding cake” approach to the United Nations’ Sustainable Development Goals (SDG) while talking about the impact of pervasive systems.

Inspired by these new constructs, D4i attempts to look into a transversal approach to the TBL of sustainability, and on how to empower the individual designer to develop solutions that can tackle complex real-world problems in the digital age and provide positive or even regenerative impact with depth and scale. This approach positions the designer as a decision-maker who is responsible for administering a systemic overview of the impact and value creation for their concept developments. An illustration of the development of this understanding on sustainability approaches is presented below in Figure 1.

The core aspect of D4i as a methodology is the human-centric approach to sustainable development by placing the designer as a change-maker, i.e. a professional who can contribute to the development of a fair and sustainable society through the design of digital/non-digital products, services, and systems with transversal positive impact.

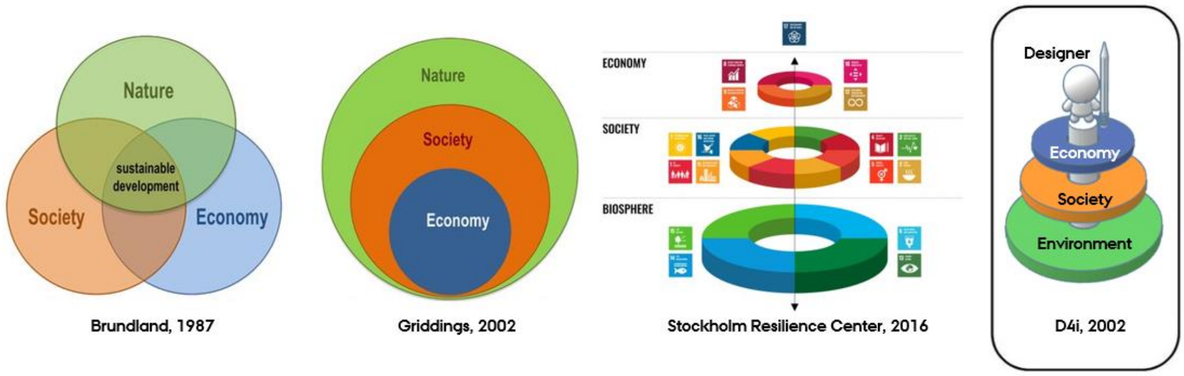

Figure 1. Evolution of sustainability models and the D4i approach

The structure of the D4i framework focuses on the need for integrating a holistic framework that relates contextual and humanistic factors with a systemic approach for technical elements as well as business understanding. The D4i framework is conceptualized as a toolkit that brings together an inventory of methodologies and techniques to facilitate a holistic understanding of the impact of a given design concept or product, aiding decision-making based on the engineers' personal drive for creating impact and business value. In this toolkit, the visual overview of D4i components tries to connect current global frameworks, human-centric aspects, and product development methodologies. D4i has three core components:

1) Context and Resources is the component that contains an assortment of existing knowledge that can guide and support the development of a new sustainable Products, Services and Systems (PSS). This component is divided into four aspects: a) Global Frameworks, which provide an overview of current assessment opportunities; b) Regulatory Framework, which provides an overview of policies, restrictions, and possibilities in relation to developing compliant solutions; c) Business and Implementations, which presents an assortment of tools and methodologies that ensure successful deployment of a solution; d) Methodologies and Resources, which provides a pool of design approaches and tools for successful engineering development. This component can be integrated in the Engineering Education (EE) as a complementary part of the traditional curricula, focusing on introducing updated frameworks and core knowledge of business along with technical methodologies. It aims at providing the students with capabilities related to systemic thinking and the overview of contextual/legal constrains. A practical example would be, in a course where the students develop new products, to present The European Union's Ecodesign Directive (Directive 2009/125/EC).

2) Human Factor is the component that contains the individual agency of the engineer. This component is divided into three aspects: e) Personal Drive, which reflects the motivation and behavioral aspect of the individual; f) Acquired Knowledge, which reflects the cognitive process and expertise of the individual; g) Professional Practice, which reflects the will for engagement with developing a solution. This component can be assessed in EE as part of a course learning outcomes, where the educator can evaluate the engagement and performance of the student. It aims to consider individuals along with their psychological states as fundamental parts of the design process. A practical example of the implementation of this component in a course would be based on regularly monitoring the level of commitment and interest of the students, thus providing adaptations in content or approach that promotes higher engagement.

3) D4i Process is the component where all the above comes together as a design process and professional practice for the solution development and is divided into four aspects: h) Design Process; i) Impact Assessment (TBL); j) Business Potential; and k) Purpose & Impact. This component is where the individual dares to question traditional approaches by making use of critical thinking to evaluate the impact creation of their solution across the TBL and its value chains, and it can be assessed in EE as innovative approaches or outcomes. It aims at consolidating the framework's components 1 and 2 into the design process. A practical example of utilizing this component in a course would be a holistic approach to PSS development, starting with an innovative concept and ending with the communication of purpose and impact based on assessments developed as part of the design process.

Based on the components listed above, the D4i framework proposes an overview of areas of interest as means to open a dialogue on what is needed to know and to do when developing sustainable solutions. Acting as a map, the information structure of D4i framework relates contextual aspects to the PSS development, assists in systemic thinking, and includes human aspect in relation to impact creation. Figure 2 illustrates this structure and the flow of information of the D4i framework, also positioning the design engineer as the mediator between information and action.

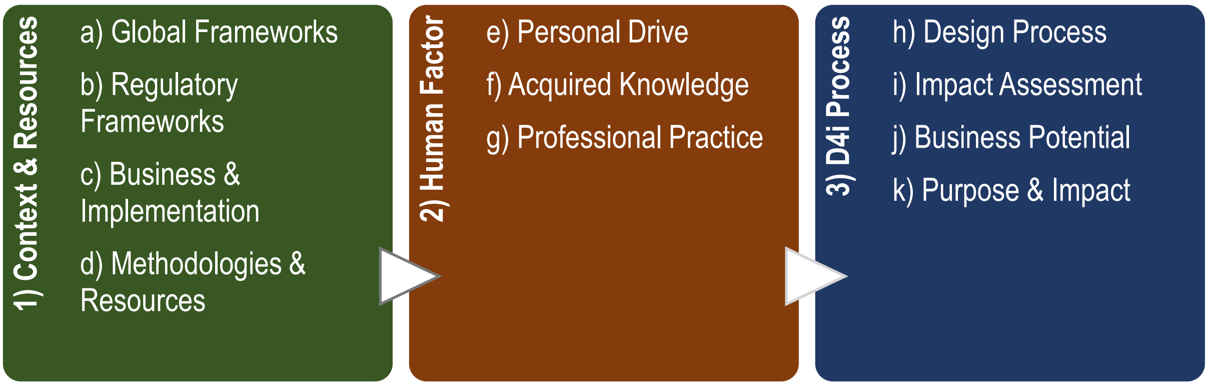

Figure 2. Information Structure of the D4i framework

The integration and testing of this framework within an educational setup should be simplified and adapted to fit into existing courses and curricula. The D4i framework can be used as an instrument for educators to plan and develop meaningful coursework that focuses on unveiling knowledge gaps, deconstructing pre-established assumptions, and communicating impact to a given concept or philosophy such as Agile (continuous iterations for integration), Lean (continuous improvement to minimize waste) or Design thinking for co-creation with users and society. Aspects of this framework are meant to be co-developed further and updated frequently in the light of new knowledge as well as changes in context or resources.

4 CASE STUDY AND RESULTS

At this stage, the D4i framework is being developed with the purpose of assisting teaching and an open discussion in higher education setups. Therefore, we further examine the deployment of the framework and provide insights from a case study where it was tested in a lecture-workshop class for the course Advanced Product Development at Master level, from the Technology Based Business Development (TBBD) degree at Aarhus University in Denmark.

4.1 Framework adaptation for case study

In order to iterate the D4i framework, and given the time limitations for deployment in a 4h lecture, we have developed a concise version of the framework focused on specific aspects. The program was divided in two parts: i) Lecture and ii) workshop. The first half of the program focused on the D4i component of ***Context and Resources***, where the students were presented with an overview of current global actions, policies and regulations in relation to sustainability and product development. The aspect of ***methodologies and resources***, was the least exploited subject during the program due to the fact that the overall TBBD curricula covers extensively these topics. Therefore, we have only focused on introducing the concepts and briefly presenting sustainability-oriented methodologies that could serve as inspiration. The second half of the program focused on the aspect of ***Practice*** by making use of a workshop format as a space for the students to explore the ***D4i Process*** component.

The students were therefore encouraged to apply a pre-developed toolkit[*] into their semester-long projects. The toolkit guided the students into three sets of activities during the workshop session: 1) Concept diagnose (individually), 2) Evaluating areas of improvements and discussing within the groups, 3) Communicating impact and potential value creation. At the end of the session, the groups pitched their products in the light of their newfound understanding of impact creation. Hence, the students were able to navigate through several aspects of D4i process and reflect upon the decisions and solutions they have been developing.

4.2 Application of D4i in a Lecture-Workshop format

This case study is centered on three student groups consisting of 2-3 participants that worked together during the class using their main course assignment as a subject. This course assignment was to develop of a product-service system throughout the whole semester, where they integrated the knowledge of all the lectures provided by the curricula. The students' projects featured in the course were very distinctive between the groups, which provides D4i with a broad scope of applications. The students' highlighted the benefits of using pre-developed templates such as the toolkit for systematically navigating the complexity of the D4i framework topics. However, the limited lecture time restricted any in-depth exploration of concepts such as Life Cycle Analysis (LCA) and materials' metadata, which created uncertainty for their solutions.

[*] *Toolkit templates available upon request to the authors.*

After going through the exercises of the D4i toolkit, the students were encouraged to hand-draw a poster about their solutions as shown in Figure 3, and provide a 5 min pitch presentation as practice in communication of impact related to their solutions.

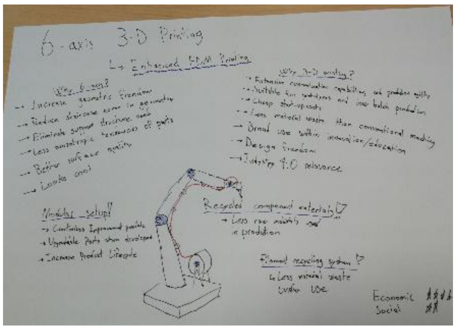

Figure 3a

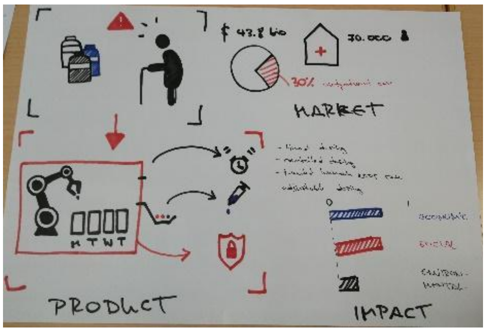

Figure 3b

Figure 3c

Figure 3. the student posters developed during the lecture in sustainable product development using the D4i framework referencing to their different group products a) a 6 axis robotic 3D printer for recycling plastic material, b) a robotic medical pill dispenser for sustainable use of medicines in elderly care dormitories, c) an industry 4.0 drone manufacturing line for repair and reuse of drones and its component materials.

The pitch and discussion session opened the opportunity for giving and receiving feedback from their peers as well as reflecting on the process of going through the exercises. The pitching practice aimed to develop communication capacity in relation to value creation across the TBL, and a space for peer discussion and support as well as to facilitate a simplified diagnosis for impact assessment as an exploratory tool for systemic thinking during product development, starting with the overlook of broad aspects related to the concept such as Product Systems Services (PSS) type, competitors and market potential, and driving to more specific design aspects such as manufacturing and components, value chain, usability and lifecycle. The students reported this class to be their first contact with a structure that allowed them to reflect on sustainability from multiple perspectives and throughout the product value chain. The toolkit and D4i framework has assisted with providing guidance and a thought flow, which inevitably aids the communication aspect of product development.

The process of assessing their previous work and evaluating impact creation in the work they developed throughout the semester has shown to provide a space for reflection and reconsideration. Among the feedback provided by the students in relation to the framework and their learnings, we observed that students present very distinct backgrounds and might not be familiar with traditional design methodologies or approaches, including basic eco-literacy, and are not familiar with the available tools for sustainable product development. As an example, despite having had previous contact with the UN SDGs, the students reported to not have a clear picture of how to integrate the goals into their concept formulations or to use the framework to reflect on the impact of their concept. Only one student had used the SDGs before as a tool to communicate value creation. By using the framework, students were able to provide clear communication on the possible impacts of their products and reflect upon the TBL aspects of their concept in relation to both manufacturing processes and usability.

5 CONCLUSIONS AND ACKNOWLEDGMENTS

This study proposes the development of D4i as a human-centric framework for teaching and learning sustainability in engineering education that aims at enticing dialog between faculty, students, and industry stakeholders in order to answer the following questions: i) How can we promote an open discussion on sustainability as a core competency in design education?; ii) How can we integrate a holistic and humanistic approach to sustainable design?, and iii) How can we empower the designer as the decision-maker towards a sustainable mindset?

The consolidation and iteration of the D4i framework shed light on the promotion of pedagogical methodologies that promote open discussion about the implementation of sustainability as a core engineering competency, and the mechanisms that support achieving this goal such as re-orienting education towards a purpose-driven practice-based-learning approach that provide tools to build long-term sustainable mindsets. Since D4i framework serves as mapping tool to identify learning gaps and promote structured reflections, educators can easily implement such framework and design their own toolkits as part of their already existing curricula and coursework, with minimal use of external resources. The limitations are mainly related to the available time during class for exploration of complex topics. However, different formats can allow for more time and for the association with multiple courses within an EE program.

This study gave us invaluable insights on the structure and usage of such a framework, approaches on how to integrate holistic elements of sustainability into restricted educational timeframes, and feedback from an initial implementation in class. Furthermore, it sheds light on new research pathways and areas that require more attention when developing useful tools for teaching, learning, and assessing competencies in the context of sustainable mindsets, professionalism in engineering, and design for sustainability approaches in education. Future work could aim to evaluating the D4i framework in a course-long setup as well as investigating what are the areas of strength and any knowledge gaps in current engineering curricula.

The authors would like to thank all students that participated in the early study as part of their coursework.

ABSTRACT

As the demands of industry are evolving and new generations of students are entering universities, many engineering faculties invest time in curriculum reforms based on inspirational innovations, underpinned by engineering education research. The Faculty of Engineering Technology (FET) of KU Leuven had an additional argument to implement a huge programme reform: this faculty, hosting more than 6000 students spread across seven campuses in Flanders (Belgium), was an amalgam of different traditions and visions. Their merger into one faculty in 2013 aimed to optimize the organisation of research, education and community service.

[1] *G. Langie, greet.langie@kuleuven.be*

doi:10.5821/conference-9788412322262.1382

The goal of the programme reform in 2020-2021 was fourteenfold: enhancing our typical profile of (1) hands-on engineering in (2) strong interaction with the labour market and setting up (3) a technology hub with more attention to (4) multidisciplinarity, (5) professional competencies, (6) personal development & support, (7) lifelong learning and (8) challenges including (9) complex problem solving. The reform also aims to increase the (10) attractiveness and (11) social relevance of the programmes. By strengthening the internal coherence in the faculty, we can exploit the (12) multicampus narrative to offer students more choices and develop their (13) future disciplinary self, supported by (14) choice guidance.

This paper describes how the curriculum was adapted in order to achieve these goals and presents the results of perception measurements organised among freshmen who followed the old programme in 2019-2020 and freshmen registered in the new programme in 2020-2021. Of foremost importance is the increased feeling that the professional competencies are essential for an engineer.

1 INTRODUCTION

All sectors of society are witnessing great changes. Higher Education in general, and engineering faculties more specifically, play an important role as leaders in teaching and learning of the future engineer. The actual engineering student should be prepared for the challenges of tomorrow. It is the task of the engineering faculties to empower engineering students by helping them to achieve the relevant competencies needed in their future professional life.

Van Damme [1] states "Universities are doing reasonably well in translating changes in scientific knowledge into course contents but do not identify similarly important changes in skill demand in the external world and transform their education programmes accordingly." Indeed, engineering education research confirms that the skill set demand in the field of engineering is broad [2], role-specific [3] and in constant evolution (e.g. responding to the challenges of the Sustainable Development Goals [4]). Engineering faculties are responding to these social and technological developments in different ways. Hadgraft and Kolmos [5] list some responses they have detected in new types of engineering programmes: "These responses are student-centred learning, integration of theory and practice, digital and online learning, and the definition of professional competencies." In her 'Global state of the art in engineering education' Graham [6] has identified the 'current' and 'emerging' leaders in engineering education and she concludes with the following list of features of this new generation of engineering programmes: "Distinctive educational features of the 'emerging leaders' include work-based learning, multidisciplinary programs and a dual emphasis on engineering design and student self-reflection.".

This paper explores how engineering students have perceived a major engineering curriculum reform in the Faculty of Engineering Technology (FET) of KU Leuven. It was developed from a blank slate, based on 14 goals which were established through a collaborative process. The research question of this paper is formulated as follows:

"To what extent have the students experienced our 14 objectives?".

The context and the 14 goals of this collaborative curriculum design process are described in section 2. This is followed by a description of the implemented methodology to monitor the students' perceptions. And in the two last sections, the results of this monitoring process are given and discussed.

2 CONTEXT AND GOALS

KU Leuven is a comprehensive, research-intensive university, active at different campuses. The university is highly ranked (most innovative university of Europe) and counts more than 60000 students.

The new Faculty of Engineering Technology is a multicampus faculty spread over seven campuses in Flanders (Belgium) and is established in 2013 after a merger of the engineering departments of six different University Colleges of Applied Sciences. The faculty has a total student cohort of over 6000 students, of which more than 1000 are in the first year of the Bachelor's programme at the time of the curriculum change. These first-year students do not have to select their major or discipline when registering at university. The selection of one of the four the disciplines (civil engineering, chemical engineering, electromechanical engineering or electronics & ICT engineering) is made at the beginning of the second year. By consequence all first-year students take the same courses.

The curriculum development process started in 2017. Three years later, in September 2020, the first cohort of students started in the new three-year Bachelor's programme. This cohort will start the new one-year Master's program in 2023-2024. This paper only focuses on the experiences of the first-year students of the first cohort.

Since this faculty is the result of a merger of six institutions with different traditions, the curriculum development process started with an in-depth review of the faculty-wide goals. This collaborative process at different levels of the faculty resulted in 14 goals for the revision of the curriculum across the whole faculty. We discuss them one by one in a logical sequence, not influenced by relative importance.

2.1 Multicampus education

In order to exploit the multicampus context, the programme of the first year of the Bachelors is *identical on all campuses*. This allows (1) to reduce the number of majors/disciplines on some campuses without limiting the choice of a student since they can move from one campus to another, and (2) to intensify cooperation among the teaching staff in faculty-wide teaching teams.

The curricula of the Masters on the other hand are on purpose very diverse across the campuses and based on the research activities performed on each campus. By consequence, a graduated Bachelor's student has a huge choice of possible specialisations if the student is willing to move from one campus to another.

This supports the idea of a student-centred learning environment that emphasizes 'student choice', our second goal discussed in 2.2.

2.2 Choice guidance

Students have to make several important decisions while studying, such as 'pick a major', 'select a specialization in the Masters' and 'choose a job'. Starting from day one of the Bachelor's programme we support our students in these decision-making processes by intra- and extracurricular activities and clear communication (e.g., a first-year project covering the four disciplines, orientation days, job shadowing, etc.).

2.3 Supportive programme

Higher Education in Belgium has an open admission policy, resulting in a very diverse population of incoming students in terms of prior knowledge. We support our first-year students with extracurricular activities before the start of the academic year (e.g., MOOC basis mathematics, on-campus summer course, etc.) and during the first year (e.g., online tools, on-campus private or group sessions, etc.).

2.4 Challenging programme

This diversity requires support for some students and extra challenges for others. In general, the faculty engages in initiatives to motivate students to push their limits (e.g., a project with a bonus for those who go the extra mile, international experiences, etc.). This is in line with our focus on a student-centred learning environment that is attractive for potential engineering students.

2.5 Technology from day one

At KU Leuven three types of engineering curricula are organised: engineering technology, bio-engineering sciences and engineering sciences. The programmes within the Faculty of Engineering Technology are more applied, technology from day one is an important element to distinguish us stronger from the other programmes. Basic sciences and technical knowledge remain important, but the programme is broadened. The new curriculum sequence 'engineering experiences (EE)' in the Bachelors (EE1 in year 1, EE2 in year 2 and EE3 in year 3) offers students the chance to operate as engineers from day one. 'Integration' is the key word.

2.6 Professional competencies

The new programme emphasizes the increased importance of professional competencies. Experts in professional competencies organize seminars about these professional competencies, integrated in the EE-curriculum sequence. Moreover, these professional competencies such as communication, leadership, project management, team dynamics, etc., are not only 'teached' in colleges, but are also 'trained' and 'evaluated' during the regular courses such as laboratories and projects. This integration is essential since this is also the way it will be applied in the professional context.

2.7 Multidisciplinarity

Engineering problems are becoming increasingly multidisciplinary. Students have to learn to think and work across disciplines. At least during EE the students have to work multidisciplinarily, but also other activities support multidisciplinarity. This starts simple in EE1 where they have to integrate the content of different general courses in the integrated lab/project and it becomes a real multidisciplinary project in EE3.

2.8 Practice in the programme

The focus on practical engineering underlines our specific profile. It is not only realised in EE, but in almost every course since most courses are split in three parts: colleges (theory), exercises and laboratories. These laboratories are expensive learning environments, but essential to understand the theory in an applied way. This profile enhancing focus is moreover for many students an attractive feature.

2.9 New technology

Technology evolution speeds up. We invest a lot of money to give students the opportunity to have hands-on experiences with new technology in projects and laboratories. But we also focus on introducing new technology through lectures and contacts with industry (e.g., company visits, Master's theses in collaboration with industry, etc.).

2.10 Interaction with the labour market

The Faculty of Engineering Technology has a long tradition of cooperating with the labour market. This programme reform wants to reinforce it by implementing e.g., job shadowing during the first year, intensified company visits, guest lectures, partnerships with some companies, etc.

2.11 Disciplinary future self (DFS)

Freshmen are usually still figuring out who they are and what they want to become in the future. We support students by developing a learning environment in which they can reflect on who they are and want to be (e.g., PREFER-explore and -match test, personal development plan, etc.).

2.12 Complex problem solving

Engineering problems are becoming increasingly complex. It is important to learn students how to deal with this complexity by building in progressively more and more complexity throughout the curriculum. The way we approach this is very similar to the way we 'teach' multidisciplinarity. It starts very simple with for example with the training of the ability to solve exercises combining topics from different chapters within one course and it ends in the Masters with dealing with authentic engineering problems which are by definition complex.

2.13 Lifelong learning

Lifelong learning is the buzzword of the moment, but not without reason. This is essential when it is our goal to empower our students to be ready for the future. Self-regulation is for example an essential competency of lifelong learners..

2.14 Socially relevant programme

We want to educate social responsible engineers, ready to tackle the Grand Challenges for Engineering. We want to stimulate this responsibility and awareness by giving them the opportunity to take part in for example community-based social projects, student competitions with a focus on sustainability, etc.

3 METHODOLOGY

A multidisciplinary team has translated each of the 14 goals (‘scales’ called from now on) into 3 to 4 targeted questions to measure the perceptions of the students. The questions can be answered with a 6 point Likert scale (from ‘totally disagree’ to ‘totally agree’). This resulted in an online survey of 54 questions given to 943 first-year students in May 2020. This was at the end of the academic year 2019-2020, the last year the former programme was organised for first-year students (old cohort). The response rate was 48% or 450 students completed the questionnaire. In May 2021, at the end of the academic year 2020-2021 in which the new programme was initiated, 798 first-year students were invited to complete the questionnaire and 267 effectively did (new cohort). This resulted in a response rate of 33%. Normality of the distributions of the scales was checked using the Shapiro-Wilk tests. Since they were not normal distributed, the perceptions of the old and the new cohort were compared with Wilcoxon rank sum tests.

The reliability and validity of the survey with 14 scales was measured with Cronbach’s Alpha and an exploratory factor analysis. A confirmatory factor analysis confirmed a necessary reduction of the scales.

4 RESULTS

The validity of the survey is discussed first, followed by the results of the perception measurements. A discussion of the (non)significant changes in perceptions between the old and new cohorts constitutes the conclusion of this paper.

4.1 Reliability and validity of the survey

The internal consistency of the scales of the survey is given in Table 1.

Table 1. Cronbach’s alpha of the 14 scales ordered in sequence of Cronbach’s alpha.

Scale (goal)	Cronbach’s alpha	Scale (goal)	Cronbach’s alpha
Interact with labour market	0.78	Choice guidance	0.67
Supportive programme	0.77	Socially relevant programme	0.58
Challenging programme	0.74	Disciplinary future self (DFS)	0.56
Complex problem solving	0.73	New technology	0.52
Practice in the programme	0.7	Multicampus education	0.51
Professional Competencies	0.69	Lifelong learning	0.49
Technology from day 1	0.68	Multidisciplinarity	0.46

Cronbach’s alpha’s of less than 0.7 are in principle not acceptable. The exploratory factor analysis also did not confirm the 14-factor model. Implementing a promax rotation and a cut-off of 0.3 for the factor loadings, 5 items of the survey were rejected, and 7 factors selected. This was confirmed with the scree plot and a confirmatory factor analysis (CFI=0.86; RMSEA=0.051). Five original scales remained, and two new scales were developed (see Table 2). The new scales are shown in italic in Table 2. ‘Lifelong learning’, ‘multidisciplinarity’, ‘Disciplinary future self’ and ‘socially relevant programme’ are not withheld.

Table 2. Cronbach’s alpha of the final 7 scales

Scale (goal)	Cronbach’s alpha
Challenging programme with complex problem solving	*0.82*
Interact with labour market	0.78
Supportive programme	0.77
Student centred programme (multicampus, choice guidance and DFS)	*0.76*
Practice in the programme	0.7
Professional Competencies	0.69
Technology from day 1	0.68

4.2 Changes in perceptions between the old and new cohorts

The results of the Wilcoxon rank sum tests are given in Table 3. The perceptions of the students of the two cohorts can be compared. Only for three scales (or goals) a significant change is measured: ‘interact with labour market’, ‘supportive programme’ and ‘ professional competencies’. Unfortunately, only for ‘professional competencies’ the students have experienced an increase so far.

Table 3. two-sample t-tests for the two cohorts in the 7-factor model.

Scale (goal)	Old cohort M (SD)	New cohort M (SD)	p-value
Challenging programme with complex problem solving	4.51 (0.58)	4.41 (0.68)	n.s.
Interact with labour market	3.96 (1.02)	3.12 (1.03)	<.001
Supportive programme	4.58 (0.78)	4.37 (0.85)	<.01
Student centred programme (multicampus, choice guidance and DFS)	4.03 (0.70)	4.12 (0.75)	n.s.
Practice in the programme	4.34 (0.71)	4.12 (0.75)	n.s
Professional Competencies	4.27 (0.83)	4.46 (0.76)	<.01
Technology from day 1	4.58 (0.64)	4.62 (0.65)	n.s.

5 DISCUSSION

The answer to the research question can be short: the first-year students of the first cohort who have followed the new curriculum do not have the impression that the interaction with the labour market has improved, neither they have an increased feeling of support yet. But they have fortunately experienced that the professional competencies are an essential part of the broad skill set. For the other four goals no conclusions can be made at this point.

This limited result is understandable considering the following contextual factors:

1. The focus was only on the first year of the programme. Not all 14 goals are achievable in the first fourth of the new curriculum. On the other hand, a first basis can certainly be laid for the 7 corrected goals. For example, we invested quite some time in a new initiative of job shadowing. This seems not to have effect, on the contrary, the interaction with the labour market was appreciated less. There is clearly something else going on.
2. Starting from March 2020 Covid-19 had a major impact on education. The old cohort was partly hindered. The new cohort started at university during the pandemic. Laboratories (practice in the program) were less frequently organised, job shadowing (interact with the labour market) and supporting workshops (supportive program) were online, etc. This puts this work in perspective.
3. And last but not least, during the first year of a huge programme reform not all that you would like to do has been achieved yet. We have the intention for example to implement in near future a personal development plan and a more intensive support programme.

As we are now only reporting on the first step of a longitudinal study, it is important to have a critical look at the survey the coming years. Not necessarily all validation recommendations of this paper should be considered in near future. After all, we have validated the survey only with first-year students. 30% of them drop-out after the first year, so they are not a representative sample of our population. A new validation should be done the coming years.

Concluding, this study proves that it is possible to make students aware of the importance of professional competencies. Since we are not the only faculty integrating professional competencies into the core of the curriculum [7-10], this is hopeful information for many curriculum reforms. Improvements are still possible, such as a stronger integration of the professional competencies in the engineering courses and not only in EE. Also, the development of a supported framework to track and evaluate the professional competencies might be helpful.

6 ACKNOWLEDGMENTS

We would like to thank all the staff and students of the Faculty of Engineering Technology. And more specifically, our gratitude also goes to Julie Vermeersch and Jolien Bynens for their punctual organisation of the surveys.

Keywords*: digitalisation, digital education, teaching methods*

ABSTRACT

The ongoing digitalisation of the learning processes has both opportunities and obstacles for the educational attainment of students in STEM subjects. In this paper, we summarise student experiences with digitalisation during the COVID-19 pandemic and provide recommendations for how to improve teaching methods of STEM education. The research was conducted through focus groups in a workshop format at 15 European STEM universities across 8 different countries obtaining 147 responses from students. This paper also aims to analyse how the digital competency of both students and professors has been impacting the effectiveness of new teaching methods and education tools during online classes since the start of the pandemic. Students have a variety of needs, with some students preferring the flexibility and anonymity online work gives them, while others thrive better when they are face to face with instructors and dislike the limitations that exist in virtual communication. In addition, we looked at how students view changes in the evaluation of projects and tests that have occurred to prevent cheating. The results show the relevance of digital education and which aspects of it need to be developed further. The paper further explores possible solutions for the issues identified in this research, including learning, methodological and skill development aspects. Overall, we propose hybrid classrooms where students have the choice to explore which method of learning best fits them and how professors can support them to ensure the best educational outcome.

1 INTRODUCTION

1.1 General overview

The educational crisis caused by the COVID-19 pandemic affected students worldwide, while teaching has been digitally transformed in the form of online learning as an alternative approach to education. This change has had a large effect on students in STEM fields since a substantial part of their program depends on project work and practical learning, which requires access to technology and close communication with instructors and group members.

By testing out the new hybrid educational model during the pandemic [1], the approach to learning has shifted to student-centred learning (SCL) where students are encouraged to take more responsibility for their education. The requirements of the digital era applied to students as the next labour force even before the pandemic, and the sudden need to shift the educational model accelerated the process of the universities acting as facilitators of the SCL model [2]. Many stakeholders have been investigating online learning in European universities stemming from the pandemic and tried to identify the differences between individual universities (tools, platforms, applications). The need to analyse students' input on challenges and opportunities for improvement has become evident.

1.2 Goal and objectives of the research

The main question tackled by this study is how COVID-19 has impacted Higher Education in terms of three objectives.

<u>To address Objective 1:</u> *Gather and examine the actions that European STEM Universities have taken in reacting to the COVID-19 pandemic of the goal,* this study sought to map innovative teaching methods, digital assessment methods, and support needed by educators and students.

<u>To address Objective 2:</u> *Gather students' perceptions and opinions*, this study aimed to evaluate how the measures taken as part of the digital move have impacted the engagement of students with their studies; and locate the main roadblocks and catalysts of the digital move for students, both in terms of digital tools and accessibility, and of digital skills.

<u>To address Objective 3:</u> *Analyse the learnings*, the study aimed to help define the most effective balance of online and offline education in the post-pandemic context; and to enhance and complement the engagement of in-person education with an optimised online one-way information transfer.

2 METHODOLOGY

2.1 Data sources

During this study, primary and secondary research were conducted in the period of January until April 2021. Primary data sources were collected through in-depth interviews of students from each target university with the goal of probing what new changes were introduced to the Higher Education activities portfolio, including the possible new teaching methods, new equipment, or infrastructure used for learning processes and support given to students and educators. Data collected through primary research was analysed and used in the creation of secondary research.

Secondary data has been collected mainly through focus groups, obtaining 147 responses from students. Focus groups were conducted in a workshop format from 15 European Universities with the goal of gathering information on students' opinions about the transition to digital education and what obstacles they have experienced, as well as what opportunities for improvement they have observed. The workshop consisted of an introduction, statement voting, brainstorming and clustering of the identified problems and opportunities. The last section was conducted in the format of World Café, the students had to focus on 5 different areas: Digital competencies; Digital tools; Teaching methods; Assessment methods; and Interaction. Methods used for data analysis include the statistical method, the method of induction and deduction and the comparative method.

3 Results

3.1 Digital competences

Firstly, this section investigates the influence of students' competences in digital education. Secondly, this section analyses the impact of the educators' digital competency on the learning process [3]. Digital competences encompass responsible usage, and interaction with digital technologies in the following areas: Information and data literacy, communication and collaboration, digital content creation, safety, and problem solving [4].

3.1.1 Results

Fig. 1 demonstrates that most of the students think that they have barely sufficient digital competencies to move digital education without hindering the learning process. Therefore, there is still a portion of students that the learning process has been limited by their digital competencies. As it can be seen in Fig. 1, students' opinions on engagement are similar to the learning process.

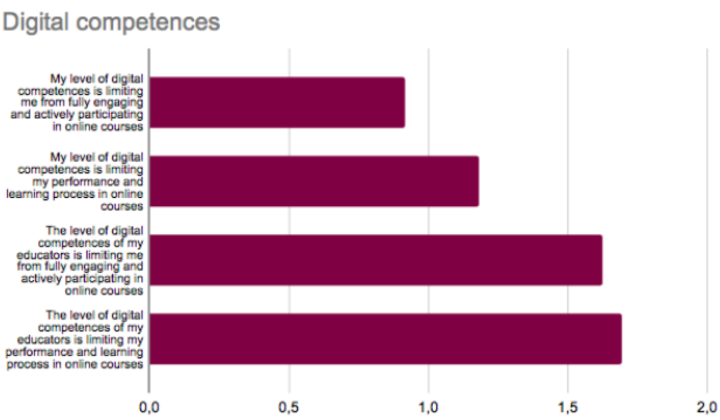

Figure 1. Histogram showing students' answers to the following questions, normalised from a minimum of 0 to a maximum of 3; with 3 being absolute agreement and 1,5 being a neutral opinion and zero being disagreement.

On the contrary, students' opinion on the limiting impact of educators' digital skills is dominant. Learning process and engagement have a similar trend. During the World Café, students mentioned the hindered impact of the poor digital skill level of professors. 87% of students stated that professors could not display information in an efficient way. Besides that, some of the professors were not capable of using the features of the digital tools in a way to engage students more in the lectures (40%).

3.1.2 Recommendations

Transitioning to digital education has allowed students to practise their digital skills, and their current level of digital skills didn't hinder their learning process significantly. Educators' digital competencies improve the learning experience by helping professors pedagogically [3], but educators' poor level of digital competencies hindered the learning process. In order to improve the learning experience in online education, universities should focus on educators' digital skills and provide training courses to use online platforms efficiently [5]. It would be needed to conduct a thorough study on digital skills of educators and assess their needs to improve digital competencies.

3.2 Teaching Methods & Digital Tools

Through teaching methods, students can engage in learning activities, reflect on them, use higher-order thinking and work in groups. Previous studies in STEM education have found that active teaching and learning methods, focused on interaction, provide more interest and engagement in the students' activity in the class [6]. Learning to use digital tools to deliver lessons has positively affected online teaching methods in most universities [7]. The aim of this section is to analyse the effort and attitude of universities facing this challenge, and in which way they chose digital tools to enhance teaching and learning opportunities. In that direction, universities had to use online platforms to enable interaction during lectures and group work, which is a crucial aspect of the learning process. Microsoft Teams, Google Classroom, and Miro are some of the online platforms which enable the interaction and collaboration between peers in the online environment [10].

3.2.1 Results

According to the presented data, it was stated by a majority (Fig. 2) that being able to follow recorded lectures at the preferred place and at the chosen schedule was a great advantage. This fact had an impact on the understanding of the subject and the final results of the final evaluation. During the class an enormous potential to make use of different information sources and activities exists. On the other hand the students admitted that online environments are full of distractions and difficult to remain focused, signalling caution on their extended use. They are related to the high amount of tasks, lack of physical contact and interaction and the content of the lectures. One of the problems stated by more than 67% of the students is that practical lectures in person are crucial for a complete and efficient learning experience. The tools (ppt) and format (non-interactive lecture format) were maintained and only the platform changed, and some courses with easy possibility to be adapted were not. This was seen as a lack of innovation and adaptation to the new environment.

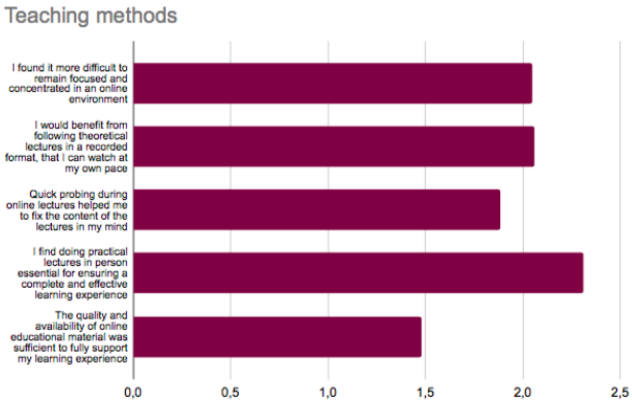

Fig.2: Engagement and learning process benefits from following lectures in a recorded format. The answers are normalised from 0 to 3; with 3 being absolute agreement and 1,5 being a neutral opinion and zero being disagreement.

Students from six universities declared the environment was monotonous and the tools were not used to their full potential in order to engage the people present in the class. The results of the focus groups show that 73% of universities used recorded lectures, which allowed students to rewatch the lectures at their own pace and choose their own learning schedule. It was also shared that with the usage of different tools, it is easier to keep the engagement of the students in the lecture. Furthermore, there were mentions of significant improvements in the usual platforms universities use, as not all learning materials were centralised in a fully-integrated platform before.

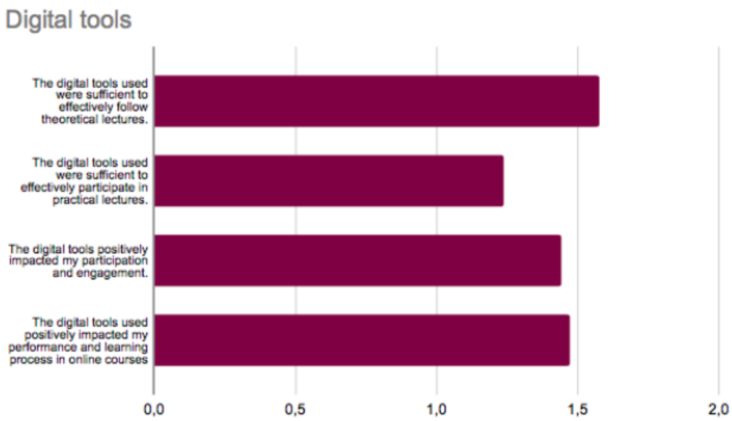

Figure 3. Overview of the impact of used technological tools in online education. The answers are normalised from 0 to 3; with 3 being absolute agreement and 1,5 being a neutral opinion and zero being disagreement.

Fig. 3 shows the impact of technological tools used in the courses from the perspective of students. There is a significant shift toward the mindset that technological tools used were sufficient for students to effectively follow online lectures. In comparison, the balance is significantly shifted towards tools not being sufficient for the practical lectures, with almost 60% of students' voting so. There is a

balance between students deeming tools affecting their participation and engagement both positively and negatively. However, as it is shown, technological tools didn't have a significant impact on students' performance nor learning process in online classes. Access to a stable internet network, as well as equipment that supports digital tools is crucial, and 60% of our respondents shared they encountered issues with it. The main issue identified for STEM students was the lack of tools that simulate practical activities, especially for work with advanced technology and laboratory work, which was noted by 73% of university students.
Fig. 4 demonstrates that students have diverse opinions on this comparison with a slight bias towards decreasing productivity with online group work. It seems that the lack of interactivity among them sets a major drawback to their productivity. Nonetheless, the non-negligible portion of students thinks that online group work increased their productivity.

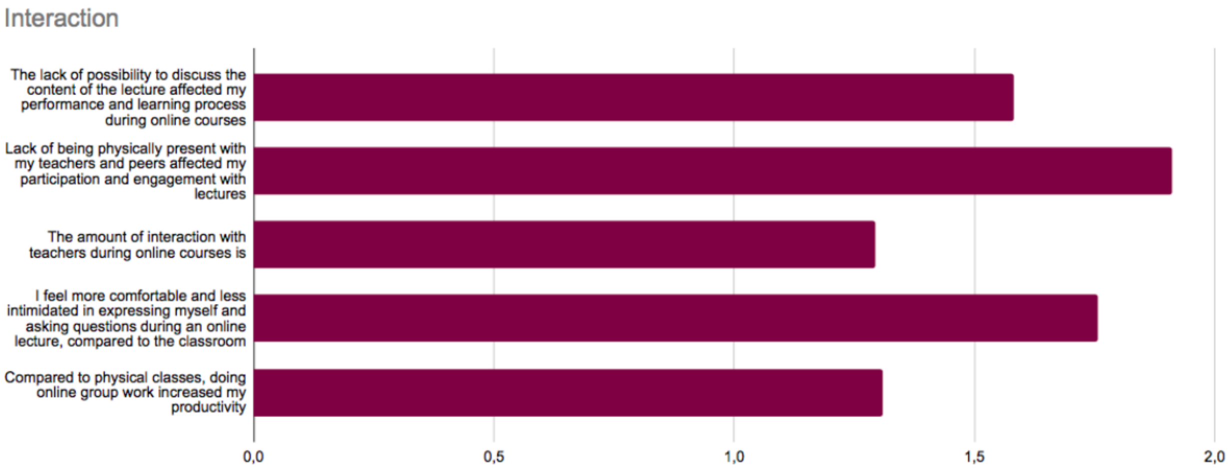

Figure 4. Histograms showing how productivity changed for students in online group work. The answers are normalised from 0 to 3; with 3 being absolute agreement and 1,5 being a neutral opinion and zero being disagreement.

A highly mentioned problem (47%) is the ineffective communication in digital education with their colleagues and teachers. According to students, their performance has decreased on group projects and exams, as a result of ineffective communications during online lectures. Another opportunity mentioned by students (33%) is flexibility to plan their schedule around online education. Lastly, workshops have investigated how the lack of being physically present at the university affected the participation and engagement with lectures. As depicted in Fig. 4, there is an outweighing opinion that lack of physical presence hindered the engagement and participation of students in the lectures.

3.2.2 Recommendations

Modifications in teaching methods have not been substantial, mainly tackling the platform used, not the content itself. Practical lessons are an essential part of some degrees and these were evaluated by the students to be better done in an onsite manner. Students feel like their learning and understanding are increased when they are able to perform the experiment or the project themselves. For teachers, more time is needed in order to revise their teaching methods for the new environment and also for students to adapt to the new online tool.

Recommendations for how to improve teaching methods of STEM education are the following: a) having all the lectures, guidelines and practical courses on a platform, so that students will be able to access them anytime; b) preparing exercises based on the lectures/videos previously provided on the platform and discussed during the actual hour; c) having the possibility to work both alone and in teams; d) providing the possibility to work with scientific tools and analyse real data from laboratories/industries; e) creating preparation tests for the final exams that can be retaken for as many times as needed and with different possible questions; f) giving students the opportunity to participate in class in smaller groups/specific laboratories; g) engaging the students to interact with the actual research topics in their fields - example: using these references for presentations. Teaching approach in this new, digital environment depends heavily on professors' ability to learn, and ultimately manage digital tools [8]. The difference in the digital competence of students and their professors is evident, where professors are expected to be experts and mentors, while in reality, they are still adapting to digital tools. To properly introduce the hybrid model, educators need continuous training and an environment where experimenting and innovating in both choices of digital tools and their purpose of implementation is encouraged. To ensure a proper environment, it is advised that universities tackle internally the choice of digital tools, via a centralised approach, and reduce the workload of professors when it comes to lecture design.

It is noted that some courses cannot be well adapted to online education, thus there is a high need to develop tools that accommodate the need of STEM students for practical lessons. While complete substitution of hands-on practice is not recommended, there is a remarkable space for improvement of existing tools used for practical learning, with many different potential ways open by designing remote practicals through recordings, simulations, quizzes, real and simulated data and augmented reality technology or gamification [9]. There is a significant distinction in the answers to the posed questions which addresses productivity and expressing themselves during lectures. These results demonstrate that students have varying preferences according to their personality or need for flexibility.

A majority of students agreed on a certain opinion: Lack of physical presence has negatively impacted students' participation in and engagement with their lectures. In addition to that, the perception of educators towards digital education is an important factor for the engagement of students with lectures. Educators should have a positive perception towards the usefulness of digital tools as a facilitator of the lectures [3], and motivate students in a way to participate in lectures as a helpful educator [11,12].

3.3 Digital Assessment

Our goal regarding this section is to show how much the assessment methods have changed during the pandemic, how the evaluation changed, how the teachers assure the fairness of their students and what are the main positive and negative aspects of online assessments from students' perspective.

3.3.1 Results

Most of the universities presented a significant or partial change in assessment methods - for example: cancelling an exam and moving the grade to a project, changing a closed book exam to an open book exam, etc. According to the received responses, four main assessment methods (Fig. 5) that have been used during the evaluation of the students are further considered: written exams in universities, written online exams, oral online exams and assignment-based examinations.

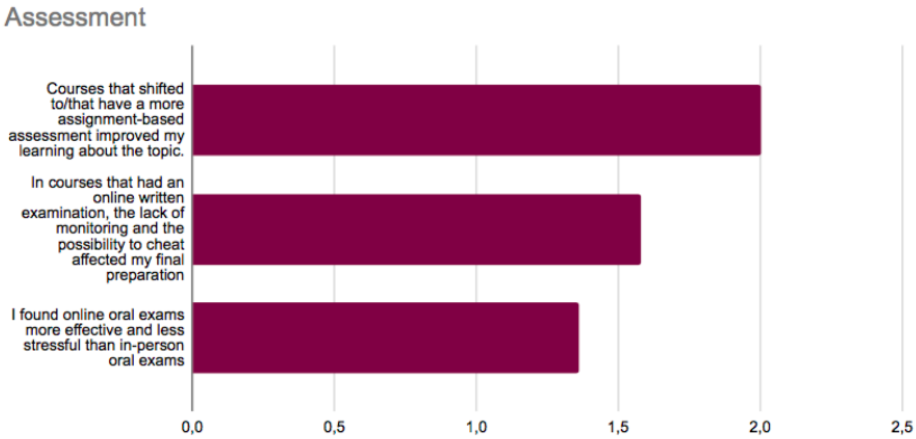

Fig. 5: Histogram with an overview of the assessment methods used.The answers are normalised from 0 to 3; with 3 being absolute agreement and 1,5 being a neutral opinion and zero being disagreement.

One of the main fears from the beginning of the global crisis caused by the pandemic was the assurance of qualitative education and the academic integrity of the students. The reformation of the evaluation to a method where controlling the class is less crucial was desirable and a common approach was the change to an assignment-based assessment. One result was the clear trend in which students found the assignments a way to improve their learning. Some students also stated that mid-term exams, projects and continuous assessments (in the form of assignments) helped them to reduce the workload of final exams and develop a deeper understanding of the subject matter.

There were also some disadvantages noticed by students. Almost all of the World Cafe groups (67%) mentioned that they were overworked by the larger number of assessments that were used to (partially) replace traditional exams. Some students even stated that they were suffering from burnout. Another interesting point: the online-only format of a lot of group projects and labs was considered less efficient, causing students to spend more time on these tasks (33%). Some assignments also cannot be properly translated to an online format and this caused less impactful learning for the related projects (25%). Some students mentioned as a problem that the exam was made harder than in previous years (42%), time requirements were more strict (33%) and students were not allowed to go back to modify answers they previously submitted (33%). Despite these measures, students still found that cheating was possible with relative ease (42%). Furthermore, students' performance during assessments was disrupted both by logistical issues and by a misunderstanding how certain digital tools worked (42%). The most-mentioned advantage of online assessment was that this kind of assessment (be it oral exams, project presentations, thesis defences, etc.) is less stressful. This lack of stress had a positive impact on performance in the exam (67%).

3.3.2 Recommendations

With the COVID-19 outbreak, most of the universities (75%) changed their assessment method to one of three formats: written online exams, oral online exams and assignment-based examinations. These methods are less considered stressful and time-saving by students. Another clear advantage that came up with the adaptations is the learning outcome: Project-based assessments and open book exams are preferred compared to conventional final exams with respect to understanding the subjects throughout the course. On the other hand, adaptation in the assessment method also brought some problems. Assignment-based examinations caused students to be overworked with more assignments, which is why this format is considered less efficient by students. Logical issues and measures against cheating negatively impacted the students’ performance during exams, nevertheless measures against cheating were considered ineffective. The recommendations would be to use „open-book” evaluations, presentations-based ones or team-based evaluations using the analysis of experimental data sets.

4 Summary

The pandemic made universities and educators shift online, but only some have managed this transformation successfully. Some mirrored the same teaching and assessment methods from live to online environment, which affected students negatively. Mainly it channelled outwards through higher disengagement rates, increased stress, etc. However, there are cases of universities which transformed their methods by incorporating digital tools which positively affected interaction in the digital classroom. This change enabled effective usage of digital tools, online collaboration and knowledge transfer. Further research needs to be conducted to have a full understanding and overview of the digital education, from both students’ and educators’ perspective.

Lessons learned, can be summarised as following:

- Digitalisation is an opportunity to improve the learning process;
- Professors need to improve their digital competences and incorporate improved teaching methods which are adjusted to the online environment;
- If digitalisation is done properly, the learning can be more engaging and effective, and pandemic can be used as an accelerator of this change.

This paper invites professors and universities to start investing in structural changes regarding teaching, to unleash the potential of digitalisation.

ABSTRACT

Project-based learning and flipped classroom approaches are often used for developing team working skills in graduates. However, many engineering schools face efficiency and effectiveness challenges when it comes to facilitating students in these settings. For neuro-atypical (NAT) students, such as those with Attention Deficit Hyperactivity Disorder (ADHD) or Autism, support for developing teamworking skills can be limited. Even neuro-typical (NT) students find teamwork challenging and can benefit from an intervention that supports development of such skills. Self, Co and Shared regulation skills are considered important for effective team working. Regulation is a multi-staged process, which includes goal setting, planning, doing, monitoring and evaluating own and a team's work. Research on use of computer scripts to successfully orchestrate the multiple stages at a shared level shows only partial success. Many Computer Supported and Collaborative Learning studies cite over-scripting as a common criticism related to orchestration of shared regulation and team work. This work investigates "How computer orchestration scripts affect the triggering and internalisation of Self, Co and Social regulation skills in NT and NAT students when using a Computer Orchestrated Group Learning Environment (COGLE)?". COGLE was used with first year neurotypical and neuro-atypical engineering students to study its impact on triggering existing and/or internalising new regulation scripts in team working. Qualitative data from two literal replication cases were analysed. This work shows how different types of scripts in COGLE helped trigger, develop and internalise regulation skills and highlights areas where more work is needed.

1 INTRODUCTION

1.1 Increase in collaborative approaches within Engineering Education

Collaboration skills are considered important within most professions. In engineering, team working skills are one of many crucial skills for the success of any real-world open-ended project. Higher engineering education curricula, in the UK and elsewhere, have seen recent changes in response to the calls from industry and professional bodies to increase focus on problem solving and team working and the use of collaborative approaches to develop these graduate skills [1-3,8-9]. Learning in groups within engineering has been shown to have greater achievement, with a moderate effect size (d=0.25), than learning individually [4]. As a result, collaborative approaches such as Flipped Classroom (FC) and Project Based Learning (PjBL) have gained popularity over the years within Engineering Education [5-6]. In FC, students are expected to prepare the content themselves and take part within collaborative active learning activities in class [5, 7]. In PjBL, students work collaboratively in a group, on a defined real-world project and are expected to learn what is needed to deliver the project. The popularity of such approaches has meant that there has been a shift in the expected role of the academics from being a 'sage on the stage' disseminating information to a more supporting 'guide on the side' role [6]. There are, however, many challenges that come with this shift in expectations and practice.

1.2 Challenges collaborative approaches bring to Engineering Education

Without theoretical knowledge that underpins the change in their role and the skills needed by staff in facilitating groups, staff often face challenges when adopting PjBL or FC approach [6-7]. Not just staff, the students also find it hard to develop and use interpersonal skills if they have not had and do not have access to any formal team skills training [6-7]. Furthermore, PjBL is resource intensive and requires more staff to facilitate teams and to put in extra effort in guiding students. This is particularly important where students are from multicultural backgrounds [6]. As PjBL needs more resources from schools or departments, it can lead to a reduction in institutional support for such approaches over time [6]. This puts any benefits of the PjBL approach, where realisable, at risk. Likewise, students find it time consuming and hard to prepare on their own in the FC approach. Due to limited student preparation, staff find it tricky to carry out their planned collaborative activities in a way that is fair and benefits the entire class [10]. In practice, staff often find themselves performing both the roles of teacher and facilitator, especially when students complain about not being able to learn or work on their own on open-ended real-world problems without being taught first and a similar criticism is faced by flipped classroom approach [6,10].

1.3 Context and Rationale

More and more NAT are entering higher education as diagnosis rates are on the rise. NAT is an umbrella term that includes (ADHD and Autism Spectrum Disorder

(ASD) students. Researchers have claimed that NAT students are more likely to study engineering and technology courses [23]. As a result, it is very likely that most engineering cohorts will have a mix of NT and NAT students learning together. Formally diagnosed, or not, these students face socio-communication challenges that may affect them in realising their full potential [23]. Social interactions and communication are crucial for success within PjBL and FC activities, making it harder for NAT students to succeed. In addition, reasonable adjustments are needed by law and teaching NT and NAT students alongside each other can pose problems [24]. In practice, the demands of PjBL and FC can put most students under pressure, including NT, diagnosed NAT and those that remain undiagnosed [25]. Therefore, the challenges faced in social interactions and communication within group work can limit the success of FC and PjBL for NT as well as NAT students.

Both FC and Project based learning are used within the School of Energy and Electronic Engineering at the University of Portsmouth. Here, teams of students may need to collaboratively design, build and test say a communication system as part of a PjBL project or collaboratively discuss design challenges related to electronic subsystems within FC activities. Disability data from Higher Education Statistics Agency show 0.9% (male), 0.2% (female) & 3.6% (other) current UK domiciled students have ASD or other social communication disorder [24]. Research suggests females can be better at masking social behaviours common in NAT and are not being diagnosed as a result [23]-[24]. As NAT students are more likely to study engineering [23], supporting the already small % of female students entering engineering degrees becomes even more important. In the last three years alone there has been an increase in students with specific learning disabilities (including ADHD) and ASD to 15.7% and 1.2% respectively within the school. This increasing trend in NAT students joining our courses, combined with potential benefits to NT students from an intervention that can cater to both NT and NAT students learning together, provides the rationale for this study. COGLE may provide an approach to teaching that is inclusive for students with socio-communication challenges and enhancing their learning and team working experience.

2 METHODOLOGY

2.1 The intervention: Computer Orchestrated Group Learning Environment

COGLE was developed within the School of Energy and Electronic Engineering at the University of Portsmouth. It orchestrates small face-to-face groups of students watching together short videos followed by orchestrating them practice related questions till they all achieve group-wide mastery, i.e. they can all show that they understand the content by answering questions. During each session students are paired several times to carry out peer instruction with those who get the questions wrong. COGLE runs within a web browser with videos hosted anywhere on the web, for example YouTube®. The questions are carefully designed to encourage discussions between students. To achieve group-wide mastery all students in a team have to get 10 questions correct in a row. Anyone making a mistake resets the count to zero and the team must continue. COGLE plays a remedial video based on the most prevalent mistake in the group.

Working iteratively to build understanding, in a constructivist way, towards a shared goal of GWM is seen as crucial in triggering and achieving SRL, CoRL, and SSRL and team effectiveness. Triggering and internalising regulation, particularly SSRL skills, through orchestrating a simple goal of achieving GWM has not been studied before.

2.2 Underpinning pedagogical theories

Zimmerman's SRL theory and its extension into the social in the form of CoRL and more recently SSRL, explain how shared goals, planning, monitoring and reflection can make individuals become more effective in regulating collaboration at different levels [11]. The repeated orchestration through textual scripts in COGLE has the potential to aid the triggering, development and internalisation of regulation skills, as predicted by *Script Guidance Theory* [25]. This theory posits that a target behaviour, such as SSRL, can be modelled in individuals by scripting it repeatedly, causing internalisation of an appropriated version of the external script [25]-[26]. Scripts can orchestrate and model collaborative behaviour and are therefore used to *"Enhance the probability that knowledge generative interactions such as conflict resolution, explanation or mutual regulation occur during the collaboration process"* [21, p. 1]. Another theory that underpins the success of scripting regulation skills is the Self-Determination Theory of motivation [27]. It posits that learners become self-motivated in a learning environment that makes them: more self-confident by making them more competent; more part of a team by enhancing their relatedness to their teammates; but also, more autonomous as they take control of the tasks themselves and internalise or remember the triggered scripts. SSRL is seen as the highest level of regulation of collaboration [11].

2.3 Research site, participants and research design

Two Electronic Engineering modules, one at level 3 (first year of foundation degree) and one at level 4 (first year of undergraduate degree), were chosen where FC and PjBL activities were being used respectively. This formed the basis for students from level 3 to use COGLE to prepare for FC activity and level 4 students to prepare for PjBL task. The module co-ordinator confirmed observing similar challenges as noted above in both the modules. The two modules also benefit from covering the same basic material in the early parts of the course to ensure students are introduced to basics of electronics before moving on to advanced topics in level 4 module. In order to investigate the potential of COGLE in supporting NT and NAT students together within a real-world setting participants were invited from these two modules to join the study.

The study was approved by the University's research ethics committee and students from the two cohorts were invited, in particular those with ASD and ADHD, and give informed consent for taking part in this study. This was the only way we were allowed to recruit students as access to entire cohort was not permitted by the ethics committee. A total of 19 students joined the study, 9 from level 3 foundation course in Engineering and Technology and 10 from the BEng Electronic Engineering course. Three foundation students did not complete and left the study mid-way as one of their teammates, an international student, left without giving any explanation leaving a group of 2 who did not wish to continue. The remaining 6 level 3 students were put in teams of 3 each randomly and were put into the FC case-study. One level 3 student self-declared as autistic based on a diagnosis in their immediate family. Low diagnosis rates are a common issue and self-identification in this way can be helpful. The remaining 10 level 4 students joined the PjBL case-study and were put in random teams of 3 or 4 students. In level 4 one student was diagnosed with Autism (comorbid with ADHD) and one student had ADHD confirmed via consent by the disability support unit in the university. 16 students completed the two case studies.

Students on the FC case-study learned together for 4, two-hour sessions in their designated teams prior to attempting a two-hour FC collaborative design challenge in the same teams. Students on the PjBL case-study, did the same 4 two hour sessions and in addition 3 further two hour sessions (7 sessions in total) to master the content needed for the PjBL task in their designated teams. The FC task involved designing a bass and treble filter circuit to be used as input to a head-phone amplifier in a two-hour Student Orchestrated Working Together (SOWT) session. The PjBL task was more complex where the students were required to design both the filter circuits as well as the headphone amplifier within a two-hour SOWT session. The content used in the FC case-study was also used in the PjBL case-study in addition to more content on advanced topics as needed for the PjBL project. The two case-studies thus formed part of a literal replication multi-case study design used here [28]. The use of orchestrated group-wide mastery in two different case-studies should generate robust evidence advocating for using such an approach with NT and NAT students within Engineering Education settings to enhance their knowledge and internalise team working scripts used within COGLE.

2.4 Success and challenges in scripting regulation skills

Self-Regulated Learning (SRL) involves planning, monitoring and reflecting on your own actions to achieve individual goals against a set standard [11], [12]. Scripting of self and co-regulation of learning (CoRL), which involves regulating actions of some other teammates, has helped learners improve their group-awareness, socio-metacognitive and socio-emotional regulation skills [12]-[17]. For developing SRL and CoRL skills scripting information sharing, argumentation and negotiations has been effective, as defined in the collaborative framework by [18]. Very few studies, however, have investigated the transfer of these scripted skills into un-scripted environments. Transfer has been more successful where adaptable scripts are used [19] or where students practice the scripted interactions multiple times [16] and where there was support to help students in challenging situations [16]. SRL, CoRL and SSRL skills are considered as key to team effectiveness [11]. In most studies CoRL by others is shown to help develop SRL and self-efficacy [20]-[22]. Dependencies of later stages of regulation on earlier stages in SSRL and the diversity in learner knowledge and skills, makes it very hard for Socially Shared Regulation of Learning (SSRL) to be successful when each of these stages is scripted separately [13]-[14] and scripting SSRL may easily be perceived by learners as over-scripting [20]. Although some success in triggering, developing and internalising Self and Co regulation has been reported, successful scripting of SSRL in teams has been limited [13]-[14], [16]

2.5 Methodology for evaluation

COGLE plays a role is the development of team working skills of these students. After each session the students completed a Daily Events Survey (DES) with free text space to answer the following questions.

1. Describe what did and did not go well, when prompted by the system, to teach or explain to other student(s) a concept.
    a. Also, describe how the system made you or others in your team contributed to improving or worsening the situations you described as “did" or "did not go well” above respectively.
2. Describe what did and did not go well, when prompted by the system, to learn from other student(s), a concept.
    a. Also, describe how the system made you or others in your team contributed to improving or worsening the situations you described as “did" or "did not go well” above respectively.

In addition, qualitative data was collected through an hour-long interview for NT students and up to two hours for NAT students. The interviews were transcribed verbatim by a professional transcriber. This paper presents some key themes from the qualitative data from the DES that was analysed using grounded theory inspired thematic analysis [29]. A full analysis from all sources will be presented in a subsequent research article.

3 RESULTS

3.1 FC Case

The daily events survey was completed by all 6 students after each of the 4 sessions and the SOWT session. Then using grounded theory inspired thematic analysis, the themes shown in Table 1, emerged in the majority of the responses from a majority of the sessions.

Table 1. FC case: Themes from the DES

Theme/ Sub-theme	Description	Sample quotes
Orchestrates GWM and CoRL	GWM script paired teammates who taught each other.	"[Pairing] was a bit weird as explaining a topic [at first but it]… went well. [Pairing] allowed us to discuss the topic."
Teammates can takeover pairing.	GWM linked penalty caused positive frustration, that triggered overtaking COGLE's pairing.	"We all helped to explain and understand concepts [on our own] when it was required [to achieve GWM]."
Co/SSRL practiced and internalised	A simple goal of GWM made them switch between working under their shared scripts and COGLE scripts.	"I think [today] it was more of a team effort rather than the system that helped us progress this time."
Shared goal and working together	Aimed to finish the SOWT task by working together.	"We were very quickly able to come up with suitable numbers and circuits between us, …we did struggle… however we worked well as a team through the issue"
Team effectiveness and satisfaction	Felt teammates worked together	"We combined all our ideas together to get it all right."

Themes in Table 1, show that the repeated computer orchestration of pairing, although initially awkward, soon enabled the externalisation of knowledge between teammates in order to achieve the GWM goal. The pairing script at first triggered CoRL in teammates, and later the students took over the pairing themselves, showing early internalisation of CoRL. The GWM script triggered shared working, monitoring and reviewing as teammates wanted to complete mastery without having to do many more questions. There was no need to script these phases with separate scripts. Students were able to develop and internalise both CoRL and SSRL skills within just 4 sessions. The scripts were appropriated, internalised and also used in the SOWT sessions even when the COGLE scripting was removed thus showing transfer. The teams were able to complete the set task in the FC without any help from any staff effectively and efficiently. They were also satisfied with their solutions. The presence of a NAT student in a team of NT students did not cause any issues to either any NT or NAT student. Thus, showing the inclusiveness of COGLE.

3.2 PjBL case

Likewise, the daily events survey was completed by all 10 students after each of the 7 sessions and the SOWT. Then using grounded theory inspired thematic analysis, similar themes emerged in the majority of the responses from a majority of the sessions.

Themes in Table 2, show that the repeated computer orchestration of pairing, helped externalisation of knowledge needed to achieve the GWM goal. Here too, CoRL was triggered by script at first and later taken over by the students, showing early internalisation of CoRL. The GWM script triggered shared working, monitoring and reviewing as teammates wanted to complete mastery without having to do many more questions. There was no need to script these phases with separate scripts. Students were able to develop and internalise both CoRL and SSRL skills within just 4 sessions. The scripts were appropriated as they were internalised and were used in the SOWT sessions even when the COGLE scripting was removed thus showing transfer. The teams were able to complete the set task in the PjBL without any help from any staff effectively and efficiently. They were also satisfied with their solutions. The presence of a NAT student in a team of NT students did not cause any issues to either any NT or NAT student. Thus, showing the inclusiveness of COGLE.

Table 2. PjBL case: Themes from DES

Theme/ Sub-theme	Description	Sample quotes
Orchestrates GWM and CoRL	GWM script paired teammates who taught each other.	“The system prompted [collaboration] at correct times which made the session go well.”
Teammates can takeover pairing.	GWM linked penalty caused positive frustration, that triggered overtaking COGLE’s pairing.	“Sometimes it was difficult for other students to explain a topic [when picked by the system] but we would work together to help explain that topic”
Co/SSRL practiced and internalized	As simple goal of GWM made them switch between working under their shared scripts and COGLE scripts.	“If the [chosen] explainer wasn't explaining well, then the other person would chip into try and help, usually it worked.”
Shared goal and working together	Aimed to finish the SOWT task by working together.	“We managed to get a lot done… we worked efficiently and as team. Choosing resistor values cause a bit of a debate but we overcame this by agreeing to one value”
Team effectiveness and satisfaction	Felt teammates worked together	“We produced a reasonable design, and was mostly happy with the outcome”.

4 Discussion and implications for engineering educators

The two cases provide repeating results adding strength to the claim that COGLE’s simple GWM goal alongside flexibility in the pairing script is able to support a mix of NT and NAT students where both shared and practiced regulation and team working skills before demonstrating effective teamworking when orchestration was removed altogether. The flexibility to rely on scripts during learning sessions as and when needed or to takeover regulation themselves, helped students practice and gain confidence in regulation skills. It also allowed those with existing skills or those becoming more confident to takeover regulation from COGLE and practice it themselves. By externalising their scripts, students shared their skills with the others in the team. The frustration due to the penalty in the GWM script, whereby the count leading up to the target of answering 10 consecutive questions was reset if even one of the teammates made a mistake, helped trigger this takeover and the shared monitoring, working and reviewing took place between teammates. It also meant that when a shared approach was successful, students would use it in future too. COGLE encouraged being supportive of each other but also supported learners when needed. Regulation changed hands between COGLE and teammates and back until the teammates were ready themselves.

Due to changes in teaching approaches during the pandemic, many staff now use chunks of video and quizzes as normal teaching material. Although orchestrating the use of these videos and quizzes still present a challenge. As higher education settles into its new normal post pandemic, orchestration systems such as COGLE offer new ways in managing classroom interactions and activities, in addition to promoting the triggering, development and internalisation of regulation skills crucial to team working.

5 SUMMARY AND ACKNOWLEDGEMENTS

This work presented the evaluation of Self, Co and Shared regulation and team working skills in collaborative settings such as FC and PjBL after using a novel group learning environment, COGLE. It shows how both NT and NAT students were motivated to come together as a team within a computer orchestrated environment which used a GWM script to prepare them for collaborative activities in a SOWT session later on. They completed the FC and PjBL SOWT activity that followed successfully without being orchestrated by any computer scripts, indicating successful transfer of Self, Co and Shared regulation skills. Furthermore, COGLE was able to support NAT students in overcoming socio-communication challenges in an inclusive manner whilst learning alongside NT students. The use of COGLE frees staff from having to teach instead of focussing on guiding students during PjBL and FC activities, making it more efficient and effective. The post pandemic classroom needs more innovative solutions like COGLE to successfully transform engineering education from being more lecture based to more interactive, skills focussed and student centric. COGLE prepares students before they set foot on collaborative tasks that require both, team working skills and mastery of technical knowledge, the two most important pillars in engineering education. The two cases show the transferability of the intervention design for mixed groups of NT and NAT students in terms of triggering, developing and internalising regulation skill and effective team working skills.

This work benefited from the dean's fund for supporting research within the school. The authors are grateful for the continued support for this project as we investigate further collaborative learning within engineering education with bigger cohort size in order to help with the transferability of the results further.

ABSTRACT

Early career experiences provide the foundation for career progression and inform career choices and decisions. For women in the engineering profession, positive early career experiences have been linked to persistence and retention within the profession A recent focus on early careers within engineering has provided insight into early career role types and related competencies, competency and capability gaps experienced by novice engineers, and their perceptions of meaningful engineering work. There is opportunity to diversify and contextualise this understanding by exploring early career experiences of women working within the engineering profession, and by considering the influence of gender on early career experiences and decisions.

This paper reports on an empirical investigation of the career experiences of 22 women engineers in senior roles within engineering organisations in the Australian context. Phenomenological and temporal analysis of their career reflections provides evidence of three early career patterns of varied sequence and focus. The influences shaping these career paths are described. By making explicit possible, diverse early career paths, determinants and outcomes, this paper aims to continue to bridge the engineering education-practice gap and to contribute to greater equality, diversity, and inclusion within the profession.

1 EARLY CAREERS IN ENGINEERING

1.1 Early Engineering Careers

Engineering careers are diverse, with divergence observed from early career [1]. The understanding of early career experiences, as an aspect of engineering practice, is important as they provide the foundation for career progression and inform career choices and decisions.

Early careers within engineering have been conceptualised according to role type and focus, for example: technical, managerial, entrepreneurial, project-based [2]. An alternative approach by [3] provides a nuanced insight into the types of roles occupied by junior engineers by considering role expectations, rather than role type. Examination of engineers' pathways to senior roles provides information about the early career paths and mobility patterns. [4] found that the length of time spent in by engineers in early roles and the mechanisms by which they moved beyond these into more senior roles varied, according to the type of senior role.

The competencies and capabilities required to perform the early engineering roles have been identified. While there are generic graduate competencies [5], early career competency priorities vary according to the type/expectation of the role and the context of the role (i.e.: organisation, industry, country) [3]. Capability 'gaps' experienced by young engineers, encompass personal attributes, relational capabilities, cognitive abilities such as lateral thinking and problem solving, and industry-specific knowledge [6].

Exploring engineers' lived experiences has revealed motivations, values and meaning for early career engineers. [7, 8] highlight the importance of agency, relational and structural factors on the quality of early career experiences.

1.2 The Current Study

While it is recognised that women in the engineering profession experience reduced rates of participation and progress than their male colleagues [9], the 'early careers in engineering' research has not considered the career patterns and experiences of female engineers. To this end, this paper explores the early career experiences of senior women engineers in Australia. The aims of this paper are to identify and describe i) their early career patterns and ii) the key factors that have shaped their early career patterns and experiences.

The paper contributes to a more expansive, inclusive, and nuanced understanding of early careers in the engineering profession. By making explicit possible, diverse early career paths and determinants, this paper aims to continue to bridge the engineering education-practice gap and to contribute to greater equality, diversity, and inclusion within the profession.

2 METHODOLOGY

2.1 Theoretical Framework

This paper draws on a broader study informed by phenomenological and feminist perspectives to investigate women engineers' experiences of transition to positions of influence within technical organisations. The phenomenological perspective focused the research on the phenomenon of movement into management and leadership roles, and placed to accounts and experiences of the participants at the centre of the research [10]. The feminist perspective acknowledged gender as a basic organising principle, and that choices made and experiences relayed by participants were shaped by gendered social systems and organisations [11]. It also acknowledged the absence of women's perspectives from the current understanding of engineering careers.

2.2 Data Collection

Semi structured in depth interviews were conducted with 22 degree-qualified engineers who self-identified as female, and as working in a managerial or leadership role in a technical organisation within Australia for a minimum of 12 months. Participant recruitment used criterion and snowball sampling, drawing on the membership of Engineers Australia (the national peak professional representative body), and the authors' professional networks.

The focus on technical organisations excluded engineers who had left the profession or were pursuing alterative careers in non-engineering centric industries or organisations. An objective of the broader study was to understand the conceptions of management and leadership form the points of view of the participants. As such, a managerial or leadership role was not pre-defined.

Participants were employed in a range of industries and organisation types, including technical service companies, consultancies, government organisations and owner companies, across resource, infrastructure, construction, transport, and defence industries. The types of managerial and leadership roles that the participants held were predominantly in middle management. Managerial or leadership experience ranged from 12 months to over 20 years.

Interviews focused on engineers' experience of becoming manager and leaders in the engineering profession. Interviews lasted between 45 to 80 minutes.

2.3 Data Analysis

The Broader Study

Interview transcripts were analysed using phenomenological and temporal approaches, informed by Van Manen and Moustakas [10, 12]. Phenomenological analysis yielded ten key themes that were condensed into three categories, representing the influences shaping the women's transition to management and leadership roles:

- Individual: relating to participants' characteristics, motivations, agency, and identity.

- Relational: relating to the influence of other people on women's career advancement, including relational capitals such as reputation, credibility, and visibility.
- Structural: relating to the influence of 'structures' including the organisation, the engineering profession, and broader society.

Consideration of the move to management and leadership roles as an experience unfolding over time generated a series of transition phases: 'Getting Started', Making a Move', 'Encountering Change and Challenge', 'Negotiating the Environment' and 'Resolving and Reconceptualising'. A detailed discussion of identified themes and categories is presented elsewhere [13].

The Current Paper

While not a primary focus of the broader study, the detail provided in interviews by participants about their early careers was surprising and indicated the importance of this career stage. Women engineers' transition to manager and leader was revealed as a process commencing in and influenced by early career experiences.

For this paper, we revisited the participants' career narratives to focus on the early career stage. To address the first aim of the paper, a chronological sequence of roles preceding and following the first management or leadership role established for each participant. Role sequences were then categorised according to the types of roles characterising early career and the timing of the first manager/leader role. To address the second aim of the paper, interpretation of the phenomenological themes and categories focused on sections of transcript relating to early career.

In engineering practice research, early career is considered as the period following graduation from an engineering qualification at university and entry to the engineering profession as a graduate or novice engineer, to the point in time when a professional engineer can work unsupervised [14]. This may be marked by a professional or organisational norm such as chartership or reaching of a certain level within the organisation. For our study, we focused on the first 7 years of participants' careers. This is a critical career point for women engineers, after which their attrition from the profession is thought to peak.

3 RESULTS AND DISCUSSION

3.1 Early Career Patterns

Three early career patterns emerged from the data. They are presented in Table 2, with indicative early career role focus and timing of the move to first managerial role (as average years of engineering experience).

Table 2. Early Career Patterns of Women Engineers

Pattern **(Number of participants)**	**Early Career Role Focus**	**First M/L Role Timing (average years)**

Early Responsibility (6)	Technical, then quickly into a management/leadership role	2 years
Solid Technical (15)	Technical	11 years
Broadening (1)	Technical plus other functional roles	9 years

Most participants described a 'Solid Technical' early career pattern, characterised by technically focused engineering roles with increasing seniority and autonomy. This is akin to the 'technical' track commonly documented in engineering careers literature. The dominance of this career path is not surprising, given the technical basis of the engineering profession. [4] describe these early career engineers as highly driven problem solvers motivated by complex technical challenges. They make career choices to align with these preferences and are likely to occupy Technical Specialist roles later in their careers. This was partly supported by our findings. Some women with this early career path did display a strong technical orientation, however others used this as a mechanism for navigating motherhood during early career, going on to occupy broader roles in later career rather than remain as technical specialists.

A smaller group had 'Early Responsibility' moving into management/leadership roles quickly. This included women in the military, where technical and managerial responsibilities are combined from the start of career. Early career engineers following an Early Responsibility pathway moved quickly out of technically focused engineering roles into project management; broader roles with a technical aspect, but not a technical focus; or, per women in the military, integrated technical-management roles. Rottman and colleagues [4] describe these early career engineers as becoming *Company Men,* likely to be tapped for progression and eventually groomed for organisational leadership roles. In contrast, the early move to management/leadership roles seen in our study was primarily due to organisational design rather than relational factors or driven by the individual.

Only one participant's early career was categorised as 'Broadening', with movement through technical engineering roles, commercial and other functional roles within the same organisation.

Early roles had a bearing on the path or opportunities available later in career:

> *You can't be the head if you haven't got the grounding. It depends on which role you take as to what your opportunity may or may not be. (M9)*

A common thread linking the three career shapes was movement and mobility between sections of an organisation, from one organisation to another, from site to office-based roles, or between geographic locations. A particular mobility pattern was observed: most of the engineers with an 'early responsibility profile' oscillated between managerial and technical roles in their early career and did not follow a consistent and linear path of increasing managerial responsibility. For some, this was related to parental leave, but more often this was associated with international relocation. This oscillation pattern was also observed in the later careers of some participants. These patterns are consistent with non-linear patterns observed in women's careers beyond the engineering profession [15], but are not reflected in current early engineering career models.

3.2 Early Career Influences

3.2.1 Individual

Participants' early career was influenced by their **individual characteristics, abilities, and preferences**. Personal qualities such as confidence, ambition, curiosity, a desire for autonomy and willingness to lead were apparent. Many expressed a clear preference for certain types of work and were aware of these preferences from early career. Self-awareness of these qualities and the ability to choose roles that enable them to exercise their preferences was noted:

> *I didn't ever see myself as purely technical, no. I always thought that my skills were broader, and I could bring more to the profession than just technical skill. And I was interested in more than that. (M4)*

During early career, participants built their **human capital**. It was important to be a 'good engineer' in early career. Early career roles enabled the accumulation of technical and practical knowledge, described as "technical grounding", and demonstration of technical competence. This generated confidence which impacted their readiness to pursue senior roles and perceived ability to perform them in later career. Technical grounding was considered an essential foundation for becoming a manager or leader in engineering related industries:

> *You have to understand what it is that you are managing if you want to be a manager, so you need a good technical grounding and a breadth of experience in the field, I think. (P3)*

In addition to technical grounding, participants gained exposure to managerial work in early career. Roles in which they were second in charge (2IC), instances in which they themselves were "doing the job anyway", informal opportunities, or exposure through small projects enabled sampling of management work and building of experience and skill for official or larger managerial roles.

3.2.2 Relational

Participants described the relationship with the direct supervisor in early career as influential. **Relationships with superiors** facilitated or hindered access to subsequent roles. Good relationships with their superiors enabled participants to demonstrate their abilities rather than being held back. Poor relationships or conflict served to limit their career prospects.

Superiors were described as role models, providing a vision of a 'possible self'. Others saw them as mentors and guides who helped them to navigate early career and provided advice on career decisions or moves. One participant recanted advice received from her direct supervisor:

He said to me after five years 'get yourself a new job because you are not getting anywhere in this company, get out, you are not made for this job, you will never get anywhere, the company is too conservative'. (M17)

Beyond early career, supervisors and other colleagues became **mentors, sponsors, and advocates**. Positive shared work experiences provided a connection and established trust used in later career.

Relational aspects of **credibility** and **visibility** created opportunity for advancement and allowed the women to build relationships with others within their organisations, which became influential in later career.

In early career, credibility was linked to accumulation of practical experience and demonstration of technical competence. Practical experience and the willingness to engage with hands-on work was especially important in establishing credibility with peers and those working in trade-based occupations:

I'd done work experience with Company A where I'd literally just driven trucks and shovelled dirt and that sort of thing. And whilst that didn't teach me a huge amount about individual sections of the work I managed, it gave you the ability to talk to the people that were doing that sort of work. (M2)

Linked to credibility and reputation, **visibility**, or being known or noticed by others within the organisation in early career was consequential in later career. In early career, visibility was established by working on high profile projects or taking on roles that gave exposure to people across the organisation. For some women, early career roles enabled the showcasing of both 'engineering' and 'non-engineering' skills:

I was involved on the bid team for the [large contract name] which was a really interesting experience. I think that might have been where others around me notice that I might have skills other than just engineering. (M3)

Gender, or being one of a small number of women, also provided heightened visibility. One woman was guided to use this point of difference to her benefit:

My supervisor always said 'Well, they'll remember you because you are a girl and there's very few other girls', he used to say it was a great thing to be remembered. (M16)

Descriptions of paternalistic relationships with a 'father / grandfather – daughter' dynamic were common and were perceived to facilitate career progression, consistent with [16]. Interestingly, this relationship dynamic was perceived as limiting in later career by some.

I won't say that I milked it, but I was grateful for it and therefore built relationships with men in that way. Sort of purged them for information that they had, that sort of thing. (M2)

Relational factors have been related to experiences of positive and meaningful work for novice engineers [7, 8]. Collaborating with others, feeling valued as part of a team, and receiving feedback and validation are important during early career. Our findings provide further detail of key relationships and relational mechanisms present in early career and highlight the gendered nature of these interactions for female engineers.

3.2.3 Structural

Organisational norms acted to facilitate and constrain the participants' early careers. Younger participants, or those that worked in government or defence organisations, accessed structured graduate programs. Other organisations did not have formal programs, but the organisational norms determined typical career and promotion pathways:

> *Yeah, it was very early. Company A were good like that. Company A were very much a sink or swim company… as a result they put you in these positions very quickly. (M2)*

Such structures enabled the building of human capital by providing developmental or significant experiences (such as site, field-based roles, or deployments) or formal professional development opportunities by design.

Prescribed pathways and **highly structured, visible, and explicit hierarchies** provided career path frameworks. Available career pathways, described as 'typical', 'well-worn, 'generalist' or 'technical' paths were also made visible by the choices and opportunities taken by others, revealing organisational values and shaping participants' impressions of career possibilities. While career pathways are highly visible and organised in many organisations, the process of accessing that path can be opaque and mysterious:

> *It was all a bit like secret men's business… there was no transparency whatsoever as how you go from A to B. (M8)*

Others felt constrained by their organisation. **Rigid recruitment criteria** – *"because of the structure of local government you have to fill the boxes"* (P2) - meant that promotions were applied for but not achieved. **Organisational attitudes** restricted women from accessing developmental experiences:

> *Most of the company's work was remote mine site construction and there was an element within the company that thought that women weren't suitable for that. Quite happy to have the site secretary and the site nurse being women, but not the engineers. (P3)*

Provision of clear and documented progression pathways have been recommended by multiple sources. Organisational culture has been posited as the key influence on women engineers' workplace experiences [9].

3.2.4 Gender

Gender was acknowledged by most women as a point of difference, however its impact in early career was contested. Some participants felt that being a woman was disadvantageous. Early career was perceived as a "hard road", or a "steeper curve" compared to their male colleagues. Others perceived their gender as having little or no impact. Regardless of position, the data revealed a focus on competence and merit as the determinants of career progression. The reaction to tempered opportunity or differential treatment was to prove competence and capability by working harder. One woman spoke of “working very tirelessly” (M8) in early roles. Another woman working in construction emphasised the importance of merit with regards to the availability of work roles through her career.

> *It wasn’t “You were given the role because you are female” I think you were given the role because of the experience that I had in the type of work that I did and the roles that I had previously. (M13)*

For women engineers, interactions and relationships in the workplace are coloured by gendered roles and stereotypes, and by heightened visibility from the beginnings of their careers. Our study highlights the gendered nature of some of these relationships and relational aspects, in particular paternalistic relationships, visibility, and credibility and competence. A strong focus on competence and credibility is a way of ‘doing gender’ in early career - that is, it is a tool for managing the male-dominated profession of engineering and masculine workplaces.

4 SUMMARY AND ACKNOWLEDGEMENTS

4.1 Implications, Limitations and Future Directions

Graduate engineers often have loosely held expectations of what their roles will entail, and the career paths available to them [17]. A misalignment between expectations and reality can lead to issues with performance and satisfaction. The possible, diverse early career patterns, the experiences (positive and negative) and drivers of early career presented in this paper contribute to a more accurate understanding of engineering practice. This serves to bridge the education-practice gap, by emphasising a variety roles and career paths available to junior engineers. This may be helpful for engineering educators who wish to better prepare their female students for engineering workplace by providing a realistic view of early engineering careers and provide focal points for skill development and provision of support. These findings are also relevant for organisations who wish to better support their women engineers.

A limitation of this study is that early careers of women engineers was not the primary focus of the broader study. Instead, the importance of this career phase emerged during the analysis of the study. In addition, several of the participants were very experienced engineers, and as such their ‘early career’ was some time ago. The nature of their early careers may be different to those of the present day. These limitations indicate an opportunity for a purposefully designed study of the early careers of women in engineering in the current societal context.

4.2 Acknowledgements

We gratefully acknowledge the professional engineers who participated in this study. We also thank the members of Engineers Australia Women in Engineering committees and the professional engineers who assisted in inviting participants.

ABSTRACT

In University environment, it is common to use multiple-choice objective tests with three or four possible answers, of which only one is correct and the rest are erroneous. In this type of tests, usually the wrong answers are penalized in order to avoid the effect of the random answers. However, there are questions that hardly students answer since their difficulty is high. On the other hand, there are also questions that answer virtually all students since their difficulty is simple. While sometimes the course professor chooses to suppress these questions, it is also common to leave them as part of the calculation of the overall score. This communication proposes a way of, without suppressing any question, making a readjustment of the grades based on fuzzy logic techniques. To do this, it is considered, on the one hand, the initial grade obtained by each student and, on the other, the total difficulty index of the test. With these two variables, an approximation can be made to a system of linguistic variables that allows correcting the final grades of each student based on the objective difficulty of the test and a set of rules established by the professor. This will revert to greater "justice" in students' mark system, since it will be a function of the difficulty of the test.

1 INTRODUCTION

1.1 Assessment system

Student assessment is the process that allows knowing what is the level achieved by these students in certain formative objectives. A fair and transparent evaluation assessment system is the one that guarantees that the student body receives a grade that does not limit their future opportunities. Notice that to approve or fair unfairly is vital and the qualification must be, first of all, fair for each student, and as close as possible to the reality of the knowledge achieved for him/her, since each person is unique and, therefore, the assessment should take into account this diversity.

In order to assess the students' performance, in terms of knowledge acquired, one of the most widely used tests is the multiple choice questionnaire (MCQ), consisting of a question and three or four possible answers. Only one of them is valid and the others, called distractors, are false. These formats are known, in a short form, as MCQ-3 and MCQ-4, respectively.

Research of [1], [2] and [3] suggest the model with three answers (MCQ-3) since it saves response time to the student and does not oblige the professor, especially junior, to use improbable and/or defective distractors. On the other hand, the four-answer model is more suitable if there is a reasonable time available for the test or if the professor is already a senior.

On the other hand, since Zadeh [4] established the principles of fuzzy logic, this has been used to solve problems in very different fields, calling attention also in the academic field as it helps to obtain fairer grades in students and with greater transparency. For instance, in a course/subject rated over 100 points, in which at least 50 points are needed to pass it, the case of a student with a grade of 49 would be considered as a "questionable" mark since it could be considered approved or not, taking into account factors such as the time taken to answer the test, its difficulty, the importance of each question, the complexity in determining the correct answer, etc. Therefore, these factors should be considered in some way when course professor defined the mark obtained by his/her student. In addition, the teacher may have different types of students in his classroom with different learning rhythms or particular educational needs, which means that not all of them, perhaps, should be evaluated in the same way, since the classroom is a very diverse human space. With fuzzy adjusts it's possible be a more accurate assessment. With diffuse adjustments, it is possible that the evaluation is more precise and even fairer by being able to attend to particular cases.

1.2 Literature Review Concerning Recalculation of Students' Assessment Using Fuzzy Logic

Following [5], fuzzy logic is a generalization of crisp set theory and traditional dual-valued logic. In fact, in fuzzy set theory the range of the membership function characterizing a set is extended from *only two values*, 0 or 1, to *any* value between 0 and 1.

Most of publications related to student assessment with fuzzy logic techniques refer to seminal articles of Zadeh and Biswas [6]. The article by Chen and Lee [7], also related to students' assessment through fuzzy logic, is also cited profusely in the literature. Since then, fuzzy logic has been used in very different academic fields, being a current of interest the adjustment of the grades obtained by students taking different adjustment parameters and mixing fuzzy logic with other techniques traditionally associated with artificial intelligence (AI) as the case of data mining. One interesting example is in [8], [9] and [10].

They are in the literature many different approachs using fuzzy logic, as can see in [11] and [12], and also in [13] to [18]; in many approaches with multiple input variables, it seems reasonable to use a fuzzy inference model by successive steps, since it allows establishing the rule bases by pairs of variables, giving rise to small and simple base rules simply deductible by the experience.

Studies carried out related to the different fuzzy inference techniques should also be pointed out, and defuzzification methods like those of related in [19], [20] and [21]. In addition, many authors use Matlab® to implement their contributions.

Regarding the geometry of the fuzzy sets used, almost all the publications consulted refer to triangular or trapezoidal sets due to the simplicity of calculation since the differences that would be obtained with other joint geometries (sigmoidal –used by [12]–; Gaussian –used by Hameed and Sorensen [17]–, hyperbolic tangents, etc.) are not relevant to the outcome. Also, the use of other geometries that are not trapezoidal or rectangular are used only when the use of Matlab® software is available.

We propose in the following section a very simple method of calculation using the inference of Mamdani [22], and taking into consideration only the difficulty of the test and the qualification obtained. Some authors such [19] have used the difficulty of a certain competence based on students' marks who studied the subject before and with a difficulty level specified by the professor. In any case, the use of the difficulty index of an objective test has not been located in the bibliography consulted by authors.

2 METHODOLOGY

In an MCQ, the calculation of the difficulty index (*DI*) of each of the questions is the one expressed in (1):

$$DI = \frac{\#Correct\ answers}{\#Questions} \tag{1}$$

It is considered a classic classification of the difficulty scale, taken from [23], which is the one that can be seen in Table 1. The scale and difficulty may vary, but authors consider that that listed in Table 1 is very convenient for academic purposes.

The overall difficulty index of an entire test, DI_{TOTAL}, may be established by taking the average of all difficulty indexes for all questions, according to (2). Therefore, it is simple, by means of a simple table with a spreadsheet that contains in the rows to the students and in the columns the questions, to have in each cell the qualification obtained by each student in each question. Applying (1) to each column, you can determine the parameter DI and identify the difficulty of each question. In addition, applying (2) the difficulty of the test, as a whole, can be obtained.

Table 1. Classic interpretation of the difficulty index (DI).

Value	***Interpretation***	***Suggested Action for the question***
DI > 0.75	Very Easy	Dismiss definitively
0.56 < DI < =0.75	Easy	Candidate to be discarded
0.46 < DI < =0.55	Regular	Review
0.26 < DI < =0.45	Difficult	Candidate to be discarded
DI <= 0.25	Very Difficult	Dismiss definitively

For MCQ-3, the optimal total difficulty would be 0.67 [24]. However, it is considered average difficulty, in general, between 0.50 and 0.60 [25]. If possible, experts suggest that items should have indices of difficulty no less than 0.20 and no greater than 0.80. It is desirable to have most items in the 0.30 to 0.50 range of difficulty. Very difficult and very easy items contribute little to the discriminating power of a test [26].

$$DI_{TOTAL} = \frac{\text{Mean of Difficulty Indexes}}{\text{Number of Indexes}} \tag{2}$$

When differentiating one category of difficulty from the next using crisp values, it is difficult to consider that a question with DI = 0.55 is “regular” and that one with DI = 0.56 is “easy” so that it seems natural to consider this variable as a fuzzy set taking as many subsets as difficulty categories. Likewise, when considering the DI_{TOTAL}, the overall difficulty of the test can be established diffusely, considering that a test with DI_{TOTAL} = 0.55 is “regular” and one with DI_{TOTAL} = 0.56 is “easy”. For this reason, and taking as reference the crisp values of this indicator, a categorization based in fuzzy subsets is established such as the proposed in Figure 1. In this article, we use triangular membership functions because this shape has been proven popular in fuzzy logic and being used extensively in student academic performance assessment [26].

In Figure 1 it can be observed, respecting the spirit of the differentiation of difficulty index, that values below 0.25 and above 0.75 as well as those between 0.45 and 0.55, will only belong to one fuzzy subset, while that the rest of values will belong to two fuzzy subsets.

Taking as reference the crisp values of this indicator, a categorization based in fuzzy subsets is established such as the proposed in Figure 1. We use triangular membership functions [27], but other shapes are possible (that not has a significative difference respect to results).

Let us take as an example, a test with 5 questions in format type MCQ-3 (three answers per question, an answer right and two answers acting as distractors), in which five students participated. In order to discard the random factor and, in some way, discourage the student to try his luck in case he does not clearly know the answer. The amount of penalty would be established, in this case, by the expression (3) taken from [28] which, in turn, [29] cites and also is studied by [30] and [31]. The unanswered questions will have zero value and the wrong answers, will have the corresponding penalty according to their weight.

$$Penalty = \frac{1}{\#Possible\ answers - 1} = \frac{1}{3-1} = 0{,}5 \quad (3)$$

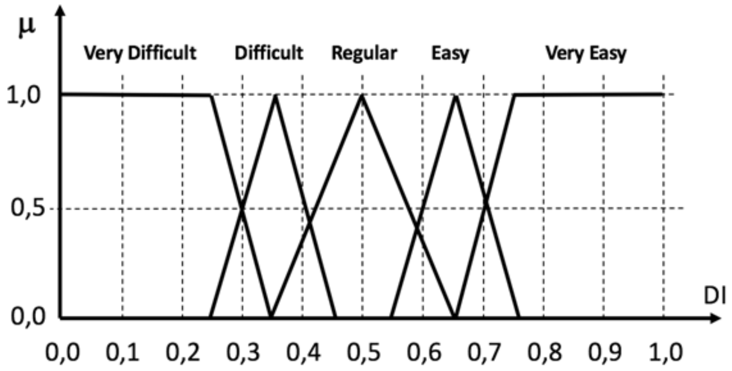

Figure 1. Fuzzy sets for difficulty index total, DI_{TOTAL}.

This means that, in case all the questions are MCQ-3 type, the penalty will be half the value of the right answered. If the number of possible answers is different in some questions, the local penalty for each different question would apply. Table 2 shows a hypothetical result of the presented example.

Table 2. Difficulty Index per question and global grade per student.

Question →	**1**	**2**	**3**	**4**	**5**	
Weight (%) →	**15**	**20**	**15**	**30**	**20**	
Student ↓						**Grade over 100 points ↓**
1 →	-7.5	0	15	30	20	**57.5**
2 →	-7.5	20	0	0	0	**12.5**
3 →	-7.5	20	0	30	-10	**32.5**
4 →	0	0	15	0	20	**35**
5 →	15	0	-7.5	0	20	**27.5**
DI →	*0.2*	*0.4*	*0.4*	*0.4*	*0.6*	

In example shown in Table 2, DI_{TOTAL} = 0.4. Thus, we can calculate the fuzzy difficulty index (FDI_{TOTAL}) with fuzzy sets shown in Figure 1. We want to highlight the use of Excel® for all calculations in this paper. After fuzzification, Table 3 shows the values of membership subsets.

Table 3. Fuzzy total difficulty index (FDITOTAL) of the questionnaire.

Fuzzy sets	Very Poor	Poor	Regular	Difficult	Very Difficult
FDI_{TOTAL}	0	0.5	0.5	0	0

In order to place the student grade in one of, for example, five categories, it is important to place his initial grade in a fuzzy environment like shown in Figure 2.

Some authors cited in [21] make a different proposal for the distribution of these subsets in order to categorize students' grades placing any grade between 0-0.2 points only in the category of 'poor' and between 0.85 and 1.0 only in the 'good' category. However, most of authors establish the limit of 'poor' between 0 and 0.1 and 'good' between 0.9 and 1.0. Continuing with the previous example, for calculate the membership to each fuzzy set, we need to obtain the equations of every subset segment, for example, for interval 0.1-0.3 (*Below Average*), the equation used is y=5x+1,5. Fuzzy grades for each student of the example are shown in table 4.

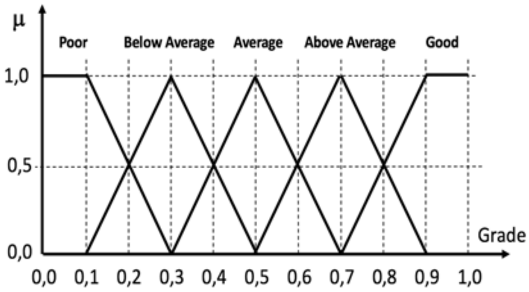

Figure 2. Fuzzy sets for grades.

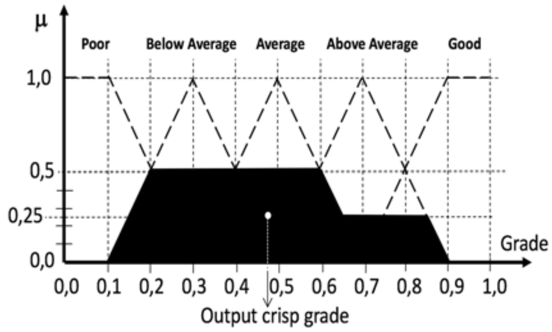

Figure 3. Output fuzzy subsets for student #4.

Table 4. Fuzzy membership grades for every student.

Student	***1***	***2***	***3***	***4***	***5***
Crisp Grade Normalized to 1	0.575	0.125	0.325	0.35	0.275
Poor	0	0.875	0	0	0.125
Below Average	0	0.125	0.875	0.75	0.875
Average	0.625	0	0.125	0.25	0
Above Average	0.375	0	0	0	0
Good	0	0	0	0	0

With this information, it is possible to make the rule base in terms of '*IF-THEN*' sentences. Consulted literature refers to different techniques for establish the rules; in this example (see Table 5), each category of output is present in five cells (it is possible to make small changes to this rule base for special cases).

Table 5. Rule base for fuzzy grades and difficulty index.

		Difficulty Index				
		Very Poor	***Poor***	***Regular***	***Difficult***	***Very Difficult***
Grades	**Poor**	Poor	Poor	B. Average	B. Average	Average
	Below Average	Poor	Poor	B. Average	Average	A. Average
	Average	Poor	B. Average	Average	A. Average	Good
	Above Average	B. Average	Average	A. Average	Good	Good
	Good	Average	A. Average	A. Average	Good	Good

Considering Mamdani inference, results of the example is listed in Table 6.

Table 6. Result of applying the base rules to each student.

	Student	***#1***	***#2***	***#3***	***#4***	***#5***
	Crisp Grade	*0.575*	*0.125*	*0.325*	*0.35*	*0.275*
Resulting fuzzy grades	Poor	0	0	0	0	0
	Below Average	0	0.5	0.5	0.5	0.5
	Average	0.5	0.125	0.5	0.5	0.5
	Above Average	0.5	0	0.125	0.25	0
	Good	0.375	0	0	0	0

If we take, for example, the student number #4, his score would be the result of calculating the center of the area resulting from the fuzzy subsets trimmed to each output value, as we can see in Figure 3.

Finally, it is necessary to return these assessment values to crisp quantities by means of one of the different defuzzification techniques that allow obtaining a unique numerical value that represents them properly in [32]. The technique of singletons [33] is the more easy and concrete way for accurate calculation. Applying singletons, the scores that the calculation would return values showed in Table 7.

Table 7. Results of defuzzified grades vs. initial obtained grades.

Student	***1***	***2***	***3***	***4***	***5***
Initial Grade Normalized to 1	0.575	0.125	0.325	0.35	0.275
Deffuzified Grade Normalized to 1	0.712	0.353	0.455	0.473	0.413

3 DISCUSSION

Some authors such as [21] rightly point out that the choice of defuzzification method depends on each context or on each specific problem, reaching the possibility of using different techniques depending on the fuzzy output subsets for each student, depending on what categories include and not use the same technique for students with grades that are *poor*, *below average*, *average*, since the same technique for all grading intervals can harm some students. This is completely true since a student with an initial score of 100 in a very easy test, could lose a grade and that would not be fair because he has guessed all the answers and should not be penalized, while a student with a poor grade in a high difficulty test, possibly know more than what the test has allowed him to manifest.

Likewise, other authors also indicate that not only is there no universal defuzzification operator but that their choice depends on factors such as the speed at which this operation should be done. For example, in the case of industrial controls in real time where computational efficiency is a very important factor or in the case of information support systems where the calculation time is not as important, as is the case of adjusting student grades. The method of extended intervals in order to defuzzify outputs is correct for the qualification in students, but considering that it will be necessary to take some correction elements to differentiate the cases in which the student may be affected by the calculation.

On the other hand, any fuzzy calculus technique is very variable since it depends on:

1) The number and geometry of linguistic subsets of each variable.
2) The number of input variables, since more variables can be used in addition to the rating and the DI_{Total}, as seen in the literature review.
3) Geometry and position of input and output fuzzy subsets.
4) Rules contained in the rules base. As it is said in [34], the rules have to be determined by expert experience and it is difficult to make a determination of a

system designed according to the fuzzy logic; that is, it cannot be estimated how the system reacts beforehand.

5) The way to make the inference, which is this case has been taken mamdani inference, but there are many other ways to do it (see, for example, [35]).
6) Defuzzification method used. They are multiple different defuzzification methods.
7) Etc.

Each change in the above factors will cause a different adjustment of results. However, at least, it is an adjustment that does not imply suppression of questions that all or no one answered correctly (with no or maximum difficulties), and should not harm anyone. In addition, it involves the concept of “justice” that each professor should establish and that, undoubtedly, it varies from professor to professor, since it is based on his personal way of understanding teaching, the fair assessment, and the corrective actions of results that are frequently doubtful.

Thus, the concept of “justice in assessment” that we apply in our case, obeys the following rules:

1) Students with an initial score of <= 10 points are considered suspended regardless of the DI_{Total} and do not considered in the correction grade.
2) Students with an initial score of >= 90 points are considered approved regardless of the di_{total} and do not considered in the correction grade.
3) Students with an initial score between 11 and 89 points, they will be compensated in function of the DI_{Total} and the corrected value will be taken.
4) If a student, after correction, obtains a negative grade, the grade will be 0 points.
5) If a student, after correction, obtains a grade higher than 100, the grade will be 100.

4 SUMMARY

This article has proposed a way of, without suppressing any question, making a readjustment of the grades based on fuzzy logic techniques. To do this, it is considered, on the one hand, the initial grade obtained by each student and, on the other, the total difficulty index of the test (overall difficulty index of an entire test, DI_{TOTAL}). With these two variables, an approximation can be made to a system of linguistic variables that allows correcting the final grades of each student based on the objective difficulty of the test and a set of rules established by the professor. This will revert to greater “justice” in students’ mark system, since it will be a function of the difficulty of the test.

The above method tends to benefit students with worse grades when the difficulty of the test is high, while not penalize students who have obtained excellent grades. The MCQ tests allow to obtain the parameter DI_{TOTAL} and, with this index, to be able to establish a re-calculation of the qualification of each student.

ABSTRACT

Several studies have explored engineering culture in terms of how it is perceived by engineers, students, or faculty members. However, less is known about how engineering culture varies (or not) when considering national culture as the lens. This study aims to explore how engineering students perceive different dimensions of national culture and identify any patterns that connect to how they perceive their engineering programs. We use Hofstede's theory of dimensions of national cultures to measure culture in different ways in the student's perceptions of engineering. Data were collected using a validated survey that explores dimensions of culture and the sample included engineering students from Chile, Colombia, Ecuador, and the

United States. The survey was translated into Spanish and was reviewed by several native Spanish speakers. We piloted the survey with several students. Data were analyzed using descriptive and inferential statistics. Results provide preliminary information on how students perceive aspects of culture like individualism, power distance, uncertainty avoidance, and masculinity. We discuss the comparison of the different countries and provide implications of these results to our understanding of engineering culture.

1 INTRODUCTION

1.1 Background

Given the central role engineering plays in technology and innovation, 21st-century engineering programs have been consistently called upon to help students develop the attitudes, mindsets, and practices that can drive innovation [1]–[4]. Similarly, the globalization of the contemporary world requires that those engineering competencies include a global perspective [5]–[7]. Culture, in this case, can be a lens that helps engineering programs understand barriers to transforming curricula, emphasizing the importance of innovation and global awareness in engineering curricula to drive knowledge-based economic competitiveness.

In this study, we focus on these issues via an exploration of culture in engineering. This approach is consistent with Matusovich et al.'s [8] argument that not only personal but collective beliefs and values are also essential in supporting change. As Godfrey et al., [9] note, calls to address change in engineering education through a cultural lens date back at least to the mid-1990s and encompass studies of national cultures, institutional and campus cultures, faculty cultures, gender, and more. Culture has been a prominent framework used with minoritized groups, particularly women, in engineering. Diverse perspectives in engineering are considered to drive innovation and global awareness, however, there is a lack of diversity in the field often attributed to cultural traits of the discipline, characterized as masculine, individualistic, and function-oriented [10]–[15].

In addition to specific work on the culture of engineering, several studies have looked at differences in academic disciplines with respect to teaching, learning, and practice. One of the earliest and most notable is Snow [16]'s Two Cultures, positing the growing divide between the "literary intellectuals" and the "physical scientists." Since then, a range of social science and education researchers have used empirical research to explore differences and similarities among disciplines more fully. Work by Becher [17], [18] focused on analyzing disciplinary differences from the micro-level (academic departments). Bradbeer [19] looked to the macro-level (interaction of different disciplines) with work based on understanding differences in disciplinary epistemologies, discourses, traditions for teaching and learning, and students' preferred learning approaches. Donald's [20] case studies examined structures professors and students create to construct and use knowledge. Nulty and Barrett [21] focused on experiential learning models. Neumann et al. [22] examined the nature of teaching, teaching and learning processes, and teaching outcomes across the different disciplines to propose broader disciplinary classifications.

As noted earlier, our particular interest in disciplinary cultures emerges from two intersecting needs: to help engineering students develop as innovators and to expand global awareness in the field. And, we argue, these two needs are intertwined. While existing work on engineering culture highlights several issues regarding the culture of the discipline, that work does not typically intersect with work on cultures that consider national differences. Similarly, much of the work on disciplinary culture seeks to describe differences in ways of knowing and learning but does not necessarily link those epistemologies to particular values or beliefs. Carberry and Baker [23] explain that cultural considerations in engineering and engineering education spotlight the importance of culture and its implications on learning, teaching, engineering practice, identity, and enculturation as an engineer. We argue that understanding our national culture's influence on the way we perceive our disciplinary culture is essential and has not been studied extensively in engineering education.

1.2 Purpose

The purpose of this exploratory paper is to present preliminary results of a larger study being conducted with engineering students in different countries around the world to compare how their national culture influences (or not) the way they perceive their disciplinary culture. In this paper, we report the results of a survey conducted in universities in Colombia, Chile, Ecuador, and the United States with undergraduate engineering students. Our overarching research question is: Are there any differences in the way students perceive their engineering culture in different countries?

In the following sections, we describe the theoretical framework used to shape this work, the context of the research in terms of the cultural differences among the countries studied, and the institutional context of the participants. Finally, we report our results and provide some discussion of our findings and directions for our future work.

2 EXPLORATION OF THE LITERATURE

2.1 Hofstede

To understand how national culture influences the perceptions of engineering culture students have, we used Hofstede’s [24] theory of dimensions of national culture to guide our work. Hofstede's [24]–[28] theory has been one of the most cited around countries’ cultural differences. His work started in the mid-1960s when he surveyed employees at IBM -with similar working conditions and responsibilities- in more than 50 countries. The survey explored employees’ values, and the information helped him identify the different dimensions in a culture that can demonstrate differences across countries. Hofstede [26] defined culture based on his data and explained that cultural patterns are rooted in the value system of major groups of individuals and became stabilized over long periods as the acceptable way of thinking. This includes patterns of thinking, feeling, and acting that every human being carries and that usually people will collectively share as the appropriate way of thinking based on where they are from. These patterns are created by social interactions and experiences collected since the early life of an individual, starting “within the family; it continues within the neighborhood, at school, in youth groups, at the workplace, and in the living community” [28] (p. 6). Hofstede’s [26] original dimensions of culture are:

- **Power Distance** addresses the degree to which the less powerful members of institutions and organizations within a country expect and accept that power is distributed unequally.
- **Uncertainty Avoidance/Acceptance** addresses how members of a culture can operate comfortably with uncertainty.
- **Individualism/Collectivism** addresses the relationship between individuals and the larger group. In an individualistic culture, individuals are loosely connected: everyone is expected to operate independently, and people do not strongly identify with a group norm.
- **Masculinity/Femininity** refers to the continuum representing how emotional roles are distributed across genders, with assertive roles aligned with the masculine pole of the continuum and caring roles aligned with the feminine pole.

Our study compares different countries in the world that are culturally different in terms of these dimensions. This paper focuses on Chile, Colombia, Ecuador, and the United States. Using Hofstede's online tool [29], it is possible to obtain an overview of some of the cultural dimensions of people in the countries we studied. Figure 1 presents a visual representation of the main dimensions.

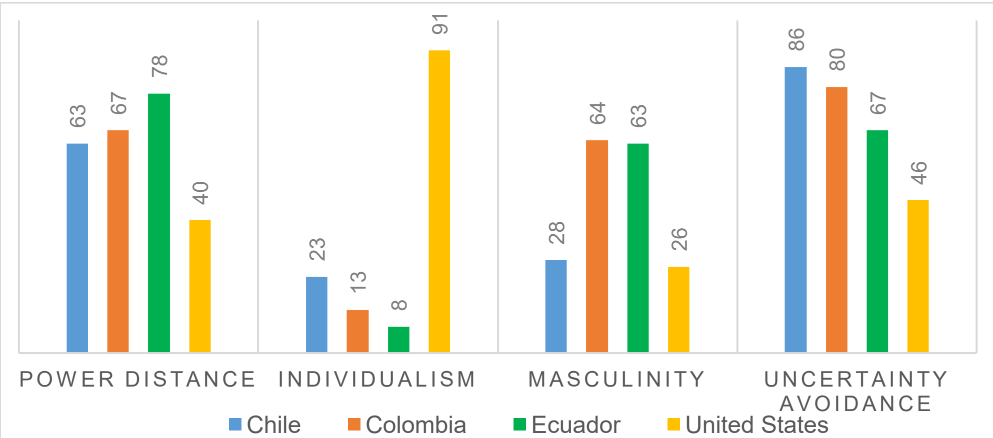

Fig. 1. Cultural comparison between the four countries in this study

From Figure 1, it is possible to see that, in terms of Individualism, the United States has one of the most individualistic societies. In contrast, Ecuador has one of the less individualistic ones. In terms of Power Distance, Ecuador has a very high power distance, Colombia and Chile are in the middle, and the United States has a relatively low one. Masculinity is also divided between Chile and the United States (low) and Colombia and Ecuador (high). Finally, uncertainty avoidance also has a significant division having Chile with the highest one followed by Colombia, Ecuador ranking in the middle, and the United States having a relatively low uncertainty avoidance.

3 METHODOLOGY

3.1 Context for the study

The study was conducted on 4 institutions in the different countries. In Colombia, the Technological University of Pereira it's a technical institution with 17971 students. The University has 93 academic programs. There are 6199 engineering students and 10 different engineering programs. In Chile, Austral University has 16893 students distributed among 52 academic degrees. There are 8 engineering programs with a. total of 2424 undergraduate engineering students. The University San Francisco de Quito in Ecuador is a private university located in Quito Ecuador and has about 7000 undergraduate students. Virginia Tech, in the United States, is a public land-grant research university and offers 280 undergraduate and graduate degree programs to some 34,400 students and manages a research portfolio of more than $500 million. The College of Engineering offers 14 undergraduate degree-granting engineering majors.

3.2 Data collection

To better understand the differences between engineering cultural perceptions of engineering students from Chile, Colombia, Ecuador, and the United States, data were collected quantitatively using a survey adapted by Sharma [30] to measure Hofstede's cultural dimensions within engineering students. This survey was validated by Sharma [30], but the authors also validated it for its use in academic disciplines [31].

Sharma's survey reconceptualizes five cultural factors--Power Distance, Individualism, Masculinity, Uncertainty Avoidance, and Long-Term Orientation as ten personal cultural orientations (PCO) and uses a 40-item scale to measure them. Sharma believed that Hofstede's national-level constructs "may not fully represent the diversity in the cultural orientations of the citizens of a country since they may not possess the same level of their national cultural characteristics" ([30], p.788); in other words, Hofstede's original scale presented challenges when measuring culture at an individual level. For our purposes, we focus on the first four original cultural factors and adapt Sharma's survey based on these factors alone. Below is a description of the four original factors reconceptualized as personal cultural orientations according to Sharma:

- Individualism-Collectivism as Independence and Interdependence, two negatively correlated dimensions in which Independence is associated with individualism and Interdependence is related to conformity
- Power Distance as Power and Social Inequality, two positively correlated dimensions, in which Power is associated with relationships between people and authority and Social Inequality is related to hierarchy versus egalitarianism

- Uncertainty Avoidance as Risk Aversion and Ambiguity Intolerance, two positively correlated dimensions, in which Risk Aversion represents reluctance to taking risks and Ambiguity Intolerance represents the extent of tolerance toward uncertain situations
- Masculinity-Femininity as Masculinity and Gender Equality, two independent dimensions, in which Masculinity represents assertiveness, self-confidence, aggression, and ambition, and Gender Equality represents the perception of men and women as equal concerning social roles, capabilities, rights, and responsibilities.

The survey was administered electronically using Google forms. It was distributed in all participating institutions in the four countries. The survey was translated into Spanish and piloted with experts. Participants included 131 Engineering students from Chile, 85 engineering students from Colombia, 167 engineering students from Ecuador, and 211 engineering students from the United States

Data were analyzed for initial differences, and in this paper, we present our preliminary results to show some of the differences between the countries selected. In the following section, we report on the mean for each of the constructs to show the general differences in each of those. In the next section, we provide some discussion.

4 RESULTS

4.1 Individualism-Collectivism

In individualism-collectivism (figure 2), Ecuadorian students reported being the more individualistic ones. These results are significantly different, with 95% confidence using the Tukey method. However, all countries have relatively high perceptions of this construct.

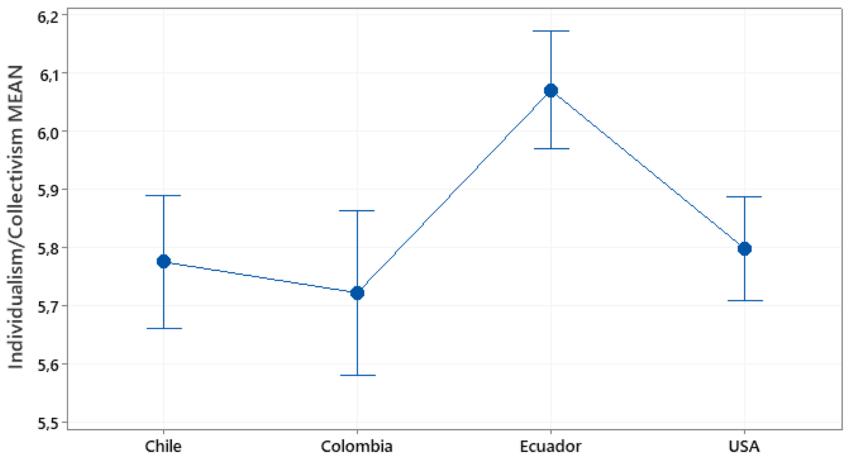

Fig. 2. Results for Individualism

4.2 Power Distance

In Figure 3, it is possible to observe that Colombia has the lowest Power Distance and Ecuador has the highest one, although all countries have a relatively low power distance perception.

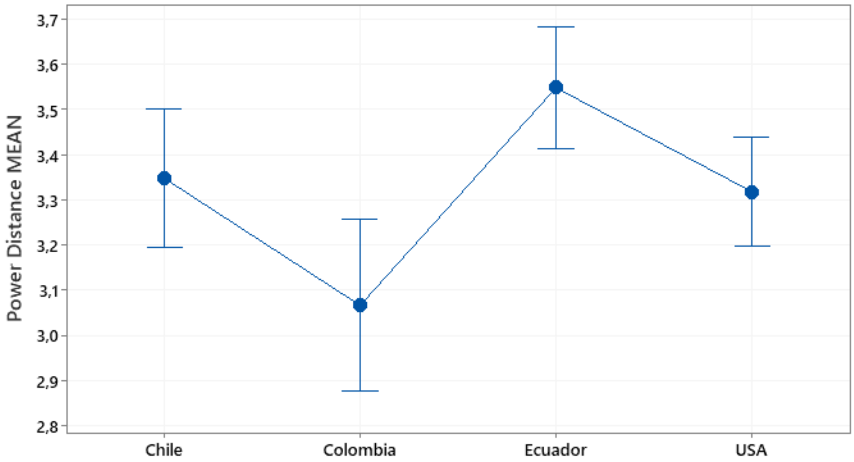

Fig. 3. Results for Power Distance

4.3 Uncertainty Avoidance

Regarding Uncertainty avoidance (figure 4), Chile ranks higher than other countries, and Colombia has the lowest one. All countries rank in the middle for this construct.

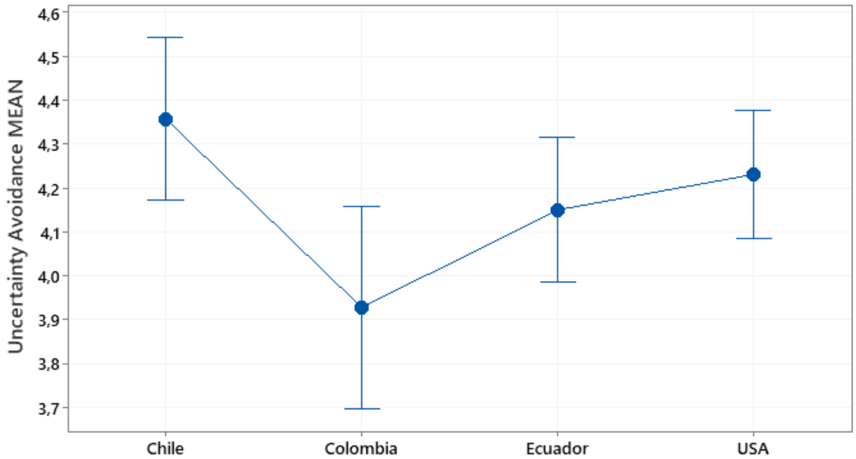

Fig. 4. Results for Uncertainty Avoidance

4.4 Masculinity – Femininity

There are no significant differences in this masculinity-femininity (figure 5), with all countries ranking high.

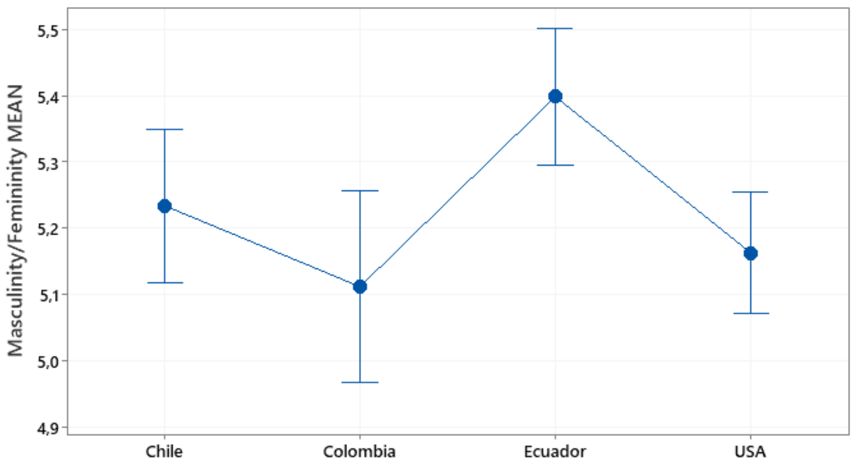

Fig. 5. Results for Uncertainty Avoidance

5 DISCUSSION

To understand the differences and similarities in engineering students' perceptions of engineering culture concerning Hofstede's dimensions of National Culture between Chile, Colombia, Ecuador, and the United States, we conducted a quantitative study. Our survey data were analyzed using descriptive and inferential statistics. We wanted to understand if engineering students' perceptions would match their national culture data when responding to the questions. We compared four institutions that, although they might look different, their engineering programs are structured very similarly.

The first interesting result is regarding individualism. Despite all 3 South American countries being very collectivistic cultures and the United States having one of the more individualistic societies, in our data, students in all countries report considerably high in individualism. Furthermore, Ecuador is one of the most collectivistic societies. However, in our data, students reported the highest perceptions of individualism. This result is interesting and worth exploring further to understand if the way that engineering programs are structured is fomenting the prevalence of individualism over collectivism, for example, the high focus on grades and the importance of finding the right solution -typical in an engineering culture- could be motivating this perception.

We were expecting some significant differences in terms of power distance, as Ecuador has one of the highest power distance indexes and the United States a relatively low one, having Chile and Colombia ranking in between. Our data confirm this finding; however, in general, our results show that all countries are ranking in the middle in power distance. Having Colombian students ranking the lowest and Ecuador, as expected, ranking the highest. It was also surprising to see the United States ranked the second-highest, despite the country having a lower power distance than Colombia and Chile. We also consider this result interesting and worth exploring further to better understand if power dynamics in engineering classrooms make students have a generally low perception of power distance.

Regarding uncertainty avoidance, we did not find any significant results. Instead, the patterns behaved similarly to what was expected based on the national cultural differences.

Finally, for Masculinity-Femininity, we expected Colombia and Ecuador to have higher scores and Chile and the United States to have the lowest ones; however, all countries ranked very high in our data. Surprisingly, we also had Chile and the United States with higher scores than Colombia. We also consider this dimension worth exploring further as it can be seen that the cultural perception of engineering might impact how students perceive this dimension.

Conference Key Areas: *Sustainability and Sustainable Development Goals*
Keywords: *Sustainability awareness, Engineering education, SDG*

ABSTRACT

Engineers have a growing contribution towards attaining the Sustainable Development Goals (SDGs). Thus, graduate engineering students' awareness and attitude will be crucial for dealing with these complex societal challenges. The purpose of this study is to investigate the sustainability awareness (SA) of engineering students from a developing country in comparison to that of those published from developed European countries. It also aims to explore engineering students' attitudes and willingness to consider sustainability challenges as an important part of their future professional role. We have conducted a quantitative

online survey (n=253) with the participation of engineering students from different majors at Bachelors and Masters levels. The data concerning students' awareness and attitude underwent quantitative statistical analysis and was compared to that in the literature. The data was analyzed using SPSS to investigate differences and similarities between majors and validate its quality. The findings show good levels of SA and lower levels of knowledge in SDGs among engineering students compared to that presented by European studies. Thus, a gap in SDGs' awareness exists between students from developed and developing countries. However, students' positive attitudes and willingness to be involved in SDGs' practices were remarkably high in understanding the leading role of engineers toward achieving the SDGs. Our results confirm engineering students' motivation and strong positive attitude for resolving sustainability issues in developing countries despite challenging lifestyles. Our findings could be further used by engineering faculties in developing countries to minimize the gap and enhance future engineers' contribution towards a more sustainable society.

1 INTRODUCTION

Engineers are commonly acknowledged as having a critical and increasing role to play in achieving the Sustainable Development Goals (SDGs) and are required to promote the principles of sustainability [1, 2, 6, 7]. The role of future engineers is not only related to the emergence of technical progress, but they are also required to lead solving complex social and environmental problems [6]. To accomplish this mission, it is essential to train graduate engineers to acquire new sustainability competences. This is considered one of the major challenges faced by engineering education institutions [7]. Consequently, there is an ongoing transformation in all developed countries for implementing sustainability competences' development in engineering curricula. However, this is not the case in developing countries, where the education for sustainability is in its early stages with starting reforms [8, 9, 10]. In this situation, engineering students' sustainability awareness (SA) and their attitudes to SDGs play an important influence on the implementation of these reforms.

In our study, we investigated engineering students' SA from the University of Balamand (UOB), Lebanon, a developing country in the Middle East, and compared the results to that of those published from developed European countries. Additionally, we investigated the engineering students' attitude and willingness to consider sustainability challenges as an important part of their future professional role. Hence, the key research questions (RQ) addressed in this study are:

RQ(1): What is engineering students' understanding of sustainable development and SDGs?
RQ(2): What is engineering students' attitude towards considering sustainability challenges?
RQ(3): To what extent engineering students are aware that their profession has a fundamental role in achieving SDGs?

2 LITERATURE REVIEW

SA is defined as the process of expanding humans' ecological consciousness and their knowledge of the environment's importance as well as its fragility [1]. This definition shares similar goals with those of the engineering profession as it involves the ability to consolidate theoretical and structural knowledge through application, interaction and decision making, in favor of the biophysical environment and its problems [1, 2]. Thus, limiting and mitigating against present and future damages respectively.

According to Flament and Kövesi [3], the French engineering students' SDGs awareness as well as their insight and efforts on sustainable development (SD) is relatively limited. They confirmed that these students acknowledge the fundamental role of SD but "have a limited knowledge and understanding of SDGs". Also, French engineering students mainly focus on the environmental and economic factors of SD and often ignore the social aspects [3]. Nicolaou and Conlon [4] observed that, similar to the French study [3], with respect to three Irish universities, final year Irish engineering students have deficient knowledge of sustainability and mainly relate SD to environmental challenges. Thus, their knowledge of the economic and social pillars of SD is equally limited.

Regarding engineering students' attitude towards sustainability, Hamón et al. [5] focused on analyzing students' SA and learning taking into consideration three dimensions: knowledge, attitude and behavior [5]. They have found that Spanish science and engineering students showed the highest levels of knowledge and readiness in the three dimensions comparing to students from other faculties. They concluded that the students could become more aware of SD following the implementation of sustainable practices at their universities.

Concerning the question whether the engineering students are aware that their profession has an important role in achieving SDGs, we have convergent results in the academic literature. French engineering students understand the global and national importance of these SDGs, but they do not consider it as an integral part of their future professional practices [3]. Similarly, it was found that Spanish engineering students highly consider SD practices with respect to their personal life [5] and not much in their professional one. As such, they lack awareness of the crucial role their profession has toward reaching the SDGs.

3 METHODOLOGY

3.1 Study context

To answer our research questions, we have conducted a quantitative online survey at the Faculty of Engineering at the University of Balamand in Lebanon, a country that has endured hardship for over three decades. Lebanon socioeconomic problems are very much associated with the civil war that had stretched from the mid-1970s till the mid-1990s, which has meant that any SD implementation has been challenging. Many attempts have been put in place to implement SD in Lebanon and to adhere to the UN 17 SDGs through many Non-Governmental Organizations (NGOs) and by infusing the information in university curricula. The latter remains low in visibility despite all 8 QS ranked Lebanese Universities' efforts to adhere to the notion of SDGs. The University of Balamand is a young university, founded as recently as 1988, established on solid infrastructure with a relatively important student body of 4500 students. Its senior management team is undertaking a concerted effort to include SD in its scholarly activities, teaching, research and community services. We investigated engineering students' SA, attitudes and professional view which is facing detrimental environmental (inefficient waste collection/disposal, lack of water supply/storage), economic (lack of local production and industry, hyperinflation of local money) and social (missing social security, religion discrimination) problems.

3.2 Participants

For our sample selection, we have targeted engineering students at (1) Bachelor of Science (BSc), (2) Bachelor of Engineering (BE) and (2) Master of Science (MSc) levels.

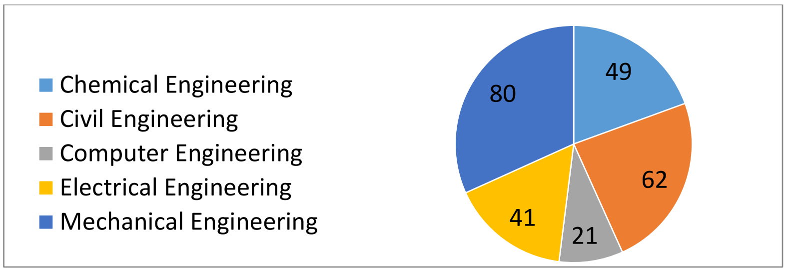

Fig. 1. Repartition of the surveyed engineering students by major

We sent out the survey to all engineering students of the faculty (total of 761) and received 253 completed surveys. We obtained a very satisfactory answering rate of 33%. We have 31% female and 69% male student participants of different majors that are considered as representative for the engineering faculty. As shown in Fig. 1, the Mechanical and Civil engineering departments have registered the highest participation of 31.6 % (80) and 23.7% (60) students respectively knowing that they have the highest number of students in the faculty.

3.3 Data collection

For our survey design, we exclusively used closed questions in line with the European questionnaires investigating the following three topics: (1) sustainability understanding and awareness, (2) attitudes to SDGs and (3) the role of engineering profession in achieving SDGs.

In the surveys introductory section, we have presented the ethical considerations of our study, i.e., detailing its objectives, confidentiality policy, participant's anonymity, data storage and handling.

We have conducted a pre-test of our survey with 15 students in order to collect their feedbacks. We then finalized the survey design by taking into consideration their comments and suggestions for improvements. The final version of our online survey was disseminated to all engineering students via email.

3.4 Data analysis

For our data analysis, we used SPSS software. At first, we have conducted a descriptive statistical analysis and then checked the quality of the survey, with regards to different tests: factorability, Kaiser–Meyer–Olkin (KMO), communality and dimensionality. The results were highly satisfactory with KMO ≥ 0.8; they highlighted that the survey is well designed, the questions were distributed without any redundancy and the participants' number is statistically acceptable. In conform to the survey's validity; we have completed a more detailed data analysis, with crossed tables to analyze the results with respect to different majors, study levels and genders.

4 RESULTS AND DISCUSSION

4.1 Level of awareness

We first displayed the level of SA among students concerning their understanding of the general sustainability concepts at different study levels. 27.1% of the BE undergraduate students selected that they are unsure of what SD means while 25.4% were neutral of the statement. However, the MSc graduate students are more aware about SD than their undergraduate counterpart. Only 15.2% MSc students selected that they are unsure of what SD means.

We further analyzed the level of awareness of engineering students per department. We can observe important differences, as shown in Fig. 2, between engineering students of different majors. Our findings show that 61.94% are familiar with the general concept of SD and only 36.94% have heard about the SDGs indicating a lack of awareness of SDGs.

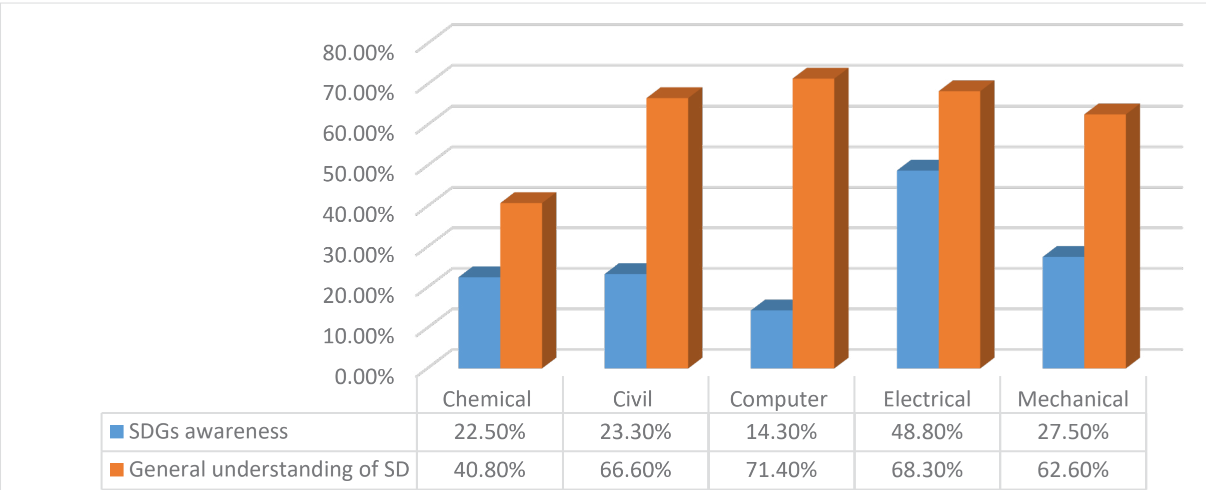

Fig. 2. Engineering students SDGs awareness and general understanding

To our surprise, the Computer and the Electrical engineering students show the highest level of SD awareness, with 71.40% and 68.30% respectively. Additionally, those majoring in Electrical and Mechanical engineering are the most aware of the SDGs, with 48.80% and 27.50% respectively. Even though, in the engineering faculty, the SD oriented projects are more active in the Civil and the Chemical engineering departments.

In contrast to the European findings in the literature, our results show a relatively good level of awareness in basic SD concepts (61.94%) and considerably lower levels of knowledge in SDGs (36.94%). In Ireland, 65% of final year engineering students could not define sustainability nor had a very vague understanding of the concept [4]. French engineering students showed better overall knowledge of the SDGs [3] and 73% of the Spanish students selected that they are familiar with the concepts of sustainability [5].

French engineering students mostly linked SD to environmental aspects with less emphasis on economic aspects and almost disregarding the social pillar [3]. In the present study, the emphasis on environmental aspect is as high as that found in France. In our results, 72.3% agreed that sustainability is more importantly related to the environment, 64.4% agreed that it is related to financial issues and 56% agreed that it is about social/cultural issues. As such, the Lebanese students acknowledged the importance of the economic and social aspects in SD too with more emphasis than the French study [3].

4.2 Attitude

Our results indicate engineering students' strong positive attitudes and willingness to engage in activities related to sustainability and its challenges. As per our analysis, 65.7% of the students are willing to help to achieve more of the SDGs. However, 28.6% of these students were unsure how to contribute. Similarly, 42.7% of Spanish engineering students' showed readiness for participating in the university's SD initiatives and 70.5% were motivated to learn more about such activities [5].

Moreover, in our study, 70.7% of the engineering students showed interest in attending workshops, courses or seminars on SD. Nearly similar to the results obtained for Spanish engineering students [5]. This confirm that engineering students in a developing country, with challenging situations and life conditions, are still motivated and eager to change their country's current circumstances. This high level of positive attitude reflected in students for each major is given in Fig. 3.

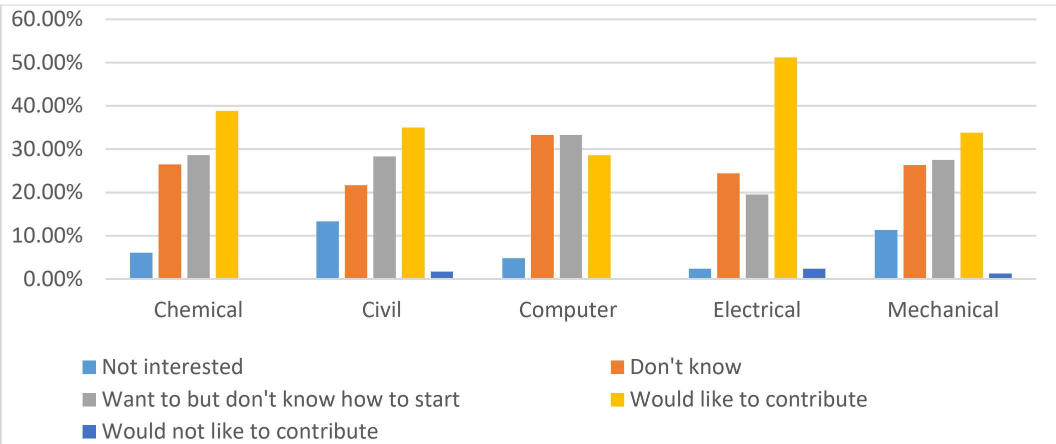

Fig. 3. Engineering students' attitude toward participation in SD initiatives

As shown in Fig. 3, 51.20% of the Electrical engineering students would like to contribute to SD initiatives, the highest amongst all other departments. Additionally, on average, 29.4% would like to contribute however do not know how to start.

4.3 Engineering profession role

Furthermore, our results show clearly that engineering students understand the importance of their responsibilities and they are very aware that their profession has a key role in achieving the SDGs.

Table 1: Engineering students' awareness towards their profession role in achieving SDGs

Q: Engineers are key players in achieving SDGs	Agree & Strongly agree	Neutral	Disagree & Strongly disagree
BSc	74.5 %	20.5 %	5.0 %
BE	81.4 %	10.1 %	8.5 %
MSc	94.0 %	6.0 %	0.0 %

As shown in Table 1, graduate students are more aware about the correlation between their profession and the SDGs than undergraduate students. In general, 83.3% agreed that engineers are key players in achieving the SDGs. However, we can see that engineering students do not have much confidence in their country, where 45.7% think that their profession in this particular country does not prepare them nor encourage them enough to apply essential SD practices.

5 CONCLUSION

The results confirmed the existence of a gap in engineering students' SDGs awareness between developed and developing countries. Similar to previous findings [3], the Lebanese students at the University of Balamand related SD to the environmental pillar as a priority. In addition, they acknowledged the importance of the economic and social aspects in SD more than the French students. They also showed positive attitude towards participating in future SD initiatives but do not know where to start. However, unlike other students from developed countries, they do consider their profession a key player in achieving the SDGs but have no confidence in the support of their country.

Our analysis highlighted the motivation and readiness of engineering students towards achieving the SDGs, despite the country's limitations and their perception of lack of support. For academic considerations, these promising results can be used to guide the implementation of SD education in different majors and for different levels, for minimizing the gap between developed and developing countries and spreading SA at a national level. Additionally, the results can assist in guiding an education for SD tailored specifically to improve the SA levels nationally and encourage the country's participation. Furthermore, it can help direct the universities' education goals to raise students' self-confidence levels and highlight their leadership role in initiating such SD practices and in building a better country.

In this study we have faced some limitations. We have surveyed engineering students from only one university from a developing country. The response rate was acceptable but a higher return would have provided a better picture.

Future work considers studying the SA of engineering students in different developing countries and comparing to students from multi-disciplinary domains.

ACKNOWLEDGEMENTS

We appreciate the support of the Faculty of Engineering at the University of Balamand, especially the Dean, Professor Rami Abboud for his encouragement, support and inspiration. In addition, we wish to thank the students for their cooperation, the instructors for their time, the GIS Center and Dr Amal Iaaly for her help in the data analysis.

ABSTRACT

Engineering (STEM) universities in Europe apply different pedagogical and didactic approaches, which are reflected in the structure of teaching and learning activities that are organised for the students. There is great variation in terms of both semester structure and how teaching activities are carried out. The aim of this study is to shed light on students' observations of the different teaching structures and teaching practices offered and to highlight the impact on students of the different teaching approaches.

The data for the study was collected through a survey distributed by the BEST student organisation with 351 respondents from students in 36 European countries. The survey contained multiple-choice questions that aimed to collect demographic data, but also focused on questions about how their programme and learning and teaching activities were structured and most importantly, their perception of the various approaches used.

Findings show the variation in teaching approaches such as the extent of teacher centred approaches, class sizes, laboratory components and project work. The variation in the delivery of project work, the number of projects, timescale and the extent of collaboration with industry are also described.

The study shows a picture of EU engineering universities from the perspective of the students. It highlights the diversity in structure and teaching activities and most importantly, the extent to which students disengage due to the way they are taught.

1 INTRODUCTION

Engineering education, in general, is very focused on how to develop the skills and competencies of engineering students, as new expectations and requirements emerge even faster each year. Concepts such as Industry 4.0, which requires competencies in digitisation and the UN's 17 SDG goals which provides a framework for sustainability, are both concepts which require universities to continuously develop their educational programmes. To meet this dynamic, it is important that universities not only pursue 'what to teach' but also progress their pedagogical and didactic methods by also pursuing 'how to teach'. Engineering institutions in Europe apply different pedagogical and didactic methods, which are reflected in the learning activities that are organised for the students. These activities provide students with different experiences in terms of both approaching their learning and their ultimate achievement.

The aim of this study is to shed light on the following questions: What are students' perceptions of the different teaching structures and teaching practices which are provided by European engineering universities and how do students encounter these different teaching approaches.

2 LITERATURE REVIEW

Understanding engineering students' perceptions of their teaching and learning experiences is an important issue in order to develop efficient, attractive and motivational engineering programmes. According to a study by Korte and Smith [1:12] engineering 'students often reported their most important learning occurred in labs and small group discussion sessions, as well as in study groups'. These teaching and learning experiences in small classroom settings not only encourages active learning but also offers opportunities for direct feedback. They also enhance contact and strengthen the social relationship between students and their lecturers by developing positive emotions and a good classroom atmosphere [2]. In their study, Klegeris and Hurren [3] investigated the impact of using PBL (Problem Based Learning) approaches in a large classroom setting and found a significant positive effect on students' motivation to attend and participate in the classwork.

As highlighted by Parpala [4], students' positive experiences of their teaching and learning environment results in a positive influence on deep learning approaches and negatively on surface learning approaches. However, we have to highlight that there are important disciplinary differences between students' perceptions of the concept of 'good learning'. In STEM disciplines, the analysis of students' best learning experiences showed that students more often refer to their motivation and emotions rather than the content or environment used in their learning [5] confirming the importance of social relations in engineering education [2].

Tayebi et al. [6] noted that having a poor relationship with professors is one of the major reasons that students drop out in engineering. The top two reasons were the difficulty of engineering studies and poor grades. Their study revealed that 46% of students have thought about abandoning their engineering studies. This is most likely related to the commonly recognised difficulty of undertaking engineering studies (identified as the first cause of students' dropout). Salas-Morera et al. [7], report that several pedagogical and organisational factors increase the likelihood of students abandoning their engineering studies. These include; inadequate class timetables or planning of exams, overloaded and long syllabi with too many targeted activities, the high level starting point of many courses and difficult exams.

It is widely recognized that university-industry collaboration is highly beneficial for developing engineering students' industry oriented professional competences. The implementation of PBL practices at the project level through partnership with industry seems to be a well-adapted and efficient way to create an emerging learning environment in engineering education. Surprisingly, based on a recent meta-analysis by Chen et al. [8], there are relatively few studies reported in the academic literature with collaboration between university and industry at the project level.

3 METHODOLOGY

This study has an explorative approach with the aim to explain students' perception of educational and pedagogical approaches applied at various STEM universities in Europe. The work is intended as a feasibility study on students' perceptions, behaviour, and preferences from which concepts and hypotheses can be drawn up for more comprehensive research. It was conducted as part of an Erasmus + research project on the future of engineering education, the A-STEP 2030 [9][10]. The data was collected through an online survey using the software, SurveyXact. It was ethically approved by Aalborg University and disseminated through the Board of European Students of Technology (BEST) network.

The survey was divided into three main parts. The first part focussed on demographic variables which depicted the students. The second part of the survey included two open-ended questions related to students' experiences in the classroom. These two questions are not part of the analysis presented in this paper. The third part contained questions that sought answers to students' perceptions of learning activities and their study structure. There were 351 respondents to the survey, however 303 completed the demographic information only and 108 completed all questions on the survey. It appeared that the 303 students became stuck in the open-ended question part of the survey and did not move on. However, 108 responses were determined to be valid for the analysis.

In total there were a vast range of Universities represented in the survey from 31 identified countries in Europe (11 from Other). Twenty four European nationalities were identified with 80 (26%) respondents indicating "Other" which denotes non-European nationality. Although the survey was circulated around students within the BEST (Board of European Students of Technology) groups, 56% of respondents identified as female, which is not representative of the gender split within STEM programmes in general. The age of respondents ranged from under 18 to over 34, but 75% of the respondents were included within the 20-24 (inclusive) age bracket. A range of disciplines of study were included, made up of 25% from computer science, 25% other and the remainder from the main branches of engineering disciplines, maths and science. Students were quite evenly spread from first year to sixth year, with the majority of respondents in third or fourth year.

As this study has a quantitative approach the data will be analysed using statistical methods such as percentages, averages, and correlations to show the diversity of students' perceptions of educational and pedagogical approaches.

4 RESULTS

4.1 Teaching Approaches

In the survey students evaluated the proportion of different teaching approaches used in their degree programme. The four teaching approaches offered for selection included: (1) the proportion of lectures in large groups, (2) small group teaching, (3) laboratory work and (4) project work.

In the survey, the response options were presented as %-categories, divided into 11 response options. In the analysis, the response options were re-coded into new categories to indicate more clearly the students' evaluations. The responses in the categories 70-80% and above were combined. The results of this category is presented in the Table 1.

Although in the survey, students were able to select the proportions within 10% graduations, for simplicity, the responses are presented here by considering how many students reported the percentage of their studies in each of these teaching approaches as 70-80% or more. So, for example, responses were counted where a student indicated that at least 70% of their programme was made up of lecturing in large groups, or teaching in small groups, or so on.

Table 1. Percentage of respondents indicating that at least 70% of their studies use each teaching approach (Response categories 70-80% and above combined).

Teaching approach	Number of respondents (n)	%
Lectures in large groups	26	23.0
Teaching in small groups	8	7.1
Lab exercises	3	2.7
Project work	8	7.1

23.0% (n=26) of the respondents indicated that they have 70% or more of their studies as lectures in large groups. This can be considered as a large amount especially as the majority of the respondents were 3rd and 4th year students. At the end phase of an engineering programme, learning should happen mainly in real learning environments instead of lectures in large groups.

7.1% (n=8) of the respondents indicated that 70% or more of their study programme is teaching in small groups. Again, this is a small number especially considering the study phase of the respondents. This is also aligned with the responses connected to lectures in large groups.

2.7% (n=3) of the respondents said they have 70% or more of their study programme as laboratory exercises. Conversely, 9.7% (n=11) said they do not have laboratory exercises at all in their studies. This is an alarming result in a STEM discipline where it is well known that students benefit from laboratory work in applying theory into practice.

7.1% (n=8) of the respondents indicated that project work made up 70% or more of their studies, which is a surprisingly small number again, considering STEM as the discipline and especially when project work is understood to be a good pedagogical choice and the main teaching approach of some universities. 4.4% (n=5) said they do not have project work at all in their studies. STEM professionals work typically in projects in industry which attests that students should have project work learning environments and experiences in their studies.

Overall, in relation to teaching approaches, the respondents typically had lectures in large groups compared with small group teaching, laboratory work and project work as indicated in Figure 1.

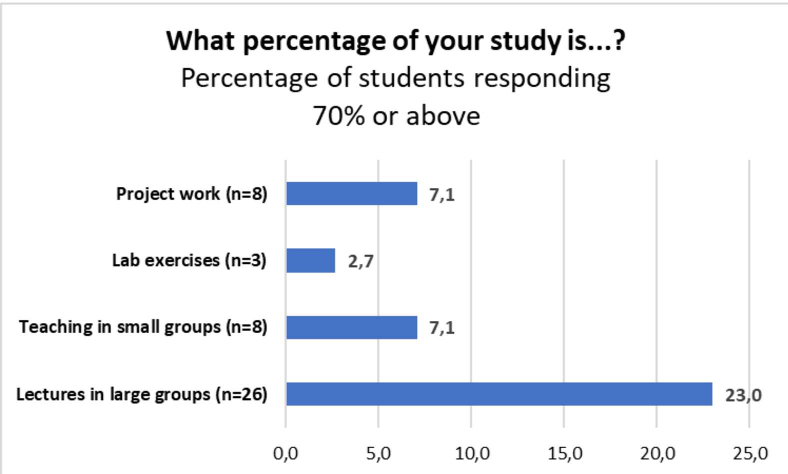

Fig. 1. Percentage of students responding that at least 70% of their studies is in each mode of learning

4.2 Study Projects

In relation to study projects, the time frame of a study project typically lasted for 1-3 weeks (mode). This category represented 25.9% (n=29) of the respondents. This can be considered as a short time period from the perspective of the development of expertise. The short time period then requires that separate projects in different modules are pedagogically aligned to support the overall learning objectives and development of expertise of the students.

The survey also collected information in relation to the percentage of projects undertaken in collaboration with industry. 48.1% (n=52) of the respondents indicated that they do not have projects in collaboration with industry/business at all (Fig. 2). This is a confounding finding for a STEM survey, especially considering engineering as a discipline. It is evident from prior research, contemporary theories of learning and their pedagogical implications that STEM and engineering education benefit from a close connection to real learning environments in the form of industry collaboration.

4.3 Impact of Teaching Approaches

The final question asked students about attendance and how often they skip a class because of the way it is taught. Overall, 90.7% (n=92) of the respondents indicated that they skip at least some learning activities because of the way they are taught (Fig. 3). In fact, 65.7% (n=71) respondents indicated that they skip up to 40% of classes as a result of the way they were taught.

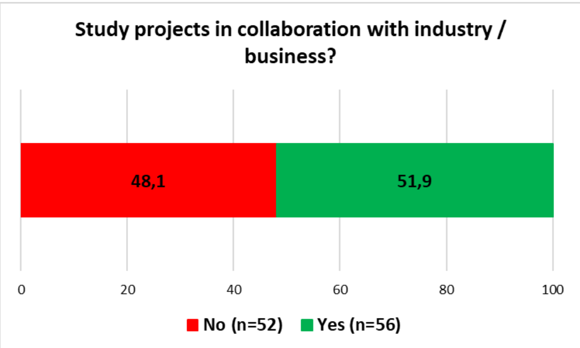

Fig. 2. Extent of Collaboration with industry

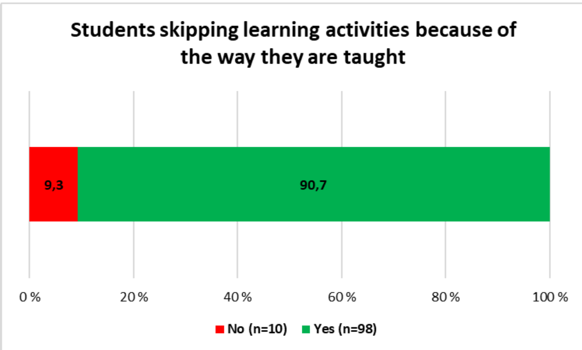

Fig. 3. Percentage of students who skip class

5 DISCUSSION AND CONCLUSION

This study sought to investigate students' perceptions of the different teaching structures and teaching practices and their resulting impact. It is clear that there is a diverse range of practices across Universities in Europe, but what is surprising is that although it is well known that small group and laboratory work are effective teaching practices, 23% of respondents still noted that they have at least 70% of their teaching in lectures in large groups. This is particularly concerning as the majority of respondents were in the latter years of their programmes (3rd and 4th year).

Perhaps more concerning still is that despite an acknowledgement in the education literature about the importance of real life projects and industry collaboration, 48.1% of respondents have no industry project collaboration at all.

However, the most illuminating aspect of this study was the finding that 90.7% of respondents indicated that they choose to skip a particular class because of the way is it taught. This is a wake up call to engineering and STEM educators to show the direct impact that their teaching approach has on student engagement not only in the classroom, but in bringing the students to the classroom in the first place.

6 ACKNOWLEDGMENTS

The authors would like to acknowledge the members of BEST (Board of European Students of Technology) for their help in the data collection. Authors also acknowledge their colleagues from the project A-STEP 2030 by the Erasmus+ programme of the European Union, for their constructive feedback.

ABSTRACT

Learning objectives are important as they provide direction to teaching staff towards what content should be taught, what activities should be undertaken and what assessments are to be used to confirm understanding. Two decades ago, the evolution of new learning modes such as recorded, remote, and simulation/virtual started the research process to define and better understand learning objectives in the teaching laboratory. Much is still to be learnt about laboratory learning objectives including which are most important, and if what is deemed important is universal. For example, do academics in Europe and Australasia align in which objectives are most important and which are not? To answer this question, European and Australasian engineering academics were asked to rank laboratory objectives across the cognitive, psychomotor, and affective domain using a predefined tool called Laboratory Learning Objectives Measurement. A total of 113 academics from Australasia and 25 from Europe responded to the survey. A statistical analysis was conducted to compare the rankings. The findings from this survey show that substantial alignment occurs across the cognitive and psychomotor domains but differs across the affective domain.

1 INTRODUCTION

1.1 Background

The engineering laboratory has always played an important role in preparing engineering graduates for their careers. Advancements in technology and industrial requirements continue to drive its importance, regardless of its mode of delivery [1, 2]. Systematic literature reviews show that laboratory learning can take place in various modes such as face to face, simulation/virtual and remote; and that learning occurs across the cognitive, psychomotor, and affective domains [3, 4]. COVID19 in particular caused many universities to alter their approaches in how they conducted their laboratory classes [5]. Academic staff did the best they could to make the most of a difficult situation right across the world, accelerating the transition to different laboratory learning modes. With the speed of such change, it is important for academic staff to reflect on the most important laboratory objectives to ensure that the objectives drive the implementation, and not the other way around.

The definition of thirteen key laboratory objectives was established in 2002 [6] and has played an important role in directing the learning outcomes for laboratory research in the last two decades. Researchers have been building upon this foundation to better refine and measure laboratory learning. One such refinement is the Laboratory Learning Objectives Measurement (LLOM) instrument as defined in [7]. The authors have used this instrument to explore if there is a commonality to recognise which are the most important objectives that need to be facilitated in laboratory learning.

This work creates the foundation for a future study being prepared by the authors that will compare objective rankings across disciplines. Due to the overweight of responses from Australasia, an understanding of location differences is necessary. Therefore, the first step is to determine if location altered rankings. For example, there are some major cultural and lifestyle differences between Europeans and Australasians. It would be interesting to know if differences in international location would influence ranking decisions. Therefore, this study explores the LLOM ranking relationships across continents. It seeks to answer the research question '*how do Australasian and European academics rank laboratory objectives compared to the international community?*'.

1.2 The LLOM instrument

Learning in the laboratory can be connected across the cognitive, psychomotor and affective domains [7]. This is because when thinking of a traditional laboratory, students must undertake activities like applying, analysing, and evaluating information (cognitive); imitate, manipulate, and articulate with their hands (psychomotor); and attend, respond and value with their presence (affective). The LLOM instrument combines the 13 objectives listed in [6] with the Blooms Taxonomy level descriptors to provide a holistic list as provided in Table 1.

It is important to note that while a separation exists, learning domains cannot be isolated from each other because almost all learning activities involve more than one domain. The objectives used allow universal application across different engineering courses and disciplines. Key words within the text of an objective have been written in italics that allow modification to match the required context or discipline. Any related word can be used, not just the sample words given for context. For example, the objective P1 written as 'Correctly conduct an experiment on [*course equipment/ software name- e.g. power systems*]?' Could be modified to be 'Correctly conduct an experiment on control systems' or 'Correctly conduct an experiment on hydraulics'.

The instrument was explained to participants taking part in the research. Examples such as the one above, were used to demonstrate how the objectives could be tailored to any particular course by swapping out the italicised words. It was the responsibility of each participant to consider each statement within the context of the course/s they teach.

Table 1. Laboratory Learning Objectives Measurement Items

Domain	Item	LLOM Objective
Cognitive	C1	Understand the operation of *equipment/software* used within the laboratory
Cognitive	C2	Design *experiments/models* (physical or simulation) to verify course concepts
Cognitive	C3	Use engineering tools (e.g. [*name of hardware/software used*]) to solve problems
Cognitive	C4	Read and understand *datasheets/circuit-diagrams/ procedures/user-manuals/help-menus*
Cognitive	C5	Draw & interpret relevant charts, graphs, tables & signals
Cognitive	C6	Recognize safety issues associated with laboratory experimentation
Cognitive	C7	Analyse the results from an experiment
Cognitive	C8	Write a conclusion summarizing your findings from an experiment
Cognitive	C9	Write a *laboratory report/entry into a logbook* in a professional manner
Psychomotor	P1	Correctly conduct an experiment on [course *equipment/ software name- e.g. power systems*]
Psychomotor	P2H	Select and use appropriate instruments for the input, output and measurement of your *circuit/system*
Psychomotor	P2S	Select appropriate commands and navigate interface to *simulate/program* a *model*
Psychomotor	P3	Plan and execute experimental work related to this course
Psychomotor	P4	*Construct/code* a working *circuit/simulation/program*
Psychomotor	P5	Interpret sounds, temperature, smells and visual cues to diagnose faults/errors
Psychomotor	P6H	Operate instruments (e.g. [*equipment name*]) required for experimentation
Psychomotor	P6S	Operate software packages (e.g. [*software name*]) required for *coding/simulation*
Psychomotor	P7	Take the reading of the output from *circuits/ instruments*
Affective	A1	Work in a team to conduct experiments, diagnose problems and analyse results
Affective	A2	Communicate laboratory setup, fault diagnosis, readings and findings with others
Affective	A3	Work independently to conduct experiments, diagnose problems and analyse results
Affective	A4	Consider ethical issues in laboratory experimentation and communication of discoveries
Affective	A5	Creatively use *software/hardware* to design or modify an experiment to solve a problem
Affective	A6	Learn from failure (when *experiment/simulation/code* fails or results are unexpected)
Affective	A7	Motivate yourself to complete experiments and learn from the laboratory activities

2 METHODOLOGY

A multi-institution and multi-disciplinary research team was assembled to investigate the research question. Members of the team reached out via direct email and social media in 2021 to their university, research and professional contacts within the field of engineering to answer a survey created in Qualtrics. The survey required participants to rank in order of importance (1 = highest ranked) the multi-domain objectives as listed in the Laboratory Learning Objectives Measurement (LLOM) instrument as outlined in [7]. Participants were required to rank the objectives from most important (ranking = 1) to least important. To determine if any of the rankings remained unchanged, a fixed initial ranking was used based on the order as listed on this page. None of the rankings were left in the default state for the responses analysed.

Approximately 3,000 academics from all continents were invited to participate in the survey with 219 survey commencements and 160 completions. From this, 113 responses came from Australasia and 25 from Europe. While higher number of survey responses were anticipated, as the numbers suggest it was difficult to encourage participation, especially outside of Australasia. European responses came from Finland, France, Germany, Ireland, Portugal, Serbia, Slovakia and Spain. Attempts to gain responses from other European countries were not successful. The sample size for each European country was too small for analysis, but reasonable as a collective to obtain a European perspective. This imbalance creates the need of this research to understand if location-based differences existed.

3 RESULTS

The platform R version 4.05 was used for the statistical analysis with the results shown in Tables 2 (cognitive), 3 (psychomotor) and 4 (affective). The data was analysed in three groups, international (all data from across the world), Australasia and Europe. The sample size for Europe was not high enough to also look at differences between majors. Rankings were determined using averages. The lower the number, the more academics ranked the objective as being more important than objectives with a higher average. In brackets, the 95% confidence interval (CI) is shown. To determine if a statistically significant difference in average values occurs, the 2 confidence intervals must not overlap. Such differences to the international collective are highlighted in green.

In the last column, the one-way analysis of variance (ANOVA) is applied, this examines whether for a particular objective (e.g. C1), the mean responses are different across the groups, i.e. if shown p-value is less than 5%, then responses differ across groups for that question, otherwise not. A multivariate analysis of variance (MANOVA) was applied to determine if there is a statistical difference overall between locations. The p-value for Table 2 is 0.05763, Table 3 is 0.1238 and for Table 4 is 0.4452. This indicates if the overall responses differ across groups.

Each table also provides a visual representation of the objectives in ranking order. Visual representations can help develop a better understanding of statistical data. Colour coding is used to show how the collective ranking, differs across the groupings. For example, in Table 2, C1 is given the colour light blue. The different ranking of C1 for each group can be easily observed in the table by following the colour trend.

3.1 Cognitive Domain

Table 2 showcases the average values and rankings for the cognitive domain. It can be seen that across the three comparison groups there is substantial alignment in ranking order.

Table 2. Learning Objectives Cognitive Domain (Averages With 95% Confidence Interval) And Ranking Order

Obj.	International	Australasia	Europe	ANOVA
C1	3.11 (2.79,3.42)	3.05 (2.68,3.43)	2.80 (2.09,3.51)	0.560476
C2	3.31 (2.92,3.69)	3.38 (2.90,3.86)	3.48 (2.64,4.32)	0.856811
C3	4.06 (3.69,4.43)	4.28 (3.82,4.75)	3.12 (2.34,3.90)	0.029015
C4	5.50 (5.14,5.86)	5.42 (4.99,5.84)	5.60 (4.62,6.58)	0.71859
C5	5.10 (4.84,5.36)	4.86 (4.55,5.17)	6.16 (5.48,6.84)	0.000537
C6	6.23 (5.85,6.61)	6.35 (5.92,6.78)	6.08 (5.06,7.10)	0.596898
C7	3.86 (3.54,4.18)	3.82 (3.43,4.21)	3.92 (3.10,4.74)	0.832927
C8	6.54 (6.22,6.85)	6.57 (6.20,6.93)	6.28 (5.29,7.27)	0.529588
C9	7.29 (6.98,7.61)	7.27 (6.89,7.64)	7.56 (6.76,8.36)	0.504093
Rank				
1	C1	C1	C1	
2	C2	C2	C3	
3	C7	C7	C2	
4	C3	C3	C7	
5	C5	C5	C4	
6	C4	C4	C5	
7	C6	C6	C6	
8	C8	C8	C8	
9	C9	C9	C9	

The most important cognitive objective is C1 '*understand the operation of equipment/software used within the laboratory*' and was consistent across all groups. This result is not surprising as engaging with hardware/software is core to laboratory work.

The least important item is C9 '*Write a laboratory report/entry into a logbook in a professional manner*'. C8, another cognitive writing-based objective was ranked second last. Interestingly, while lab reports and writing are deemed as least important, the work by Nikolic, Ros [4] found that they were one of the most used assessment types. This provides a strong case of the need for further investigation.

The only major difference identified between the three groups is that the Europeans valued the laboratory objective C3 '*Use engineering tools to solve problems*' higher. This difference was found to be statistically significant. They valued solving problems as more important than design (C2) and analysis (C7). This provides a future research opportunity to find out why this is the case. While C4 and C5 were also interchanged, within the overall positioning this can be seen as negligible. Therefore, it is possible to conclude that regardless of location, ranking order across the cognitive domain is mostly aligned.

3.2 Psychomotor Domain

Table 3 showcases the average values and rankings for the psychomotor domain. Across the three comparison groups a complete alignment in ranking order was achieved. Some of the items had statistically significantly greater weight but remained consistent in ranking order. This suggests that regardless of location, there is a strong consensus of which objectives in the psychomotor domain are most and least important.

The most important objective being (P1) '*Correctly conduct an experiment on [course equipment/ software name]*' and the least important being (P5) '*interpret sounds, temperature, smells and visual cues to diagnose faults/errors*'. The importance of P1 appears self-explanatory, success comes from carrying out an activity correctly. This is a core outcome of laboratory work.

However, the lack of importance given for troubleshooting is a curious observation. P5 has substantial overlap with cognitive skills and is complementary to items C1-C4. It extends beyond the cognitive by considering the actual practice of using the tools to undertake the fault finding. For example, using and reading the display or hearing a beep of a multimeter on an electrical circuit, or moving a hand over an item to feel that it is heating up.

Much engineering practice revolves around knowing how to fix things. If one knows how to fix things, that demonstrates a full/deep understanding of the operation of equipment/software (highest ranked in the cognitive domain). Previous work [8] has highlighted the importance of fault-finding ability on the student experience and understanding, therefore it is possible to assume that the relationship between the two items should be stronger. This is another avenue for further investigation.

Table 3. Learning Objectives Psychomotor Domain (Averages With 95% Confidence Interval) And Ranking Order

Obj.	International	Australasia	Europe	ANOVA
P1	2.46 (2.19,2.73)	2.52 (2.17,2.88)	2.28 (1.77,2.79)	0.5432
P2H	4.13 (3.78,4.48)	4.04 (3.63,4.44)	4.04 (3.04,5.04)	0.9925
P2S	5.24 (4.93,5.56)	5.21 (4.84,5.59)	5.52 (4.70,6.34)	0.4873
P3	3.02 (2.72,3.33)	2.89 (2.53,3.26)	3.88 (3.02,4.74)	0.0253
P4	5.23 (4.87,5.60)	5.35 (4.90,5.79)	5.04 (4.08,6.00)	0.5634
P5	6.86 (6.56,7.16)	6.79 (6.43,7.15)	6.92 (6.12,7.72)	0.7568
P6H	4.90 (4.55,5.25)	4.88 (4.49,5.28)	5.00 (3.92,6.08)	0.8159
P6S	6.50 (6.15,6.85)	6.73 (6.34,7.13)	5.52 (4.42,6.62)	0.0144
P7	6.65 (6.29,7.01)	6.58 (6.15,7.02)	6.80 (5.80,7.80)	0.6775
Rank				
1	P1	P1	P1	
2	P3	P3	P3	
3	P2H	P2H	P2H	
4	P6H	P6H	P6H	
5	P4	P4	P4	
6	P2S	P2S	P2S	
7	P6S	P6S	P6S	
8	P7	P7	P7	
9	P5	P5	P5	

3.3 Affective Domain

Table 4 showcases the average values and rankings for the affective domain. Across the international and European groups much commonality is shown, noting that the first three items for the Europe group have the same average. The Australasia group differs substantially for this domain. It is of substantial interest to understand why such a large variation occurs. Such differences are not surprising though, during the authors submission of previous papers involving LLOM, the greatest reviewer debate has been on the affective items. Could it be that differences in culture are most present in this domain due to the focus of less technical items? With the larger Australian sample, a future study will need to look at the differences across Australian institutions. Should alignment occur across the affective domain in Australia, this would create an interesting research pathway to investigate further.

It can be observed that (A1) '*work in a team to conduct experiments, diagnose problems and analyse results*' is deemed most important, not surprisingly as much work and focus in recent years has been placed on teamwork throughout the world [9, 10]. All groups placed 'C*onsider ethical issues in laboratory experimentation and communication of discoveries*' (A7) as least important. With ethical laboratory practises uniformly positioned last, this can be concerning, and it does suggest engineers need greater reflection on affective skill development. Is it wise for engineers not to value ethical practice as highly important? What negative consequences can result on the engineering profession if data collection and communication is not been completed ethically? As is implied by Gwynne-Evans, Chetty [11], does ethics need repositioning?

Table 4. Learning Objectives Affective Domain (Averages With 95% Confidence Interval) And Ranking Order

Obj.	International	Australasia	Europe	ANOVA
A1	2.49 (2.21,2.77)	3.00 (3.00,3.00)	3.00 (1.15,4.85)	0.514

4 SUMMARY

Regarding the research question, *how do Australasian and European academics rank laboratory objectives compared to the international community*, this work has found that substantial commonality exists across the cognitive and psychomotor domains. The greatest differences occur in the affective domain. This is not surprising given the attention to cognitive learning and somewhat psychomotor learning found through assessment [4]. Further research will need to investigate why the greatest differences occurred across the affective items. Do the non-technical items integrate with cultural expectations and differences? With topics such as emotional intelligence largely missing from the engineering curriculum, but highly sought after in the workplace [12], it appears greater research, discussion and reflection on the affective items is needed by the engineering academic community. Future work will look at comparisons across disciplines and laboratory modes.

ACKNOWLEDGMENT

ABSTRACT

There have been many advances over the past four or five decades in understanding brain architecture, and how the process of learning aligns with this architecture. One of the more interesting results has been that of John Sweller [1] and his theory of cognitive load. Sweller identifies the task of learning as effecting change in long-term memory. This long-term memory is, in his view, almost limitless. The problem lies in working, or short-term memory, which has a bottleneck of around five items. Any instructional mode which places too many items into working memory will be, at best, inefficient, and at worse, pointless.

It is interesting to note that over the same decades new instructional modes, such as Problem-Based Learning (PBL) have become popular [2]. Sweller, and others such as Paul Kirschner [3], argue that PBL cannot work as advertised, as the student is faced with too high a cognitive load; they can either learn how to solve the problem, or learn the underlying concepts, but not both.

This paper outlines the theoretical background to this issue, and presents an intervention undertaken over the last decade in TU DUBLIN to devise new instructional modes which take account of cognitive load problems, whilst maintaining some of the advantages and benefits of PBL. This intervention initially followed the ideas of Louis Bucciarelli [4] of MIT on open design in Engineering education but was later adjusted to take into account the ideas of Kirschner on minimizing cognitive load in developing problem-solving skills.

1 INTRODUCTION

In March 2017, the president of MIT, L. Rafael Reif, launched a new research initiative into learning, asking the question, 'If we don't know how we learn, how on earth do we know how to teach?' [5] Whilst this is undoubtedly a very noble and worthwhile enterprise, it is, at one level, surprising. Surprising because, for the last five decades, great progress has been made by neuroscientists, educational psychologists and others in understanding the architecture of the human brain, and how that architecture affects human learning.

New innovations over the past few decades, such as Problem Based Learning and other minimally guided instruction methods is perplexing when one considers the weight of psychological evidence against it, particularly the 2006 paper by Kirschner et al arguing against all forms of PBL as they conflict with how the human brain learns [6].

A related goal of much modern teaching is the acquisition of critical thinking and problem-solving skills, much in demand by companies, and hence by governments. Unfortunately, as the American psychologist Daniel Willingham points out, no such skill exists. [7]

Finally, there is the work of Nobel Prize winner, Daniel Kahneman, an Israeli psychologist who studies how decisions are taken. His results suggest, somewhat surprisingly that 95% of decisions are taken automatically, based on experience, and only in a very small number of cases do humans sit down and work it out. [8] This he calls Type I thinking, fast, but not necessarily accurate. The quality of most decision making therefore depends on the domain specific knowledge base of the person, not on their problem-solving abilities, which Kahneman calls Type II, slow, deliberate, but costly for humans in terms of time and energy.

What all this diverse work points to is that both expertise, critical thinking and problem-solving skills all depend on a large domain specific knowledge base. Given those facts, it seems reasonable that teaching should concentrate on building a student's knowledge base and helping them use it in problem solving.

As Frederick Reif points out [9], science has acquired a large body of knowledge over many centuries. Is it reasonable to expect the average student to have the same keen analytical mind as Newton, or Einstein, in discovering that knowledge themselves?

This paper outlines the current knowledge about human memory, and how it actively supports learning. It then gives a brief overview of PBL and outlines the problems identified by a number of educational psychologists in this approach. Finally, it presents an intervention in TU DUBLIN, which has been developed over the past 13 years, that attempts to build an instructional design that reflects what psychologists know about learning.

2 THE PSYCHOLOGY OF MEMORY

If there is one major research finding in the psychology of learning in the past twenty years, it is the role of memory. Long regarded as merely a passive store of information, psychologists now see long-term memory as an active and critical component of problem solving.

The modern theory of human memory derives from the work of Atkinson and Shiffrin in the 1960s [10]. They distinguish between sensory memory, a passive recording of incoming sensory data that runs on a continual loop lasting around 3 seconds. That data is lost unless conscious attention transfers it to the working memory. That data too is lost after 30 s unless the brain rehearses it, a process that transfers it to long-term memory. This is shown in Figure 1 below.

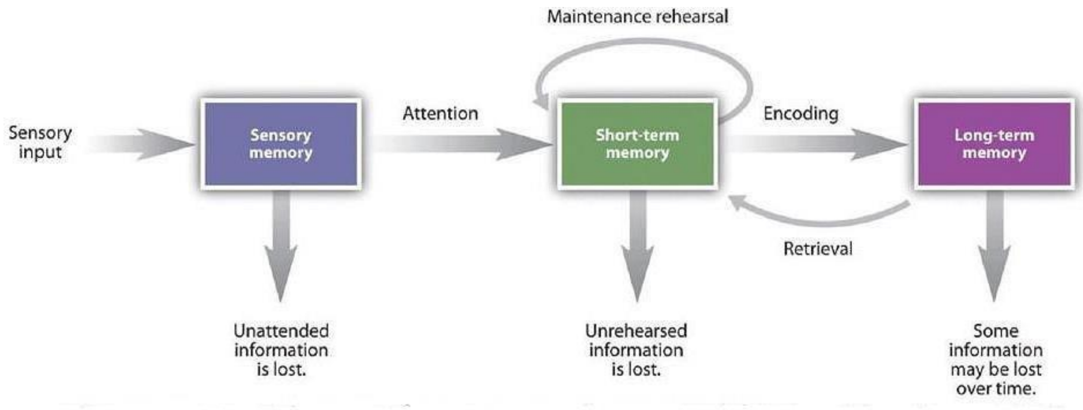

Fig. 1. Atkinson and Shiffer's 1968 Model of Memory [10]

It is clearly crucial that a student pays attention, or else they cannot learn: no transfer occurs from sensory to working memory. This is an area where some misunderstandings can arise. All psychologists studying memory agree that a passive student cannot learn, because attention is an active task. That does not mean that a student cannot learn by listening to a teacher; attentive listening is an active task. It is not necessary for the student to be physically doing something, in order to learn.

The desire to learn comes from humans' innate curiosity about their world. Curiosity is founded upon metacognition, thinking about thinking. The French scientist Stanislaus Dehaene writes: "in order for children to be curious, they must be aware of what they do not yet know. In other words, they must possess metacognitive faculties at an early age. "Metacognition" is cognition over cognition: the set of higher-order cognitive systems that monitor our mental processes." [11]

Sweller develops the theory of how long-term memory acts, by focusing on the work of the Dutch psychologist, de Groot [12] who studied chess grandmasters. "He showed masters and weekend players a board configuration from a real game, removed it after five seconds, and asked them to reproduce the board. Masters could do so with an accuracy rate of about 70% compared with 30% for weekend players."

It is not that chess grandmasters have superior problem-solving skills; rather that they have acquired, over many years (at least ten), a database of chess games, and can recognise the strategic value of a game, whereas the novice cannot. It is the strategic value that they are using to remember the positions of the pieces on the board, not the actual pieces, which are too numerous for short-term memory.

Sweller et al continue: “They tell us that long-term memory, a critical component of human cognitive architecture, is not used to store random, isolated facts but rather to store huge complexes of closely integrated information that results in problem-solving skill. That skill is knowledge domain-specific, not domain-general. An experienced problem solver in any domain has constructed and stored huge numbers of schemas in long-term memory that allow problems in that domain to be categorized according to their solution moves.”

Kirschner, Sweller, Clark in their 2006 paper, ‘Why Minimal Guidance During Instruction Does Not Work’ [13] emphasise the key importance of long-term memory in learning: “It is no longer seen as a passive repository of discrete, isolated fragments of information that permit us to repeat what we have learned. Nor is it seen only as a component of human cognitive architecture that has merely peripheral influence on complex cognitive processes such as thinking and problem solving. Rather, long-term memory is now viewed as the central, dominant structure of human cognition. Everything we see, hear, and think about is critically dependent on and influenced by our long-term memory.

Lord Kelvin famously remarked: “When you can measure what you are speaking about, and express it in numbers, you know something about it; but when you cannot measure it, when you cannot express it in numbers, your knowledge is of a meagre and unsatisfactory kind: it may be the beginning of knowledge, but you have scarcely, in your thoughts, advanced to the stage of science, whatever the matter may be.” [14]

Kirschner et al define learning as: “The aim of all instruction is to alter long-term memory. If nothing has changed in long-term memory, nothing has been learned.” [15]

This is a critical problem for PBL, which assumes that learning occurs when problems are solved. There is no direct way to measure this, and so by Kelvin’s definition, it is not science.

They then tackle the nub of the problem, which is the limitations of working memory when dealing with new information. Those limitations are temporal and physical. Unless new information is rehearsed, and transferred to long-term memory within 30 s, it is lost. Physically, working memory can handle between 4 and 7 new items, and for items that require intensive processing, this may be as low as 2 or 3. Sweller has published [16] on the extreme load that problem solving places on working memory. Kirschner et al point out that: “The consequences of requiring novice learners to search for problem solutions using a limited working memory or the mechanisms by which unguided or minimally guided instruction might facilitate change in long-term memory appear to be routinely ignored." [17]

There have been many responses to the 2006 paper, but none have really answered the Kelvin question: how is successful learning via the minimally guided problem solving being measured?

3 PROBLEM-BASED LEARNING

Many types of student driven, minimally guided learning developed from the 1960s onwards. Perhaps the best known is Problem Based Learning (PBL), in which students work in small groups (8 to 10) to solve unstructured problems. PBL was first developed in medical schools in the 1970s, to provide medical students with more realistic situations that they would encounter in practising medicine. From an early beginning in McMaster's University in Canada, it spread to other medical schools, such as the new University of Maastricht, which became the first university in the world to apply PBL methods across all faculties [18]. It is interesting to note that the development and adoption of PBL in medical programmes grew out of dissatisfaction with the clinical skills of new graduates.

The 1990s saw PBL being applied to other university disciplines, and even to second-level education (K-12). In his chapter on PBL in the 2007 *Handbook of Research on Educational Communications and Technology*, Woei Hung, stated that a key assumption of PBL is that when we "solve the many problems we face everyday, learning occurs". Educational psychologists such as John Sweller would profoundly disagree. For them, learning occurs only when there is a change in a person's long-term memory. When a problem is solved during PBL, there may be no change in a person's long-term memory, because the students may have hit upon the solution by random chance, as they poured over search engines. [19] Hung goes on to say that, "PBL proponents assume the primacy of problems in learning; that is, learning is initiated by an authentic, ill-structured problem". Notice the crucial word in that sentence: 'assume'. There is no evidence produced for it.

He then goes on to say: "Problem-based learning is based on constructivist assumptions about learning, such as:

- Knowledge is individually constructed and socially co-constructed from interactions with the environment; knowledge cannot be transmitted.
- There are necessarily multiple perspectives related to every phenomenon.
- Meaning and thinking are distributed among the culture and community in which we exist and the tools that we use.
- Knowledge is anchored in and indexed by relevant contexts."

The constructivist perspective, as outlined by Chan et al [20] is that: "Constructivism is a view of learning that knowledge is not a thing that can be simply given by a teacher at the front of the classroom to students at their desks. Rather, knowledge is constructed by learners through an active, mental process of development and learners are the builders and creators of meaning and knowledge. The constructivist conception uses student-centred teaching strategies because this type of learning will help students develop critical thinking and collaboration skills and learning takes place in environments where students are able to participate actively".

The constructivist position that knowledge must be actively constructed by students, or else it doesn't exist, is problematical for scientists and engineers. It may be of limited validity in the social sciences but is simply not appropriate in science and engineering. To return to Reif, science is a highly complex enterprise, created by the best minds of the time; it is not possible for the average student to construct such knowledge ab initio. However, it is easy to see from this definition the appeal of PBL based on constructivist principles in medical education. Knowledge per se is useless for doctors if they cannot apply it in a clinical context.

4 TU DUBLIN INTERVENTION

In 2009, Larry Bucciarelli of MIT [21] spent a semester in TU DUBLIN (or DIT as it then was).

This was the beginning of the attempt to introduce open design problems in the Mechanical Engineering programme. The initial results of this intervention were presented at REES 2015, held in DIT, Dublin. [22] During REES 2015, Professor Ference Marton, of the University of Gothenburg, Sweden, gave valuable feedback, making the suggestion that pre and post tests used to evaluate student learning, should be conceptual, rather than the standard numerical problems then in use. This was done in subsequent years, and the initial results presented at the Portuguese Society for Engineering Education (CISPEE) conference in 2018 [23].

The results from that paper were encouraging:

Over the two sessions, pre and post the open design exercise, the mean scores for the concept questions were 20.61 and 23.98.

There is a significant difference ($p = 0.0402$) between the students' conceptual understanding at the end of the exercise than at the beginning; in other words, the null hypothesis, that the two means are similar, is rejected at the 95% Confidence Interval.

The student t-test results for the 41 pairs involved showed similar results, i.e. at a 1% Confidence Interval and a one-tailed test, the result was significant, with a p-value of 0.006457.

The intervention with a single cohort of TU Dublin Mechanical Engineering students is limited, and with a relatively small number (41), difficult to generalize. None the less, it does show that a modest intervention, not requiring major changes to the curriculum or to the module delivery, can have measurable effects in improving student learning.

In 2020, the Coronavirus pandemic forced teaching to go online in TU DUBLIN, as elsewhere. To help students engage with the material in an active manner, the idea of using Mind Maps as a Continual Assessment (CA) tool was introduced. Mind

Maps are a method to make learning active and to aid retention of knowledge in long-term memory. They were popularized in the 1970s by psychologist Tony Buzan. [24] Mind Maps draw out the relationships between concepts, making the overall structure clear, in a visual manner. They require the student to actively engage with the material, and also to apply judgement as to what things are important (metacognition).

5 SUMMARY

PBL is based on a constructivist philosophy of knowledge, which is not compatible with science. It is also based on a flawed understanding as to what is meant by active v passive in learning. PBL can be passive, if someone is not engaged, traditional lectures can be active, if students are motivated and attentive, and taking notes intelligently.

Changes in long-term memory define learning, not problem solving. Active attention is the only way in which learning can occur, and this relies heavily on a student's intrinsic motivation. Millions of years of evolution have made humans curious, and anxious to learn. This should be exploited by educators.

The clash of scientific instruction with constructivism lies in science's foundation with Aristotle's empiricism. There is another aspect of Aristotle, his ethics, which should also be borne in mind by all educators. In his Nicomachean Ethics [25], Aristotle talks of the importance of the Golden Mean, a position between extremes. Too much courage is recklessness, too little, cowardice. Traditional instruction, where a teacher dispenses knowledge to students, who passively acquire it (or perhaps, not), is not a very effective method of teaching. Neither is its opposite extreme, active learning with no (or very little) guidance.

The Golden Mean for teaching and learning is surely to do both, provide instruction and guidance to the novice to build up expertise, and also to provide open-ended problem-solving opportunities to develop their skills. This is how doctoral programmes work, where students are guided by an expert supervisor. Only as a post-doc, does the successful student can engage in their own unsupervised research. At that point, they have completed the transition from novice to expert.

Constructivism began with the work of the Swiss psychologist, Jean Piaget, whose theories of how children develop centered around the idea of the child construction and testing ideas, mainly through the medium of play in the early years. A century later, the French neuroscientist, Stanislas Dehaene [26] suggests that the child acts much like a scientist, being genetically hard-wired to create and test hypotheses, and having an innate understanding from birth of both numbers and probability. Dehaene prefers to define humans as *homo docens*, as the key difference between humans and the rest of the animal kingdom is the ability to learn. It is an educational tragedy, according to Dehaene, that in the last thirty years research has "elucidated the algorithms that our brain uses; the circuits involved, the factors that modulate their efficacy, and the reasons why they are uniquely efficient in humans", but educators are unaware of this work, and so are not applying it. Dehaene identifies four key components to learning: "focused attention, active engagement, error feedback, and a cycle of daily rehearsal and nightly consolidation" [27]

Memory is critical here: nothing will move from sensory to working memory, or from working to long-term memory unless the learner is paying attention and is actively engaged in the task. It doesn't really matter what kind of instructional design is being used, as students can be using their smartphones to check social media in a traditional lecture or in a PBL group session. 'Active' is in the mind of the student, not in the structure of the lesson.

There is no need for a complete revolution from traditional teaching to PBL or any other radical implementation of active learning. It is possible, as has been done in TU Dublin, of building gradually, reflecting the latest research into learning. This suggests seven steps:

1. Teach students the basic facts, e.g., the gas laws.
2. Take them through worked examples.
3. Get them to tackle traditional closed problems.
4. Get them to create Mind Maps for the topic (metacognition)
5. Give them an open-ended problem to tackle on their own or in groups.
6. Give them conceptual tests on the topic before and after the open exercise to test its effectiveness.
7. Give them good feedback, so they can improve.

Students are results focussed, and that often means a final exam. Daniel Willingham asks his students not to revise by looking over notes [28], but to create new notes from memory, and then compare them to the original notes. It would be even better to get students to draw new Mind Maps as they revise, and then compare them to the originals. This reinforces learning, and as students compare the two, they are made aware of errors. And error correction is, as Dehaene emphasises, one of the keys to successful learning [29].

In fact, he goes as far as saying: "Organisms only learn when events violate their expectations." The learner as scientist continually updates their mental model of the world when outcomes are not as expected. Dehaene believes one of the most important roles of the teacher is to provide good, non-judgemental feedback to the student as quickly as possible.

Education is not about traditional or modern; it is about both. All innovations in teaching and learning must be founded upon research findings, especially neuroscientific and psychological findings into how the brain, and especially the memory, works. New research does not mean throwing away all traditional methods. It is all about the Golden Mean.

ABSTRACT

Through the project "Technology Education of the Future" (FTS), NTNU has developed a framework for re-design of its study programmes in technology and engineering. One of the main findings is the need for a broader, more multidimensional view of graduate competence, showcasing the need to fully integrate training of several important non-technical professional skills in future programmes. To enable such integration, student-active pedagogical methods in combination with integrated learning principles are often seen as key tools. This paper quantitatively investigates to what extent study programmes' facilitation of active student participation actually makes a difference to perceived learning outcomes across a variety of competence areas. The research question under consideration is *"How does the extent of student-active learning in engineering programmes influence students' perceived learning outcomes?"* Using statistical analysis of data from a national student survey, correlation was investigated between students' perception of how well active student participation is facilitated by the teaching in their study programmes, and their self-evaluated learning outcomes in 10 different competence areas. Regression analysis was done based directly on individual student responses and on responses averaged over study programmes. The results show statistically significant positive correlation for most competence

[1] *Corresponding Author Geir Egil Dahle Øien, geir.oien@ntnu.no*

doi:10.5821/conference-9788412322262.1263

areas. Students' perception of how well their programmes facilitate active student participation is found in good agreement with actual known programme characteristics. The results thus provide quantitative indication that improving facilitation of student-active learning in engineering programmes indeed improves learning outcomes for a broad set of future-relevant competence areas.

1 INTRODUCTION

1.1 Background and context

In August 2019, NTNU launched a project (FTS) for renewal of the university's programme portfolio within engineering and technology, with an ambition to *"promote a new generation of engineering and technology education which is updated in all areas according to international development and society's needs."* Initially FTS reviewed international trends and global best practices in technology and engineering education, as a starting point for SWOT analysis [1] and subsequent quality development in the FTS programme portfolio [2, 3]. This initial phase consisted of an outside-world analysis focusing on future global and national needs, major technology trends, and recent and expected developments in the higher education sector. Insights from this analysis were subsequently "triangulated" with input from faculty and students, advice from Nordic educational experts, and official university statistics, strategies and policies. Based on this foundation FTS subsequently created a set of overarching objectives for the future FTS programme portfolio consisting of a *vision*, a set of *principles,* and *competence profiles.* Finally FTS developed a *roadmap for implementation*, documented in [3, 4].

FTS identified some significant gaps between the status quo and international state-of-the-art in NTNU's engineering and technology portfolio at large, [1], e.g. widespread use of traditional lecture-based pedagogical practices, lack of integrated learning and coordination across courses, and too little emphasis on important '21st century' competences. It is however known that there are significant differences between programmes: Among the 5-year integrated technology master programmes, *Electronic System Design and Engineering (MTELSYS)* and *Industrial Design Engineering (MTDESIG)* in particular stand out positively wrt. student-active and experiential learning: Student-active learning and contextual learning are combined e.g. in an integrated set of courses in the first two MTELSYS years, focusing on conceive-design-implement projects, real-world problems, flipped classroom, campus spaces for student-active learning and peer-learning, and peer assessment and feedback. Peer assessment and team teaching are also prominent elements in MTDESIG, students being taught in dedicated studios and in-house workshops.

1.2 The national portal 'Studiebarometeret'

Among the most important data sources used in FTS' SWOT analysis [1] was *Studiebarometeret*, a national portal initiated by the Norwegian Ministry of Education and Research (KD) in 2014, and conducted by NOKUT (the Norwegian Agency for Quality Assurance in Education), an independent expert body under KD. Each

February, the portal presents results from an annual, extensive *student survey* sent to more than 70 000 2nd and 5th year students in around 1800 programmes nationwide [5]. Students are asked how they perceive many aspects of educational quality in their study programmes, for the purpose of strenghtening quality work in higher education and give education institutions, authorities, students and potential applicants useful information about educational quality and development over time.

Data from Studiebarometeret were used in several ways in FTS' SWOT analysis: For example, to analyze *overall student satisfaction, student workload, facilitation of active student participation, feedback from academic staff and fellow students, and perceived learning outcomes* for different types of programmes in the FTS portfolio.

1.3 Motivation for the present study

The focus of this paper is statistical analysis of data from *Studiebarometeret* to investigate *correlation* between *students' perceived degree of active student participation facilitated by their study programmes*, and their *self-evaluated learning outcome for 10 different competence areas.* The research question under consideration is: *"How does the extent of student-active learning in engineering programmes influence students' perceived learning outcomes?"* This is relevant because student-active pedagogical methods in combination with *integrated learning principles* are often promoted by educational developers and scholars of teaching and learning as key tools to achieve deeper learning and efficient integration of important professional skills into graduates' competence profiles (see e.g. [6]). *The CDIO Community*'s Standard 8, *Teaching and learning based on active and experiential learning methods*, states [7]: "*Active learning methods engage students directly in thinking and problem-solving activities. There is less emphasis on passive transmission of information, and more on engaging students manipulating, analyzing, evaluating and applying ideas.*"

At the same time, one sometimes sees a reluctance or scepticism among university faculty when it comes to making the move from traditional 'one-way' lecture-based pedagogy (often with an emphasis on theoretical aspects) to active and experiential methods as described above. Among the arguments heard against such a move are that it de-emphasizes the importance of theoretical knowledge and thus might threaten students' academic knowledge foundation; it is expensive and difficult to scale up to large classes; faculty are not trained in such methods and therefore do not know how to use them efficiently - thus the change might not work as intended.

The motivation for the investigation is to contribute to the understanding of *what the actual impact of student-active teaching methods is in the current FTS portfolio* - by seeing if it is possible to find a systematic coupling between students' self-assessment of their learning, and their perception of how well their programmes facilitate active student participation. The hypothesis is that a *positive* such coupling exists in a statistical sense, i.e. that *better facilitation of active student participation in study programmes on the average contributes to better learning among students*. If such a statistical coupling can be quantitatively demonstrated to be significant, it might serve as motivation for more programmes and courses to move quicker to a stronger emphasis on student-active learning, and for faculties and departments to invest more in competence development and infrastructure to enable the move.

2 METHODOLOGY

2.1 Student survey questions under consideration

In one section of Studiebarometeret's student survey, students are asked to assess their *Own learning outcome* so far, by answering the following question Q1 for the competence areas C1 – C10 in Table 1: *How satisfied are you with your own learning outcomes so far, concerning …*

Table 1: The 10 graduate competence areas investigated in Studiebarometeret.

C1	Experience with research and development work
C2	Discipline- or profession-specific skills
C3	Knowledge of scientific work methods and research
C4	Oral communication skills
C5	Critical thinking and reflection
C6	Cooperative skills
C7	Ability to work independently
C8	Written communication skills
C9	Innovative thinking
C10	Theoretical knowledge

In the survey's *Teaching* section students are asked how they agree with the following statement S1: *The teaching is organised so as to facilitate active student participation*. Answers are given on a 1 (Do not agree) to 5 (Completely agree) scale.

2.2 Statistical analysis – data and methodology

The data applied in the analysis in this paper are based on "NOKUT National Student Survey 2021, Subject Groups", financed by KD. The data are provided by NOKUT, and prepared and made available by the NSD (Norwegian Centre for Research Data). Neither NOKUT, KD nor NSD are responsible for the analyses/interpretation of the data presented here. Due to space limitations, the focus is only on data from NTNU's 17 5-year integrated Master of Science in Technology (*siv. ing.*) programmes [8]. Student responses are collected from the 2nd and 5th year of study, based on survey data from all years 2018 – 2021. The statistical significance of the relationship between learning outcomes and active student participation is tested by *regression analysis* [9]. Outcome is regressed on reported level of activity, year of survey, and overall satisfaction with study programme and year of study, for 4 underlying data distribution models:

A. Learning outcome is treated as a *cardinal variable* (underlying continuous distribution, discrete levels 1 – 5 uniformly spaced), and separate effects are estimated for different levels of active participation. Such effects are estimated with a reference category, in this case the lowest level of activity.

B. Both learning outcome and the measure of active student participation are modelled as *binary variables*, i.e., the original 5-point scales are quantized to binary scales. Values 4 and 5 are quantized to '1', values 1, 2 and 3 to '0'.
C. The learning outcome responses are modelled as binary as in B, but separate effects are estimated for different levels of active participation.
D. Like B, but the learning outcome variable is in its original ordinal form, estimated by *ordered probit* [9].

3 RESULTS AND DISCUSSION

3.1 Results from data analysis

All regression models A-D above support a statistically significant relationship between students' self-evaluated learning outcomes and their perception of study programmes' facilitation of active student participation. This indicates that the trends and conclusions presented in this section are robust wrt. varying model assumptions.

Initially, results are presented from all 17 study programmes. In Fig. 1 the following competence areas, all important '21st Century Skills', are considered: C6 *Cooperative skills*, C5 *Critical thinking and reflection*, C9 *Innovative thinking*, and C4 *Oral communication skills*. For each of these, individual programme data points are shown, each point averaged over all individual responses to statement S1 (x-coordinate) and answers to question Q1 (y-coordinate) from students within a study programme. *Best linear fits* to these points are also shown. Stronger correlation between x- and y-axis data corresponds to a *larger rate of change* (RoC) in the linear fits (positive RoC for positive correlation, negative for negative correlation). Note that the two programmes scoring highest on facilitation of active student participation are the MTELSYS and MTDESIG programmes (cf. Section 1.1).

Fig. 2 collects the best linear fits to the programme-averaged data points for *all* competence areas C1 – C10 in Table 1, plus a curve for the average over all the areas. For clarity, individual programme data points are excluded in this figure.

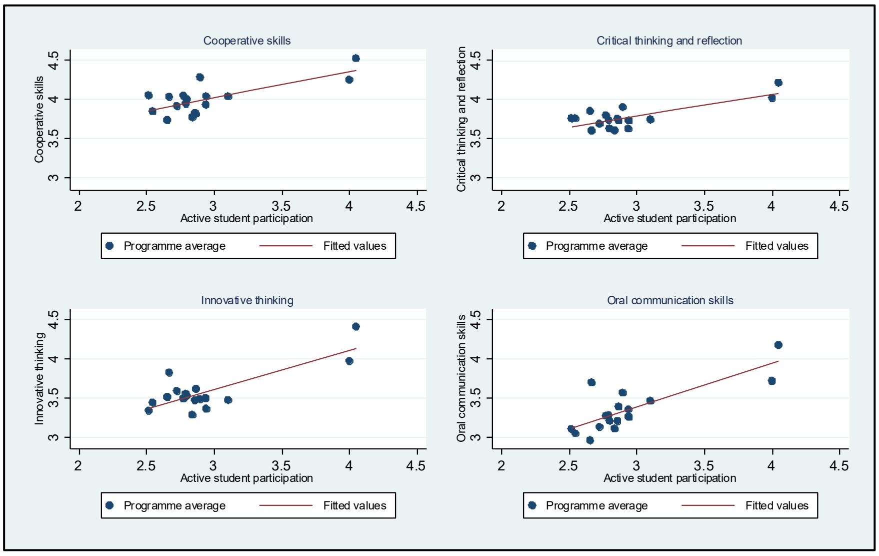

Figure 1: Individual programme data points and linear fits for Cooperative skills, Critical thinking and reflection, Innovative thinking, Oral communication skills. All programmes.

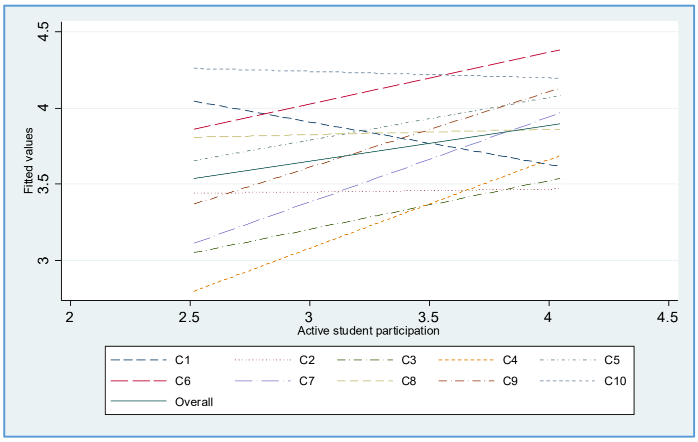

Figure 2 Best linear fits to study programme data for all competence areas. All programmes.

When including data from all 17 master programmes under study as in Fig. 1 and 2, the results show, for most competence areas, a statistically significant positive correlation between students' self-assessed learning outcome and their perception of how well their study programme facilitates active student participation. This is interpreted to indicate the importance of emphasizing student-active learning when designing study programmes with intended learning outcomes reflecting this range of graduate competences. However, the negative trend for competence area C10 Theoretical knowledge in Fig. 2 is potentially worrying: It seems to indicate that strengthening of competence areas C1 – C9 may come at the expense of less deep theoretical knowledge, thus supporting some of the faculty scepticism mentioned in Section 1.3. Upon investigation one however sees that the effect is isolated to only one of the 17 programmes: MTDESIG, whose data point is the lowermost of the two data points with highest x-axis score in Fig. 3 (the other one belongs to MTELSYS).

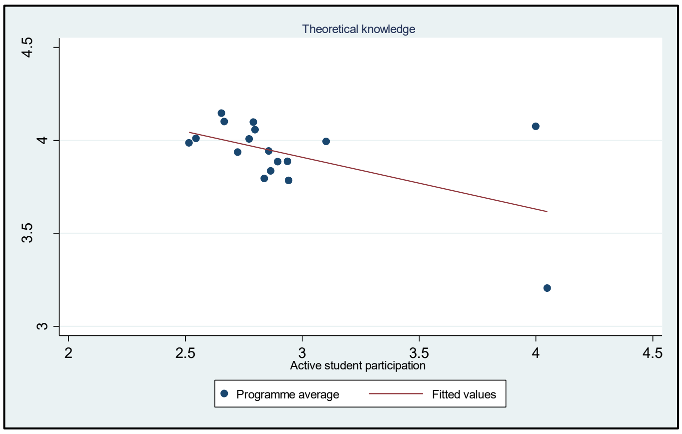

Figure 3 Individual programme data points with linear fit, Theoretical knowledge. All programmes.

Although its students are given a similar theoretical fundament during the first two years as those of the other programmes, MTDESIG as a whole is significantly more oriented towards design and aesthetic aspects, and less towards engineering identity, advanced technology development, and mathematical modeling, than the other programmes. One might therefore argue that a more fair and relevant analysis of 'typical' engineering programmes is actually achieved by excluding MTDESIG data. Fig. 4 present the same results as Fig. 1, but with MTDESIG data excluded.

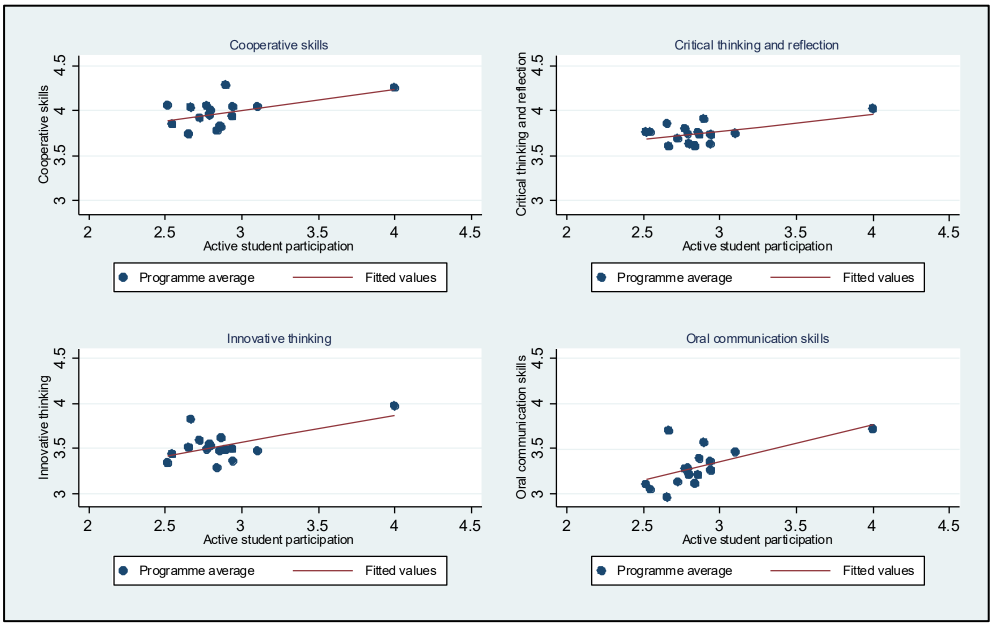

Figure 4: Individual programme data points and linear fits for Cooperative skills, Critical thinking and reflection, Innovative thinking, Oral communication skills. MTDESIG excluded.

When excluding MTDESIG one can no longer see a negative effect on competence area C10: Students' theoretical knowledge now appears not to be influenced at all by the level of active student participation (Fig. 5). The same holds for C1 *Experience with research and development work.* For C2 – C9 correlation is positive (Fig. 6).

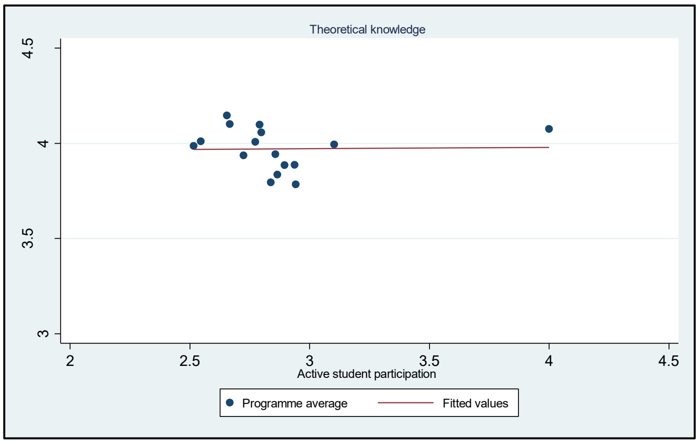

Figure 5 Individual programme data points with linear fit, Theoretical knowledge. MTDESIG excluded.

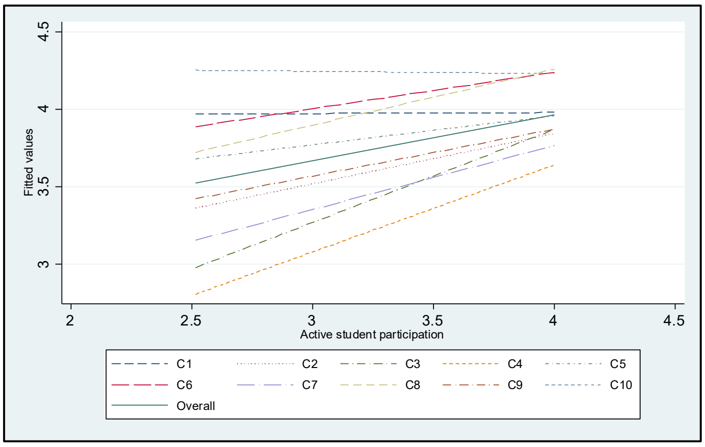

Figure 6 Best linear fits to study programme data for all competence areas. MTDESIG excluded.

3.2 Concluding remarks

One might ask: To what extent can one actually trust students' individual self-evaluation of their learning outcomes, and their perception of how well their study programmes facilitate student participation – i.e., how close are their judgments to actual fact? The answer to this question seems strongly linked to another important engineering competence: *Evaluative judgment* – '*the capability to make decisions about the quality of work of oneself and others*' [9]. The better universities are at developing this competence in students, the more one can probably trust their responses in studies such as this to be in line with actual fact. The authors of this paper acknowledge that as long as there is uncertainty or lack of knowledge about students' evaluative judgment ability, the results should be interpreted with caution, i.e., be treated as indications, not proof, of positive impact of student-active pedagogy in engineering programmes (also, statistical correlation is of course not synonymous with statistical dependency). Nonetheless, results seem to be well in line with recommendations based on state-of-the art research on learning [6].

As mentioned earlier, factual knowledge regarding the characteristics of the programmes under study may be used to gauge how students' perception agree with reality, when it comes to the programmes' facilitation of active student participation. The consistent scoring of the MTELSYS and MTDESIG programmes' teaching as the best in facilitating active student participation is in full agreement with known facts about those two programmes relative to the other 15 programmes under study (again, see Section 1.1). The fact that the other 15 programmes come across as more closely clustered around a narrower range on the x-axis is also in agreement with the fact that these programmes share many similarities in terms of overall structure, common basic and supporting courses, and pedagogical traditions and practice. Thus students' perception of their programmes' facilitation of active student participation seems to be in good agreement with known programme characteristics.

To gauge the reliability of students' *self-assessment of their learning outcomes*, one could e.g. analyse students' grades to check if the systematic differences between programmes are reflected there. However, this has not been done in this study. Also, results from such an analysis might not be so relevant or easy to interpret in practice, since the assessment methods used at present (with final written exams focusing on theoretical knowledge still the most common assessment method) are not necessarily well adapted to evaluation of all competence areas discussed here.

In conclusion, we believe that our results do provide a quantitative indication that

- More emphasis on student-active teaching methods in engineering programmes may indeed improve students' learning of a broad set of future-relevant engineering competences, and that
- it is possible to achieve this without weakening graduates' theoretical knowledge.

ABSTRACT

Students in engineering-science programmes often struggle with theoretical concepts, while they tend to adopt a surface approach to learning. We suggest that this can be tackled by promoting a specific higher-order thinking skill (HOTS) that enables drawing connections between physical phenomena and theoretical concepts representing them. We designed an intervention to support students in achieving deep insight into electrochemical phenomena, while developing this HOTS. Such intervention aims to scaffold students' learning and development by introducing conceptual modelling as an essential thinking skill of engineering-scientists, and as a strategy to build scientific understanding of natural phenomena. Therefore, conceptual modelling constitutes a main learning objective of this novel course. This paper reports an empirical investigation into how students deal with concepts and complexity, and to what extent the intervention has any measurable effects on the learning outcomes. This phenomenological investigation integrates considerations from various disciplines, and relies on multiple data sources, i.e., students' documents (lab journals and reports), observations of students in action (in discussions with their tutors and while performing lab experiments), and video stimulated-recall interviews. The results show little effect of the intervention, as implemented, suggesting how challenging it is for students (and instructors) to shift from traditional learning-and-teaching approaches, towards an epistemology of knowledge construction for specific problems. The findings are informative for revision of the intervention and generate specific recommendations. Concurrently, our operationalisation of the conceptual framework proves powerful in detecting qualitative differences in HOTS. Plausible implications for research and educational practice in science-engineering education are discussed.

1 INTRODUCTION

1.1 Background, building blocks and overview

Electrochemistry is an essential scientific and practical domain within Chemical Science Engineering (CSE) [1]. Concurrently, students often struggle with conceptual aspects [2] , and many adopt a surface approach to learning [3].

An action research [4] project was conducted to design and implement a pedagogical intervention aiming to support students in achieving deep insight into electrochemical phenomena, while developing higher-order thinking skills [2]. This new 'thinking as a scientific researcher' course[2] taps on inquiry-based learning (IBL) principles [5], while approaching the teaching of thinking in an explicit and content-related fashion, according to a mixed general-infusion approach [6]. Importantly,

[2] The laboratory experience is used as a means of discovery and new theorisation, rather than to confirm given theories empirically (as more traditional lab courses often do). In short, the aim is to promote a different epistemology concerning the role and contribution of science to problem-solving, that is not commonly conveyed in engineering education.

students' learning and development was scaffolded by conceptual modelling [7,8], as a strategy for conducting scientific research that seeks to promote the understanding of natural phenomena. Conceptual modelling is considered an essential reasoning ability of (engineering) scientists and is a chief learning objective of this new course [2]. It is proposed that the conceptual modelling skill can assist students in understanding and theorising (electrochemical) phenomena, so that they will be able to creatively think about such phenomena in new technological problem-solving contexts.

Our empirical educational research witnessed the implementation of this intervention [2]. This phenomenological investigation sought to explore (RQ1) how students learn electrochemistry under the intervention as implemented and in terms of indicators of progress in reasoning, to describe (RQ2) in what ways the student learning is embedded in the learning environment, and to evaluate (RQ3) to what extent the intervention has any measurable effect on the learning outcomes.

This interdisciplinary project, including the instructional design of the course and the educational research design, integrates considerations from Chemical Science, Philosophy of Science in Practice, and Education Sciences. This empirical paper builds on our conceptual work [2], where we elaborate on the relevance of electrochemistry in engineering-science education, and we present an overarching methodological and theoretical framework, as well as a a thorough description of the pedagogical intervention. The present contribution further introduces our analytical framework, which is based on levels of complexity [9] and on recurrent difficulties [10].

1.2 Levels of complexity

In line with our theoretical framework [2], we are interested in qualitative differences in learning; these are best observed in connection to the content, and in both the process and the outcomes of learning [11]. The 'levels of complexity' framework [9] appears appropriate as analytic tool because it takes a situated cognition perspective on learning and cognitive development (which aligns with the IBL approach), and it is developed within a comparable empirical context.

The original framework proposes 8 categories denoting increasing complexity. The first category group refers to 'objects' the students use in the laboratory, their aspects, and their properties[3]. The second category group refers to covariations of aspects and properties of objects and materials[4]. First, we had to grasp in what ways one category is more complex than the preceding one and what it takes to move from one category level to the next. Our reading is that growing complexity means

[3] During the operationalisation of Wenzel's original framework, we broadened 'objects' to include any materials (e.g., electrolytes, salts, buffer solutions) and added a crucial feature, i.e., their purpose. These modifications emerged during our initial data analysis and, therefore, they are part of our research findings (which were engaged in the fine tuning of the analytical tool).

[4] These (co)variations, we add, are not just present or absent. They can be accompanied by a qualifier indicating an effect size and a description of the conditions for the covariation to occur

increasing generalisation, systematisation, acknowledgement of what is contingent and what is stable, connectivity of associations, and covariation (not causality). Finally, we operationalised those categories into an analytic tool that resonates with our particular empirical context. A summary is presented in the methods section.

1.3 Recurrent difficulties

Prior research on teaching and learning Electrochemistry [10] proposes a set of known recurrent difficulties (KRD) experienced by students and teachers. Such KRD are rote application of concepts and algorithms, use of multiple definitions/meanings (from different contexts[5]), use of multiple or hybrid models, wrong interpretations of language, too early connection of labels to meaning, and misleading analogy. To this list, we added 'attribution' to consider groundless or wrong attribution of effect (e.g., causality, mediation, interaction, contribution), as often observed in our experience. These KRD allow one to think about the plausible cause of difficulties, for which knowledge of the disciplinary content involved is required.

2 METHODOLOGY

The research methodology is phenomenological, i.e., interested in the subjects' experiences, next to their performances. Therefore, in seeking methodological consistency [4], we choose to use qualitative methods of data collection and analysis. The project has three educational research purposes (i.e., to explore, to describe, and to evaluate) which were translated into distinctive research questions, as presented in Section 1.1.

2.1 Empirical context

The new lab course consisted of 5 practicums, each to understand a particular electrochemical phenomenon, while addressing an electrochemical question. The students worked in groups of 3 and their learning process was facilitated by learning assistants (LAs). In the preparatory and reflective work around each practicum, the conceptual modelling activity was supported by the B&K method [7], as a cognitive scaffold for the learning and persistent use of conceptual modelling as a conducive scientific way of reasoning. The sustained and effective use of this scaffold was taken as an indicator of the attained level of cognitive skill development [2].

2.2 Data collection

For this study, we selected practicum 2 (about a specific electrochemical cell) and practicum 5 (about cyclic voltammetry) for being particularly challenging, distributed

[5] Based on a historical analysis on 'electrochemical concepts and their meaning in context', i.e., the phenomenological, the particulate, the measurement, and the thermodynamic contexts. This analysis is not to fragmentate what the Conceptual Modelling approach aims to unite (by organising it coherently), but to understand the epistemological difficulty and complexity that electrochemistry represents for students, teachers, and researchers.

in time, and integrative. For additional details on the content and objectives of these practicums, see our conceptual paper [2].

Twenty students (out of 45) consented to participate in this investigation, among whom 8 also accepted to be interviewed. Their data was considered at an individual level. Furthermore, all students had been grouped into 15 work groups of 3. This distribution resulted into 2 full participating groups, whose data was analysed in an aggregated fashion, according to a case study design [12].

The multiple sources of data were (i) documents, i.e., intermediate, and final lab journals, and group reports, (ii) video recordings and transcripts of observed meetings among students and their LAs, (iii) video recordings of students while performing their lab experiments, and (iv) audio recordings and transcripts of video stimulated-recall interviews. The pieces of data were matched to individual students and to groups, allowing for triangulation of the findings.

2.3 Data analysis

In line with the phenomenological approach to research, we were interested in the data that captures subjects' experiences, and further in how various sources of data speak to each other. A case-study logic[6] was used, seeking validity in terms of the depth and robustness of the analytical work [12,13] .

The usable data was prioritised according to availability and richness criteria. The thematic coding[7] relied on the categories in Table 1. After open, axial, and selective coding of the data sources by project group (2 cases), we integrated further pieces by student (8 individual subjects) until we estimated that data saturation had been reached.

Table 1. Summary of the operationalised 'levels of complexity'

Levels	**Description**
Objects	construction of stable figure-ground distinctions
Aspects	links between objects and/or identification of specific features
Properties	construction of classes of objects, based on common/different aspects
Purpose	the intended purpose, function or use of objects and other materials
Variations	changes relating two or more aspects/properties of objects/materials
Operations	systematic variation of objects according to their aspects
Events	links between some stable properties of the same/different classes of

[6] A case-study logic contrasts to a sampling logic, i.e., rather than seeking statistical representativeness, the validity of the conclusions resides in the quality of the analysis, which seek explanatory connections and theoretical replication until data saturation.

[7] To some extent, coding the data according to these categories was interpretative. Often the attribution of a character (e.g., specificity/generality, contingency/stability, concreteness/abstraction, or disorder/organisation) to variations had not been made explicit by the subjects and required a reading of latent meanings (which was supported by the conversational context and/or warrants from the same subject in another data source).

	objects
Programmes	systematic variation of a property according to other stable properties
Principles	construction of stable co-variations of pairs of properties for classes of contexts
Connections	links between several principles with the same/different variable properties
Networks	systematic variation of a principle according to other principles
Systems	construction of stable networks of variable principles

3 RESULTS

3.1 Levels of complexity

Students ’skip’ several levels (e.g., passage from *aspects* to *events*), i.e., rather than 'true discovery', the students appealed to prior knowledge or by-pass the instructional sequence by searching on the Internet. Also, there was much centrality of *objects and materials*, even more than the phenomenon under study (which was often not made explicit). Moreover, students’ reasoning and comprehension seems to benefit when they consider the *purpose* or function of the materials in the experimental setup; they often did this spontaneously, while several difficulties appear to stem from unclear purposes. Furthermore, the students often played attention to *aspects of covariations*, mainly in terms of quality and quantity (e.g., an effect is stronger, a reaction is slower). Causality or directionality were only denoted.

In all, the students seldom went beyond the level of *events*. No measurable[8] growth over time was observed (neither within each experiment, nor between experiments), i.e., students seem to stagnate at a relatively low level.

3.2 Recurrent difficulties

The biggest category is the *rote application of concepts and algorithms*, which seems to give students a false sense of understanding. Indeed, they often used concepts without grasping any meaning, e.g., ‘the salt bridge is used to maintain electroneutrality’. Also, some tended to use algorithms and equations (while neither grasping their basis nor implications) to replace the explanation of a phenomenon, rather than to substantiate it. Their language and reasoning showed a strong tendency to ‘apply’, ‘confirm’, and ‘satisfy’ equations.

We observed quite some use of *hybrid models*, e.g., “the slope is constant and at some point, it starts changing again […] that's where the actual reaction starts happening again”; which denotes an unnoticed mix of explanatory routes. Further, the groundless or wrong *attribution* of effect (e.g., causality, mediation, interaction, contribution) appear to be connected to the rote application of equations, e.g.,

[8] Alternative research methods could be more sensitive and reveal some measurable growth that escaped from this investigation.

"increasing the concentration of reductor results in a lower voltage *because* the concentration is in the denominator of the Nernst equation".

Instances of *too early labelling* (i.e., too early connection of labels to meaning) were observed a few times. E.g., using the terms 'cathode' and 'anode' without understanding what happens at each electrode, as if the very name would convey some meaning. Instances of *misinterpreted language* were infrequent, though observable, e.g.., 'scanning' was understood as 'monitoring, measuring, reading', while 'scanning' in voltammetry is used to denote the deliberate variation of a potential difference at a constant rate. Such misinterpretation has significant consequences on the students' interpretation of the kind of variables, the objective of the experiment, and their very role as engineering-scientists.

Few instances of *mixed meanings* (i.e., simultaneous use of multiple definitions) were observed. No instances of *misleading analogy* were identified.

3.3 Other qualitative differences in terms of content

We captured (evolving) conceptions of the task, as students acknowledged aspects of the task in conversation with the LAs. On the one hand, the students seemed initially concerned about not grasping what was expected from them and about the complexity of the task; on the other hand, they tended to reduce complexity in some (inappropriate) way.

3.4 Use of conceptual modelling

The B&K method was insufficiently used (either implicitely or explicitly). Basically, we found lack of identification of the phenomenon of interest, and vagueness about the epistemic purpose of the conceptual model. In general, there is lack of prediction or hypothesis. Moreover, variables are often mentioned, but (almost) invariably in terms of their measurability (i.e., at the expense of the distinction between manipulated and controlled variables). These findings are likely to be connected to each other. The students often behaved as passive observers of variables that can only be measured, without acknowledging the possibilities to 'play', intervene, manipulate, so to produce a change that they may wish to predict, test, and describe or explain.

4 DISCUSSION AND CONCLUSIONS

To address RQ1 is to explore how students learn electrochemistry under the intervention as implemented and in terms of indicators of progress in reasoning. Although the implementation of the conceptual modelling approach [7,8] seems not to have reached its full power, the findings are certainly informative. They suggest that students (and instructors) still struggle with shifts from traditional epistemologies, and from traditional learning-and-teaching approaches. On the other hand, students do not necessarily have to comply with the 'levels of complexity' [9] framework, i.e., it is desirable that they reach higher levels regardless of the path they follow. Rather than attempting to force the students into certain steps, instructional designers and educational researchers could analyse the shortcuts students take and plausibly adopt them (i.e., capitalise on them) with appropriate guidance and in a way that is consistent with the overall pedagogical approach. This may contribute to students' embracing complexity and adopting deep learning strategies [3]. Finally, our findings on KRD are line with and add specificity to the existing knowledge [10]. These insights call for micro-interventions aiming to prevent such 'known recurrent difficulties' in learning and teaching from re-occurring. Such micro-interventions might not be easy to realise and should attack the underlying reasons for those difficulties to remain recurrent, despite being well-known.

Addressing RQ2 is to describe in what ways the student learning is embedded in the learning environment. A 'thick description' [4] is available, integrating behavioural aspects of learning (e.g., indicators of progress in reasoning) to contextual conditions of the learning environment (e.g., sequencing of the learning activities). This aims at a generalisation to non-observed cases [13] , so our claims can be extended beyond the empirical context. The analytical description of the context, next to the connections to relevant theoretical frameworks[9], allow us to suggest that our conclusions are tenable and valuable in other engineering-sciences disciplines, as students also struggle with theoretical concepts and with epistemological shifts.

In its turn, RQ3 seeks to evaluate to what extent the intervention has any measurable effect on the learning outcomes and needs to be addressed in a further investigation, as soon as the intervention has been re-implemented (as much as feasible) as designed, or with modifications.

Our findings are informative for revision of the pedagogical intervention and generate some recommendations which can be grouped in three areas. First, about students' conception of the task and believes about their roles: (i) help students to embrace complexity rather than reducing it, (ii) request the thorough use of the B&K method, (iii) distinguish 'manipulated' variables from 'controlled' variables. Second, concerning building on previous for further growing: (i) consider reducing the number of 'different' practicums to allow for a second lab experience around the same topic, (ii) emphasise the connections between 'different' practicums. And third, on collaborative learning: (i) introduce peer review of intermediate/final products, (ii) continue investing in the professionalisation of the LAs.

To conclude, this investigation may be expected to contribute directly to the learning and professional development of those involved, which is consistent with the spirit of action research. The plausible implications on engineering-science educational practice regard new insights and recommendations likely to raise awareness among instructional designers and teachers, thus motivating them to reconsider their own practices, be it in line with an epistemological shift towards scientific reasoning in

[9] We propose that the frameworks used in this action research project, as well as our operationalisation of such frameworks, are valuable for engineering-science education in general. We refer to frameworks of conceptual modelling, surface/deep approach to learning, levels of complexity, and known recurrent difficulties. Also, we refer to pedagogical ideas about sequencing of activities (e.g., IBL) and a mixed general-infusion approach to instruction and learning (e.g., deliberate/overt, and both general and content-bound).

and for practice. Concurrently, this contribution advances an operationalised framework of levels of complexity for other educational researchers to study learning in engineering-science education.

ABSTRACT

This study aims to investigate if previous managerial or entrepreneurial experiences of entrepreneurs could moderate the use of a scientific approach to decision-making. To test this, we embedded a field experiment involving 132 real start-ups from Italy. We collected data on performances using phone calls for 64 weeks. Using econometrics analysis, we find that previous managerial or entrepreneurial experiences moderate the effect of this entrepreneurial decision-making approach on start-up performances, such as whether they decided to terminate their entrepreneurial idea, the number of pivots and the amount of revenue gained. The moderating effects differ according to the experiences possessed by entrepreneurs.

1 INTRODUCTION

Entrepreneurs face several issues when starting and developing their entrepreneurial ideas, especially in the early-stage phase, which involves several critical decisions (Gans et al., 2019).

These critical decisions range from deciding to hit the market, changing core parts of their business or whether or not to give up on their entrepreneurial idea (Camuffo et al., 2020; Gimeno et al., 1997). According to previous literature, entrepreneurs can take these decisions using different approaches to decision-making, ranging from more structured approaches to less structured (Dencker et al., 2009; Sarasvathy, 2001; Camuffo et al., 2019). Focusing on critical decisions, previous studies have shown how using a scientific approach to decision-making can influence decisions regarding whether or not to hit the market, to pivot or to terminate an entrepreneurial idea. Entrepreneurs using a scientific approach to entrepreneurial decision-making act like scientists do in developing and testing their hypotheses in labs. More precisely, entrepreneurs using this approach ground their decisions on hypotheses carefully elicited from a theory they build (Felin et al. 2019) and on thoroughly built evidence, thus mitigating the risk of incurring false positive and false negative decisions (Camuffo et al. 2019). Building on this, entrepreneurs using this approach seem to terminate more their entrepreneurial idea, pivot less – i.e. change a core part of their business model - and gain much more revenue than other entrepreneurs (Camuffo et al., 2020, Camuffo et al., 2019).

On the other hand, these critical decisions could also be influenced by human capital of entrepreneurs (Ott et al., 2017). Previous studies show how previous managerial experience can increase the likelihood of carrying on with an entrepreneurial idea compared to other entrepreneurs (Gimeno et al., 1997). In the same vein, previous entrepreneurial experience seems to lead entrepreneurs to gain higher performances and survive more. (Cooper et al., 1994).

Despite the previous knowledge on approaches to entrepreneurial decision-making and entrepreneur's human capital, we have few pieces of evidence on how human capital – like previous managerial or entrepreneurial experience - might influence the use of an approach to entrepreneurial decision making, such as scientific approach to decision making. Entrepreneurs usually rely on their previous experiences to develop strategies and make critical decisions when operating in an unknown market (Hashai and Zahra, 2021). Similarly, they can leverage an approach to decision-making to gain critical information about the value of their entrepreneurial idea and their customers. Despite this, we still do not have evidence on whether these previous knowledge gained during their experiences might moderate the adoption of an entrepreneurial decision-making approach, improving or not the performances of the entrepreneurs using it. Building on this, this research aims to understand if entrepreneurs' previous managerial or entrepreneurial experience could moderate the adoption of a scientific approach to decision-making and impact start-up performance, such as termination of the start-up, number of pivots, and revenues.

RQ: Do previous managerial experiences or entrepreneurial experiences moderate the use of a scientific approach to entrepreneurial decision making?

This study aims to offer several contributions. Firstly, we aim to shed a first light on how entrepreneurial decision-making approaches – like scientific approach to decision-making – could lead to different outcomes according to entrepreneur’s previous managerial or entrepreneurial experience. Secondly, we aim to offer contributions to the entrepreneurial education field. This work shows how both novice and experienced entrepreneur can benefit from learning and using an entrepreneurial decision-making approach. Furthermore, we show how the benefits differ depending on whether entrepreneurs have previous experience or not. Finally, this study might offer governments, policy-makers, and universities interesting results on the impacts of entrepreneurship courses on early-stage start-up’s performances. Moreover, it shed light on how teaching the same approach to different entrepreneurs could lead to different outcomes. In this vein, we hope to provide governments, policy-makers, and universities with useful evidence on the effects of the entrepreneurial programs.

2 METHODOLOGY

2.1 Empirical Setting

To study the moderation effect between previous managerial or entrepreneurial experience and the use of a scientific approach to decision making, we replicate the experimental settings presented in Camuffo et al. (2019) and Camuffo et al. (2020).

Accordingly, we embed a field experiment in a pre-accelerator program by randomly assigning entrepreneurs to either a treatment (being taught how to use a scientific approach when developing a business idea) or a control group (being taught how to develop a business idea). This pre-accelerator program provides training to early-stage entrepreneurs for a short period of time (three months). Inspired by these previous works, we targeted early-stage entrepreneurs. We launched a call for applications at a national level involving both online and offline channels. The call for applications lasted two months and resulted in 149 applications. After the call for application, we excluded seven applicants as they were already in a later stage of the development of their start-up. Our initial sample thus included 142 start-ups admitted to the program. Using STATA software, each start-up was randomly assigned to either a treatment or a control group through simple randomization. We checked using t-tests that treatment (71 start-ups) and control groups (71 start-ups) were balanced on several key covariates, such as previous experience level at both team and leader level, that might affect the absorption of the treatment and subsequent outcomes. Just before the beginning of the program, 10 start-ups decided not to take part in the training. We checked for the balance check and the randomization was still robust on the covariates. The final sample was composed of 132 start-ups, 67 in the treated group and 65 in the control group.

Treated and control teams were trained during seven sessions from October 2018 to February 2019 (21 hours of training for each group). Our pre-accelerator program focused on market validation, a series of activities aimed at testing the desirability of a product or service concept against a potential target market. The content and length of each session were the same for both groups, but start-ups in the treatment group were taught how to take entrepreneurial decisions according to the scientific approach. In each class of the treatment group, start-ups were taught to elaborate a theory behind their choices, articulate hypotheses and test them rigorously. The control group, instead, did not learn about the scientific approach but followed the traditional approach to decision-making used by entrepreneurs. We avoid contamination and other threats to internal validity by following the same approach as Camuffo et al. (2019).

Data collected refers to 132 real early-stage start-ups operating in Italy. We performed a two steps data collection. The first step began before the training, during the call for application. Before enrolling in the program, we asked to the leader of the start-up to fill a pre-survey concerning information about her start-up and the founding team. The information refers to the demographic and human capital of the founding team - such as the years of entrepreneurial experience of each member of the team - and information about the start-up, such as industry, when its development was started and if it has already gained revenue. These data were used to randomize the start-ups between treatment and control groups and create the variables for the econometrics analysis.

As far as post-training data are concerned, data collection lasted approximately one year, involving 18 points of observations. Data were gathered through phone interviews led by the research assistants (RAs). Data collection involved data referred to start-up performances, such as the amount of revenue gained, wherever they had quitted their entrepreneurial idea or they have changed a core part of their business model. Phone interviews were lead using a semi structured approach. The interviews started after six weeks from the beginning of the program. The first four interviews were lead every two weeks, while the remains were performed every four weeks.

2.2 Variables

We use three main categories of dependent variables to test our hypothesis. The three categories of dependent variables refer to the decision of terminating a start-up, the number of pivots – i.e. if they have changed some key components of their value proposition or their target customers- and the amount of revenue gained. Table 2.2.1 reports the descriptions of the three dependent variables.

Table 2.2.1 : Dependent Variables

Variable	Description
Quit	Binary variable equal to 0 until entrepreneurs quit their idea (they abandon the program and cease their start-up), 1 when entrepreneurs decide to exit. Missing after they quit

Number of pivots	Binary variable equal to 1 when an entrepreneur makes a pivot, 0 elsewhere
Revenue Flow	Amount of revenue earned by the start-up

We developed the econometric analysis using four explanatory variables, one related to the use of the scientific approach to decision-making and the remains related to the human capital of the leader of the start-up. The first explanatory variable is the *Intervention*. *Intervention* was used to discriminate between treatment and control group. This is a binary variable which takes the value 1 when a start-up has been taught how to use a scientific approach to decision making, and 0 elsewhere. As far as human capital is concerned, we defined two independent variables to assess whether a leader of a start-up had previous managerial or entrepreneurial experiences. We define these two variables using data related to the experiences of the leader gained in the pre-surveys. The first dummy variable, *No Managerial Experience*, is equal to 1 if the leader of the start-up has no managerial experience and 0 elsewhere. In the same vein, *No Entrepreneurial Experience* is equal to 1 if the leader of the start-up has no entrepreneurial experience and 0 elsewhere. Table 2.2.2 shows the independent variables used in the econometrics analysis.

Table 2.2.2 : Independent Variables

Variable	Description
Intervention	This is a binary variable equal to 1 for start-ups in the treatment group, and 0 otherwise.
No Managerial Experience	This is a binary variable taking the value 1 if the leader of the founding team has no managerial experience, 0 elsewhere
No Entrepreneurial Experience	This is a binary variable taking the value 1 if the leader of the founding team has no entrepreneurial experience, 0 elsewhere

3 RESULTS

All the regressions include control for time and instructors and errors are clustered by firms.

Model (1) and Model (2) show the results for the likelihood of terminating a start-up. As far as managerial experience is concerned, it seems that the intervention is more efficacy on start-ups which are led by a leader without previous experience as a manager. Moreover, the moderating effect between intervention and not having previous experience as a manager has a positive and significant effect on the decision of terminating the start-up. In a similar vein, start-ups led by a leader without previous experience as entrepreneurs and using a scientific approach to entrepreneurial decision-making are more likely to terminate their start-up than the other entrepreneurs in the sample.

Model (3) and Model (4) show the results on number of pivots made by entrepreneurs. Model (3) shows a negative and significant effect of the moderation between not having previous experiences as manager and the intervention. Thus, it seems that entrepreneurs without previous experiences as manager benefit more from using a scientific approach to decision-making, making fewer pivots than other entrepreneurs. On the other hand, the moderation effect among intervention and previous experiences as entrepreneur seems not to affect the number of pivots made by an entrepreneur.

Model (5) and Model (6) show the results concerning the moderating effect of being treated and previous managerial or entrepreneurial experience. As we can observe from Model (6), it seems that treated start-ups with a leader with previous experiences as an entrepreneur benefit more from using a scientific approach to decision making. The moderation between the intervention and previous entrepreneurial experience has a positive and significant effect on the amount of revenue gained by the start-up. As far as leaders without previous entrepreneurial experience are concerned, the moderation shows a positive but non-significant effect on revenue. In the same vein, there is a positive moderation effect between previous managerial experience and intervention. Entrepreneurs with previous managerial experience who use a scientific approach to decision-making seem to gain more revenue than other entrepreneurs in the 18 point of observation.

4 CONCLUSION

Our study shows the results of a field experiment involving 132 early-stage start-ups from Italy. We find evidence that the use of a scientific approach to decision-making is moderate by the previous managerial and entrepreneurial experiences of an entrepreneur.

This study offers contributions to academics, practitioners and policy-makers. At first, this paper gives contributions to the literature regarding the scientific approach to decision-making. Our results provide insights on the use of this approach to decision-making, suggesting that its outcomes are moderated by the human capital of the entrepreneurs. On the one hand, entrepreneurs without previous managerial or entrepreneurial experiences using a scientific approach to decision-making seem to terminate more their entrepreneurial idea. On the other hand, entrepreneurs with previous managerial or entrepreneurial experience seem to benefit more from an economic point of view when using a scientific approach to decision making, gaining more revenue.

Secondly, this work gives insides to the entrepreneurial education field. This work shows how both entrepreneurs with previous experience or without experience can benefit from learning a specific approach to decision making. Moreover, entrepreneurs using a scientific approach to decision-making seem to gain superior performances than entrepreneurs who use a more classical approach to take their decisions. These results give a further understanding on how entrepreneurial education can be effective for entrepreneurs with or without previous experiences and which approach can be more beneficial for them. In the same vein, this work shows that teaching the same entrepreneurial approach could lead to different results based on the human capital of entrepreneurs. Finally, this work gives interesting insights to policy-makers and universities. Entrepreneurs seem to gain different benefits when using a scientific approach to decision making according to their previous experiences. Entrepreneurs without previous managerial or entrepreneurial experience seem to terminate more their entrepreneurial idea when they use this approach, while entrepreneurs with these experience seem to gain a superior amount of revenue. These results might be important evidence for policy-makers and universities involved in creating entrepreneurial education programs. Based on their own goals, universities and policy-makers could set up course on scientific approach to decision making focused on novel or more experienced entrepreneurs to boost the outcomes related to this approach.

ABSTRACT

This paper presents the results of a research study on the profile of the participants in a postgraduate lecturer training program (15 ECTS) based on competencies in a STEAM (Science, Technology, Engineering, Arts and Mathematics) University. The study research questions are: (1) "In which competences do the participants perceive a personal improvement during the programme?", and (2) "Can we identify a profile of the candidates most suited to take better advantage of the training?" . The study includes current participants and students who have completed the program in the last 5 years. A mixed research methodology was used including both quantitative and qualitative analysis. Data from the program alumni and current candidates have been quantitatively analysed to identify common personal and background features among them. Structured interviews and focus groups have been conducted to find out how their initial expectations matched with their perception of what was offered in the program. The qualitative interviews include a discussion about their experiences along the programme and their ambitions for their further professional development, and put in context with their specific background. This research has important implications for the future, such as the need for increased training in digital skills. The majority of the teachers surveyed have a positive impression of the training and are in the middle of their careers. However, because of the pressure to satisfy other Academia requirements, many potential applicants in their early career stages do not complete or even contemplate participating in the program.

1 INTRODUCTION

Teacher’s training is particularly challenging in the particular context of engineering studies, which traditionally have one of the highest dropout rates in higher education. Patricia Cross [1] stated that teaching will not acquire status until teachers do consider their classes as laboratories for research and innovation. The problem probably comes from the fact that the innovation and research that are conducted at our technical universities do not use the same methods as those traditionally used in the social sciences, which are precisely the ones that would apply to education. Thus, it is necessary for a faculty also to acquire competencies related to these issues.

Hence, we focus our work on the pedagogical training of university teachers in higher education, in a technical university. Lecturers’ opinions of their day-to-day teaching practice usually arise from their culture or previous background as former students, and mainly on their own beliefs, which induce them work as if these beliefs were true. Such beliefs are usually very resistant to change, as well as being consistent with the teaching style of each lecturer [2].

Competency-Based Education (CBE) is increasing its role in Higher Education worldwide. The *KoKoHs* project in Germany, for instance [3], has revealed significant deficits in student competencies, proposing different ways to address them, among others, to promote lecturers’ training in pedagogical competencies. However, few studies can be found about teachers’ competencies. A positive effect was found, for instance, by Muzenda [4] who has described how lecturers' competencies improved students' academic performance. Some authors have proposed CBE programs for training lecturer's competencies in particular fields: Schina et al. [5] outlined some lecturers' training programs in robotics education, while Ulubey and Basaran [6] have reviewed existing lecturers' initial training programs in Turkey. However, which competencies should be trained in a STEAM university is still a matter of discussion, and as far as these authors know no similar programs as the one introduced herein have been analysed in European Universities.

In order to tackle these points which are common to many European STEAM universities, we herein introduce and analyse a teachers' training program designed at our university,(*Universitat Politècnica de Catalunya – BarcelonaTech*) and promoted by its *Institut de Ciències de l'Educació*, to which the authors of this work belong. This training is non-mandatory for the participants, because, no specific pedagogical background is required for teaching at our universities, other than knowledge of the subject to be taught. Since the training programme is voluntary, lecturer enrolment in the program is usually rather low when compared to the total number of lecturers in the university. A matter of concern is how this participation in teacher training programs in higher education can be raised.

The University in which this program is proposed is a technical one, specialized in technology, mathematics, architecture, science and engineering (STEAM). There are no schools and departments of psychology or education within our institution, or any tradition of using social science methods aside from the Economics department. Moreover, our lecturers have the technical competencies required for teaching, but it cannot be taken from granted that they have the professional competencies required for conducting this teaching.

Our previous training programme followed the pre-Bologna pattern: it measured on-site hours and was based on course content rather than on the competencies to be acquired by the teachers participating in the training activities. Degrees have moved from content-based learning to competencies-based learning, the focus being on learning rather than on teaching [7]. Many authors [8 - 12] have discussed the relevance of teachers training in the quality of the teaching received by higher education students, particularly in challenging studies such as those related to STEAM studies. Hence we proposed a training program whose objectives were:

- To design a training itinerary for lecturers based on the competencies they must acquire as teachers, as well as providing a qualification certifying to that fact. This training should also cover lecturer evaluation and promotion.
- To increase the number of lecturers enrolling in our training programme.
- To use this training programme to promote a scholarship in engineering education research, a field of scientific inquiry that has usually been ignored by our teaching staff.

The following six competencies were identified as part of the curriculum training: 1) Interpersonal; 2) Methodological; 3) Communicative, 4) Planning and Management; 5) Teamwork; and 6) Innovation. A final 7) "Digital Training" competency was added in the year 2020/21 as it was perceived that there was an important need for this training during the outbreak of the pandemic.

- Interpersonal: to be able to help participants to develop critical thinking, motivation, confidence and diversity recognitions; by creating a framework of empathy and that includes ethics in their professional practice as well as interacting with other individuals.
- Methodological: to be capable of applying appropriate strategies and evaluation tools in accordance with each educational context.
- Communicative: to be able to conduct appropriate and efficient communication processes in the teaching context which means reception, performance, production and transmission of messages through various media channels. These channels include face-to-face or online interactions as well.
- Planning and management: to know how to design, guide and develop content, training and evaluation so that the results are measured and suggestions for improvement are made.
- Teamwork: this skill is not about teachers leading a group of students working together, but rather about teachers being able to collaborate among themselves. It deals with the topic of taking responsibilities and commitments according to the common objectives, agreed procedures and considering the educational resources available.
- Innovation: to be able to create and apply new knowledge, perspectives, methodologies and resources in the different dimensions of their teaching.
- Digital Training: to be able to use telematics tools, new technologies and software tools to conduct semi-presential or online teaching.

The program has a total of 15 ECTS to be conducted in different courses and workshops including training in all the previous competences. All the courses include, as a general framework a general introduction and an overview of the pedagogical principles. However, a practical approach is enforced. Active methodologies are proposed by the trainers of the courses and workshops which specifically aim to make the participants reflect on their own teaching. Individual and group practical work is proposed in order to discuss whether their teaching day-to-day duties include the principles which motivate good practice teaching in higher education. For example, in the course of Interpersonal training, participants learn to develop an electronic teacher's portfolio which is aimed to reflect and discuss their day-to-day practice and interactions with both students in class and their staff colleagues.

A final project is mandatory to complete the degree with a real innovation being conducted in the class by the participant in the program [13]. Active methodologies and student engagement are intended to be implemented by participants during this training [14]. The final project includes a final memo and is finally presented and discussed after an evaluator board of experts.

2 METHODOLOGY

2.1 Description of the participants sample

Two focus groups were included for this research. Group A was specifically organized for this work with only alumni of the program, while Group B was added as conducted before in 2021 but with the same aim as the first one. Focus Group A included only alumni from the program, and Group B included only participant candidates.

Regarding Group A, five former participants from different departments who have finished their degree in the last five years were interviewed with a structured script. One of the participants was in the initial stage of his career when he was a participant of the STEAM program, aged 27 years old. The other four belonged to a middle stage (Associate professor) aged between 32 and 43 years old. None of the subjects who could be interviewed belonged to the advanced stage (Professor). Three were male and two female. Two belonged to the Management department, 1 to the Physics department and 2 to the Information Technologies (IT) area.

Focus group B was held in 2021, with the aim of answering this Research Question 1. One of the teachers in the training program was in charge of moderating the focus group, and the participants were lecturers chosen from among those who had attended a workshop taught by the moderator. Eight men and eight women were randomly chosen to achieve gender parity, and of the sixteen people invited to participate in the focus group, fourteen accepted (8 female, 6 male). Finally, for practical reasons they were grouped into three subgroups, one of 4 and two of 5 people. The participants in Focus Group B had a wide range of teaching experience from between one and a half and 33 years. Five participants were at the beginning of their academic career, with 5 years of teaching experience or less (many of them were teaching assistants while doing their doctorate) and an age range of between 20 and 30. Four people were in their thirties, and four people were over 40 years old, all of them with over 15 years of teaching experience. The distribution in areas of knowledge in Focus Group B covered all groups at the university: lecturers from the science area (3), industrial engineering (5), architecture (2), civil engineering (2) and IT (2).

With respect of the whole group of participants in the STEAM program, 68% of the students enrolled belong to the middle-stage career teachers (associate professor), with less than 5% of Professorships and a remaining 27% are on the initial-stage teaching career. Lecturers enrolled in the program belong to a wide variety of departments and knowledge areas. The most represented areas are Management, Architecture and Computer Science. This data was used for quantitative and qualitative analysis as described in section 2.3.

2.2 Improvement as perceived by the participants

We used a qualitative approach to answer to this research question ("In which competences do the participants perceive a personal improvement during the programme?") with semi-structured interviews and focus groups.

All five participants have successfully finished their degree with excellent marks and they all found that their involvement in this training program had a significant positive impact in their careers. The semi-structured interview was focused on finding what specific part of training had a real impact on their teaching, how their training was influential in their advancement (if any) in their professional careers, and specifically, which particular competences were perceived by the participants as having improved because of their training. Computer Assisted Qualitative Data Analysis Software (CAQDAS) such as NVivo 11 was used for text analysis.

2.3 Profile of the candidates

A mixed methodology, both quantitative and qualitative was used in order to find out the answer to the second research question ("Can we identify a profile of the candidates most suited to take better advantage of the training?").

Regarding the quantitative analysis, data from the program alumni and current candidates have been quantitatively analysed to identify common personal and background features among them. Previous background, current stage of their professional career, age and gender, as well as time to complete the degree (or credits remaining to obtain it) were taken into account. A multifactorial analysis was performed using SPSS version 25. Correlations between the independent variables and indicators of their success when completing the program were computed.

Qualitative analysis was used to find clues on which are the best indicators from the professional practice of the participants that best correlate with their success, and in which specific parts of the training have they focused on. Again, both the aforementioned structured interviews and focus groups were used.

3 RESULTS

3.1 Research question 1

The participants in the semi-structured interviews all were very satisfied with their participation of the program. Regarding its specific impact on their professional career the results were mixed. Four of them showed that they perceived that their day-to-day teaching was improved, while the remaining participant, the one in his initial stage of his career argued that, while little impact could he perceive on the quality of his teaching, the awarded degree was something valuable that added to other merits to achieve a promotion in his academic status. Four of them noted that the final project was meaningful for their reflection skills on their teaching. Regarding the question on which specific competences the program can be accounted as a booster for them, 3 of them mentioned "Innovation", 2 of them mentioned "Communicative" and "Methodology" and only one included "Teamwork" in their comments in the interview.

The text analysis showed that "Innovation" or "research" was the most frequently mentioned theme, with "active methods" leading the second place and "qualifications" being third. The results may reflect the impact of their training on the perceived new innovation capabilities as well as the importance of the active methodologies being introduced in their day-to-day teaching and their related impact on the qualifications obtained by their students.

Participants in the focus groups believed that the workshops offered were both interesting and useful. The opportunity to include these workshops, and especially the postgraduate degree in the education section of their CVs, is advantageous for young teachers seeking to obtain a `promotion. It is also interesting for teachers in a more advanced stage of their academic career to hold a postgraduate degree when applying for positions as a senior reader or Professor. However, for promotion and recruitment, research experience prevails over teaching and training experience. A consensus exists about the advantages of completing these workshops as a means of distinguishing oneself from other applicants, although it is believed that universities do not value these workshops to the extent that they should. This is the reason why participants think that most teachers do not sign up to these workshops (in a normal situation), since it is more profitable for their academic careers to spend this time publishing papers or securing a project than devoting it to workshops on education. Lecturers found themselves overnight in a pressing situation requiring an accelerated and in-depth course of training in new educational tools and methodologies, to which end they enrolled in the workshops provided. Even so, participants are of the opinion that many lecturers have tried new ways of doing things and have become aware of their own limitations as teachers, so it is likely that a considerable number of newcomers will continue in the program.

3.2 Research question 2

After a multifactorial analysis of the data from the participants in the program and alumni in the last five years was performed, some interesting results can be noted.

Regarding knowledge background areas, 38% belong to Foundation Sciences (Mathematics, Statistics, Physics, Chemistry, Biology, Economics), 18% belong to Industrial Engineering, 21% to IT (Information Technologies), 18% to Architecture and 5% to Civil Engineering. Some of the knowledge areas are overrepresented in the program, such as Economics (usually linked to Engineering and Applied Management topics) and Civil Engineering, which is due to the existence in their departments of a tradition and interest groups on innovation and teaching topics. Most participants and alumni were in their middle stage of the program (62%), many of them were in their initial stage (35%) and very few in the upper stage as Professors (3%). The differences in gender (63% male and 37% female) may reflect the presence of more men than women in STEAM universities staff such as the one herein analysed. Most of the participants (73%) had more than 10 years of experience as university teachers while less than 13% had less than 3 years of experience with only 14% between 3 and 10 years of teaching experience in higher education. Only the combination of Middle-stage career with an Economics ($r=0.85$, $p<0.05$) or Civil Engineering ($r= 0.78$, $p<0.05$) background was positively correlated with finishing the degree.

In the semi-structured interviews it was interesting to find out that all five participants in the interview mentioned their vocational interest in pursuing a training for their teaching. They unanimously perceived, even in strong terms, that their promotion in Academia will not be the result of this training but rather, from their research results in their specific fields of knowledge. This impression was also found in the focus groups. Another significant finding was that during and after the pandemic, they realized that a better training in digital tools and skills was needed to better serve their students.

4. CONCLUSIONS

All participants having been surveyed had a positive perception of the training they had received during the program. The inclusion of active methodologies in their day-to-day practice as teachers, and innovation skills was the competence that stands out to be the best improvement in their teaching practice they could mention after completing this postgraduate program. We could not find a particular background that was most suitable for completing this degree as most teachers did not come from a pedagogical or social sciences undergraduate training. There was a positive correlation with Economics and Civil Engineering backgrounds for a positive completion of the degree, but this fact could be probably due to more tradition in teaching, learning and innovation in their departments in this particular University. Both participants and alumni were particularly satisfied with the practical approach of the program. Some of them reflected that the tools and methodologies proposed to them had a turning point effect on the effectiveness of their teaching. However, organizational restrictions were also often noted as a strong limitation for change. These conclusions can be easily generalized to other STEAM Higher Education institutions in Europe.

This research has important implications for the future. As it has been outlined, no similar studies specific to teacher's training in competencies in Engineering Faculties had been proposed. Among our findings, we remark the need for increased training in digital skills. There is also a significant lack of initial stage participants, who are the teachers who might most likely benefit from such a teaching training program. This is probably due to a small number of full-time professors being hired by this STEAM university (due to economic lack of funds for new hiring) and also to the pressure they are facing to meet research requirements to be promoted. Although economic constraints may vary throughout European Institutions, the problem of being promoted mostly because of research merits and not competencies training is fairly common. Many potential applicants in their early career stages do not complete or even contemplate participating in this program, therefore we suggest that universities may contemplate this teaching training as a merit, or even as a requisite in order to be further promoted in their careers. The potential for improving students' effective learning is of paramount importance.

ACKNOWLEDGMENTS

We are grateful to all participants in the interviews and focus groups, as well as to the UPC *Institut de Ciències de l'Educació* (ICE) staff for providing us with the relevant data to conduct the study.

ABSTRACT

Higher education institutions aim to incorporate competency development into their engineering curricula, which can help engineering students become independent critical thinkers with entrepreneurial mindsets. However, no solid methods exist to evaluate the acquisition of these competencies. Such assessments' objectivities are often ensured by distinguishing between who supervises a student group and who grades its project. The assessor's active involvement in the learning process is essential for assessing competency development during the learning process, but such involvement may lead to assessor bias. This study aims to investigate whether and under what conditions coaches can be objective assessors. An intraclass correlation coefficient (ICC) was used to measure the level of agreement between assessors and coaches when using the same rubric to assess students' deliverables. Four assessors and seven coaches from the University of Twente assessed 24 students' individual learning processes based on individual reflection deliverables. The coaches assessed the students they supervised during a challenge-based learning (CBL) course, while

doi:10.5821/conference-9788412322262.1290

the assessors were without participating in the learning process assigned randomly to students. The means were compared using SPSS, which indicated, among other things, that coaches generally awarded higher scores than assessors. This may indicate that coaches are biased because of their involvement in the learning process. Despite this, the results also indicate that coach assessment was in line with assessors when the coach was an appointed and experienced examiner.

1. INTRODUCTION

Higher education institutions aim to better prepare their students for the labour market by facilitating their development of transferable skills and lifelong learning competencies [1], [2]. The inclusion of competency development in higher education calls for new assessment methods, and one of the most promising and innovative approaches that can support such a transition to futureproof higher education is challenge-based learning (CBL) [3]. Challenge-based learning builds on experiential learning theories that view the learning process as being more important than the learning outcomes. Furthermore, these theories argue that skills are learned best in environments that resemble real-life situations [4].

This research was conducted on the Autumn Challenge programme, which is an extracurricular, international CBL programme organised by the University of Twente between October 2021 and January 2022. In this online programme, students from four ECIU[2] member universities worked on seven different challenges that resembled real-life situations and were under the theme of UN SDG 11. The programme was open to second- and third-year bachelor's and master's students from all ECIU universities.

1.1 Assessing competency development

Higher education institutions are increasingly exploring whether students can learn pass tests but also to gain a deeper understanding of the knowledge. The difference between knowledge assessments and assessments that focus on the learning process is that the latter also enables students to develop further after examination. Even though certain difficulties exist when assessing competency development, benefits exist as well. For instance, assessment drives learners to develop transferable skills [5], but also generates a higher level of commitment [6], thereby leading to more motivated students. Feedback also plays a key role, as does the active role that students play in their learning processes. To be able to assess students' learning processes, assessors should play an active role in these processes as well.

An important requirement for competency assessment is objectivity, which is often ensured by distinguishing between those who supervise students and those who assess their final outcomes [7]. In a CBL course, this means that those who coach students should not play a role in assessing the students' deliverables and vice versa [8]. However, due to the focus on the learning process in CBL, the assessor's active involvement during the learning process may provide valuable insights in addition to the deliverables on which the students can be assessed [7], [9]. Thus, combining the assessor and coach roles may provide additional insights into students' learning processes, but also can elicit assessor bias. Such a bias, whether positive or negative,

[2] https://www.utwente.nl/en/eciu/

can cause errors in assessor judgements, eliciting the potential to negatively impact an assessment's objectivity and quality [10].

1.2 On (perceived) biases in the case of the Autumn Challenge programme

An objective assessor is one who assesses the students' deliverables based solely on the criteria of the relevant assessment rubrics and the weighing thereof. However, when subjective factors (partially) influence an assessment, the assessment is 'biased'. Subjective factors can surface in many forms, e.g. the assessor's impression of a student, considering factors that are not part of the assessment rubric, or focusing too much on parts of the assessment rubric that are closest to the assessor's interest(s) or perspective(s) [8]. Various types of grading biases are recognised in the literature [8] and are summarised in Table 1. Due to the coaches' involvement in the learning process in the Autumn Challenge programme, there were five types of bias with increased potential: the contamination effect*,* halo effect, horn effect, norm shift and signal effect.

Table 1: Overview of the most common types of grading biases [8]

Type of bias	Information
Contamination effect	The contamination effect is the effect that occurs in grading when the freedom in grading, involuntary or random, is used for purposes other than those of an uninhibited, unbiased assessment. This is the case, for example, when assessors give lower scores to show that their subject is difficult.
Halo effect	The halo effect occurs when assessors allow their judgement to be influenced by other performances of the student than those expressed in the performance to be assessed. In this case, assessors tend to judge a 'good' student's performance as somewhat higher than warranted by the student's performance. The performance is overvalued.
Horn effect	The horn effect is the opposite of the halo effect. The Horn effect occurs when assessors allow their judgement to be influenced by the student's performance other than expressed in the performance to be assessed. In that case the assessors tend to assess a 'bad' student at a somewhat higher performance level than the performance of the student justifies. The performance is undervalued.
Norm shift	The norm shift is the effect that occurs when an assessor adjusts to the performance of students. For example, an appraiser may become less harsh if after a number of assessments, it is found that most students answer the same question incorrectly.
Restriction of range	Restriction-of-range is caused by the freedom in the assessment task that willy-nilly leads to certain distributions of the ratings that express general human or personal tendencies. For example, one appraiser may use all scale values (scores from 1 to 10), while another will always assign values near the middle.
Sequence effect	The sequence effect occurs when an assessor incorrectly allows the assessment to be guided by one or more previous assessments. For example, assessors review test questions in a certain order. A large number of bad answers followed by a correct answer may then lead to the correct answer being graded disproportionately.
Signal effect	The signal effect occurs when assessors pay attention to different aspects, or when they weigh the aspects differently in their judgement. This effect occurs, for example, when assessors evaluate writing products. One assessor pays attention to grammatical (in)correctness and the other to structure or content.

1.3 Problem statement

In this paper, we use the term 'grading bias' to refer to unintentional grading bias. There is a considerable body of literature on how to prevent this, but these solutions are mainly aimed at eliminating situations where bias can be stirred up, such as intensive collaboration between lecturers and students. Is a certain degree of bias a real issue?

Research has shown that, when students have the feeling that they are not being judged for their work but, for example, for their personality or their past performance, both the student and their peers may feel that they have no influence on the outcome, no matter their efforts.

2. METHODOLOGY

This section of the paper outlines the methodology used to answer the following research question: Can coaches be objective assessors, and, if so, under which conditions?

2.1 Subjects

Student population

In total, 24 second- and third-year bachelor's and master's students participated in the programme in teams of three to five members each based on multidisciplinary, intercultural diversity and their preference for an overarching project. The teams' progress were monitored at weekly team coaching sessions as well as during three programme milestone moments.

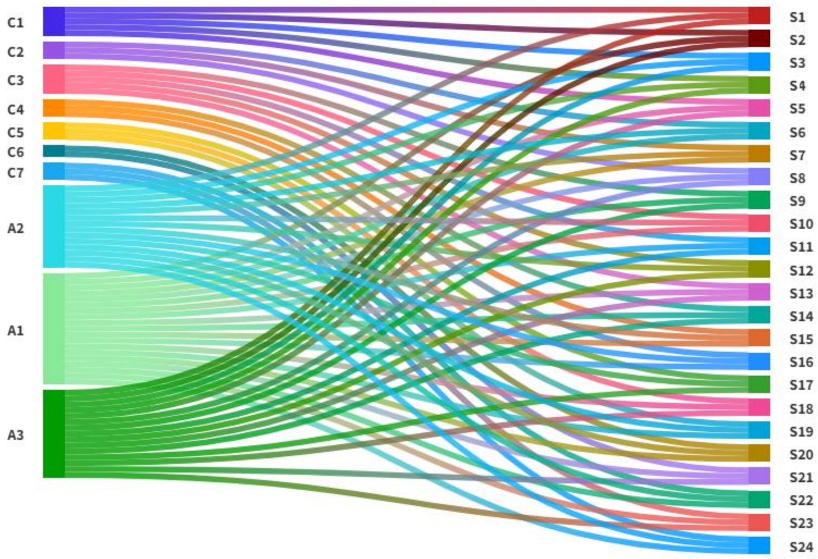
Challenge-based learning coaches

The seven student teams were each supported by their own team coaches. The coach's role in the learning process was to provide proper, flexible, and personal support to the students in their teams in order to enhance the learning process and team dynamics [11]. Two of these coaches were experienced academics and trainers with a University Teaching Qualification (UTQ) and experienced with CBL. All seven coaches received training on coaching in a CBL prior to the start of the programme. The coaches have been actively involved in the students' learning processes throughout the course, unlike the assessors.

Assessors

Just like the coaches, there were also four assessors that evaluated the students' final learning outcomes. Unlike the coaches, the assessors have not been involved in the students' learning processes. Each student has been assessed by his own coach and by two assessors. Details on who assessed the students can be found in Figure 1.

Figure 1: Distribution of the individual deliverables among coaches and assessors. A 'C' refers to a 'coach', an 'A' to an 'assessor' and a 'S' to a 'student'.



2.2 Assessment rubric

The assessment rubric for individual reflection was developed to provide students with the freedom to reflect in a way that suits them. Table 2 shows a summary of the assessment rubric (see Appendix A for the full rubric), which consisted of three levels of 'pass' scores (Excellent, Satisfactory, Sufficient) and one 'Insufficient' score for each assessment topic. For this analysis, each assessment scale received a corresponding score as shown in Table 2. Three assessment criteria were used to score and analyse five assessment topics, namely Professional growth, Skill development, Team role, Problem solving and Development of new skills and competencies. The 'report/video length' assessment criterium was excluded from the analysis, as no differences between the raters' assessments would be found.

Table 2: Overview of the assessment criteria used in the analysis

Assessment criteria		**Insufficient**	**Sufficient**	**Satisfactory**	**Excellent**
		2,5	5,5	7,5	9,5
Individual development	Professional growth	Reflects upon their educational and professional growths. Provides examples and reflects upon the BuddyCheck matrix related to individual development and programme components (Skills Labs, Thematic Lectures, Virtual Teams Group Work).			
	Skill development	Reflect upon the development of skills/competencies related to their individual learning goal set prior to the programme.			
Individual role	Team role	Reflects upon their role in the team. Provides examples.			
	Problem solving	Reflects upon their contribution to the problem-solving process. Provides examples.			
Individual effort	Development of new (interdisciplinary) skills and competencies	Reflects upon their effort to develop new skills and obtain new competencies in the programme. Provides examples and reflects upon the BuddyCheck matrix related to individual effort and programme components (Skills Labs, Thematic Lectures, Virtual Teams Group Work).			

2.3 Reliability of agreement

To ensure that the rubric provides sufficient consistency, and therefore any found differences are not likely to be caused by the interpretation of the assessment items but rather by the assessment itself, an intraclass correlation coefficient (ICC) was used. The outcomes were interpreted as follows: < 0.50, poor; between 0.50 and 0.75, fair; between 0.75 and 0.90, good; above 0.90, excellent. The ICC for intra-rater reliability for rater 1 and rater 2 was fair as it was 0.62 (0.25-0.83); for rater 1 and rater 3, was fair as it was 0.58 (0.19-0.81); and for rater 2 and rater 3, was excellent as it was 0.93 (0.82-.0.97). We can thus conclude that the rubric used ensured a high enough level of agreement between the raters to be able to compare the results.

2.4 Measures

In the case of the Autumn Challenge programme, the assessment structure is two-fold, i.e. assessors and student groups' coaches assess reflection deliverables. The assessors are not involved with the students in the course and, thus, can only base their assessments on the students' deliverables. To investigate this phenomenon further, perceived bias was measured.

Two outliers were detected that were more than 1.5 box lengths from the edge of the box in a boxplot. Inspection of their values did not reveal them to be extreme and they were kept in the analysis.

3. RESULTS

3.1 Data preparation

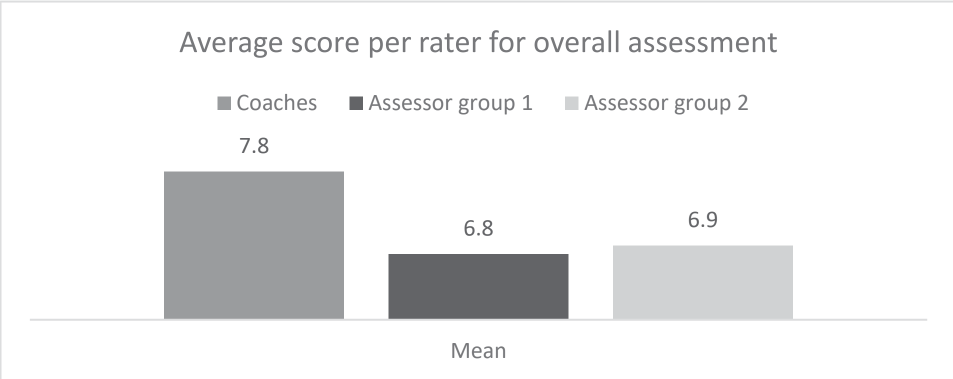
Before comparing the rater groups with one another, the first step was checking for the assumptions of normality and outliers. One outlier was found in the coach group. However, the coach in question is the most experienced teacher in that group, possesses the UTQ, and is very experienced in CBL education. Additionally, the outlier was not more than 1.5 box lengths from the edge of the boxplot. For these reasons, the outlier was not removed. In the first assessor group, outliers were detected, but both of them were no more than 1.5 box lengths from the edge of the box. Inspection of their values did not reveal them to be extreme and they were also kept in the analysis, as both outliers were detected in the overall score and the assessment criteria 'individual development'. In the second assessor group, there were no outliers. Furthermore, six individual cases were excluded from the analysis due to incomplete information, thus 18 cases were used.

3.2 Analysis

Assessment means comparison

The means of the assessment of the students' individual deliverables of the three raters (Coaches, Assessor group 1, Assessor group 2) are firstly compared as a whole as shown in Figure 2, and then on the three assessment criteria as shown in Table 3.

Figure 2: Means comparison of the three groups of raters for individual deliverable



Coaches score, on average (M = 7.8, SD = 1.096), much higher than the assessors, respectively (M = 6.8, SD = 1,535) (M = 6.9, SD = 1.944), who have not worked intensively with the students. Additionally, the average score for the 'individual development' assessment criterium given by the coaches was the highest (M = 7.8) followed by the second assessor group (M = 7.2) and the first assessor group (M = 7.0). Similarly, the highest average score for the 'individual role' assessment criterium was given by the coaches (M = 8.2), followed by the second assessor group (M = 7.2) and the first assessor group (R2 = 7.0). For the assessment criterium, 'individual effort', the highest average score was given by coaches (M = 7.3), which was followed by the second assessor group (M = 6.3) and the first assessor group (M = 6.2).

Looking at the individual assessment criteria, the differences are smallest for development and largest for role and effort. A higher assessment of 'individual role' and 'individual effort' by the coaches may indicate the influence of the halo or signal effects because, in CBL, coaches are part of the team and this may lead to an overvaluation of the students' roles and efforts in the project (*halo effect*). The coaches may also consider the role the students play and the effort they put into the project group to be more important than the students' individual development (*signal effect*).

Table 3: Means comparison of the three groups of raters for different assessment criteria. The highest scores are highlighted in bold.

		Individual Development		Individual Role		Individual Effort	
	N	Mean	Std. Deviation	Mean	Std. Deviation	Mean	Std. Deviation
Coaches	18	**7.8**	1.331	**8.2**	0.943	**7.3**	1.886
Assessor group 1	18	7.0	1.996	7.0	1.098	6.2	2.346
Assessor group 2	18	7.2	2.211	7.2	1.816	6.3	2.624

T-Test

Overall, the coaches scored statistically significantly higher on the overall assessment score compared to both assessor group 1 ($t(17) = 3.817$, $p < 0.001$) and assessor group 2 ($t(17) = 2.447$, $p < 0.026$). The coaches scored statistically significantly higher on the assessment criterium 'individual role' compared to assessor group 1 ($t(17) = 6.059$, $p < 0.001$) and assessor group 2 ($t(17) = 2.749$, $p < 0.014$). The coaches ($t(17) = 2.247$, $p > 0.38$) did not score statistically significantly higher on the assessment criterium 'individual effort' compared to assessor group 1 ($t(17) = 2.294$, $p > 0.35$). As expected, the assessment criterium 'individual development' was not significant compared to assessor group 1 ($t(17) = 1.750$, $p > 0.98$) and assessor group 2 ($t(17) = 1.225$, $p > 0.24$).

Pass/Fail comparison

As stated in the literature, an assessment that is not only based on visible and expected assessment but where other factors are also taken into account is undesirable [8]. This is the case regardless of whether this leads to a more positive or negative result. Apart from the fact that a grade should reflect the actual performance, there is an even greater risk that students who do not sufficiently master the learning objectives will still receive a 'pass' grade or vice versa. Table 4 shows that, based on the scores of the coaches, 10% of the students would have received a pass score without having objectively achieved the learning objectives.

Table 4: Differences between pass/fail scores given by the three groups of raters.

		Individual Development		**Individual Role**		**Individual Effort**	
	N	Pass	Fail	Pass	Fail	Pass	Fail
Coaches	18	17	1	18	0	17	1
Assessor group 1	18	14	4	18	0	15	3
Assessor group 2	18	14	4	16	2	14	4

It can, therefore, be concluded that coaches are less likely to fail students than assessors. The coaches may overvalue their students' performance (*halo effect*) because they may, to a certain extent, feel responsible for their individual development and the effort they put in.

4. CONCLUSION

Ensuring objectivity in competency assessment is one of the key requirements for valid assessment and future facilitation of transferable and lifelong learning competencies in higher education. The research data indicates that, in the case of the CBL Autumn Challenge programme, coaches were not always objective assessors. Coaches rewarded students whom they have coached with overall higher scores as compared with the assessors who were not involved in these students' learning. Moreover, the coaches gave a fail to fewer students than the assessors did. Based on these outcomes, it can be concluded that bias influenced the coaches' assessments. The coaches either tended to overvalue their students' performances (*halo effect*) or give more weight to the role they played in the group work than to the other assessment criteria (*signal effect*). Nevertheless, our results also indicate that, when a coach was an experienced and trained teacher, disagreement between the assessment of the coach and the assessors was eliminated. This finding is also in line with Sa et al.'s [7] research, which concluded that more rigorous training for coaches in an open-ended project is required in order to assure valid assessment. However, because only two coaches in the Autumn Challenge programme were experienced and trained teachers, further research into the objectivity of experienced and trained coaches as objective assessors is recommended in order to further validate our outcomes.

APPENDIX A
Assessment rubric: Individual Reflection

Criteria	Pass			Insufficient
	Excellent	Satisfactory	Sufficient	
INDIVIDUAL DEVELOPMENT	Reflects **extensively** upon their educational and professional growth. Provides **specific** examples and **fully** reflects upon the BuddyCheck matrix related to individual development and programme components (Skills Labs, Thematic Lectures, Virtual Teams group work), so **no** additional clarification is needed.	Reflects **adequately** upon their educational and proffesional growth. Provides **some** examples and reflects upon the BuddyCheck matrix related to individual development and programme components (Skills Labs, Thematic Lectures, Virtual Teams group work), so **some** additional clarification is needed.	Reflects **sufficiently** upon their educational and professional growth. Provides **few** examples and briefly reflects upon the BuddyCheck matrix related to individual development and programme components (Skills Labs, Thematic Lectures, Virtual Teams group work), so **substantial** additional clarification is needed.	**Absent** or **very limited** reflection upon their educational and professional growth
	Reflect **extensively** upon development of skills/competencies related to their individual learning goal that they set prior to the programme. Provides **specific** examples, so **no** additional clarification is needed.	Reflects **adequately** upon development of skills related to their individual learning goal that they set prior to the programme. Provides **some** examples, so **some** additional clarification is needed.	Reflect **sufficiently** upon development of skills related to their individual learning goal that they set prior to the programme. Provides **few** examples, so **substantial** additional clarification is needed.	**Absent** or **very limited** reflection upon upon development of skills related to their individual learning goal.
INDIVIDUAL ROLE	Reflects **extensively** upon their role in the team. Provides **specific** examples that support their reflections.	Reflects **adequately** upon their role in the team. Provides **some** examples that support their reflections.	Reflects **sufficiently** upon their role in the team. Provides **few** examples that support their reflections.	**Absent** or **very limited** reflection on their role.
	Reflects **extensively** upon their contribution to the problem solving process. Provides **specific** examples that support their contribution.	Reflects **adequately** upon their contribution to the problem solving process. Provides **some** examples that support their contribution.	Reflects **sufficiently** upon their contribution to the problem solving process. Provides **few** examples that support their contribution.	**Absent** or **very limited** reflection upon their contribution to the problem solving process.
INDIVIDUAL EFFORT	Reflects **extensively** upon their effort to develop new skills and obtain new competencies in the programme. Provides **specific** examples and **fully** reflects upon the BuddyCheck matrix related to individual effort and programme components (Skills Labs, Thematic Lectures, Virtual Teams group work), so **no** additional clarification is needed.	Reflects **adequately** upon their effort to develop new skills and obtain new competencies in the programme. Provides **some** examples and reflects upon the BuddyCheck matrix related to individual effort and programme components (Skills Labs, Thematic Lectures, Virtual Teams group work), so **some** additional clarification is needed.	Reflects **sufficiently** upon their effort to develop new skills and obtain new competencies in the programme. Provides **few** examples and **briefly** reflects upon the BuddyCheck matrix related to individual effort and programme components (Skills Labs, Thematic Lectures, Virtual Teams group work), so **substantial** additional clarification is needed.	**Absent** or **very limited** reflection on their effort.
REPORT/VIDEO LENGHT	Written report: The report lenght is **within** the given word count (600-650 words, excluding references) Video/animation: The video/animation is **within** the given time count (5-10 minutes)	Written report: The report lenght **slightly violates** the given word count (by <75 words, excluding references) Video/animation: The video/animation lenght **slightly violates** the given time (by <2 minutes)	Written report: The report lenght **violates** the given word counts (by >75 but <150 words, excluding references) Video/animation: The video/animation lenght **violates** the given time (by >2 but <5 minutes)	Written report: The report lenght is **largely outside** the given word count (by >150 words, excluding references) Video/animation: The video/animation lenght is **largely outside** the given time (by <5 minutes)

THE EXPERIENCES OF STUDENTS TRANSITIONING BACK TO IN-PERSON LEARNING POST-COVID-19

ABSTRACT

This paper reports on a preliminary study that was carried out to understand the experiences of engineering students transitioning to on-campus learning following the Covid-19 pandemic. Two cohorts were considered: year 1 students joining the university for the first time after having experienced considerable disruption for the final two years of their schooling and year 2 students who experienced their first year at university almost entirely online. Data was gathered from student surveys which found that the greatest areas of difficulty for students were the academic level of the programme and the workload. A limited comparison was drawn between this finding and some pre-pandemic data which suggests that the difficulty that students had in this area was higher than for students before the pandemic, indicating that two years of disrupted education may have had a negative impact on students' preparedness for higher education. Qualitative open-ended responses by students showed that there was a clear preference for face-to-face teaching, but that students see clear benefits to online resources and lecture recordings, and value having some flexibility in how they learn. Some reduction in student performance was noted.

1 INTRODUCTION

1.1 Background

The onset of the Covid-19 pandemic forced educational establishments across the globe to switch to online and blended modes of delivery, and the impacts of this have been widely reported on. For higher education institutions this has posed a myriad of issues, not only at the time of the emergency responses and rapid online shift, but it is likely that the effects of the pandemic will be felt for many years to come. One of

the main areas of concern is how to support students on an ongoing basis who have experienced large gaps in their educational experience or who have struggled with transitioning between online and in-person learning.

1.2 School closures and their impact on incoming university students

It has been estimated that 168 million students under the age of 18 in primary and secondary education missed in-person schooling for almost a full year by February 2021 due to the Covid-19 pandemic [1]. The issues faced by school pupils and students during this time are well documented, with many adverse consequences of school closures being identified from lost learning to increasing social disparities and serious welfare issues for vulnerable groups. For school-age children it has been reported that daily learning time was more than halved on average during online delivery, with low-achieving children undertaking even less than this, and receiving less parental engagement with learning activities thus widening the gap between high and low-achieving students [2]. Correlations have been drawn between lower educational level of parents and lower attainment of pupils during this time [3]. School age young people have also been reported to be at higher risk of mental health issues as a result of the pandemic, particularly those who were already more vulnerable, those who were approaching key examinations following the lockdowns, and those who had parents who were keyworkers [4].

Concerns have also been raised about lowering of academic standards due to difficulties in properly assessing students. For example, in the UK, those completing their final year of schooling were awarded calculated A-level grades in both 2020 and 2021 rather than sitting formal examinations, in a process fraught with much difficulty and dispute. Initial studies have reported reduced validity of these calculated grades compared to actual grades, and this is likely to cause difficulties for students when progressing into university, and pose issues for higher education institutes, as they may not accurately reflect student ability [5]. Francis et al highlight a variety of issues for incoming students and their new institutions, including variation due to different educational experiences, lack of experience with examinations and formal assessment, and knowledge and practical skills gaps [6]. This presents specific challenges for engineering subjects which require a combination of theoretical knowledge and practical skills.

1.3 Effects of university closures on existing students

Within higher education in the UK and many other countries, almost all university in-person teaching was halted in favour of online modes of delivery. Within the authors' institution, less than 6 weeks of on-campus teaching took place between the end of March 2020 and September 2021. For those students already at university during the campus closures, problems caused by the switch to online learning were widespread. From an educational perspective these included difficulties accessing appropriate technology and reliable internet connections [7], reduced engagement with course content, limited opportunities to engage with teaching staff, and significant shifts in assessment procedures and practices. From a wellbeing and social point of view, students have reported difficulties in establishing and maintaining social networks and increased mental health issues [8].

1.4 Positive aspects of the online learning experience

Despite the challenges of the online switch, a number of aspects that students find beneficial for learning have emerged. Among these the flexibility afforded by online resources to allow students to access material at a time and place that suits them [9]. This may be particularly beneficial for students with additional learning needs, or who have commitments outside of university such as caring responsibilities. Students have expressed an appreciation for being able to review material, in particular recorded lectures, as this helps with the learning process and is an excellent revision tool. Students have reported increases in self regulation as a result of learning online, and more control over their own time. They have also reported satisfaction with having materials available in advance to allow them to prepare before attending live classes, either online or in-person.[10]

1.5 Rationale

The aim of this study is to evaluate if the prolonged disruption to learning due to the pandemic has had a negative influence on the experience and preparedness of undergraduate students starting on-campus learning in the school of Mechanical and Aerospace Engineering (SMAE) at Queen’s University Belfast. Comparison will be drawn between the experiences of students joining year 1 after over a year of disruption to their schooling, with students joining year 2 after a year of online university teaching. Some limited comparisons will also be drawn with previous data gathered from students transitioning directly into year 2 prior to the pandemic, and outcomes compared with pre-pandemic data.

2 METHODOLOGY

2.1 Selected Cohorts

Analysis was limited to year 1 and 2 undergraduate students in SMAE for several reasons. Firstly, the year 1 students entering in the 2021-22 academic year were the first cohort of students to commence their university studies on a fully on-campus basis since the Covid-19 pandemic. It was of interest to assess whether the disruption to their secondary school education over the previous two years had a discernible impact on their experience, and on the ease with which they transitioned into university. The year 2 students were selected as they had completed most of their first year online, and had virtually no on-campus experience prior to 2021-22.

2.2 Learning environment

The students in this study returned to full on-campus teaching in September 2021. Classes were held in the same manner as they had been pre-Covid, but with additional safety measures in place, such as a requirement of students to wear masks, and a 2m exclusion zone between staff and students, to allow staff to remove masks for teaching. In addition to the traditional lectures and tutorials, a number of the beneficial aspects of online learning that had been identified during the pandemic were retained, such as providing recordings of the live lectures and providing digital resources on the virtual learning platform (VLE) well in advance of live classes.

2.3 Survey

A survey was sent to the students around one month after the first semester started, asking them to rank the difficulty of the following areas on a 5 -point Likert scale:

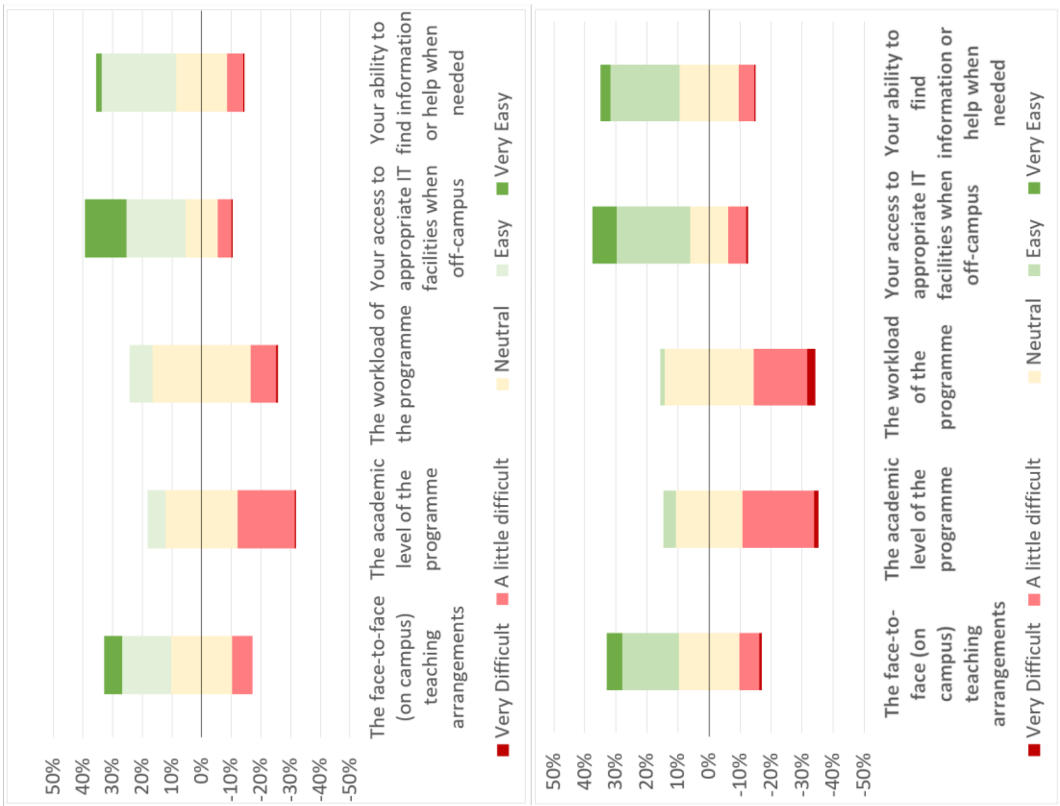
1. The face-to-face (on campus) teaching arrangements
2. The academic level of the programme
3. The workload of the programme
4. The accessibility of appropriate IT facilities when off-campus
5. The ease of finding information and help when needed

A further section of the survey consisted of a number of freeform comment boxes to allow further detail on the five areas above, or any other comments, to be provided.

3 RESULTS

3.1 Survey data

The survey received 109 responses from year 1 students (62%) and 110 responses from year 2 students (64%). Responses to the Likert scale questions on the perceived difficulty of various areas are presented in figure 1 as a percentage of students choosing each option from “very easy” to “very difficult”.



(a) Year 1 Students (b) Year 2 students

Fig 1: Responses to question “How challenging were the following issues?”

Responses were also weighted from (1-5), from “very easy” to “very difficult” and these are presented as mean scores in table 1, along with the median and mode responses for each question. A T-test was also carried out to determine if the responses from the year 1 and year 2 students were significantly different.

It can be seen that students found the academic level and the workload of the programme the most difficult aspects, and this was true for both year 1 and year 2 students, although year 2 students found these more challenging than year 1. This could be simply a reflection of the higher academic level in year 2. No significant differences were seen between the two groups on any of the other questions.

Table 1: Weighted scores from survey responses

	Weighted means - level of difficulty from 1-5 (from very easy to very difficult) [median] {mode}		**Significantly different? P Value**
	year 1	year 2	
The face-to-face (on campus) teaching arrangements	2.57 [3] {3}	2.60 [3] {3}	no p=0.706
The academic level of the programme	3.28 [3] {3}	3.44 [3] {4}	yes p=0.038
The workload of the programme	3.04 [3] {3}	3.43 [3] {3}	yes P<<0.001
Your access to appropriate IT facilities when off-campus	2.15 [2] {2}	2.35 [2] {2}	no p=0.101
Your ability to find information or help when needed	2.55 [2] {2}	2.55 [3] {2}	no p=0.932

3.2 Comparision with pre-pandemic data

It was desirable to determine whether the issues that the students reported with academic level and workload were unique to these post-pandemic cohorts. The only somewhat comparable data that exists from pre-Covid was a survey carried out on two groups of students who entered the same degree programmes at year 2 from two different foundation programmes [11]. One of the groups consisted of international students, mainly from China, and the other cohort was a group of students mainly from the Northern Ireland region, where the university is located. These students had been asked if they felt prepared for the academic level of the programmme, and ranked from “strongly disagree” to “strongly agree”. The responses have been weighted with the same weighting system used in this study, where 5 is “strongly disagree” and 1 is “strongly agree” and presented in table 2.

It can be seen that the students entering the university in 2021 showed clearly more negative responses than those entering pre-Covid. Caution should be drawn in making definite comparisons between these two as the questions were not asked in exactly the same way under the same context, but may give some indication that the disruption to learning over the course of the pandemic has had a negative influence on student preparedness for university level study.

Table 2: Comparison of perception of level of difficulty pre- and post-Covid

	Weighted means - level of difficulty from 1-5 (from very easy to very difficult) [median] {mode}			
	2021 year 1	2021 year 2	Pre-Covid International students	Pre-Covid "local" students
The academic level of the programme	3.28 [3] {3}	3.44 [3] {4}	2.42 [2] {2,3}	2 [2] {2}

3.3 Student comments

Open-ended responses were collated for each of the five areas surveyed. When asked for comments on the mode of delivery, a clear majority expressed preference for face-to-face teaching, with 42 different comments explicitly expressing this opinion and 21 generally positive comments about the current on-campus arrangements out of a total of 104 comments on the teaching arrangements (table 3). Among the year 2 students there were two students who stated they had preferred the online teaching the previous year, and six students who expressed a wish for more options where they could choose to attend online or in-person flexibly.

Both sets of students expressed some difficulty in following face-to-face lectures, however, several students stated that they found online resources very helpful, including the lecture recordings (table 4).

Students appeared to be comfortable in the learning environment, and would have preferred less Covid-19 restrictions rather than more. Several year 1 students found the requirement to socially distance from the lecturers to be difficult, while only 4 students expressed any safety concerns about being on campus (table 5).

Table 3: Selected comments on face-to-face teaching, online learning and flexible delivery

Year 1 students	"*Much better than my previous two years of online teaching.*" *"It's really good and helpful that we are able to attend in-person lectures and classes with the Covid pandemic currently."*
Year 2 students	*"I am enjoying the face to face arrangements and much prefer it to the online content last year"* *"I find it very helpful to learn from and help my peers as we learn together instead of isolated."* *"I am happy to attend face to face teaching when necessary. It is nice having the option to work from home"* *"I think I prefer a mix of face-to-face teaching and online classes to have a little variety."*

Table 4: Selected comments on note taking and online resources

Year 1 students	*"I am struggling to make the appropriate notes from the board whist listening to my lecturers."* *"The backup of the recordings and live stream is very useful"*
Year 2 students	*"Finding it hard to follow FTF lectures after using pre-recorded video lectures for a whole year."* *"I think the recorded lectures are a helpful resource"*

Table 5: Selected comments Covid-19 restrictions

Year 1 students	*"I find this difficult as students aren't able to be shown how to do something because of the restrictions."* *"Sometimes it's a bit difficult in modules like engineering design when the lecturers can't come up to us to help because they must socially distance."*
Year 2 students	"*Due to the situation of Covid, the face-to-face teaching is still a bit dangerous"*

3.4 Overview of outcomes

At the time of writing, end of year results have just become available. Initial impressions from teaching staff were that student performance through the year on coursework and continuous assessment was comparable to previous years, but that exam performance was much poorer. This view may have been influenced by the fact that performance during the last two years, where a significant amount of assessment was online and open-book, was higher than normal. An initial comparison has been drawn up comparing the averages and failure rates in 2018-19 (pre-Covid) and this year (2021-22), across three engineering science year 1 modules (MEE1001, MEE1004 and MEE1008), and two year two modules (MEE2001 and MEE2007). These modules were chosen as they have have similar assessment types and weightings (40% coursework and 60% exam), and have not had significant changes between the two years.

Table 6: Overview of student outcomes in selected year 1 and 2 modules

	2018-19				**2021-22**			
Module	Overall average	No. of fails (1st attempt)	No. of students	% Fail	Overall Average	No. of fails (1st attempt)	No. of students	% Fail
MEE1001	63%	22	160	13.8%	60%	33	168	19.6%
MEE1004	56%	19	160	11.9%	49%	36	168	21.4%
MEE1008	60%	11	158	7.0%	55%	18	169	10.7%
Year 1 averages	**60%**			**10.9%**	**55%**			**17.2%**
MEE2001	52%	27	145	18.6%	52%	18	111	16.2%
MEE2007	51%	24	134	17.9%	48%	21	97	21.6%
Year 2 averages	**52%**			**18.3%**	**50%**			**18.9%**

The results (table 6) indicate that for year 1, there has been a notable drop in averages for the modules in 2021/22 compared to 2018/19, and a clear increase in the percentage of students failing the modules on their first attempt. This would agree with the high perceived difficulty that the students reported, and indicate that students joining university directly from school in 2021/22 were not as well prepared for university as students joining pre-pandemic. For year 2, there was a modest drop in module average and increase in failure rate for one of the modules, but not for the other, which had the same average and a decrease in failure rate compared to 2018/19. This would suggest that while the second year students perceived the difficulty level to be higher than year 1 students at the beginning of the year, this may simply be due to the higher academic level in year 2, and that a previous year of online university study may still have prepared them adequately for in-person learning in year 2. This data compares only two years, and does not give a full picture at module or programme level and more in-depth analysis will be completed in due course.

4 SUMMARY AND ACKNOWLEDGMENTS

A survey of students returning to in-person learning after the pandemic has shown that both year 1 and year 2 students expressed difficulty in dealing with the academic level of the programme and the workload, and this was seen to a greater extent in the year 2 students. The level of difficulty experienced by students appears to be more pronounced than for students who joined the programme as direct entry into year 2 before the pandemic based on some limited historical data that is available. Comments made by students show a clear preference for face-to-face learning over online learning, however students see great benefits in supplementary online resources and in retaining innovations that were introduced during the pandemic such as the provision of lecture recordings as standard, and use of advanced features in the VLE. This correlates well with student feedback during online learning which expressed clear satisfaction with asynchronous elements including lecture videos, and other content on the VLE. Students appear to appreciate the opportunity to access content at a time and a pace that suits them, and to be able to revise content with the full lectures available to watch and review as many times as needed. It is hoped that the availability of this additional content will support the students as they develop their skills in independent study, providing additional opportunities for note-taking and revision as they become accustomed to the lecture environment. Initial data on student outcomes indicates some drop in performance, with notable increases in the percentage of students failing modules on their first attempt. The next steps in this study will be to assess attendance data, engagement with online resources and student outcomes in detail, and to determine if the indications of an increase in perceived difficulty level has had a significant effect. It will be important to continue to monitor the experiences and performance of these groups of students, and to design appropriate interventions where necessary to ensure that they are not disadvantaged by the disruption to their education in the long term.

ABSTRACT

Previous studies have reported that many engineering students struggle to develop a conceptual understanding of mathematics in university calculus courses. Engaging with mathematical proofs is one of the approaches to developing a conceptual understanding of mathematics; however, it is not always easy to use standard proofs for this purpose. In the present study, we focus on a type of mathematical proof known as Proof Without Words (PWW). A PWW typically consists of pictures or diagrams that help readers understand why a mathematical statement is true without

[1] *Corresponding Author*
F. Radmehr
f.radmehr65@gmail.com; farzad.radmehr@ntnu.no

doi:10.5821/conference-9788412322262.1223

providing verbal justifications. This study investigates how engineering students engage with PWW tasks related to calculus and also how they perceive its usefulness for teaching and learning calculus. Twenty undergraduate engineering students participated in semi-structured group interviews (in groups of two students), engaging with three PWW tasks related to calculus. Afterwards, students' perceptions of PWW tasks were explored using several open-ended questions. The findings indicate that many students engaged well with this type of activity. Furthermore, all students perceived that PWW tasks could positively impact their mathematical understanding, and many believed they could be used for teaching and learning calculus. Furthermore, several students highlighted that PWWs could also help with comprehending standards proofs and make mathematics learning more enjoyable.

1 INTRODUCTION

Engaging students with mathematical proofs could help students develop a conceptual understanding of mathematics [1]. However, past research has shown that students often have difficulties with constructing and comprehending formal proofs [2]. Therefore, mathematics educators focus on ways to improve the teaching and learning of mathematical proofs [2-3]. On the other hand, improving engineering students' conceptual understanding of mathematics has been the focus of several studies, and previous studies have reported that many engineering students struggle to develop a conceptual understanding of mathematics in calculus courses [4]. In this study, we focus on exploring how a proof type, proof without words, could be used to improve the teaching and learning of calculus to engineering students.

2 PROOF WITHOUT WORDS

There are different classifications for mathematical proofs. For example, Sigler et al. [5] have classified mathematical proofs into *standard proof*, *elegant proof*, and *proof without words (PWW)*. The focus of this paper, PWW, could be defined as "pictures or diagrams that help the reader see why a particular mathematical statement may be true, and also see how one might begin to go about proving it true" [6, p. 118]. Mathematics educators have provided several reasons why PWWs could be used in teaching and learning mathematics. For example, Bell [7] highlighted that using PWWs could help students understand the proof process, develop reasoning skills, and learn how to begin to construct a formal mathematical proof. PWWs could be a supplement for formal proofs and help students understand why a mathematical theorem is true in a more interesting way than some of the formal proofs [6]. Nelsen [8] highlighted this by quoting Martin Garnder, a famous mathematician, at the beginning of his third collection of PWWs: "A dull proof can be supplemented by a geometric analogue so simple and beautiful that the truth of a theorem is almost seen at a glance" (p. vii). More recently, Kristiyajati & Wijaya [9] pointed out that many mathematics teachers also perceived that PWW tasks are interesting activities for students to engage with.

PWW tasks could be used in mathematics classrooms to develop visual thinking in all levels of schooling, from primary to tertiary levels [6]. Many PWWs have been constructed to prove theorems in different mathematical domains such as geometry, algebra, inequalities, and calculus (see, for example, [8]). The majority of previous research that explored the teaching and learning of PWW focused on school mathematics (e.g., [10]). Only a very few studies (e.g., [11]) have explored university students' understanding of PWW tasks and how PWW tasks could be used at the tertiary level. Our literature search indicates that such studies have not been conducted within the context of teaching and learning calculus, particularly for engineering students. Therefore, the present study explores how engineering students engage with PWW tasks and how they perceive its usefulness for teaching and learning calculus to explore the possibility of using such tasks in teaching and learning calculus to engineering students. We considered the following research questions to address this matter:

RQ1: *How do engineering students engage with calculus-related PWW tasks?*

RQ2: *How do engineering students perceive engagement with calculus-related PWW tasks?*

3 METHODOLOGY

In this qualitative study, we take a phenomenological approach where we describe "the lived experiences of individuals about a phenomenon as described by participants" ([12], p.14). The participants were 20 undergraduate engineering students from a major university in eastern Iran who participated in semi-structured group interviews in groups of two. Based on their calculus grades, the students are labelled as S1 to S20 from high to low performance to help readers identify any possible association between students' perception of PWW tasks and their achievement in response to RQ2. The interviews were conducted in Adobe Connect because of Covid 19 pandemic, and they were video recorded and transcribed. Students first engaged with three PWW tasks related to calculus, and then their perceptions of PWW tasks were explored individually using four open-ended questions (e.g., what are your opinions about using PWW tasks for teaching calculus?). The PWW tasks were adapted from Nelson (2015) and were related to (a) the integral area relationships in the context of the natural logarithm, (b) an integral transform, and (c) the relationship between harmonic series and integral. Each task has three parts, and students were given each part separately. In part A, students were asked to respond to the following question: *What mathematical concepts or procedures do you think the figure refers to?* In part B, they were asked to prove the given formula or equalities using the given figure(s). In part C, students were asked to prove the formula/equalities formally. These figures and formula/equalities are provided in Table 1. A correct solution to the tasks was discussed with students before they responded to the four opened-ended questions.

4 RESULTS

We first describe how engineering students engaged with the three PWW tasks in response to RQ1. Then, we discuss students' perceptions of PWW tasks to respond to RQ2.

Table 1. The figures and formulas/equalities in the three PWW tasks

Figure	Formula/equalities
	$\int_a^b ln(x)\,dx$ $= b\ lnb - a\ lna - \int_{ln\,a}^{ln\,b} e^y\,dy$ $= x\ lnx\|_a^b - (b-a) = (\ x\ lnx - x\ )\|_a^b$
	$\int_a^b f(x)\,dx$ $= \int_a^b f(a+b-x)\,dx$ $= \int_a^{\frac{a+b}{2}} [f(a+b-x)+f(x)]dx$ $= \int_{\frac{a+b}{2}}^b [f(a+b-x)+f(x)]dx$
	$\sum_{n=0}^{\infty}(-1)^n \frac{1}{n+1} = ln\ 2$

4.1 Students' engagement with the PWW tasks

Overall, students engaged relatively well with the first two tasks. In response to Task 1, Part A, 90% of groups referred to the concept of integral and mentioned that the shaded area is $\int_a^b \ln x dx$ when the figure was presented to them. For Task 2, Part A, similarly, 90% of groups referred to the concept of integral when the figure was presented to them. These groups also identified that $\int_a^b f(x)\,dx = \int_a^b f(a+b-x)\,dx$. Furthermore, 80% of groups stated that $f(x)$ and $f(a+b-x)$ are symmetric with respect to the line $x = \frac{a+b}{2}$. Regarding Task 3, Part A, all groups mentioned that the figure is related to the concept of integral and series. Moreover, 80% of groups referred also to the integral-area relationship and how a series could be used to calculate the area of rectangles. Thirty percent referred explicitly to the concept of Riemann integral. One group (10%) was also able to construct $\sum_{n=0}^{\infty} (-1)^n \frac{1}{n+1}$ based on the given series under the figures.

The overall success rate of groups for Parts B and C are summarised in Table 2. The findings indicate that many groups were able to prove the formulas using the given figures for Tasks 1 and 2. However, Task 3 was more challenging for students, and even with the interviewer's help, only 60% were able to prove the formula using the figures successfully. Furthermore, the success rate for formally proving the formulas in Part C of Tasks 2 and 3 was much lower compared to Part B. The provided help for Task 1, Part B was that $blnb$ is the area of the largest rectangle in the Figure and in Part C was what could be considered as U and dv in the integration by parts. Regarding Task 2, Part B, the interviewer help some groups to amend their drawing for $f(a+b-x)+f(x)$ in $[a,b]$. For Part C, the provided help was related to students' calculations; some students made a mistake when using the integration by substitution. They incorrectly calculated $dx = dt$ when they considered $a+b-x=t$, and the interviewer told them their mistake. Regarding Part B of Task 3, students realised that the given series under the figures are related to shaded areas; however, they struggled with justifying how the shaded area is exactly calculated with the given series. The interviewer helped them with that. Finally, for Part C, the help was that they could use geometric series to formally prove the given formula.

Table 2. *The overall success rate of groups for Parts B and C across the three PWW tasks*

	Part B			Part C		
	Without help	With the help of the interviewer	Total success rate	Without help	With the help of the interviewer	Total success rate
Task 1	7 (70%)	2 (20%)	9 (90%)	8 (80%)	1 (10%)	9 (90%)
Task 2	5 (50%)	5 (50%)	10 (100%)	2 (20%)	3 (30%)	5 (50%)
Task 3	0 (0%)	6 (60%)	6 (60%)	0 (0%)	3 (30%)	3 (30%)

4.2 Students' perceptions of PWW tasks

All students agreed that PWW tasks could help them with learning calculus. They also pointed out several benefits of using PWW tasks for learning calculus, such as helping comprehend mathematical proofs and learn mathematical concepts (Table

3). Some students also enjoyed engaging with PWW tasks, and a few found it helpful for keeping mathematical concepts longer in mind.

Table 3. The benefits of using proof without words

Themes	N	%	Sample responses
Helping students comprehend mathematical proofs	17 (S1-12, 15-19)	85	"PWWs are more interesting and attract students' attention more than standard proofs. They are presented with figures, whereas standards proofs have only a few symbols or parameters. One can understand the processes in the proof by looking at the figure; they are more understandable than standard proofs" (S4)
Helping students to prove standard proofs	12 (S1-4, 6, 7, 9, 10, 13, 15, 17, 18)	60	"When learning a standard proof, if we have seen a PWW of it, the figure helps us identify its relationship with the standard proof, and consequently a better understanding of the standard proof." (S9)
Improving students' attitudes towards mathematical proofs	12 (S1, 5, 6-10, 12, 14, 16, 19, 20)	60	"In general, PWWs are more interesting to follow, and therefore, it helps us to have a more positive attitude towards mathematical proofs." (S5)
Helping students to learn mathematical concepts	10 (S3, 5-7, 10, 11, 13, 16, 17, 19)	50	"In fact, it makes learning the main concepts easier for us. If we encounter an integral formula without a visual illustration, we would have to memorise formulas and not understand their applications. But in PWWs, using figures makes learning better." (S11)
Enjoyable activity for students	9 (S2, 4, 5, 9, 12, 14, 15, 17, 20)	45	"PWWs... are fun for me, and I enjoy engaging with them..." (S14)
Helping mathematical concepts last longer in students' minds.	4 (S1, 7, 12, 20)	20	"When I come across this series later, its figure will appear in front of my eyes and will last in my mind longer..." (S1)
More accessible to students that standards proofs and less likely that students make mistakes when engaging with them	2 (S9, 19)	10	"We are not experts in proving mathematical theorems; we may not notice if something goes wrong in standard proofs; however, we have figures in PWWs to help us check our work." (S19)

A few challenges of engaging with PWW tasks were also reported, such as some students perceived that comprehending PWWs could be challenging for learning advanced mathematical concepts such as those found in multivariable calculus (Table 4).

Table 4. *The challenges of using proof without words*

Themes	N	%	Sample responses
Comprehending PWWs could be challenging and require strong visual thinking	7 (S4, 5, 9, 12, 14, 15, 20)	35	"In some mathematical topics, it is easier to use standards proofs because if we want to prove using a figure, we need a multi-dimensional figure and paying attention to details requires good visual thinking skills..." (S15)
Analysing the information provided in PWWs could be challenging	3 (S1, 4, 20)	15	"Information in figures of PWWs could be difficult to analyse, and we might make a mistake when analysing them. For example, surfaces have three variables in multivariable calculus and mostly have complex relationships. If we have not mastered them, we might mistake in distinguishing surfaces in the figures." (S1)
Comprehending PWWs is time-consuming	2 (S12, 14)	10	"The teaching time in university courses is short, and the volume of content to teach is high while PWW requires a lot of time to comprehend." (S14)

5 DISCUSSION AND CONCLUSIONS

Helping students develop a conceptual understanding of calculus concepts is one of the main goals of engineering calculus courses [4]. In this study, we explored to what extent PWW tasks could be used to achieve this goal as previous studies reported that engaging with PWW tasks could be interesting for students and could contribute to improving students' mathematical learning in different ways [6-10]. This study also contributes to the existing literature in mathematics education regarding the affordances and constraints of using PWW tasks in teaching and learning of mathematics at the tertiary level, including for engineering students, as most studies related to using PWW tasks were conducted in the school context (e.g., [7, 9-10]).

The findings suggest that all engineering students perceived that engaging with PWW tasks is useful for learning calculus. The reasons they provided for such perceptions are in line with what is highlighted in the literature about the benefits of using PWW tasks. For instance, students perceived that engaging with PWW tasks could help them to have a better understanding of mathematical proofs and how to construct standard proofs. Similarly, Bell [7] highlighted using PWWs in teaching mathematics "can help students improve their ability to reason when asked to explain an illustration, and this heightened reasoning can lead to understanding how to begin a formal proof." (p. 690). Furthermore, many students enjoyed engaging with PWW tasks, as pointed out in [9]. In terms of their engagement with the PWW tasks, students performed relatively well on the first two tasks; however, they faced more challenges when engaging with the third task as they needed to associate their knowledge of integral with their knowledge of series. In line with the previous studies regarding comprehending and constructing proofs [2], several students faced difficulties constructing standards proofs and were more successful in the PWW tasks. Overall, the study findings suggest that PWW tasks could be used in teaching calculus courses to engineering students to provide more opportunities for students to develop a conceptual understanding of mathematics and contribute to making calculus courses more interesting to engineering students.

ABSTRACT

Mathematics constitutes a key component in engineering education. Engineering students are traditionally offered a number of mathematics courses which provide the knowledge needed at the workplace. Unfortunately, many students perceive mathematics as a discipline that teaches mostly procedures not relevant to their

future careers and often view it as one of the main obstacles on their way to an engineering degree. In this paper, we discuss how introducing university students in a standard Differential Equations course to mathematical modelling (MM), a powerful strategy for solving real-life problems, contributes to the development of their mathematical competencies, motivates their interest to mathematics, promotes the use of advanced mathematical thinking, methods of applied mathematics, and digital computational tools.

1 INTRODUCTION

1.1 Mathematics in engineering education

Mathematics is an integral part of engineering education; it helps to establish connections between different physical quantities and furnishes powerful tools to model the behaviour of complex engineering and industrial systems. Methods of applied mathematics are efficiently used to develop new technologies and simulate various real-world phenomena. Analysis of mathematical models reduces the costs for setting experiments '*in vivo*', allows us to evaluate different scenarios, explore feasibility of solutions, and make comprehensive decisions.

The increasing computational difficulty of the engineering tasks and wider implementation of technology in teaching and learning inevitably lead to a more extensive use of computer algebra systems (CAS) in mathematics courses for engineering students. Kent and Noss argued that “advances in the use of information technology and computers have transformed engineering analytical techniques, and production and management processes” [3, p. 4]. Nowadays, students are expected to combine the power of theoretical knowledge with that of modern digital technologies, and the efficient use of both requires advanced mathematical thinking. Not all engineering students are prepared to meet high demands set in mathematics courses and often view them as an obstacle - “some see mathematics as the gateway to engineering, paving the way to sound design; others see mathematics as a gatekeeper, denying entry to otherwise talented would-be engineers” [13, p. 305].

Faulkner et al. [2] emphasised that engineering faculty want students to acquire “mathematical maturity” rather than calculus skills as the learning outcome from mathematics courses. Although “any single construct will provide a complete view of mathematical maturity” [2, p. 100], it is often used by mathematics faculty to describe students “who have achieved a certain combination of technical skills, habits of investigation, persistence, and conceptual understanding” [1]. Faulkner et al. argued that “these engineering faculty believed that the mathematically mature student would have strong mathematical modelling skills supported by the ability to extract meaning from symbols and the ability to use computational tools as needed” [2, p. 97] concluding that a successful mathematics course should be situated on the cross-roads between engineering, mathematics, and programming. The reform of engineering mathematics education requires timely adjustment of course curricula to the changing demands set by the employers. According to Niss and Højgaard, the three main components in the curriculum of a mathematics course are: (a) purpose of the teaching, (b) syllabus, that is, mathematical content, and (c) assessment including instruments to estimate the extent to which the students have learned the mathematical content [5, p. 45].

1.2 Current trends in mathematics education of future engineers

In response to new trends in engineering education, several efforts have been recently made to include modelling tasks and promote the use of CAS in mathematics courses [4, 8-10]. However, time limitations make the use of CAS in the classroom quite demanding, many difficulties also arise with the assessment of students' learning in courses heavily relying on digital tools. Finding a suitable form of assessment in a mathematics course has always been challenging for teachers. The traditional form of assessment in service mathematics courses in engineering departments is a graded written final examination after which the grade for the entire course is assigned. Quite often, restrictions on the time allocated for the exam and associated stress negatively affect students' performance also impacting the assessment results. To avoid this unpleasant situation, efforts have been made to develop different assessment forms, including several forms of embedded assessment and continuous assessment [12].

In order to develop students' mathematical maturity, some changes in teaching practices should be made. Schoenfeld explained that "mathematics is an inherently social activity in which a community of trained practitioners (mathematical scientists) engages in the science of patterns – systematic attempts based on observations, study; and experimentation to determine the nature or principles of regularities in systems defined axiomatically or theoretically ("pure mathematics") or models of systems abstracted from real world objects ("applied mathematics")" [11, p. 335]. Engineering students often think about mathematics as a set of formal rules which should be used to solve a problem and may apply them even without attempting to understand the logic behind the actions taken. The important role of mathematics lecturers is to motivate students to learn how to "do mathematics" and how to "think mathematically", thus enculturating students into the world of advanced mathematical thinking. A social component is especially important in the process of the development of abstract mathematical reasoning. Collaborative work in groups develops students' use of mathematical language, helps to improve both the mathematical argumentation and communication skills. The importance of the project work in engineering education was emphasised in the recent evaluation of engineering degree programs in Norway: "Making the teaching more project-based offers a means of exercising and evaluating the students' communication skills, of participating in interdisciplinary collaboration and demonstrating professional and ethical practices" [7, p. 10].

In this paper, we discuss how mathematical modelling (MM) projects were introduced in a Differential Equations course for graduate students in mechatronics. The first author modified the traditional course curriculum including a small group project work with MM tasks offered in the format of graded course projects counting towards the final grade. Engaging students into solving applied problems relevant for engineering, we connect their knowledge gained in mathematics, physics, and engineering courses. Furthermore, our MM projects promote students' conceptual understanding of differential equations and show how abstract mathematical ideas can be efficiently combined with the possibilities offered by the modern computer algebra systems. The organisation of students' work in small groups introduces essential elements of collaborative learning and enhances students' social skills. Last but not least, the use of graded projects in the assessment distributes students' work more evenly through the semester and reduces the exam stress.

The research question we address in this paper is: *How modelling projects in a mathematics course contribute to the development of engineering students' mathematical maturity and integration of mathematics and engineering?*

2 METHODOLOGY

2.1 Mathematical competency framework

For the data analysis, we use the concept of mathematical competency defined by Niss and Højgaard as "a well-informed readiness to act appropriately in situations involving a certain type of mathematical challenge." [5, p. 49]. An overall mathematical competence is composed of eight competencies which are defined separately but may overlap. These are: (1) thinking mathematically, (2) reasoning mathematically, (3) posing and solving mathematical problems, (4) modelling mathematically, (5) representing mathematical entities, (6) handling mathematical symbols and formalism, (7) communicating in, with, and about mathematics, and (8) making use of aids and tools [5, p.14]. Designing the tasks that contribute to the development of all mathematical competencies at the same time is challenging. However, we argue that project-based MM assignments not only provide an opportunity to improve mathematical competencies of engineering students, but also make the assessment in a mathematics course more efficient.

An important learning outcome of a mathematics course for engineers is the ability to transform a physical or, more generally, an engineering problem into a mathematical problem (mathematisation) and then solve it using appropriate mathematical and computational tools. To achieve this goal in our standard course in Differential Equations, changes to parts of the course introducing theory and methods of solving differential equations were made. These modifications had the following objectives: (i) development of conceptual understanding of differential equations, (ii) meaningful application of differential equations in practical problems, (iii) improvement of students' computational and analytical skills, including the use of programming for solution and simulation in modelling problems, (iv) improvement of students' communication skills and acquaintance with main principles of collaborative work in groups typical for practising engineers, (v) improved, fair, and less stressful assessment of students' work more evenly distributed throughout the semester.

2.2 Teaching experiment and data collection

The teaching experiment was organised in a one-semester course “Mathematics for Mechatronics” for the class of senior students in mechatronics. Three project-oriented assignments, accounting for 30% of the total course grade, were distributed to the students. Each assignment was related to one of the main topics in the course: (a) first order linear differential equations, (b) higher order linear differential equations, and (c) systems of linear differential equations. The class was divided into small groups of 2-3 students, according to their own choice. Students' written reports for each of the projects were collected and graded during the course. The data analysis was conducted after the final grades were assigned to all students in the course.

3 DATA ANALYSIS

3.1 Sample modelling task

In one of the tasks students were asked to conduct a small experiment with a falling chain and observe how the physical parameters affect the result exploring, for example, what is needed for the chain to start moving. For the mathematical analysis of the problem, it is necessary to describe physical forces acting on the chain and analyse the impact of friction by considering the type of the surface.

Modelling task. Lay a uniform chain on a horizontal surface (say, a table) with a part of it hanging down the table. Release it so that it starts moving down. Find the time when it slips off the table.

(a) What conditions and parameters affect the experiment outcome?

(b) Consider cases without and with friction. What are the conditions for the chain to start moving (for both cases)?

(c) Give the explanation of the physical problem and set it in mathematical terms (for both cases).

(d) Set the differential equation describing your model (for both cases).

(e) Solve the problem mathematically (for both cases).

(f) Use Maple/MATLAB to solve the problems numerically, plot and analyse the solution (for both cases).

(g) Validate your model in practice: conduct an experiment and present a small video showing the timer. Do the experimental data correspond to your analytic solution? Which of the two solutions describe your experiment better?

(h) Submit your video as a media file and your report in a PDF format.

3.2 Analysis of students’ solution

Students were asked to experiment with the chains and table surfaces of their own choice. The weight of the chain, its initial position, and the smoothness of the surface had an effect on the time required for the chain to fall off the table. In this paper, we discuss the solution produced by one group of students only. Students illustrated the experiment with Figure 1. They used a necklace to make a chain with the length $L = 0.46\ m$ and the mass $m = 22\ g$.

After several experiments, the students concluded that for the chain to start sliding down the initial length h (see Figure 1) has to be about $0.11\ m$. At this stage, they used the competencies to *pose a problem and ask questions*, and to *describe the relations* between various parameters. The possibility of choosing their own experiment settings allowed students to conduct practical tests prior to designing a mathematical model.

Fig. 1. Group's illustration to a model and snapshots from the experiment video

Next, the students considered the distribution of forces for the frictionless case. They modelled the chain representing it as two masses connected with a massless rope and a frictionless pulley. At this stage, students were engaged in the process of *mathematising*, that is translating a physical problem into a mathematical problem. In the modelling process, one does not need to reinvent a wheel. Usually, if we want to model with differential equations, the motion of bodies is described by Newton's laws, in particular, by the second Newton's law. We emphasise that it is important for the students in advanced mathematics courses to synthesise relevant knowledge from different courses and apply it for solving the problem.

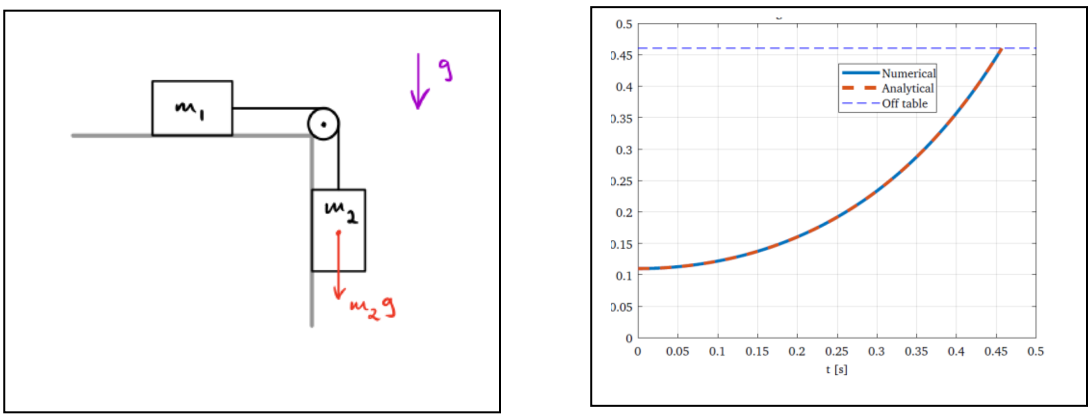

Fig. 2. Illustration of the frictionless model and results of numerical computation

Mathematically the system can be described by the second Newton's law which leads to the differential equation of motion, $m_2\, g = (m_1 + m_2)a$, so the acceleration

$$a = \frac{m_2\, g}{m_1 + m_2}.$$

Using the chain's linear mass density $\frac{m}{L} = \lambda$, we have $m_1 = (L-h)\lambda,\ m_2 = h\lambda$. Then the equation of motion assumes the form

$$a = \ddot{h} = \frac{h\frac{m}{L}g}{(L-h)\frac{m}{L} + h\frac{m}{L}} = \frac{h\frac{m}{L}g}{m} = h\frac{g}{L} \quad \text{or} \quad \ddot{h} - h\frac{g}{L} = 0.$$

The students formulated a mathematical problem by *thinking and reasoning mathematically*, they relied on their previous knowledge in physics for solving the problem. Interestingly, they used the notation "double dot" for the second derivative, as it is used in a physics course, not in mathematics courses. Students identified the differential equation as a second order linear differential equation, and found its general solution in the form

$$h(t) = C_1 e^{\sqrt{\frac{g}{L}}t} + C_2 e^{-\sqrt{\frac{g}{L}}t}.$$

Given that at the initial moment the chain velocity equals zero, the particular solution assumes the form:

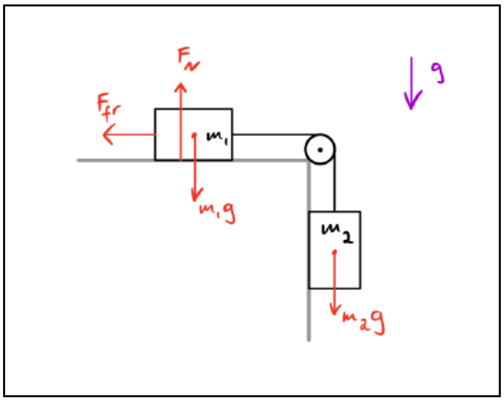
$$h(t) = \frac{h_0}{2} e^{\sqrt{\frac{g}{L}}t} + \frac{h_0}{2} e^{-\sqrt{\frac{g}{L}}t} \quad \text{or} \quad h(t) = h_0 \cosh\left(\sqrt{\frac{g}{L}}\,t\right).$$

In the process of solving the mathematical problem, students demonstrated the *ability to represent mathematical entities* and *handle mathematical symbols and formalism*. Solving the problem numerically, they plotted the graph of the solution with the help of CAS MATLAB demonstrating good skills in using technology.

Finding the time for $h(t) = L$, they obtained $t = \sqrt{\frac{L}{g}}\cosh^{-1}\left(\frac{L}{h_0}\right)$. Using the values of the parameters L, g, h_0, the students concluded that

$$t = \sqrt{\frac{0.46}{9.81}}\cosh^{-1}\left(\frac{0.46}{0.11}\right) \approx 0.457 \text{ sec.}$$

Including additional forces in the diagram, the students discussed the second scenario with the friction. The condition for the chain to start moving should depend on the length of the chain hanging down from the table. Compared to the previous scenario, the start of the motion was only dependent on whether a part of the chain was hanging from the edge of the table or not, regardless of how long it was. The reason for this change in conditions is that now a friction force acts in the direction opposite to that of the chain's motion. The strength of this friction force depends on the mass which is in the contact with the horizontal surface of the table, m_1. As the chain starts moving, m_2 increases, and so does the gravitational force. At the same time, the mass of the chain remaining on the table decreases proportionally and leads to a smaller friction force. This reasoning requires the change in the second Newton's law, $m_2\, g - F_{fr} = (m_1 + m_2)a$.



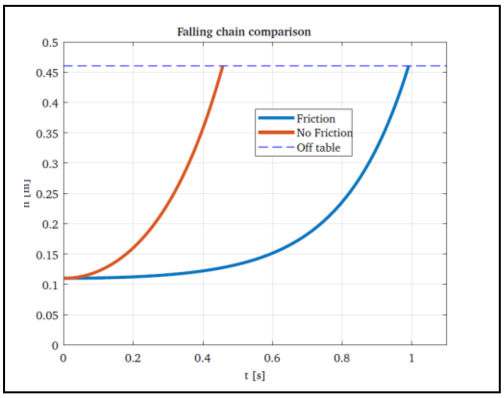


Fig. 3. Illustration of model with friction and results of numerical computation

Then $F_{fr} = \mu F_N$, $F_N = m_1 g$, and $a = \frac{m_2 g - \mu m_1 g}{m_1 + m_2}$. The equation of motion assumes the form

$$a = \ddot{h} = \frac{h\frac{m}{L}g - \mu(L-h)\frac{m}{L}g}{(L-h)\frac{m}{L} + h\frac{m}{L}} = \frac{hg + \mu hg}{L} - \mu g, \quad \text{or} \quad \ddot{h} - h\frac{(\mu+1)g}{L} = -\mu g.$$

Denoting $k_1 = \frac{(\mu+1)g}{L}$, $k_2 = -\mu g$, and solving the equation, students obtained the following solution:

$$h(t) = \frac{1}{2}\left(h_0 + \frac{k_2}{k_1}\right)e^{\sqrt{k_1}t} + \frac{1}{2}\left(h_0 + \frac{k_2}{k_1}\right)e^{-\sqrt{k_1}t} - \frac{k_2}{k_1} = \left(h_0 + \frac{k_2}{k_1}\right)\operatorname{csch}\left(\sqrt{k_1}t\right) \; - \frac{k_2}{k_1}.$$

Substitution of $k_1 = \frac{(\mu+1)g}{L}$ and $k_2 = -\mu g$ yields

$$h(t) = \left(h_0 - \frac{\mu L}{\mu + 1}\right)\cosh\left(\sqrt{\frac{(\mu+1)g}{L}}t\right) + \frac{\mu L}{\mu + 1}.$$

Finding the fall time $t \approx 0.990\ sec$, students compared the two cases in Figure 3.

From the video snapshot in Figure 1, one can see that the fall time in the experiment was 0.925 seconds. After the validation of both models against experimental data, students concluded that the model with friction describes the real system better.

4 DISCUSSION AND CONCLUSIONS

Discussing the role of mathematics in contemporary engineering education, Nethercot and Lloyd-Smith emphasised that it “should be seen as a medium for communicating concepts, ideas, and information in a parallel way to text – and not as the mastery of a series of abstract processes with little or no linkage to physical understanding and application. It should instil disciplined thinking and rigour in the development of arguments based on assumption and simplification in modelling, should teach the importance of controlled approximation, and, above all, impress upon students its value as a tool to be invoked when quantitative evidence is needed to underpin assertion, hypothesis, or sheer physical intuition” [6, p. 14]. We believe that the use of mathematical modelling projects in a standard mathematics course for senior mechatronics students presents mathematics as a medium for communicating ideas and concepts much better.

The research question we asked is *How modelling projects in a mathematics course contribute to the development of engineering students' mathematical maturity and integration of mathematics and engineering?* Using as an example only one of many modelling projects offered to our students, we illustrate how a standard mathematics course can be modified to bring together knowledge and skills from engineering, physics, mathematics, and programming in a meaningful way, cf. [2]. Working on mathematical modelling projects, students combine advanced mathematical thinking with physical intuition, they set experiments, make assumptions, suggest, test, and validate models – all these components contribute to the acquisition of mathematical maturity so much wanted by engineering faculty and employers. At different stages of all projects, eight mathematical competencies [5] are employed and tested without additional exam stress. The work in small groups also provides useful social experience needed for future collaboration in communities of practitioners, cf. [11].

Our experience with the use of modelling projects in a course was positive and encouraging - projects engaged students in collaborative work, contributed to their learning, stimulated exploration, and creativity, and brought positive emotions. Students encountered many practical problems relevant to their engineering specialisation where the theoretical knowledge of linear differential equations and systems of linear differential equations was applicable. Last but not least, students experienced much less stress at the exam since project work contributed to the total grade, and an overall performance in the course improved.

ABSTRACT

Courses in Differential Equations (DEs) have been an important part of engineering education for decades. However, students experience difficulties with the understanding of main concepts including differential equation itself and diverse types of solutions (general, particular, stationary). In this paper, we discuss how the work on non-routine problems on the Existence and Uniqueness Theorems (EUTs) helps students to make sense of DEs and their solutions thus contributing to the development of advanced mathematical thinking.

1 INTRODUCTION

1.1 Importance of mathematics in engineering curricula

Teaching mathematics to future engineers is challenging; one has to maintain a correct balance between theoretical knowledge and techniques for solving relevant applied problems. On the one hand, "the teaching of 'practical' mathematics is becoming much more focused on the process of modelling of engineering systems - this results in a decrease in the teaching of calculation techniques" [11, p. 9]. Furthermore, due to a rapidly growing use of digital technology in engineering education, "there are significant dangers in losing the teaching of pen-and-paper mathematical techniques to 'button pressing'" [11, p. 10]. On the other hand, Clark [7, p. 149] argued that all structural engineers "should experience a rigorous mathematical education, not necessarily because they will use the mathematics in their future careers, but because of the mode of thinking that such education develops." On a similar note, Devlin stressed that "the main benefit they [software engineers] got from mathematics they learned in academia was the experience of rigorous reasoning with purely abstract objects and structures" [9, p. 22].

Although both educators and students acknowledge the importance of abstract mathematical thinking, educational research often points towards the lack of students' conceptual understanding and the tendency of engineering students to take an instrumental approach to their studies. Many students are surprised by the elevated level of demands set in mathematics courses which are often perceived as obstacles on their path to the engineering degree. One of the difficult but important for engineering curricula courses is that in Differential Equations (DEs).

DEs are used for modelling of a wide spectrum of phenomena including nonlinear oscillations in mechanical systems, complex dynamics of financial markets, currents in electric circuits, and spread of infectious diseases. Students should learn both useful solution techniques and fundamental theoretical results and be prepared for the analysis of applied problems described by DEs using analytical techniques in combination with numerical methods and computer. As Bickley pointed out, "in the end, it is not the number of tricks that the student has learned, but rather the understanding of the concepts and awareness of the relevance of the techniques, which is important – and, finally, his approach to the new learning which an encounter with a new problem may demand" [3, p. 383].

1.2 Research on teaching and learning differential equations

Current research on teaching and learning DEs is rather scarce, there are "fewer than two dozen empirical studies published in top journals" which is surprising "given the centrality of differential equations (DEs) in the undergraduate curriculum" [13, p. 555]. In fact, teaching and learning of DEs at the university level is a quite new area of educational research, and "we need to explore the variety of ways in which content, instruction, and technology can be profitably coordinated to promote student learning" [12, p. 84].

New didactic approaches and modern digital technology have a positive impact on students' understanding of DEs. However, many of them erroneously believe that the success in DEs courses can be achieved by learning only solution routines. Recent empirical research actively explored students' understanding of the concepts of a DE and its solutions [1, 6, 12, 14] revealing many difficulties. Students concentrate attention on specific solution techniques and "often fail to relate them to other concepts or ideas" [6, p. 76]. They experience difficulties with the fundamental concepts including a DE itself, the general and particular solutions [1]. Students "made little or no attempt to place the solution in context, be it a solution to an equation or a DE" [14, p. 48]. Unfortunately, "students were successful in algebraic solutions of DEs, but not in conceptualising DEs and the solution of DEs concepts … algebraic solutions of DEs can be found even without a deep understanding and conceptualization of DEs, which is why students do not feel any need to understand DEs and related concepts" [1, p. 887]. In summary, "research has pointed to the various challenges that students face with this concept" [13, p. 555].

The authors [17] analysed several tasks suggested in the literature for assessing students' conceptual understanding of the general and particular solutions to DEs concluding that only one out of five problems encourages students' inquiry and can contribute to their conceptual understanding of DEs. We argued that the correct formation of the concept as Vygotsky's *scientific concept* can be achieved only through the rigorous explanation of all relevant definitions and theoretical results, including the Existence and Uniqueness Theorems (EUTs), which meaningfully complete the definition of a solution to a DE and link all important notions. We believe that conceptual understanding of DEs can be fostered by the use of inquiry-based pedagogy [12] and non-routine problems [2]; first steps in this direction were recently made by the authors [17-19].

The research question we address in this paper is: *How does the work on non-routine problems impact the conceptual understanding of the notion of a DE and its solutions by senior engineering students?*

2 METHODOLOGY

2.1 Inquiry-based mathematic education

Contemporary trends shift mathematics teaching from instructor-centred to student-centred, and the terms inquiry and inquiry-based mathematics education (IBME) appear increasingly often in research literature and in educational policy documents. Simply put, inquiry-based learning and teaching mean the organisation of students' work similarly to that of professional mathematicians. Rasmussen and Wawro [13] argued that the three important components of inquiry-oriented instruction are (i) student deep engagement in mathematics, (ii) peer-to-peer collaboration, and (iii) instructor inquiry into student thinking. A three-layer inquiry model developed by Jaworski [10] takes this idea further considering the inner layer where students engage into inquiry in a classroom with peers and a lecturer, the middle layer where lecturers engage into professional inquiry aimed at creating new learning opportunities, and the outer layer where education researchers and lecturers extend inquiry further to the developmental research.

The ultimate goal of IBME is to empower students to inquire independently and with confidence. Practical strategies that teach inquiry include rephrasing usual problems as questions, searching for hidden patterns, formulating, and verifying conjectures, designing counterexamples, searching for alternative solutions, etc.

2.2 Conceptual understanding and non-routine problems

Reframing standard textbook tasks into inquiry-oriented ones often turns them into *non-routine problems,* that is, problems “for which students had no algorithm, well-rehearsed procedure or previously demonstrated process to follow” [5, p. 2318]. Such tasks introduce uncertainty and associated risks, their use in teaching is challenging both for lecturers and students, but the benefits are significant – “if more time were spent in classrooms with students engaged in working on cognitively demanding nonroutine tasks, as opposed to exercises in which a known procedure is practised, students’ opportunities for thinking and learning would likely be enhanced” [20, p. 92]. By cognitive demands we understand the form and level of thinking needed by students for successful engagement and solution of the given task. Empirical evidence confirms that “the highest gains on a mathematics-performance assessment were related to the extent to which tasks were set up and implemented in ways that engaged students in high levels of cognitive thinking and reasoning. […] Starting with a good task does, however, appear to be a necessary condition, since low-level tasks almost never result in high-level engagement” [21, p. 344]. The use of high-level tasks in teaching encourages student reflections, facilitates generation and exchange of ideas, fosters creativity, stimulates further inquiry, and contributes to the development of advanced mathematical thinking.

2.3 Teaching experiment and data collection

The teaching experiment was organised in a DEs course for senior mechatronics students in their fourth year of studies. A total of thirty-seven students enrolled in this course based on a popular textbook by Boyce and DiPrima [4]. In the final part of the course, students worked for three weeks on an assessed assignment – a set of non-routine problems on EUTs designed by the authors with the focus on the development of conceptual understanding. Our aim was to explore how non-standard questions can challenge students, develop their analytical skills, and contribute to conceptual understanding of important notions and ideas in an ODE course for engineering students. Furthermore, introducing a small group work in the project, we could explore the extent to which individual work and group discussions contributed to students’ conceptual understanding of EUTs and influenced their individual solutions submitted for final assessment.

Participation in the teaching experiment was voluntary. We expected that by the time of the assessment students acquired necessary theoretical knowledge and developed required computational skills. In the first week, students worked on the problems individually in the tutorial and submitted a copy of their solutions to the lecturer (script #1). Then they worked on the assignment at home and handed in individual solutions in the next tutorial (script #2). During the second week, students discussed their individual solutions in small groups, audio-recorded the discussions and submitted the audio files to the lecturer. In the last, third week, students presented solutions they agreed upon in small groups to their peers during the tutorial. The lecturer was present in the class but did not participate in the discussions and did not comment on students' solutions. In the end of the third week, students submitted individual solutions (script #3) for grading and received lecturer's feedback by email afterwards. During these three weeks, students had no lecturer's feedback on the scripts but had the possibility to reflect (individually or in groups) about their solutions and modify them, if desired, in the next script. We collected students' written work (three scripts), answers to pre- and post- questionnaires, audio recordings of the small group discussions, and the recording of the class presentation of solutions. The audio records were transcribed, and the data were analysed after the course work was completed and the letter grades were assigned.

3 DATA ANALYSIS

3.1 Sample tasks and expected reasoning

The problems on the EUTs that do not require the use of computer in the course textbook fall into the following four categories: (i) determine (without solving the problem) an interval in which the solution of the given initial value problem is certain to exist – six problems; (ii) state where in the ty-plane the hypotheses of the theorem are satisfied – six problems; (iii) solve the given initial value problem and determine how the interval in which the solution exists depends on the initial value y_0 – four problems; (iv) explain why the existence of two solutions of the given problem does not contradict the uniqueness part of the theorem – *one* problem.

Since the nature of sixteen out of seventeen problems on EUTs in the course textbook [4] is procedural, the problems in our assignment were designed to engage students in a deeper reflection about EUTs and related notions. In this paper, we discuss students' approach to the following two problems.

Problem 1. (a) Verify that $y(x) = C_1 + C_2x^2$ is the general solution of a differential equation $xy'' - y' = 0$. **(b)** Explain why there exists no particular solution of the given equation satisfying initial conditions $y(0) = 0,\ y'(0) = 1$. **(c)** Suggest different initial conditions for this differential equation so that there will exist exactly one particular solution of a new initial value problem. Motivate your choice.

Problem 2. The coefficient $p(x) = \frac{2}{x}$ in a linear differential equation $xy' + 2y = 18x^4$ is discontinuous at $x = 0$. **(a)** According to the EUT will a solution satisfying the initial condition $y(0) = 0$ exist or not? **(b)** How does your answer to part (a) agree with the fact that $y = 3x^4$ is the exact solution of the initial value problem $xy' + 2y = 18x^4$, $y(0) = 0$? Explain.

Both problems are non-routine; no similar examples or problems are discussed in the textbook [4]. The tasks encourage exploration and set cognitive demands at the higher levels of using procedures with connections to concepts and meanings and doing mathematics [21]. In Problem 1, we expected that students (i) verify that a given function is *the general solution* and (ii) show that the first initial condition yields $C_1 = 0$ whereas the second one leads to a meaningless equality $2C_2 \cdot 0 = 1$. The exploration in part (c) includes two options: either choose the initial value $x_0 \neq 0$, in which case the EUT always assures local existence of solution to a system of differential equations $y' = u,\ \ u' - \frac{1}{x}u = 0$, (an easier one) or change the second initial condition to $y'(0) = 0$ obtaining a one-parameter family of solutions $y(x) = C_2x^2$ (a more difficult one). In Problem 2, one has to show first that the discontinuity at $x = 0$ of the coefficient in the differential equation written in the standard form $y' + \frac{2}{x}y = 18x^3$ does not allow applying the EUT, and the theorem is inconclusive. However, the existence of an exact solution emphasises the fact that the EUT provides only sufficient conditions and if these are not met, a unique solution to the given initial value problem may or may not exist.

3.2 Analysis of the students' work

We illustrate students' reasoning using the transcripts of small group discussions, group A with students, A1-A4 and group B with students B1-B5. We selected episodes where the discussions are particularly succinct. Although students are not native speakers of English, we did not edit the original text in transcripts.

Episode 1 – Problem 1 (b).

A2. My approach there was just to put in the initial conditions and then see that $C_1 = 0$, that is okay, and then I tried the derivative $y'(0)$, it's supposed to be equal to 1.

A3. 0 is never equal to 1.

A2. So the equation does not compute.

A3. So it is not possible to determine C2. […]

A2. It is 0=1.

A1. I did the same thing as well, but I tried thinking why is it this way, and my sort of conclusion was that it's in the bottom of a parabola, where the derivative always is 0.
A3. It cannot be anything else in a bottom of a parabola which is a minimum point.
A1. So, therefore if you state that the derivative at that point should be anything other than zero it doesn't make any sense because it's the minimum point.

A2. It has to be a minimum or maximum point.

In Episode 1, students employed analytical reasoning pointing to the inconsistency of the system of algebraic equations for determining coefficients of particular solution (A2 and A3) and combined it with a geometrical argument referring to the particular shape of solution curves (parabolas) and the zero value for the slope of a line tangent to these curves at the origin (A1 and A3).

Episode 2 – Problem 1 (c).

B4. For my part, I just made up some initial conditions, I just tried them, so $y(1) = 2$, $y'(1) = 2$. Then we can get $C_1 = 1$ and $C_2 = 1$. So, this will possibly be a suitable initial condition.

B3. I also made up some initial conditions and tested them. I used $y(0) = 1,\ y'(0) = 0$, and I get $C_1 = 1$ and $C_2 = \frac{1}{2}$.

B4. Ok, there will possibly be multiple initial conditions.

B1. You can choose any x-value, and arbitrary … anything except $x = 0$ will work?

B4. Ok.

B5. I did the same, I used the existence and uniqueness theorem because of discontinuity at x=0, so no guarantee there, but for all other x there is a solution guaranteed.

B2. That might be the correct solution. We must be sure that we have a solution by referring it to the theorem. I think you can show it by solving, too.

The developments in Episode 2 perfectly matched our expectations. We observe that students discussed both possible modifications of initial conditions that ensure the uniqueness of solutions. B1, B4 and B5 opted for a different initial point whereas B3 suggested the only possible value for the derivative, $y'(0) = 0$.

Episode 3 – Problem 2 (a).

B4. We have a linear equation, like $xy' + 2y = 18x^4$, and if we put it in the standard form, we have a coefficient like $p(x) = \frac{2}{x}$ and that will be discontinuous at $x = 0$. And according to the existence and uniqueness theorem does a solution satisfying the initial condition $y(0) = 0$ exist or not? As a start, I think that is a tricky question […] trick question. So, my suggestion is, due to the discontinuity, the EUT does not apply. The theorem cannot say anything about the existence and uniqueness of that solution.

B2. I agree.

B4. All of us.

B3. Yes.

Episode 3 demonstrates that students understood the meaning of the EUT. They noticed the discontinuity of the coefficient of a DE at $x = 0$ and unanimously concluded that in this case the theorem is inconclusive.

Episode 4 – Problem 2 (b).

B5. The existence and uniqueness theorem just says that I cannot say anything, I cannot tell you anything whether there is a solution or not because of this discontinuity, so the solution could exist or not exist. It does not violate the theorem in any way if it exists or does not exist. But it exists.

B4. But should someone improve the theorem to make it better?

B5. Maybe. I think in mathematics a lot of the times you have some theorem it cannot tell you everything. There is no universal answer for everything.

In Episode 4, the student B5 explained that the EUT does not provide necessary but only sufficient conditions for the existence of a unique solution. His concise and correct explanation confirms a good understanding of the issues discussed in Episode 4 where he seemingly was less active.

4 DISCUSSION AND CONCLUSIONS

The teaching experiment reported in this paper was designed to explore how the use of non-routine tasks stimulates student inquiry and contributes to the advancement of the conceptual understanding of the notions of a DE, its solutions, and related theoretical results, including EUTs. Preparing the assignment problems, we employed the *inquiry by design technique* where lecturers "design tasks and projects that stimulate to ask questions, pose problems, and set goals" whereas students "must learn to inquire systematically" and "must actively construct their own knowledge" [16, p. 38]. Working with senior students who had previous experience with other mathematics courses, developed appropriate learning strategies and social skills needed for collaborative work, we deliberately provided no lecturer's support because "students operating at the frontiers of their conceptual knowledge have no reason to build new conceptual structures unless their current knowledge results in obstacles, contradictions or surprises" [8, p. 82]. Substantial academic maturity of students facilitated their engagement in unguided inquiry. Four episodes from small group discussions in Section 3 illustrate an overall success of the teaching experiment and positive impact of the use of non-routine tasks on the development of students' conceptual understanding of the EUTs for DEs.

In line with [1, 6, 14], we also acknowledge students' difficulties with the concept of the general solution of a DE introduced as the expression which contains all its possible solutions [4, p. 11] and defined only for linear DEs. Integration of the first order linear DEs always furnishes the general solution although the fact that no other solutions are available is not emphasised. Furthermore, the concept of the general solution is used in [4] primarily to develop the theory of higher order linear DEs with constant coefficients. For nonlinear DEs, the situation may be much more complex, and the textbook prompts that "the existence of "additional" solutions is not uncommon for nonlinear equations" [4, p. 11]. However, in attempt to facilitate students' learning, many textbooks use the term "general solution" only to discuss linear DEs. This might be one of the main reasons for students' lack of attention to this important concept explaining the difficulties experienced when asked to demonstrate that a given function is the general solution to a DE, especially if the equation is nonlinear. The issue can be resolved if the notion is properly introduced and illustrated with relevant examples where "additional" solutions are produced. We plan to address this important problem in one of our forthcoming papers along with the analysis of changes in the views on teaching of DEs during the last fifty years.

ABSTRACT

Engineering education is to prepare engineers for real-world challenges and seek novel solutions to cater to society's different needs. There is an increase in the global demand for industry-ready engineers. Engineering education sustainability and industry readiness are mutually inclusive, where the former is the combination of different skills and transversal competencies, while the latter is all about their applicability. Transversal competencies, transferable across disciplines, chisel engineering students to become versatile and practical on the shop floor.

Sustainability in engineering education is usually discussed only from the ecological/environmental viewpoints. This paper tries to find out the relevance of transversal competencies from the perspectives of engineering students at three levels: the most recurring competencies, the competencies they lack, and the ones that need improvement. Recurring and essential transversal competencies such as problem-solving, creativity and innovation, communication, lifelong learning etc., were identified from different policy frameworks of accreditation agencies, industry reports, organizational reports, and academia. Primary data was collected from final-year engineering students for this exploratory research through semi-structured interviews. These transversal competencies, latent throughout the formative years, have a definite role in the engineer's industry readiness, making engineering education sustainable. The need for industry readiness of the engineering students indicates the sustainability of engineering education, which can bridge the gap between the industry and academia. The paper reveals opportunities for further expansion of the competency frameworks in the policymaking and accreditation procedures.

1 INTRODUCTION

1.1 Background

The role of engineers in the world is significant. The world is developing every day and so is the concept of engineering. The world has successfully entered the phase of Engineering 5.0. The main concept in Engineering Education 5.0 is sustainable engineering, which refers to the implementation of engineering solutions without much hindrance to the environment using fewer resources and materials to enable the engineers to face unforeseen challenges (Lantada, 2020). According to the United Nations sustainable development goal 2030, engineers are the solvers of global challenges. Traditional education, which focuses on knowledge, cognition, and technical skills (Care, 2017), often in a pedagogic model, is not enough to keep pace with this multifaceted transformation in the industry. Hence, to prepare the engineers for sustainability, innovative approaches in the learning are rapidly increasing (Cropley 2015; Payzin, 2017). Engineering education is constantly evolving due to new technology and a changing global context. Therefore, learning needs to be active and learner-centred with the help of problem-based learning, project-based learning, research-based learning, etc. (Care, 2017). The learning process evokes behavioural attributes of the learner which work in combination with domain knowledge in the situated context. These learner-centred experiential processes are more effective than a lecture which does not include the participation of the learner (Crasovan, 2017; Cruz et al., 2019). The development of transversal competencies works through these experience-based learning processes.

1.2 Sustainable engineering education

Sustainability, reaching out to all disciplines and levels of engineering education at the university, is likely to extend into lifelong professional development (Lantada, 2020). The sustainability of engineering education depends upon the industry and competency readiness of the engineer. In the engineering industry, the term industry readiness has different dimensions such as process, technology, and organisation. Industry readiness at the engineering graduate level is dependent on the workforce learning and development, leadership, and transversal competencies (Devika et al., 2020). To address the current changes and future challenges across the engineering industries, there is a call for more explorations in sustainable engineering education.

The level of different competencies and interdisciplinary discourses affects the industry readiness of the graduated engineers (Murugesan et al., 2021). There are many definitions, frameworks, and categorisations of transversal competencies by accreditation agencies, international organisations, academicians, and employers. All these domains have overlapping, recurring, and shifting patterns which are defined by the scope of the respective studies/documents (Devika et al., 2021). The needs and objectives of engineering education are already well defined. But there is a need to integrate and work with other disciplines to form a sustainable engineering education platform which is the current need. In engineering education 5.0, the focus has also shifted to the practical part where both domain and theoretical knowledge rely on/are supported by the sub-skills and competencies to attain the desired result. The key stakeholders in this process are the engineering students. For these reasons, a key element of transformed engineering education is that it addresses the sustainability of its human resources: the engineer individually and the engineering community collectively. Crucial to such a transformed engineering education will be the incorporation of elements to help graduate engineers maintain and enhance their abilities over their careers and to adapt to future times and conditions (Sulej, 2021).

In this paper, the meaning of sustainable engineering education is broadened to include the sustainability of the engineer's lifelong learning. The paper tries to analyse the awareness of final year engineering students about transversal competencies at three levels: the most important competencies, the competencies they lack, and the competencies which need improvements.

2 METHODOLOGY

The study has used qualitative research design. Interview was conducted to collect data using a semi-structured schedule as an instrument. Using relevant literature from academia, accreditation agencies documents, industry reports, and project reports and organisational reports, recurring and important transversal competencies in engineering education were narrowed down to creativity and innovation, communication, teamwork, lifelong learning, problem-solving, ethics and environmental awareness. To identify the importance and use of these six transversal competencies, semi-structured interviews were conducted with thirty-five final year engineering students at BITS, Pilani, India. The questions for the semi-structured schedule were prepared with the help of education experts, research scholars, relevant literature and engineering graduates who have extensive industry experience. The interviews were conducted in two phases. Prior to the interviews, the respondents were properly oriented with specialised guidelines. In the first phase, the use, awareness, and purpose of the selected transversal competencies were asked to the students. In the second phase, they were asked to rank and arrange these competencies at three levels; competencies that are important, lacking, and need improvements. For the data analysis, the interviews were audio and videotaped for better documentation and clarity which were later transcribed word-for-word. Content analysis approach (Krippendorff, 2013) was used for data analysis using MAXQDA software (see Table 1). The inter-rater-reliability of the competencies was 0.95 which is considered as a strong value.

3 RESULTS

Based on the content analysis results from the first phase of the interviews, the six transversal competencies (theme), considered important by the final year students – teamwork, communication, creativity and innovation, problem-solving, ethics and environmental awareness, and life-long learning – were extracted from codes via category. The table 1 shows the absolute and relative coding identified for the use of these transversal competencies by the students.

The students were also asked to rank the competencies to gauze the importance of these competencies as per their knowledge. The students ranked problem solving, required to face the uncertainties, as the most important competency followed by innovation and creativity, communication, teamwork, lifelong learning, and ethics-social and environment awareness. Students thought that they needed improvement in communication, teamwork, and lifelong learning; they were aware but lacked the applicability of ethics and environment awareness. The students had the understanding that problem solving abilities, acquired over the period of graduation, would help them at the workplace. For innovation and creativity, communication, teamwork, lifelong learning, and ethics-social and environment awareness, many of the students acknowledged the importance of practice schools (shop floor visits) and internships which would help them to assess and use the other competencies. The study revealed that although the students were aware about the environment impact and ethics in the engineering fields, the knowledge was only peripheral. Students were aware of the need for the competencies which would make them industry ready. But the students were unaware of the identification and integration of the competencies when they faced a problem.

Table 1. Use of transversal competencies by the final year students

Transversal Competency Domain (Theme)	Category	Codes	Coding absolute: the number of codes identified by students/ the total number of codes extracted from the literature review	Coding relative: %
Problem Solving	Problem Identification	• critical thinking • holistic problem approach • clarity	62/62	100

		• observation		
	Cognition (Application)	• possible outcomes notion • decision making • concepts clarity • differences identification • comprehension	64/70	91.42
	Reflection	• finding similarities/uniqueness • learning from errors	60/60	100
Innovation and Creativity	Motivation	• challenge • freedom • idea support and idea time • motivation • cognitive abilities • thinking style • knowledge	50/59	84.74
	Idea Generation	• intelligence and curiosity • autonomy • hard work and perseverance • technical resources • openness	41/50	82
	Reflection	• flexibility • encouragement and recognition • challenge and pressure • risk taking	39/50	78
Communication	Presentation Skills and Client Interaction	• feedback • ideas sharing	48/67	71.64

	Intercultural Communication	• experience field/area • self-confidence • self-exposure	42/59	71.18
	Team Communication	• listening and reading • cooperation • mutual responsibility • shared field of experiences	40/54	74.07
Teamwork	Leadership	• agreement • authority • accountability • trust • adaptability • decision making methods	60/77	77.92
	Communication	• clarity • direction • shared purpose • individuality	44/57	77.19
	Workflow Procedures	• dedication • working relationship • conflict management	52/73	71.23
Lifelong Learning	Initiation	• engagement • motivation and curiosity to learn • willingness	50/65	76.92
	Learning Process	• self-efficacy beliefs • empowerment • learning (study plan) • intellectual development • information location and scrutinisation	46/62	74.19

	Reflection	• self-reflection, self-monitoring, self-regulation • satisfaction • metacognition	46/62	74.19
Awareness on Ethics and Environment	Environment and Sustainability	• responsibility towards environment • knowledge on health hazards	20/37	54.05
	Awareness on Ethics	• commitment • job value • integrity	17/35	48.57
	Application of the Knowledge	• offer constructive criticism • treat everyone with respect • heed critical reviews	15/35	42.85

4 DISCUSSION

The responses from the interviews revealed that each competency had its relevance at each stage. These competencies work in relation to each other. The domain knowledge is to be strengthened with the process knowledge as well. Exposure to organisation and its working creates the environment to learn the competencies at the scale of real task execution. These transversal competencies are relevant in multiple ways (see Table 1). Competencies are not flat or unidimensional but dynamic and multidimensional. An explicit exposure and experience seems to create an understanding which may help them implement these competencies more effectively. Theoretical understanding about the process gets challenged and fine-tuned by the real work with people from different academic backgrounds, cultural sensibilities, communication ease, etc. The terminologies take different understandings when put in the context of real-life situations/industries/workplace. The learning turns out to be lifelong and life wide.

According to the study, students tend to learn more from errors and try to remember and not repeat the same in a similar problem. By the final year of graduation, the students develop their own ways of problem solving. Problem identification, cognition, and reflection, the components of problem solving, are most sought after by the final year engineering students. To solve the problem, the students are expected to include experiences of other people. Hence, teamwork plays an important role in it. Teamwork includes leadership, communication in the team, workflow procedures. The values reflect that teamwork is one of the areas the students think that they need improvement and many of them think that this can only be achieved when they are in a real team in the industry. The students who had industry internships suggested that they needed more such practice-based learning methods in engineering education. The team can only work in a comprehensive manner if the team members are engaged in active communication. Communication also contributes to other competencies as well, such as teamwork, where the students are concerned about the linguistic capabilities and clarity in the oral presentation of ideas. The data suggests that the intercultural communication competence also needs to be improved while student interaction in the teams is better compared to the other components of communication. Innovation and creativity is one of the competency domains the students are well aware of. In the formative years of graduation, they get the opportunities and freedom for innovation. The students think that the education gives more space for them to think creatively and to come up with novel ideas and solutions. In the process of innovation and creativity, final year students use motivation, idea generation, and reflection. For them, motivation is the most used part of innovation and creativity followed by idea generation and reflection. Most of them think that they need more freedom and flexibility to work innovatively, a concern once they are placed in an industry.

As the industries are expanding their reach in terms of ethics and environment awareness, the least preferred competency domain by the students. The students know the environmental sustainability of a particular product or process, theoretically. But they think many times before applying the knowledge. They are more profit conscious and would consider the economy and profit parameters before thinking about sustainability. Ethical perspectives are yet to be developed for the final year students as they have only some general information on the domain.

Many of the students expect to cover these competencies in the upcoming training programs once they are placed. They are aware but need the exposure to industry to see the application of competencies at the workplace. The learning scope is wide and varied with no-definite and no-fixed notions.

5 SUMMARY

The awareness, use, and integration of transversal competencies from the formative years help the holistic development of the engineers. This sustainability in engineering education can only be achieved only when the transversal competencies are identified and used according to the needs by the students. As a first step, this study identified and classified the transversal competencies according to the perspective of engineering graduates. Following, learning from, and using an integrated framework of transversal competencies may help learners attain industry readiness and engineering education sustainability.

ABSTRACT

The fibre of engineering education has evolved from knowledge to competencies. This is a logical consequence of the technologically advanced and multifaceted learning environment where engineers are expected to be technically acute along with a set of essential non-technical competencies. This change is referred to as a 'paradigm shift' in engineering education. Hence, the vision of learning is to immerse a progressive, learner-centric, and competency-based learning environment to face the uncertainties of the 21st century. There are various ways to improve the performance of learners by implementing the available competency frameworks, but the need is to initiate a set of essential competencies according to their nature and purpose that can endure across disciplines. In this paper, the evolution of competencies from the essential to the necessary is reviewed. Finally, the benefits of these competencies in relation to the performance of the engineers are discussed in detail through semi-structured interviews conducted with the engineers. MAXQDA, a qualitative data analysis tool, is used to analyse the data. The findings will help the engineers in grooming their competencies according to the industries.

1 INTRODUCTION

There is a paradigmatic change in engineering education - a shift from mere technical knowledge to transversal competencies. The learning has to be more inclusive, multi and interdisciplinary, oriented towards the situated social and political scenarios. Its vision is to create a progressive, learner-centric, and competency-based learning environment. Active learners and executioners need these competence and skills to deal with the ill-defined and unthought-of problems of the 21st century (Sangwan et al., 2022). Most learners today are natural investigators, researchers, and information synthesisers as a result of their continued use of digital and mobile technology. These competencies help learners to groom themselves as lifelong learners capable of acclimatising flexibly of changes, and collaborative learning and working environment (Redecker & Punie, 2013). Hence, development of 21st century competencies has to be more inclusive (Neeley, 2021) in accordance with current workplace advancements (Moczek et al., 2015).

Preparing engineers for work, global citizenship, and life in the 21st century is a challenging task. Globalisation, new technology, relocation, international competitiveness, ever-changing markets, and transnational environmental and political challenges influence engineers' capacity to survive and succeed. These talents are referred to as 21st century competencies, higher-order thinking skills, deeper learning outcomes, complex thinking, communication skills, etc. by educators, education ministries and governments, foundations, employers, and researchers. Engineering students overestimate their understanding and acquisition of competencies, sometimes cherishing even an idealised perception. If engineers want to be a part of this phenomenon, they must have a deep understanding of competencies (Wilson & Mukhopadhyaya, 2022). This study focuses on the indispensability of essential competencies for 21st century engineers. The questions addressed are: what are the crucial talents that 21st century engineers must develop and master today; how these may assist learners in navigating the problems; and which competencies will engineers require to face these tumultuous and unpredictable problems?

2 LITERATURE REVIEW

Personalisation, informal learning, communication, teamwork, productivity, and content formation, kernel aspects of the competencies and skills, are critical to the overall concept of 21st century education (Singh et al., 2019; Redecker & Punie, 2013). The rising use of technology is changing how learners learn and create new social norms, and finally leading to lifelong and life wide learning. Furthermore, personal skills (initiative, resilience, personal accountability, risk-taking, and creativity), social skills (communication and collaboration, networking, empathy, and compassion), and learning skills (managing, organising, metacognitive skills, and failing forward - or changing perceptions of and responses to failure) are critical to peak performance at the 21st century workplace (Raj & Sangwan, 2020, Redecker & Punie, 2013).

Over the previous two decades, international organisations and commissions, governments, commercial consortia, and private institutions have developed frameworks to address the challenges of the 21st century. While there is no one-size-fits-all approach to educating young people for the 21st century, there are a number of competencies available (Sangwan, 2021). The International Commission on Education for the Twenty-First Century’s Delors Report (1996), at the very onset, established the four visions of learning - knowledge, understanding, life skills, and action skills. Several studies (Sangwan et al., 2022; Devika et al., 2020; Griffin, 2012; Partnership for 21st century Abilities (P21), 2005) have highlighted the main skills required to prosper in the globalised world of the 21st century. Creativity and innovation, critical thinking and problem-solving, communication, collaboration, information literacy, technology usage, career/life skills, and personal/social responsibility are found to be dominant 21st century competencies.

Engineers, working in multidisciplinary teams, coordinate multiple competencies to address complex problems (Passow & Passow, 2017) (environment, sustainability, resources depletion, societal living standard, etc.), which call for social competencies as well (Wilson & Mukhopadhyaya, 2022). Service learning (Muñoz-Alcón et al., 2022), active learning (Hernández-de-Menéndez, Marcela), competency-based learning (Henri et al., 2017), learning factories (Devika, 2021), an outcome based and learner-centred pedagogy, may help the engineers groom themselves at personal as well as the citizenship level. Evidence-based competencies have relook at teamwork as coordination, ethics as responsibility taking, lifelong learning as information collection and skill expansion, etc. to exchange information and plans, apply knowledge and skills, and seek problems and solutions (Passow & Passow, 2017).

3 METHODOLOGY

The research approach is categorised as interpretive research with the goal of gaining a deep understanding of the contextual factors and the interviewees’ perceptions about the importance of the competencies in 21st century environment. In this qualitative study, open-ended questions and non-numerical analysis were used. The unit of analysis was the critical incident reported by the participants. A critical incident refers to a work situation. This technique allows the interviewees to express their views in their own terms, helps avoid misunderstandings and can create reliable, comparable qualitative data. We used the Critical Incident Technique (CIT) to derive all critical competencies (Koch, 2009). Interviewees were asked the following subquestions: (1) What were the challenges you faced during the initial period of recruitment? (2) How did you overcome these obstacles and progress? (3) What were the consequences of your actions regarding the concrete work situation? (4) What impact did effective problem-solving have on the work’s future progress? A total of 30 responses (freshly graduated engineers in recent two years) were collected for this study. To determine how many people needed to be sampled, the concept of theoretical saturation (Glaser, 1992) was used.

All the interviews were recorded and transcribed using the software MAXQDA to conduct content analysis. Although we asked the interviewees all the sub-questions (e.g., what led to this work situation?) together with the main question about a critical incident (please recall an important work situation), the interviewees often did not describe the incident in chronological order, and instead skipped back and forth from one stage to another. Similar incidents and phenomena were then compared and contrasted with each other, and correspondingly coded where they were found to be similar. With the newly added data, the iterative reflection of the already coded data was carried out. Several iterations were done to narrow down the level of granularity of work situations (the consequences of the analysts' behaviour). Subsequently, we compared existing competency models with initial codes to select a model that fitted the data well. It consists of eight competencies and 30 components of competencies at the finest level of detail, where no competency is subsumed by any other competency. The framework of the competencies contained detailed definitions, including behavioural indicators, which were adapted to the role of the engineers.

4 RESULTS

Based on the perception of the graduated engineers, the study identified eight competencies (see Table 1) which cover eight high-level competency factors. When the participants were asked about the challenges they faced during the initial period of recruitment, they reflected on various problems, including the transition from the learning environment to the execution environment. Working under pressure (dominated by seniors), taking responsibility (afraid of taking the responsibilities of the task due to their newness in the working environment), working by themselves (working on their own without seeking assistance from experienced people), working with people from different backgrounds, being afraid of failure, dealing with superiors, not knowing enough languages, etc. The second interview question referred to the methods (competencies) of overcoming the challenges used in situated work. The definitions of these competencies garnered against the setup of particular work situations, contextual factors (antecedents) are shown in Table 1. The third interview question dealt with the consequences of the actions taken regarding the concrete work situation. The fourth interview question addressed the stages of the implementation of the competencies at various levels, which can help the engineers in managing and solving the problems.

Table 1. 21st century competencies of the engineers

Competencies	Components	Findings
Creativity and innovation	Fluency of ideas	Generate a variety of ideas about a given issue (the number of ideas is important, not their quality, correctness, or creativity)
	Flexibility (variety of ideas)	Be flexible in developing a wide range of thoughts and reactions across several categories to observe things

		from various perspectives. Also think about and transition between different notions at the same time.
	Originality (uniqueness of ideas)	Originality is frequently related with qualities like imagination, persuasiveness, and creativity.
Critical thinking and problem-solving	Critical thinking	Analyse, interpret, infer, explain, observe, reflect, self-regulate, and self-evolve to solve the problem.
	Application skills	Apply domain knowledge and skills, contribute to the assigned role, and accomplish work tasks smoothly.
	Problem finding	Develop critical thinking to necessitate observation to identify and resolve the problems, based on previous experience, to forecast the problems.
	Information collection	Check the data's origins and credibility to see if the findings are based on facts or merely views.
	Reflective thinking	Develop higher-order thinking skills, relate new knowledge to prior understanding, think in an abstract way, develop questioning attitude, identify areas for improvement, and encourage active engagement.
	Decision making	Take work responsibility, demonstrate commitment to appropriate decisions to ensure work ethics, generate and evaluate alternatives before making a decision, and select the option that balances risk and reward.
Communication	Verbal	Communicate verbally in straight forward and appealing ways especially during discussions where the managers/team take appropriate actions.
	Confidence	Be confident during hostilities to solve and understand the problem and communicate with the higher positions people to state the ideas and intentions clearly.
	Concise	Be concise in communication by sticking to the point, keeping the information brief, constructing sentences carefully, and using grammar properly.
	Feedback	Take and give feedback to evaluate the effectiveness of messages by ensuring no miscommunication.
Collaboration	Negotiation	Exercise general, special, and specific coordination to provide reliable psychophysical readiness and suitability for quick, effective, and successful solutions.
	Cross-cultural sensitivity	Accept and respect other cultures and others' cultural identities. Cultural sensitivity counters ethnocentrism, and involves intercultural communication.

	Organisation	To be organised, prioritise and organise tasks meritoriously, share information equally in a team, create a plan for success, ensure proper training, and conduct regular meetings to get suggestions.
	Open-mindedness	Be open- minded and unbiased to listen to others and reduce interpersonal or intra-team conflicts in the team.
Information literacy	Digital/social media management	Have a great understanding of digital marketing and online based digital technologies such as desktop computers to promote products and services.
	Critical media content evaluation	Access, retrieve, understand, evaluate, create, and share information/media content in all formats through media platforms with regards to the materials available for scrutiny in the different forms of media/information.
	ICT attainment	Be critical in applying logical/critical thinking to evaluate the information. Use computer operating systems to produce common digital information and use internet to update the company's social media accounts.
Technology usage	Technical writing	Express difficult information in writing in a clear and understandable manner about products and services.
	Project management	Develop technical initiatives and project management skills to master complicated systems and programmes.
	Productive software applications	Master productivity in general and customised software such as word processing, spreadsheet, and presentation to complete tasks professionally.
Career/life Skills	Self-awareness	Perceive self-strengths and preferences to recognise effective stress management strategies.
	Coping with stress	Be physically and mentally healthy to deal with stressors in the company. Identify what causes stress, how to cope with them, and how to avoid them.
	Coping with emotions	Understand/manage personal emotions in the company to entail greater knowledge of the conditions that trigger negative feelings and investigate the appropriateness of emotional responses to certain situations.
	Healthy interpersonal relationship	Maintain a healthy interpersonal interaction in the team through compassion, empathy, emotional reciprocity, effectual communication, etc. to create and sustain a healthy relationship in the company.
Personal/social responsibility	Environmental responsibility	Work in an ecologically responsible manner. Reduce pollution, increase reliance on sustainable resources, and offset negative environmental impact to maintain corporate social responsibility.

	Ethical responsibility	Ensure ethical responsibility to certify that the organisation operates in a fair and ethical manner. All stakeholders, including leaders, investors, employees, suppliers, and customers, should be treated fairly by organisations.
	Economic responsibility	Take responsibility for all the economic factors related to the environment to give a positive impact, not just maximise profits.

5 DISCUSSION

On an average, important work situations described by the interviewees required two main competencies to identify the problem (communication and collaboration). When freshly graduated engineers joined industry, they faced challenges in terms of adjusting to and understanding the working environment. In such situations, they are expected to learn from an expert (feedback/suggestions) about their performance. This can only be done if the team members are open-minded and willing to share.

The second stage is to solve the problem, where engineers are to use critical thinking and problem solving, creativity and innovation, information literacy, and media literacy (four competencies). Critical thinking and problem-solving abilities allowed them to apply higher-order thinking to new problems through acceptable reasoning and suitable decisions (for non-routine problem solving). Critical thinking requires an understanding of the surroundings and resources to avoid problems; creativity and innovation assist in inventing new ideas/approaches to look at the problem from a different perspective. In the new technological environment, special emphasis is placed on knowing how to best apply technological knowledge during a crisis. Such technology usage strengthens the ability to find and apply appropriate tools resourcefully, ethically, and successfully. Information literacy and technology go hand in hand, where information literacy provides the capacity to obtain, assess, synthesise, and disseminate information from a variety of disciplines.

When it comes to the third stage of the experiences that are learned from both the stages, two competencies (personal/social responsibility and career/life skills) are important. Personal and social responsibility allow us to collaborate with others by identifying and respecting cultural differences while dealing with people from various cultural and social backgrounds. Career/life skills make engineers self-directed and autonomous learners who can embrace change, manage projects, exhibit ownership of their work, lead others, and generate outcomes.

While conducting the interview, an interesting observation comes in terms of competency knowledge. Barriers seem to be that the competencies are either not widely known by the participants or they tend to avoid the effort of understanding and implementing the learned competencies in the workplace, such as career and life skills, critical thinking, and creativity. Additionally, the criticality of having high technical knowledge and information literacy is not sufficient in conducting the smooth functioning of the work. The interviewees also stated the importance of these skills in getting the job. Individual Competencies assist individuals by (a) summarising the experience and insight of seasoned practitioners; (b) providing a tool that individuals can use for their self-development; and (c) outlining a framework that can be utilised to help select, develop and understand the effectiveness of engineers. Thus, the effectiveness of engineers' jobs often depends upon specific combinations of these competencies.

Engineers should be able to communicate across a wide range of cultures because they work with such a diverse group of people. Collaboration concentrated on the active integration of all the team members into all aspects of the decision-making process. The participants' most common theme was that they needed to improve their communication abilities. They regarded communication essential for successful career advancement. Regular communication, early presentation of concepts, and feedback seeking help in maintaining a healthy and friendly environment at the workplace. However, it was not always sufficient to solely concentrate on creating a friendly environment. In some cases, this even led to unsuccessful project outcomes when teams, for example, wanted to keep doing their work exactly the same way despite possible improvements or when they underestimated the technical complexity of the desired software product. In this situation, the team has to develop innovative ways of working by improving their information literacy and technological knowledge. Blurring the barriers of culture and behaviour leads towards a healthy relationship and a positive outcome of the work. Engineers are required to behave independently, make judgments, and collaborate with peers in real-life situations. As a result, collaboration provides an opportunity to engineers on the periphery to integrate their knowledge and abilities into the core of the engineering community.

6 CONCLUSIONS

The paper elaborates on a 21st century competency model, thus contributing to theory in the critical area of competency evolution. The study sheds light on the specific situations at the workplace for newly recruited engineers. Overall, the paper triggers the need to link competencies with specific situations and stages so that the newly graduated engineers can consciously work on grooming their competencies. Based on the result, it might be possible to connect the identified competency profile with existing standard tests used in HR management. This would enable a better and easy-to-apply recruitment process. It also facilitates better individualised training programmes for engineers. Moreover, this paper shows how other engineering-related job profiles can be analysed and, correspondingly, explored and developed. The main limitation of research refers to the derivation of the model from interviews. However, the participants explained in detail how a specific behaviour had impacted the further advancement of the work.

ABSTRACT

In today's fast-moving world, we must continuously adapt to changes in all areas of life, and the ability to do so is increasingly highlighted as a key skill particularly for engineering graduates. At the same time, research shows that having a stable professional identity, and identifying with one's field is important for aspects such as job-satisfaction and productivity, in addition to overall well-being. However, research of higher education have been critizised for apparently viewing professional identity and employability as synonymous, and an end 'goal' of education, rather than exploring the continuous processes of professional socialisation that take place in the everyday practices of universities. Accordingly, we ask: what affects engineering students' professional identity constructions *while* they are students?

To explore the proposed research question, a quantitative survey instrument measuring professional identification, as well as previously identified related aspects has been constructed. In the research literature, there is little consensus on how to measure professional identity quantitatively, thus, developing a comprehensive measure that can provide insight into these processes is the focal point of the study. Subsequently, the data material consists of 271 engineering students at the Norwegian University of Science and Technology.

1 INTRODUCTION

In today's ever changing world, flexibility is highlighted as key competency in both education and the working life. Within the field of engineering education, flexibility is important for teachers and academics when educating the engineers of tomorrow while at the same time handling the fast-paced developments of technology and modes of communication. In addition, educators have to balance between contributing to students constructing clear professional identities, all the while they have to aid them in developing the highly requested flexibility. [1] In this context, engineering education has been subject to various changes and reforms due to the experienced mismatch between the scientific focus of universities, and the multifaceted demands of professional practice, with the links between engineering degrees and the realities of an engineer's working life are often put at the forefront of engineering education. [2]

On a more general level, research literature emphasises how constructing stable senses of selves and being able to separate oneself from others is fundamental for how we lead our lives. [3] For adults, the workplace and one's professional identity therefore becomes perhaps the most influential source for the ongoing negotiations of identities and (self-)perceptions. [4] Consequently, higher education emerges as a significant arena for adults' identity constructions, especially in terms of professional socialisation and identification. [3, 5] From a sociocultural perspective, identity is both social and personal, as well as dynamic and ongoing, embedded in the surrounding contexts, and can be viewed as the result of dynamic mediation and negotiation between individual behaviours, social contexts and cultural structures. [4] 'Professional identity' thus, reflects the sense identification to or with a profession or field, on both a personal and social level. [3] Research on professional identity also shows that a strong sense of belonging to one's field and identification with one's professional 'group' can affect several aspects of life, such as general wellbeing and self-esteem, as well as job-satisfaction and work performance. [5, 6] However, Daniels and Booker argue that higher education research generally puts too much emphasis on professional identity as an end 'goal' rather than exploring the ongoing socialization in the everyday practices of university students. [5]

Keeping the growing interest on students' professional identities in mind, we find it interesting to approach identity construction and negotiation processes from an engineering education research perspective. Based on the previous line of reasoning, there appears to be a need to explore these processes of professional identification through the experiences of students. In accordance with a dialectal pluralistic perspective, one can argue that it would be advantageous to employ both qualitative and quantitative measures to attain a comprehensive understanding of such a complex phenomenon. However, as there appears to be a lack of quantitative instruments examining professional identity, especially within sociocultural theoretical frameworks, the aim of the current paper is to present such a quantitative measure, in addition to exploring students' professional identification the research question: what affects engineering students' professional identity constructions *while* they are students?

2 METHODOLOGY

2.1 Development of the instrument

Informed by a dialectal pluralistic perspective, it is believed that employing a variety of approaches is useful to research complex social phenomena, such as professional identification. The questionnaire is part of a larger mixed methods research project on students' professional identities with a planned sequential explanatory design. Thus, in developing the survey instrument, a key aim was to have an open and broad approach to be able to explore an array of possible connections and relationships to be delved deeper into through later qualitative approaches. In this regard, it was important to establish a clear theoretical understanding of the phenomena at the 'heart' of the project, harmonious with both quantitative and qualitative approaches.

Starting from a sociocultural and discursive perspective on identity, possible quantitative operationalizations were explored. First, we attempted to translate and employ the Professional identity Scale Questionnaire (PISQ-5d) by Mancini et al., however through the pilot study it became apparent that it did not work as intended in our context. [7] The subsequent revision of the instrument and analysis of the results (e.g. factor analysis and correlation matrix) also showed that there were some ill-fitting aspects of the instrument. The further development of the instrument included revising the conceptualisations, operationalisations and measures to better suit the specific context and participants. For instance, changing the main dependent variable from 'professional identity *status'* to a two-folded measure for professional identity through measuring 'professional *identification*' an 'professional *commitment'* with the latter being greatly based on some of the items from PISQ-5d that had consistent results in the pilot study. The former measure is based on an adaption of Mael and Ashforth's scale for Organizational Identification. [8] In addition, a single-item social identification measure (SISI) ('*I identify with engineers'*) has been included as research has highlighted consistent high validity and reliability across a broad range of social groups [9, 10]. It is the SISI that is at the centre of this paper, while the other measures will be analysed later on. However, we believe that the SISI encaptures the previously presented perspective of identification with a social group as a key aspect of professional identity, thus being suitable for the scope of this paper.

In addition, students from academic disciplines found it difficult to relate to and respond to items including 'neutral' term for professional identification such as 'a professional' in the pilot study. Consequently, each questionnaire was adjusted to fit the field and ensure that the participants understood the questions, e.g., '*engineers', 'chemist'* or *'sociologist'.* This also impacted the method of distribution which will be explained in the next section.

2.2 Sample and distribution

The target group of the project as a whole is 'students at the Norwegian University of Science and Technology (NTNU)'. However, as noted in the previous section we were not able to produce a 'general' questionnaire that we could distribute to all students at the university and had to adapt each questionnaire to the given programme. NTNU is also a relatively large university with close to 45 000 students and more than 330 programmes, and thus selecting a number of programs to focus on appeared appropriate.

Additionally, based on the pilot survey we changed the previously intended method of distribution. Before the pilot, the plan was to distribute the survey digitally through informal forums run by the students themselves, i.e., Facebook-groups, group-chats etc. to make the project as participant driven as possible. However, in the pilot, the response rate of the group targeted through this approach was 18,75% (N = 21), while the response rate of the group in which we conducted the focus group who had time during their lecture to respond was 100% (N = 12). Of course, there are most likely other aspects influencing these response rates, nevertheless the main method of distribution was changed from predominantly student-driven, to recruiting lecturers and faculty to aid in the distribution. To ensure the informed consent of the participants, as well as the convenience for all parties, the distributors received an information document, a short information film, a direct link to the survey and a QR-code that was linked to the survey, making it possible to show on a PowerPoint or other presentation devices.

As a result, 522 students from 50 different study programmes have participated in the survey. Due to the nature of the distribution method, in addition to most lectures being non-obligatory and the low attendance after COVID-19, as well as several courses consisting of students from an array of different programmes, it is challenging to make any claims about the response rate. Subsequently the number of students reached might not be equivalent to the number of students enrolled in the programme nor the specific subject of the lecture in which the questionnaire was distributed in. As the focus of this paper and conference is engineering education, the results are based on the 271 engineering students that have participated in the survey so far, and not the remaining 251 students.

2.3 Operationalizations and varibles

To measure students' professional identification, we have employed the SISI to explore wether the students' identify with engineers. As stated, previous studies have highlighted the strong validity and reliability of this measure across samples and contexts. [9, 10] Despite this recognized scientific quality of the measure, we discussed changing from 'I identify *with*' to 'I identify *as*', however, due to the full project including other measures for identification and commitment in addition to the SISI we chose to keep it as is to see whether they would complement oneanother or overlap. Preliminary results show a significant ($p = <.001$) moderate correlation between the single-item measure and the composite measure of identification (.30), indicating that they to some degree are related to oneanother. In addition, using 'with' instead of 'as' is believed to encapture the social aspect of the previously presented understanding of professional identity, while also pointing to it being an internal identification with a social group, thus fitting well with the aim of the paper.

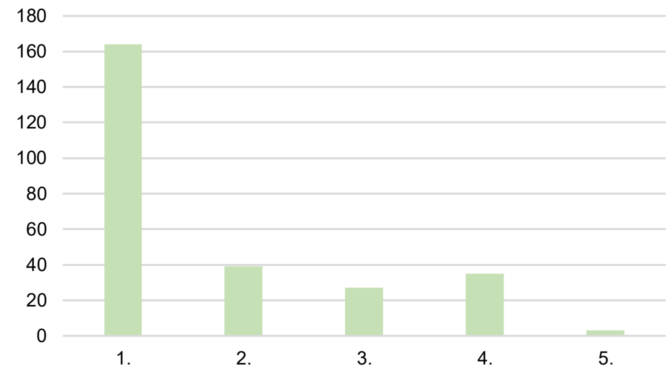
Furthermore, we have included composite variables of intrinsic and extrinsic motivation based on the works of Skatova and Ferguson, and Ryan and Deci. [11, 12] The measures consist of four and three items, with the factor analysis proving a high degree of inner reliability for both variables with factor loadings ranging from .649 to .867, and Cronbach's alfa .741 and .728 respectively. In addition to these composite variables, we asked the students about their previous work and/or volunteer experiences, and whether they found it relevant for their degree, as well as praxis as a part of their programme.

3 RESULTS

3.1 Participants

As mentioned, the data consists of 271 engineering students from 21 of NTNU's 32 engineering programmes. The distribution of participants across programmes is varied, with the larger groups being Bachelor's degree in Civil Engineering (16,3%), Electrical Engineering (10,0%), Mechanical Engineering (11,4%) and Master's degree in Industrial Economics and Technology Management (9,2%). Due to the varied number of participants from each programme, we will not differentiate between programmes in this paper, but rather uncover similarities and important factors for engineering students as one group. However, we also acknowledge that there could be important distinctions between programmes, which we hope to be able to explore further in the future. On the note of the future research, we also intend to perform comparative analyses between engineering programmes and programmes of other professions and disciplines at a later time to gain a more comprehensive understanding into these processes of socialisation and identification.

Figure 1. Year on programme



As can be seen from Figure 1 over half of the participants are first-year students (66,3%), while less than 20% are third to fifth year-students of their current programme. This might to some degree be explained by the method of distribution, as physical lectures and mandatory subjects are typically more prevalent during the first two years of the programmes, while the later years often contain more independent work, i.e., Bachelor's or Master's thesises. There are some limitations to having such a clear majority of students in the beginning of their degrees, as one can argue that the process of socialisation and establishing a sense of identification is dependent on experiences that one can argue students are gradually exposed to throughout their time at university. Furthermore, it could complicate the comparative analyses between students from the different years due to the differences in respondents. However, having a large number of first-year students participating opens for the possibility to perform a longitudinal analysis in the future. In addition, despite the majority of participants being first year-students (61,2%), only 41% state that they are currently doing their first year at university overall. Thus, several of the first-year students have some previous experience in higher education, which might affect the results.

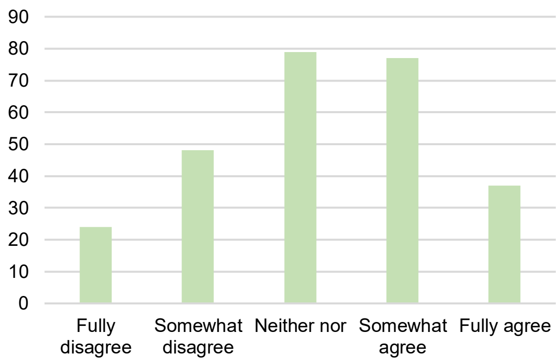
As expected, the majority of engineering students are male (66,4%), with 33,2% female respondents, and 0,4% of respondents identifying with another gender identity. This is in accordance with official numbers from NTNU which shows that the amount of women in three-year engineering programmes were approximately 22% in 2019, while it was closer to 38% in in the five-year programmes. [13] Furthermore, the official statistics have not included a category for other gender identities, and even though the number of respondents is too low to explore analytically we argue that it is important to include the option of a third gender to ensure the inclusion of the entire student body.

In terms of age, most participants are between 20 and 26 years old (94,4%), with the mean age being 22,9 years old (median = 22, mode = 21). This is somewhat low compared to the national average of Norwegian students of approximately 28 years old. [14] However, the latest numbers informing the national averge are from 2016, where it is highlighted that a majority of students take several years off school before beginning higher education. One of the most noticeable effects of the recent pandemic however, have been that less people take one or more gap-years from education after finishing upper secondary school, and that more people enter directly into higher education. Thus, the national average might be lower in 2022 than it was in 2016, making the discrepancy between our participants and the student body in Norway as a whole less extreme than it might appear.

3.2 Distribution of the dependent variable

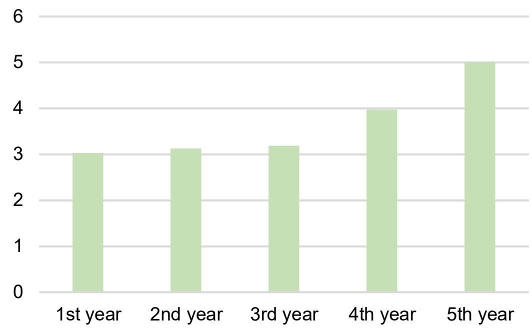
As is visible in Figure 2 the students' responses to whether they identify with engineers are slightly positively skewed, with 40% either somewhat or fully agreeing, and 28,6% either somewhat or fully disagreeing. Whereas, about a third (31,4%) are neutral to the statement, neither agreeing nor disagreeing. This could again indicate that there are some socialisation processes within the enigeneering education programmes at NTNU that contribute to students identifying with engineers.

Figure 2. SISI distribution



Furthermore, Figure 3 highlights the average score of identification dependent on year on programme. We can see that first- to third-year students on average answer neither nor (2,03, 3,13 and 3,19 out of 5 respectively), while the average fourth year student somewhat agrees (3,97) and the average fifth-year student fully agrees (5,0). This could suggest that engineering students identify more and feel a stronger sense of belonging to the field of engineering throughout their time as students, which indicates that the socialisation process does in fact depend on the time spent at their programme. It could also suggest that the way the programmes at NTNU are structured support students' professional identification, and/or provides them with the necessary tools and experiences to feel ready for the professional life. However, it is once again important to note the low number of responses from fourth and fifth year students, and that we have to perform more complex analyses to claim anything about what influences these scores, as well as the statistic significance.

Figure 3. SISI distribution by year



3.3 Findings

The findings presented in the below section is based on a bivariate analysis with Pearson correlation, as well as linear regression analysis of the dependent variable (SISI) and the chosen independent variables.

As can be seen in table 1, there are only six out of the 21 correlations that are significant ($p = <.05$). Not surprisingly, one of these are relevant work experience and relevant volunteer experience, suggesting that if a students have had one, they are more likely to have also experienced the other. Furthermore, for the identification measure, year on programme (.28), extrinsic motivation (.13) and intrinsic motivation (.22) were significantly correlated, however with a correlation coefficient below .3, thus indicating a low correlation. Interestingly, the two strongest correlations in the correlation matrix is between year on programme and relevant work experience (.29) and relevant volunteer work experience (.41). In light of the previously mentioned interconnections between engineering education and demands of the working life, it is not too surprising that more experienced students appear more likely to have relevant work or volunteer experience as well.

Table 1 Correlation Matrix

	1.	2.	3.	4.	5.	6.	7.
1. I identify with engineers	-	.28**	.13*	.22**	.09	.11	.08
2. Year on programme		-	.08	.02	-.04	.29**	.41**
3. Extrinsic Motivation			-	-.11	.09	-.11	-.07
4. Intrinsic Motivation				-	.03	.11	.07
5. Praxis					-	-.05	-.06
6. Relevant work						-	.23**
7. Relevant volunteer work							-

**. Correlation is significant at the 0.01 level (2-tailed). *. Correlation is significant at the 0.05 level (2-tailed)

Furthermore, the regression analysis showed that our model is significant (p = <.001) and explains about 11.8% of the variance in students' identification (.118). Table 2 shows all the coefficients and related significance.

Table 2 Linear Regression Analysis

	B Coefficients	Sig.
Year on programme	.23	.022
Extrinsic Motivation	.17	.023
Intrinsic Motivation	.43	<.001
Praxis	.13	.195
Relevant work	.07	.661
Relevant volunteer work	-.08	.624

Based on the correlation analysis, we expected at least three significant relationships in the regression analysis, which was confirmed, as the only significant variables were year on programme, extrinsic motivation and intrinsic motivation – the same as in the correlation matrix. Unlike in the correlation analysis, intrinsic motivation (.43) appears to have the distinctly strongest influence, with a moderate correlation, and year on programme (.23) and extrinsic motivation (.17) having weak correlation coefficients. These results might change or paint a slightly different picture if we performed a hierarchal regression analysis, but this has not been done as of today. In the context of the proposed research question, we can argue that motivation and years spent at their programme affects students' professional identification. Still, we cannot make any claims based on the presented research about whether the students are intrinsically and/or extrinsically motivated *before* starting their degrees or if the universities provide them with tools or experiences that facilitate and strengthen their motivation which further impacts their professional identification. On the other hand, since year on programme is significant in the regression analysis as well, the university appears to provide *something* that contribute to engineering students identifying with engineers.

However, in line with the dialectal pluralistic perspective established previously, these relationships and the related ‘how’s’ and ‘why’s’ should probably be explored further through e.g., qualitative interviews to gain an even more comprehensive understanding of these processes.

4 SUMMARY AND CONCLUSIONS

To conclude, it appears that the single-item measure of social identification could be a useful tool in measuring students’ professional identification, however more research within this context is probably needed. Furthermore, the analyses show that students motivation, both intrinsic and extrinsic, are influencial when measuring their identification with engineers, in addition to how long they have studied at a programme. Interestingly, work praxis as a part of the study programme, previous relevant work and volunteer experience did not come out as having a significant impact on the students professional identification, despite the engineering programmes at NTNU continuously highlighting the importance of their close-knit relationships with the working life. However, as the regression analysis shows that the engineering students appear to identify more with engineers the further along in the programme they are, there must be something during their time at university which facilitates this gradually increasing identification. What exactly this is, will have to be explored later on.

THE FUTURE OF WOMEN AEROSPACE ENGINEERS IN ACADEMIA – A NUMBERS GAME

G.N. Saunders-Smits [1]

Conference Key Areas: *Attractiveness of Engineering, Gender and Diversity*
Keywords: *workplace diversity, gender, aerospace engineering, careers*

ABSTRACT

The gender divide for women in the engineering domain in academia is still very large today, even though most institutions are committed to changing this. Although there are slow improvements in the number of women working in academic positions in Engineering, the Netherlands, in particular, is still lagging badly behind the rest of Europe with women making up only 17.6% of all full professors in the engineering domain and for 25.7% in the entire academic domain. This is despite many efforts across the board to improve this situation.

The situation is even worse in the field of Aerospace Engineering and within this field, the lack of progress is not unique to the Netherlands with similar issues being reported in the United States of America and wider afield.

This paper reports on research on the capacity building among women required within the aerospace engineering domain to reach the commonly defined critical mass percentage of 30% of women full professors using metrics on career progress and on as well as labour market data on the career development of Aerospace graduates to show where potential new interventions can be made.

1 INTRODUCTION

Women Aerospace Engineers to date are still few and far in between, despite the many campaigns worldwide by both industry and governments to change this. This is especially true for women aerospace engineers in academia, which should be seen as a major concern as research has shown that there is a strong correlation in engineering between student diversity and faculty [1].

Although the Faculty of Aerospace Engineering at Delft University of Technology (TU Delft) in the Netherlands is the largest aerospace engineering school in Western Europe with over 2800 BSc and MSc students enrolled in 2021/22, only 14% of its students are women, a number that has only slowly increased over the last decades. Of the 19 full professors in aerospace engineering at TU Delft, only 2 (10.5%) are women, ranking at the lower end of TU Delft's representation of women full professors (17.9% over the whole of TU Delft). TU Delft ranks last in the list of Dutch universities when it comes to the number of women professors in the Netherlands [2], which averages at 25.7%, making the Netherlands one of the worst-performing countries in the EU in this respect. The Dutch Network of Women Professors has therefore set itself a target of reaching a "critical mass" with 30% women professors by 2024 [2].

The critical mass percentage of 30% is widely attributed to the political scientist Dallerup as the threshold when women's participation is no longer tokenism. After reaching this critical mass a qualitative shift will take place in an organization. As she states, however, this idea of a specific absolute turning point of 30% has been found not to exist but the notion that a certain mass of representation has to be build-up to achieve a qualitative shift in an organisation remains [3].

With the number of women in aerospace in academia in the Netherlands still being so low, this paper reports on research into the required capacity building to reach the suggested target of 30%. Is this an achievable number within the next 10 years given TU Delft's capacity for training aerospace engineers also compared with other countries?

2 HISTORIC CONTEXT

To provide some explanation as to why the current numbers are still so low, it is important to take into account the historical context of the academic field of aerospace engineering and the socio-economic context of the Netherlands over the past 100 years.

2.1 Development of the Field of Aerospace Engineering

Aerospace or Aeronautical Engineering as a recognised academic field of study is itself not that old. Initial degrees were named Aeronautical Engineering and from 1958 onwards the term Aerospace Engineering was often adopted to also reflect the Space content of the programmes. Although the discussion still rages on who exactly is the first to start teaching courses in aerospace, the first courses are taught in Europe from 1907-1910 onwards[4] in London and Paris with today's 'ISAE

SUPAERO' now in Toulouse, France the first to establish a formal degree programme. In the USA, the University of Michigan follows suit in 1916 and M.I.T founds its aeronautical engineering programme in 1926. At TU Delft the degree programme in aeronautical engineering was founded in 1940, days before the outbreak of World War II in the Netherlands. Today, aerospace engineering schools are spread all over the world covering every continent apart from Antarctica, and the demand for aerospace engineers in the job market remains high and is expected to continue to increase [5].

2.2 The History of Women in Aerospace Engineering

With the field of aerospace engineering itself still being so young, it will not come as a total surprise that it was not until 1929 that Canadian woman Elsie McGill was the first woman to graduate with a Master's degree in aeronautical engineering from the University of Michigan. This did not mean there were no female aircraft designers before this: Lilian E. Bland (Ireland, 1909) and E Lillian Todd (USA, 1910) designed and build their own aircraft, both of which flew. Like many other early aviators, they schooled themselves in aircraft design. In Europe, not all countries had established degree programmes in aeronautics yet, but this does not mean that women are not interested in studying aeronautics. In Germany, Ilse Essers (nee Kober) in 1926 and Melitta von Stauffenberg (nee Schiller) in 1927 also obtain Master's degrees with aeronautical-related theses in Mechanical Engineering at what is now RWTH Aachen and Applied Physics at what is now TU München, respectively. The first European woman with a master's degree in aeronautics is likely British woman Hilda Lyon, who obtained a Master's in aeronautical engineering at MIT in 1932. However, it was not until 1965 before the first woman graduated in aeronautical engineering from TU Delft, Indonesian national Koo Siu Ling, with the first Dutch woman Hedwig Ritzen graduating in 1969. It would not be until 1996 that the first PhD degree in Aerospace Engineering was awarded to a woman at TU Delft and it took until 2006 before Hester Bijl (now rector at Leiden University) was appointed as the first woman professor in Aerospace Engineering at TU Delft.

2.3 Socio-Economic Development of Women in the Netherlands

To understand why it took so long for the first women to graduate in aeronautical engineering at TU Delft, it is important to understand the socio-economic context in the Netherlands at the time. Until the end of the 19th century, secondary education in the Netherlands was only open to the privileged few. A change in the Dutch education system in 1876 allowed anyone with the national advanced secondary education diplomas *Gymnasium* and *HBS* to gain entry to university, although not all universities were equally happy to admit women.

Admittance policies differed per university but the first woman to graduate from TU Delft was Maria Elizabeth Bes, a chemical engineer, in 1904. This did not mean that women were flocking en mass to universities. Although women were given the right to vote in 1919, married women were deemed legally incapacitated and a marriage ban was in place at all government institutions, often mirrored by industry, under pressure from unions and Christian political parties. They favoured the breadwinner economic model and successfully argued that allowing women to work would take away jobs from men with families and lead to lower wages. Even after the abolishment of these laws in 1957, the lack of childcare facilities or the ability for children to eat lunch at school instead of going home for lunch until well into the 1980s made having a professional career as a woman an uphill battle. In addition, until 1988, a person was not deemed to be of age until they reached the age of 21, meaning that young people needed parental permission to enrol at university. Only from 1990 onwards, the breadwinner model was abandoned and men and women were expected to each be able to earn their own income regardless of their marital status and women were actively encouraged to gain professional qualifications. As a result, the percentage of financially independent women rose from 25% in 1990 to 64% in 2020 - compared to 80% of all men)[6].

3 METHODOLOGY

3.1 Data sources

All data reported and used as input in this paper is publically accessible data from various government sources and international organisations. When comparing different countries the same base year for all countries was used, being 2018 as that was the year the most complete data set could be determined. Relevant international data was found for the United States of America [7], the United Kingdom, and Spain. Next to that, the European Union's *She Figures* report [8] was also consulted. All data for the Netherlands as a whole came from the Universities of the Netherlands, all TU Delft data came from the TU Delft data tableaus.

3.2 Netherlands Academic Career Model

Different countries will have different academic career progression models. In the Netherlands, to enter a PhD programme at a Dutch university a Master's degree is mandatory and as a general rule, a PhD is the minimum requirement for an Assistant Professor position. Although PhDs have been awarded at TU Delft since 1906, only since 1982 have formal PhD programmes been in place at Dutch Universities. The Dutch academic system until recently has largely been a hierarchical system, meaning that full professors were only hired when a vacancy occurred or when a new research group was started. More recently, qualifying associate professors can also be promoted to full professor, but this is not an automatic system and the qualifying conditions can vary greatly.

3.3 Capacity Modelling

The Royal Society [9] reported in 2010 that in the United Kingdom 0.45% of all PhD graduates will become full professors and 3.5% will become permanent research staff. How this number is determined differs from country to country based on methods, different academic career models and definitions of academic positions. It is however important to realize that, especially in the field of engineering, the university system is an open system. It means that people leave academia for other employment, but also that people come back to academia. Research by the Rathenau institute shows that overall the in- and outflux are almost in balance [10]. In the capacity model proposed in this paper, it is therefore assumed that the in- and outflux are in balance.

Equation (1) is proposed to calculate the number of PhD graduates needed to appoint 1 full professor. Divide 100 by the multiplication of the percentage of people progressing from 1 academic rank to the next:

$$N_{PhD\ per\ full\ prof} = \frac{100}{\%(PhD \rightarrow PostDoc) \cdot \%(Postdoc \rightarrow Asst.) \cdot \%(Asst. \rightarrow Assoc.) \cdot \%(Assoc. \rightarrow Full)} \tag{1}$$

Using the reported data by the Rathenau institute over the 2003-2013 period this comes to 333 PhD graduates per full professor appointment or 0.3% of all PhD graduates become full professors. This is slightly lower than the reported 0.45% by the Royal Society for the United Kingdom [9] but is likely more accurate as Dutch universities require a Master's degree before entering a PhD programme whereas in the UK a Bachelor's degree suffices.

It is proposed that Equation (1) can be expanded to calculate the number of graduates with a Master's degree that are needed to appoint one full professor:

$$N_{Mdegree\ per\ full\ prof} = \frac{100 \cdot N_{PhD\ per\ full\ prof}}{\%(Mdegree \rightarrow PhD)} \tag{2}$$

The earlier mentioned *She Figures* report [8] by the EU indicates that 0 - 20% of all women with a Master's degree enter a PhD programme and 0 - 30% of all men. For the Engineering, Manufacturing and Construction domain, this is 10% for women and 13% for men in the Netherlands [8]. To see if this data was representative for TU Delft a further step was taken: To estimate the percentage of Master's graduates that obtain a PhD degree the 5-year average of the number of awarded PhD degrees at TU Delft over the 2017-2021 period, 387, was divided by the number of awarded MSc diplomas over the same period, which averaged at 3496, which comes to 11%.

3.4 Glass Ceiling Index

The Glass Ceiling Index (GCI) is used by both the EU and the Dutch government as a measure of career progression for women. Each has a slightly different definition. The EU definition of GCI is [8]:

$$GCI_{EU} = \frac{\%\ all\ woman\ full, associate\ and\ assistant\ professors}{\%\ all\ women\ full\ professors} \tag{3}$$

The Dutch government defines GCI per academic rank [2]:

$$GCI_{NL} = \frac{\%\ women\ in\ highest\ rank - 1}{\%\ women\ in\ highest\ rank}$$

(4)

In both cases a GCI of 1 means there is no difference between men and women being promoted, a GCI > 1 means there is a Glass Ceiling effect with the higher the value, the more women are underrepresented in higher academic positions, whereas a GCI <1 means women are overrepresented in a higher academic position.

4 RESULTS

4.1 Capacity Building

From a capacity-building point-of-view, it is interesting to see how many woman PhD graduates in AE are needed to reach the "*magic*" number of 30%, which in the case of AE is 6 full professors and compare those numbers to the actual number of women PhD graduates. A similar calculation can then also be made with respect to the number of woman MSc graduates needed to reach 30% full professors.

As was mentioned before, 333 people must have gained a PhD in Aerospace to appoint 1 full professor which means 1,998 women must gain a PhD in Aerospace from TU Delft and subsequently using Eq. 2 and the percentage MSc - PhD of 11% results in a requirement of 3,003 people with an MSc degree in Aerospace in order to appoint 1 full professor. Therefore to reach the number of 6 woman professors at TU Delft without using capacity from outside, some 18,000 women must gain a Master's degree in Aerospace Engineering from TU Delft.

This naturally leads to the following question: How many women have obtained a PhD or MSc degree in AE at TU Delft so far? Based on aggregated TU Delft data, by 31 August 2021, 7,140 MSc diplomas have been awarded in total since 1943 when the first diploma was awarded, of which 576 were awarded to women. The total number of PhD -degrees in AE from TU Delft that have been awarded since the first one in 1947 is 605 of which 75 were women. It is worthwhile noting that only recently, in March 2022, TU Delft awarded its 10,000th PhD degree.

It is safe to say, that based on these numbers AE at TU Delft is not educating sufficient Aerospace Engineers at Master's and PhD levels to even sustain its current total of 19 full professors, let alone women. This probably also goes a long way to explaining why of the current 19 full professors in aerospace engineering only 6 hold a PhD in Aerospace Engineering from TU Delft of which only 1 is a woman and of whom only half hold any aerospace PhD or MSc degree.

Is there perhaps additional capacity for aerospace engineers elsewhere? To find out several international databases and publications on aerospace engineering graduates were consulted, notably in Spain (Educa database), The United Kingdom (HEPA), and the USA [7]. The data shown in table 1 lists the number of MSc and PhD graduates of the 2018/2019 academic year in each country and the total population of the country with the exception of the USA which shows the data for the 2017/2018 academic year.

Table 1. Number of MSc and PhD degrees in Aerospace Engineering awarded in 2018/19 (USA in 2017/2018) in the Netherlands, Spain, the United Kingdom and the United States of America in absolute and normalized by million of population.

	NL		Spain		UK		USA	
Population (mln)	17		47		67		332	
Number	**Abs**	**Norm**	**Abs**	**Norm**	**Abs**	**Norm**	**Abs**	**Norm**
MSc (total)	296	17.4	419	3.9	935	14.0	1,587	4.8
MSc (women)	39	2.3	92	2.0	161	2.4	233	0.7
PhD (total)	37	2.2	N/A	N/A	180	2.7	412	1.2
PhD (women)	7	0.4	N/A	N/A	22	0.3	54	0.2

It is clear from the small selection of countries that capacity is also limited in other countries. If the numbers are normalised per million inhabitants, the Netherlands outperforms all countries when it comes to the number of MSc degrees awarded per year and forms the top 2 with the United Kingdom when it comes to the number of PhD degrees awarded per year per million inhabitants. It also shows the even direr situation in the USA.

EU	2.1	1.4	1.4	1.4

4.2 Glass Ceiling Index

Using the public data files of the Universities of the Netherlands and the data available from TU Delft data tableaux, the GCI_{NL} indexes were calculated for the Aerospace Engineering (AE), TU Delft, the entire Dutch Research Universities Engineering Domain and all Dutch Research Universities (excluding healthcare). Healthcare is not reported as this domain is reported separately. Also, Dutch universities of applied sciences are not included in this data as they have a different academic structure. The share of women in academia is shown in Table 2. The GCI indexes are presented in Table 3.

It is clear from the GCI_{EU} index that Aerospace has a solid glass ceiling when it comes to women advancing in their academic careers. *T*he GCI of TU Delft, the Dutch Engineering domain, and the Netherlands as a whole *are* all at 1.4 which in itself is also still far away from parity. There may be a slimmer of hope in that GCI for transitioning from PhD to Assistant Professor is smaller than 1, indicative of a better possibility of transitioning for women who have just finished their PhDs.

To give a better idea of how big the problem is, it is important to also compare these numbers to international data. The EU report She figures 2021 [8] reported an EU-average for GCI_{EU} of 1.5 based on 2018 data with the Netherlands also 1.5 which is in line with the EU28 average and based on the 2020 data provided in this data the situation overall in the Netherlands and the engineering domain continues to improve, with AE lagging.

*Table 4. Share of Women in Academic staff in the Engineering Domain of the Dutch Research Universities (Source: WOPI data Dec 2020 – Universiteiten van Nederland), the USA and Canada [7]. * excludes external PhDs and bursary students*

What about the Aerospace domain? An attempt was made to find staff data for the aerospace domain. Sadly, the EU and ASEE do not report at degree level so no comparison within the aerospace domain could be made when it comes to GCI. It is possible to do so on an engineering domain level with the USA and Canada but for the EU the domain definitions are incomparable and the level of data reported in She Figures [8] has insufficient depth to make good comparisons.

From the data in tables 4 and 5, it can be seen that on the more holistic GCI_{EU} level the Dutch engineering domain scores comparable to the USA and Canada but there are differences in the GCIs between the different academic ranks. It is, however, worth noting that the ASEE's Engineering by the Numbers - report [7] does state that aerospace engineering only has 11.8% female academics (compared to 22% at AE TU Delft) and women only made up 13.1% of all doctoral degrees awarded in aerospace in 2018, against 25.7% at AE TU Delft so *again* the situation may be even direr in the USA.

5 DISCUSSION

More women can indeed go some way to solving the capacity problem in aerospace. As this paper shows women are still woefully underrepresented in academia in engineering and thus should be a welcome pool of available additional capacity that is currently underused. University Leadership will often say that there are not enough women out there to increase the number of women in aerospace in academia. The data presented in this paper goes a long way in proving that point when you look at the current available capacity, not just in the Netherlands, but also elsewhere. It is unlikely that the 30% target will be met in the next 10 years. Combine that with the ever-increasing industry demand for aerospace engineers [5] and the capacity problem will not be solved instantly. At the same time, universities themselves are not without blame either. Many universities have limited capacity in terms of the number of students admitted to study aerospace engineering and as the GCI index shows, it is still very difficult for women to rise to the top in aerospace academia. This lack of ability to progress is also what is holding women back in pursuing an academic career in engineering: lack of progression, unconscious bias in recruitment and promotion processes and finally, structural barriers such as work-life balance. One might argue that those who made it are miracle workers as they defied all odds. Better hiring and recruiting practices and, more importantly, better retention practices are needed and are needed fast.

However, it is too easy to just appropriate all the blame on the universities themselves: Governments are restricting education and research funding is also limited which affects the number of available places for students across the tertiary education spectrum. Almost all aerospace degree intakes are capped and the number of PhD positions is highly dependent on external funding. Access to degrees is becoming more expensive year on year and the quality and offering of STEM teaching in secondary schools are declining due to insufficient capacity of STEM teachers thus unnecessarily limiting the pool of (woman) candidates as well. Industry could also step up and take their responsibility: If the (aerospace) industry continues to insist on lower taxes but yet expects an ever-higher yield from (government-funded) universities and other education sectors, they are frankly delusional. If they want to keep their competitive and innovative edge, both in terms of highly trained human capital and in research-based innovation, they must generously invest in the (aerospace) university sector and improve their often not-so-positive image in the eyes of women to make themselves more attractive. It is after all a basic economics question of supply and demand. If you are short in supply, you can choose whom you want to work for.

DEVELOPMENT AND APPLICATION OF SIMULATION GAMES TO INTRODUCE MODEL-BASED SYSTEMS ENGINEERING

T. Schumacher[1]**, T. Ammersdörfer, D. Inkermann**
Technische Universitaet Clausthal, Institut fuer Maschinenwesen
Clausthal-Zellerfeld, Germany

Conference Key Areas: *Physics and Engineering Education, Teaching methods*
Keywords: *simulation game, engineering education, Model-based Systems Engineering*

ABSTRACT

Model-based Systems Engineering aims at increasing consistency of information in complex engineering processes that involve different engineering domains. A major challenge when introducing Model-based Systems Engineering is to highlight the interactions of different process activities, like requirement definition, specific methods and available tools as well as roles. These interactions have to be demonstrated to members of the engineering team in order to induce awareness for potential hurdles within the implementation process and to increase acceptance for required changes of processes, methods and tools. Simulation games present a promising approach to generate awareness as well as the needed expertise for successful implementation of Model-based Systems Engineering, in both teaching of students and training of experienced engineers. In this contribution a development process and essential aspects for the game design of simulation games are proposed. The structured process and its specific steps are illustrated by the development of the simulation game *MbSys*.

1 INTRODUCTION

Modern products incorporate crucial technical changes, like dynamic behaviours, intensive networking, connection to the Internet of Things or the use of on demand services [1]. Consequently additional requirements, like cyber security, are placed on the

[1] *Corresponding Author: Thomas Schumacher, E-Mail: schumacher@tu-clausthal.de*

doi:10.5821/conference-9788412322262.1420

product and have to be handled within the engineering process. In most cases a more holistic view on the system and its environment is required to handle the complex requirements and interactions. Therefore the use of different system views are key elements of an engineering process that follow the Model-based Systems Engineering (MBSE) methodology. However, application of MBSE results in new processes, methods and tools (PMT) and the adaption of the existing PMT ecosystem [2]. To generate awareness for required adaptions of the PMT ecosystem, we research the design and application of simulation games.

1.1 Value and Benefits of Gamification Approaches

Gamification within education has become a central opportunity to drive behavioural change among individuals and to enable new methods for training within complex systems [3]. Additionally gamification increases the motivation to study or learn new items [4] within an enjoyable format. With regard to MBSE gamification provides various benefits. First, gamification supports harmonizing terms and wording, e.g. what is meant with the term *model* within MBSE? Second, gamification facilitates the definition and design of engineering processes as well the selection and application of appropriate methods and tools. Furthermore, gamification can be a great support by understanding the interactions between processes, methods and tools within an organisation. The understanding of these interactions are essential for the implementation and permanent application of MBSE within an organization. The following section gives an insight into the basic benefits of MBSE and typical challenges that occur. Target of this paper is, to address these challenges with a simulation game in order to improve engineering design education.

1.2 Benefits and Challenges of MBSE

Systems Engineering (SE) is a holistic interdisciplinary approach for successful development and realization of systems [2, 5]. Thereby, SE involves processes, methods and tools which focusses either single aspects, like architecture definition, or overall challenges, like comprehensive system understanding or interdisciplinary communication [2, 6]. MBSE extends SE by capturing engineering information, like interface control and system description documents, within an overall system model [5] in order to ensure data consistency and traceability along the complete product life cycle. Additional benefits which are reported in literature [5, 7] are: better communication and information sharing, improved system understanding and design, improved collaboration, better management of complexity, increased capacity for reuse, better requirements engineering and management. These selection of expected MBSE benefits highlights the support of MBSE when engineering complex products. However, introduction of MBSE frequently faces different barriers, which can be organizational, processual or educational justified [8]. With this paper and the corresponding simulation game mainly processual and educational barriers will be addressed. Key factor as well as big hurdle, due to widely established discipline and component oriented thinking, for successful SE implementation is holistic systems thinking [2, 6]. A second pivotal element for successful implementation of MBSE is an appropriate PMT framework, based on the PMTE paradigm pyramid introduced by Martin [9]. Especially, the relations between processes, methods, tools and their environment needs to be understood and respected while definition of new or adaptation of established PMT.

1.3 Research questions and paper structure

This paper propose the use of simulation games for the implementation of MBSE. Therefore, a structured development approach for simulation games is proposed and preliminary experiences from application are presented. The following research questions will be answered within this paper: (1) Which development steps and elements should be considered for a successful design of simulation games? (2) How can the identified development steps and elements be integrated within a structured development process? The presented paper is structured as follows. Within section 2, different gamification approaches are distinguished and based on established literature typical development steps and elements for the design of simulation games are presented. Section 3 describes the proposed development process focussing on the simulation game *MbSys*. The paper closes with a summary and outlook for future work.

2 STATE OF THE ART

The term gamification is used with different understandings in literature. In Fig. 1 a basic distinction of relevant terms for this contribution is illustrated.

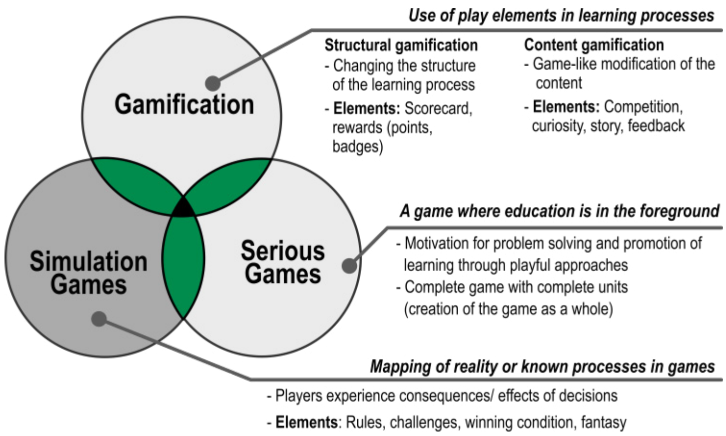

Fig. 1. Differentiation of learning games based on [10, 11, 12, 13]

Thus, different ranges of game-based learning have to be differed, resulting in gamification, simulation games and serious games as basic types. Gamification is the use of game design elements in non-game [10]. As soon as game elements such as fantasy, rules, challenges or winning conditions are added to the simulation, it becomes a simulation game [11]. Here the focus is on the representation of processes and effects known from reality. A third approach are serious game that focus on education rather than entertainment [12]. This paper focus on the development of simulation games and presents therefore a typical development process in the following section.

2.1 Development of Simulation Games

In general the evolution of simulation games can be described as an iterative problem-solving process. Therefore, the identification and the comprehensive understanding of the problem is fundamental. After problem analysis the design evolution, including technical and project management processes, follows. Thereby the use of development cycles including prototypes, which presents the key functions and a previous visualization of the game, is established. Important for successful game development is the addition of an implementation and evaluation phase, which compares the initial problem and the developed solution. Fig. 2 presents a engineering process, which contains the mentioned development steps, for the introduction of a simulation game.

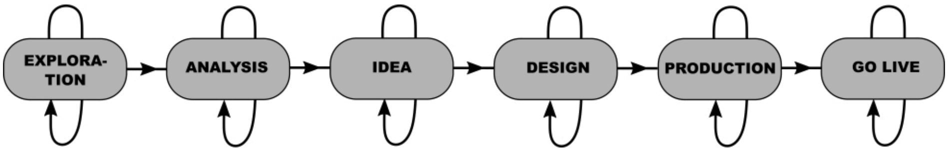

Fig. 2. Development process for simulation games, based on [14]

Especially the exploration phase at the project start, which contains the problem analysis and the definition of contentual and gameplay targets, functions and evaluation criteria, is important. Thereby also first ideas concerning the game content can be considered. Based on different concept sketches within the analysis phase important artefacts, like use cases and context of the game will be described. Methods for requirement definition, like system context analysis or use case scenarios can support these activities. Leveraging on the described concept sketches and artefacts within the idea phase detailed concept papers, including game mechanic, will be elaborated and evaluated. The idea phase closes with the selection of one concept which will be operationalised within the following design phase. Thereby prototypes evolve within an iterative development process. These prototypes will be used for evaluation of the realized game with the initial defined targets and functions. Finally the developed game design needs to be produced and introduced into the defined context. [14]

2.2 Pivotal elements for the development of simulation games

During application of the presented development process (chap. 2.1) we identified that the content of each development phase needs more structure. One possibility for better structuring can be the *Serious Game Design Assessment Framework* [15]. These framework was initially developed to assess games based on essential elements, but can also be a great support for structuring the development phases. Fig. 3 presents the pivotal elements that should be considered while developing a simulation game.

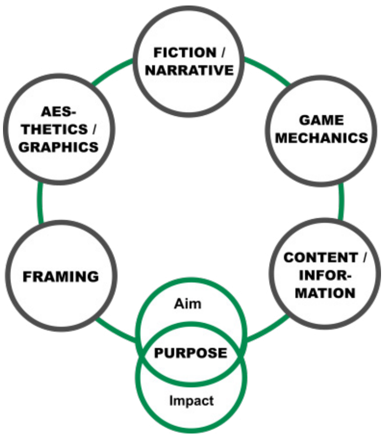

Fig. 3. Essential elements for game design, based on [15]

The *purpose* contains the *aims* of the game and the *impact* on the players, which the game should evoke. These elements are essential and should be reflected in all other elements. The element *content / information* represents all information and data offered and used in the game. The interaction between the players and the game is part of the *game mechanics*. To describe these interactions definition and visualization of actions can be helpful. Typically the *game mechanic* contains basic rules, space for decision making, in-game targets, challenges and events. Therefore often a simulation model is used in the background to define all existing relations. *Fiction / narrative* are needed to give the game mechanics a fictional content. Especially for simulation games the fiction and narrative should illustrate the real-world situations. The *aesthetics* and *graphics* refers to the audio and visual illustration of the game and present the game to the player. All listed elements should consider the target group of the game. Therefore the *framing* of the game has influence on all other elements and should answer at least the following questions: What is a suitable game type? Which prior knowledge attendees require? Are the learning targets easy or difficult to acquire? Which kind of game events can motivate players and affects the game dynamic? [15]

The presented elements should be considered within the development process of a simulation game in order to generate a purposeful game design. In section 3 these elements will be integrated into the presented development phases, see section 2.1.

3 DEVELOPMENT OF SIMULATION GAME MBSYS

Key element of this contribution is the description of the development process for simulation games *MbSys*. For a better structuring we integrated the pivotal elements of a simulation game into the presented development process, see Fig. 4. The production and go-live phases are out of scope within this contribution.

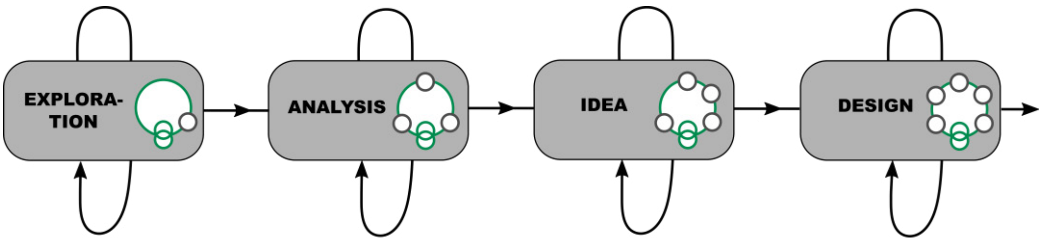

Fig. 4. Integration of essential elements into simulation game development process

While integrating the essential game elements into the development phases we identified that each phase considers different or additional elements. The exploration phase meanly focusses the *purpose* and the fundamental *content* of the game. During the analysis phase additionally the *framing* and *fiction* will be considered by a more detailed use case description. Afterwards an appropriate *game mechanic* needs to be selected, which is the core of the idea phase. Finally, during the design phase all elements based on the previously phases will be operationalised and the *graphical* visualization will be developed. Following the application of the introduced development process will be presented for the simulation game *MbSys.*

Exploration phase

Within the exploration phase we defined the aim of the game and the impact that the game should have on the player. *MbSys* has the aim to make MBSE including essential development processes and artefacts perceptible for the attendees. By knowing important artefacts, engineering decisions and influencing factors within MBSE, the attendees should adjust their functioning to a more model-oriented working behaviour. Additionally, we defined first aspects of the game content. We will use a typical product development process, which includes gates and artefacts, as an established game fundamental. These known fundamental should enable an easy game access, which is one of the game targets. The outcome of the exploration phase was an abstract product development process as the game vision, see Fig. 5.

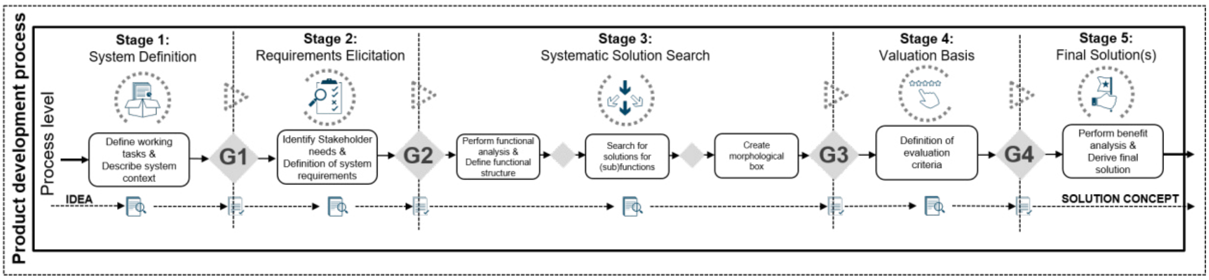

Fig. 5. Product development process as game fundamental

This development process includes different development stages and gates. Within each stage exemplary development activities are included, which are required to provide the needed artefacts at the individual gate.

Analysis phase

Part of the analysis phase is the consideration of the defined game use case (Fig. 5) in more detail and an in-depth understanding of the game attendees in this context. Thereby the initial game content was extended by an appropriate selection of development methods and tools, which are needed for successful MBSE, see Fig. 6.

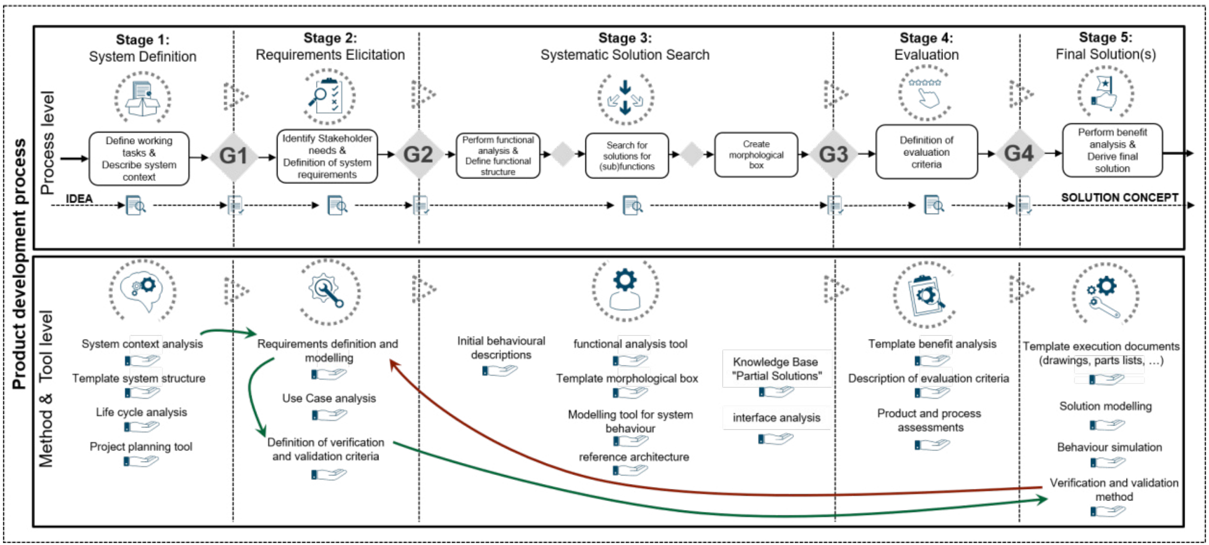

Fig. 6. Product development process including processes, methods and tools

One of the key question in these phase was the game opportunities of the players. Within a simulation game the players require some freedom to act within the defined content. In the case of *MbSys* we determined that the process level in the development process is fixed as a frame for the game and the players should select appropriate methods and tools to provide the needed artefacts at the individual gate. Thereby needs to be considered that typically not one method leads to the needed artefact. The players should understand the relations between different kind of methods and tools. A second aspect that increases the opportunities of the players is the integration of a quality classification for the applied development methods. That means a player has to decide in which quality (poor, medium, best) a method should be applied. While framing the game we identified the need that the game should have a flexible structure, e.g. the amount of gates, the required artefacts or the selected methods and tools should be adjustable. This is causes by individual stakeholder requirements.

Idea phase

Core of the idea phase was the evaluation of different game mechanics concerning the described use case. For *MbSys* we selected a role play oriented game mechanic, because the use case presents a sequence of events (stages, gates) that happened successively and the players can be seen as development team members. This can be compared with a guiding storyline including operating characters. In addition we wanted to simulate events (e.g. test case failed, post freeze requirement changes) that could occur within a development process. Therefore the described mechanic is also suitable. The occurrence of events can happen randomly, e.g. by rolling a dice.

Design phase

During the design phase the game concept and mechanic will be operationalised. The iterative development of prototypes supports evaluating the content and experience-oriented game targets, which were defined during the exploration phase. In case of *MbSys* we identified that additional resources (available development time) for each player increases that game dynamic intensively. Accordingly, each player has a defined amount of development time and has to decide which development methods should be applied and which quality level should be considered. Typically a higher quality level requires more development time. In parallel the aesthetics and graphical appearance of the game was defined and evaluated. *MbSys* uses classical elements for game appearance, e.g. printed game plan, 3D-characters, playing cards and dices. For game introduction and special events announcement the narrator will be support by audio-visual elements.

Presently *MbSys* is in the production phase and it is planned to apply *MbSys* for Model-based Systems Engineering education in the second half of this year.

4 SUMMARY AND FUTURE WORK

MBSE can have various benefits for the development of complex products but different barriers can inhibit a successful implementation. Gamification approaches can support by overcoming these barriers. Therefore this paper presents an appropriate development process, including different phases and essential elements, for simulation games. Furthermore, this paper gives an insight into the development of the simulation game *MbSys*, which follows the evolved development process. The target of future work is the application *MbSys* to support MBSE implementation and the identification of conclusions for the educational success.

ABSTRACT

The traditional scoring is based on the difficulty of the task. However, the same total score can be earned with different knowledge, hence it is difficult to create homogenous groups by only relying on the total score. In our work, we aim to present a new scoring method where such knowledge-based groups can be created, as opposed to the previous point-based method.

For comparison of the test result done by the students, we utilized different distance measures. The main challenge with finding the similarities between the results is the high dimensionality of the data compared to the total number of observations.

First, we used the traditional Minkowski distance with different p values, then we used local similarity hashes and high dimensional embedding techniques designed originally for natural language processing. With these never before used techniques, we were able to identify students with similar skillsets and knowledge. Furthermore, we utilized dimension reduction methods (t-SNE and UMAP) to make a lower dimension representation where we can cluster the data easier. These clusters and pairwise similarities were assessed by oral exam subjective scores.

The teacher's subjective scores correlated more with this new metric-based method of scoring than the total test score itself. The presented procedures can not only be used effectively in research but can also help to get a more complete picture of the students' knowledge we teach in everyday practice.

1 INTRODUCTION

Testing has several functions in the learning process. However, in many educational contexts, it is still used only to check knowledge: the test is the way in which the student reports on the extent to which he or she has mastered what has been learned. However, recent brain research suggests that tests may have a greater role: testing can be seen as part of the learning process, because rather than repeatedly introducing the knowledge to be learned, recall is a more effective tool for learning. With tests of the right difficulty and taken at the right time, we can acquire long-term knowledge.

The analysis of the results obtained is also an essential element. We can now visualise data in a number of ways, some of which are almost artistic, but they are not all about beauty . A well-done visualisation can also lead to the discovery of new correlations. Assessing the results obtained in different ways can enrich our analysis.

Evaluation as feedback is an important part of the learning process. There is evidence that timely feedback during learning increases the effectiveness of the process [1], [2]. Correct assessment and appropriate feedback also inform the learner whether his/her preparation has been adequate. As well as being fair, good assessment should also be motivating. It should encourage the student to progress to the next level by doing more work.

Good assessment of knowledge and ability is also important for the person doing the assessment, for example, if you want to create smaller, more homogeneous groups in a large, heterogeneous group of students to increase the effectiveness of teaching, it is important to define the groups well.

It is not uncommon for students to come to a course with very different levels of knowledge. Then, when evaluating their tests, it may be important to be able to find errors that result from a lack of knowledge (for example, a student cannot solve a problem because he or she does not know how to calculate scalar multiplication), in order to distinguish them from those that result from, for example, an incorrect algebraic transformation. With this knowledge, we can form groups of students much more effectively.

As the drop-out rate in STEM fields is also high in Europe, many higher education institutions are measuring first-year students to identify those at risk and start catching them up as soon as possible. It is also important to find first-year students with exceptional potential, for whom talent programmes offer the opportunity to develop their skills in a way that is appropriate to their abilities.

For many first-year university courses, it is a prerequisite that the student has passed a test from the secondary school curriculum at the appropriate level. Such tests, which can cover several subjects, are designed to check the knowledge required for entry to studies. It should be borne in mind, however, that if an incoming student fails a few tests in the first week, this may discourage him from starting his studies. It is also not ideal if, after the admission procedure, a lengthy series of tests is used to determine who needs catching up. In addition, there is often insufficient time to complete tests in class, and extra-curricular activities are difficult to organise for large classes. It is important to use the same or very similar assessment tests, but in this case, it is not possible to write at different times.

In the case of voluntary participation, we have found that the very people who do not attend the sessions advertised in this way are those who later have difficulties in progressing according to the curriculum. We therefore consider this solution to be of limited effectiveness.

It can therefore be seen that, while measurement is certainly desirable, it is not so easy to implement. And once we have measurement results, it is worth making the most of them. We now have increasingly efficient algorithms to help us with the evaluation.

In the following, we would like to show examples of what we can learn about a population by evaluating the results of a test using different methods. Often, we are looking for answers to the question of who wrote similar tests, how far apart the students are according to a metric of our choice.

One of the major problems to be solved in online education was to reduce the amount of cheating. The EduBase online education platform that we use has several features that try to reduce the use of illegal devices [3]. For example, the system alerts when the screen is being recorded or when the person completing the test leaves the page. The order in which the test taker progressed through the tasks and the time spent on each task can also be accurately tracked. But there are still plenty of opportunities for cheating. With the analysis we present, we have been able to filter out students who may have been communicating on another device.

Furthermore, we demonstrate a data visualisation procedure using graphs that displays the results of a test in an easy-to-understand format. In all cases, we will try to present our computational results in a visual way.

2 DATA

For our analysis, we use the results of a test we developed at the Budapest University of Technology and Economics, which consists of mathematical and linguistic elements and is used to identify those at risk of dropping out and those who deserve talent support. However, the procedures presented here can be used to analyze the results of any test. Only a handful of parameters are required for the analysis, the most important is the results of each question. This can be a continuous variable, an integer, or a binary value. Other parameters also can be used, for example, the time it takes to answer each question or the background of the student (ie: high school, study group). At our university, we have study groups and in online settings, they tend to work together, even if they should work independently. Previously, we used a single-component test with only mathematics problems to measure the proficiency of first-year students, but we found that the picture is more nuanced when language problems are included [4], [5]. Indeed, the results of the mathematics tests are distorted by the fact that students focus on practising different types of tasks already in preparation for the exam. This proved to be a winning strategy in that situation, the lack of real understanding did not significantly affect the outcome - the grade obtained. We often find that students who come to us are calculating derivatives or doing integration, but they do not have the correct understanding of the meaning of derivation or infinitesimal summation. The greater variability of language tests makes it much more difficult to learn without a deeper understanding, so the use of a complex test has proved more effective.

The maths part of the test consisted of 14 tasks, while the language part consisted of 30 tasks, with 90 minutes to complete. (The larger number of language tasks is due to the more detailed breakdown of the tasks for electronic evaluation, while in mathematics it was not necessary to break down the tasks into smaller parts.) Language questions are similarly varied. The tasks are weighted by difficulty. This provides us with a data set that measures a wide range of knowledge.

The other test on which we present a possible form of evaluation and data visualisation is the results of a test measuring geometric reasoning, compiled by Usiskin based on van Hiele's theory.

The subjects of both our tests were first-year students of mechatronics and energy engineering admitted to the Faculty of Mechanical Engineering of BME in 2020. A total of 153 participants took the test. They are students with high admission scores, high aptitude and the most homogeneous knowledge levels. So, when we define distances, we are actually looking at a population of very similar elements, according to their secondary school results, their matura exam, and trying to find the subtle differences that can be taken into account to create effective groups of students and to identify the gaps that need to be filled for them to succeed in the obstacles.

3 METHODS

Determining the distance between two data points is not always straightforward. Mathematicians have developed several methods to characterise this distance. There are two main directions: one is designed to measure the distance of binary vectors (vectors containing ones and zeros), and the other is for real-valued vectors. An example of the former is the Jaccard distance, which we use, and the latter is the Minkowski distance. The Minkowski distance reproduces several well-known distances with the appropriate choice of parameter, such as the Manhattan distance ($p = 1$) or the Euclidean distance ($p = 2$). There are also much more complex metrics with area-specific properties, but these will not be discussed due to space limitations.

These metrics can also serve as a basis for the construction of a graph. One way to create such a graph is to construct a matrix of pairwise distances, which becomes the adjacency matrix of the graph. On this basis, the weight of the edge between two data points will be proportional to the distance between them. The resulting matrices can now be well studied using graph theory methods but can also be used as a basis for manual studies using, for example, a Force Atlas visualization. In this case, the edge weights act as virtual springs, with samples of similar properties pulled together and outlier points pushed apart.

The best known and frequently used dimensional reduction method is principal component analysis. This allows us to identify the directions with the largest variance, which is useful information in the reduction process because it tries to keep the differences in those directions that allow the data to show distinct groups. This procedure gives a good picture of the distribution of the data globally but is not as detailed locally.

The t-SNE method tries to preserve this local relationship by keeping points that are nearby in the higher dimensions as well as in the lower dimensions. This closeness is mostly controlled by the adjustment of the number of nearest neighbours. The UMAP method similarly focuses on maintaining local similarities but is also more effective at maintaining global similarities. This method is also based on nearest neighbours and builds a graph based on their distances, optimizing the lower dimensional similarity using a stochastic gradient descent method. More modern versions of these latter two methods have appeared (TriMAP, PaCMAP), which are now able to produce good dimensionality reductions without complex parameterization, considering global and local features, but they do not always provide better results. These were also tested but did not give significantly better results.

We used Python for our analysis because it provides easy access to huge amounts of statistical and computational methods. The first step is data ingestion and cleaning. The data comes in XLSX format for the online learning platform. After removing the unnecessary variables and missing values we can compute the distances between the students. Based on these distances we can find the most similar students. A graph can be created based on this distance matrix, the distance matrix is as assigned as the graph's adjacency matrix.

This similarity can be due to knowledge similarity or due to cooperation. Based on the timing of the test and the order of the questions we can sort out the cheaters. Overlapping time and the same order of completion can be telling in this situation. In the last part, we reduce the dimensions of the data with the aforementioned methods. This step is for visualization, manual similarity checking, and clustering.

4 RESULTS

The most common way of evaluating a test is to weight the tasks according to difficulty and then add up the scores for each task to get a final score, which can be used to give the student a grade. Students with the same score will then receive the same mark, but their knowledge may be different. Consider an essay where you want to check a wide range of knowledge. If you have hundreds of students taking a test, online testing is preferable as it is quicker to correct. Another advantage is that the results of the tasks corrected by the machine can be easily retrieved and used immediately for analysis.

Figure 1 illustrates the results obtained using UMAP on the study population. Each dot represents a student, the same colour indicates that part of the maths-language test that was designed to test how the knowledge acquired in high school was applied in situations that they had encountered in high school. (The first third of the math test assessed procedural skills, here were algebraic transformations, and calculations with identities. The second third was the part mentioned above, while the last third was to solve problems for which the students had acquired the necessary knowledge in high school, but the task was unusual, most likely they had not or had only rarely encountered the application of their knowledge in such a setting.) Although the colouring was done according to the scores on the middle block of the mathematics test, the separation, finding students with close knowledge of each other, was done based on the overall test scores. We can see that there are dense clusters of the same colour in the point cloud, marking students who are close to each other in terms of knowledge, but it is also clear that points of the same colour can be very far apart. If we want to create groups with homogeneous knowledge, then students represented by the distinct point clusters in the figure can be placed in a group.

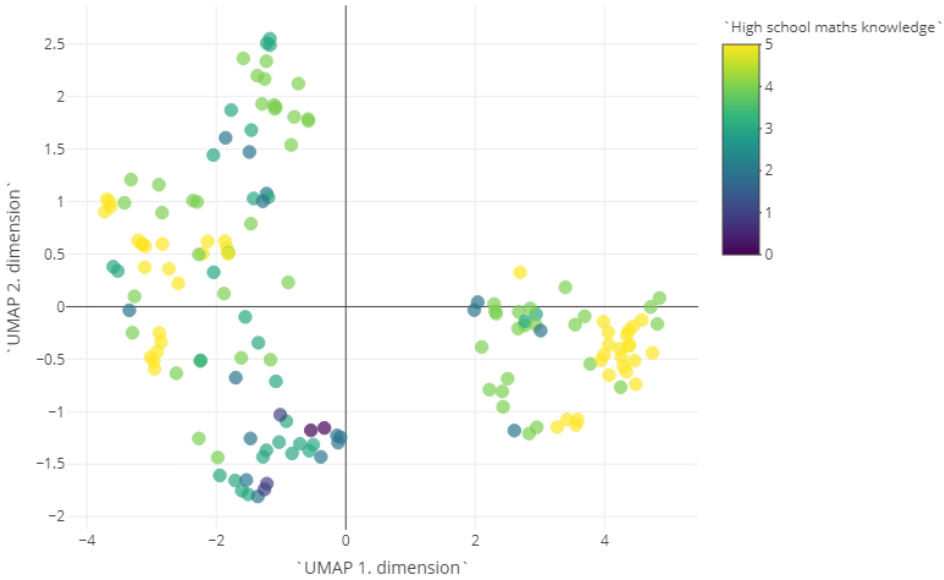

Fig. 1. UMAP results – the colour represents the high school math knowledge

The result of the clustering obtained by t-SNE is shown in Figure 2. Here again, each point represents one student, and the colours are defined according to the maths scores in the maths-language test. Red represents a score of 0, while purple represents the maximum score. The figure shows several small clusters, with those making the same type of error closer together. No larger, distinct clusters have emerged. It is also striking that students with a medium score are almost evenly distributed in the point cloud. This follows from the fact that they may have made the most type of mistakes.

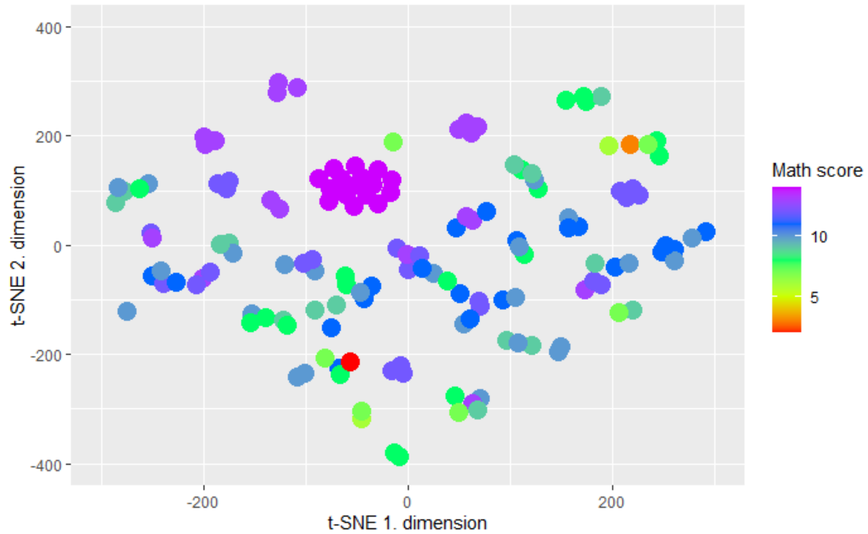

Fig. 2. Result of t-SNE based on the test – the color represents the total math score

In Figure 3, the dots are coloured according to the score on the mathematics test, representing one student. The figure illustrates the distance of each completer from a correct completion.

In the figure on the left, we have used the so-called L1 norm (Manhattan distance), while in the figure on the right, we have used L2 (Eucledian distance). The left graph shows that students with identical scores in mathematics are close to each other in this respect but can be very far apart in terms of their scores on the language test. Note, however, that those who scored poorly in maths were also far from perfect in the language test.

The figure on the right shows the distance according to the L2 norm. Here the reason for the clustering is due to the metric calculation, not to a real separation.

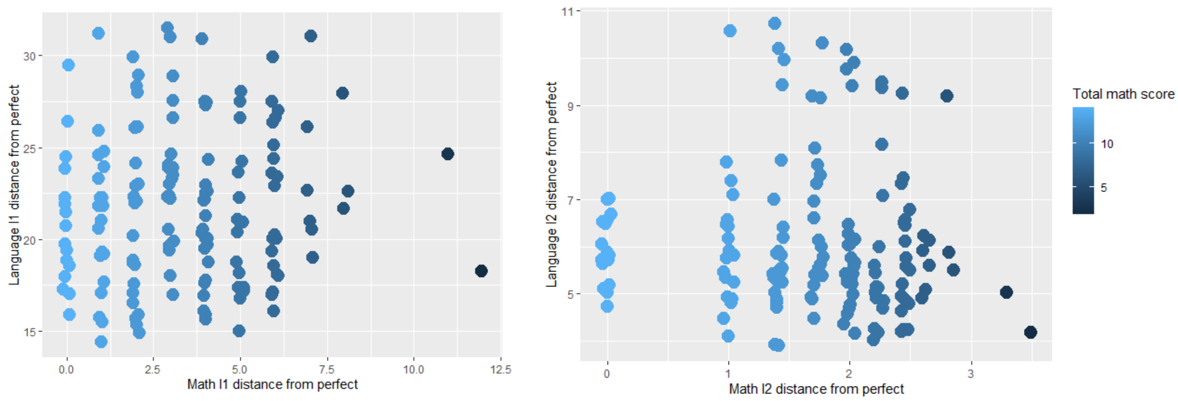

Fig. 3. L1 (left) and L2 (right) distance from a perfect test both in the math and language part

4.1 Investigating cooperations and cheating

The use of distance metrics and the overlapping of time periods allows cheating to be detected. If the match is high and the temporal relationship is given, cooperation may be at work in many cases. Proving this is difficult, but the closeness suggests that the students were working together. Cheaters are detected by examining the distance matrix and analysing it. There does not have to be a perfect match, just look for deviations much smaller than the average distances, for example, based on the histogram. The next step in the analysis is to examine the overlap in time. This procedure can play a key role in making online examinations more secure. A visualisation of our calculations is shown in Figure 4. The group circled in blue is the group of near-perfect candidates, where the reason for near-perfection is not cheating but few errors, while the group of a few candidates circled in green has the same number of errors and a similar temporal pattern. There is a suspicion that they wrote their test jointly.

4.2 Finding redundant questions

The 25 vertex graph in Figure 5 illustrates the results of the 25-question van Hiele test in the study population. The test reveals levels of geometric thinking. The van Hiele pair defined 5 levels of thinking, each level is measured by 5 questions. The first level is assessed by the first five questions, the second level by the second five questions, and so on. The test, questions and evaluations are described in detail in Usiskin's work [6]. The vertices of the graph are the tasks, which are connected by weighted edges. The weight of the edges is given by the probability of solving the problem of the two vertices of the edge. In the figure, the weight of the edges is represented by their thickness, length and colour. A thicker edge indicates a higher probability of solving. These are the short green edges in the graph. For example, many people solved problem 13 and 18 correctly. While the problems represented by the thin, long pink vertices (e.g., 2 and 9) were solved by few.

When assessing performance, we would like to assess the knowledge of those completing the tasks in depth. We would like to set a wide range of tasks, but the completion time should not be too long. The question arises as to which tasks can be discarded. The results of a test written in the framework of a pilot study can be visualised using the above procedure and it quickly becomes apparent that the middle tasks can be omitted from those that are linked with a heavy weighting edge. In this way we can optimise the completion time and reduce redundant items. This procedure can also help us in the teaching process: we can easily identify the types of tasks that need further practice and those that our students are already solving with good results.

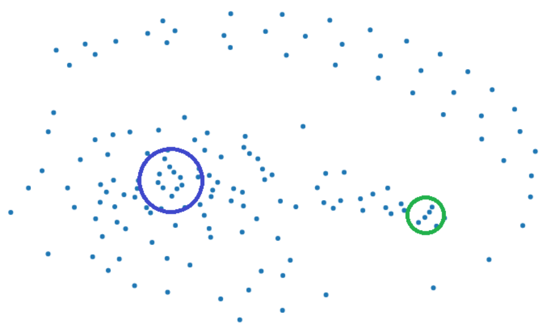

Fig. 4. Force-directed graph drawing of the knowledge similarity graph – blue circle shows the perfect tests, green circle for the suspicious students

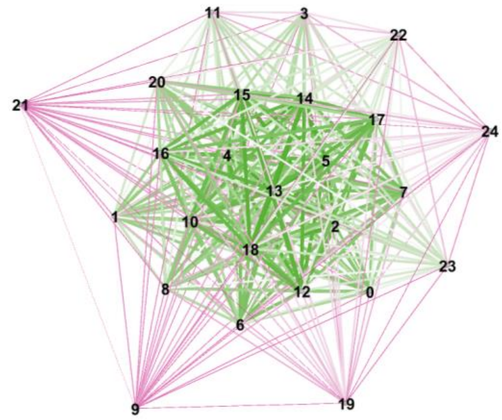

Fig. 5. Question similarity graph – green edge connects the similarly completed questions, purple for the large differences

5 CONCLUSION

Cheating became a huge problem in online exams during the pandemic and its detection requires manual reviews which is not feasible for large student groups. We encountered problems with knowledge homogeneity, some students lack a basic understanding of math due to inefficient online learning during their last year in high school. These large disparities make catch-up lessons essential.

Above, we have presented methods for evaluating test results, which not only visualize the results obtained in the exams but can also be useful for detecting cheating or for group creation based on similar knowledge, which can be crucial for efficient teaching.

ABSTRACT

University studies were also significantly affected by the pandemic. The first-year students had already spent the last months of high school, which are especially important for graduation, in distance learning. In Hungary, the graduation procedure was changed due to the epidemic. Education was completely digital in hybrid form: the lectures were held online, and the seminars were attended in-person and from September of 2021 again in-person. Our research team has been monitoring learning time and effectiveness for years using the EduBase online educational platform, which provides a framework for all teaching aids for the calculus subject. In our research, we analysed the learning processes and their effectiveness of mechatronic and energy engineering students who were admitted to BME in 2020. The results were compared with the learning habits of the class of 2018, with whom a detailed study was also performed. It can be stated that the pandemic greatly influenced the learning time: students took advantage of the available practice opportunities to a greater extent in digital education, which did not reduce the practice time during the end-of-semester spurt, thus, learning became more balanced. Considering the high school results, it can be observed that on average, those who took advantage level subjects spent more time practicing, even though they had

doi:10.5821/conference-9788412322262.1358

already mastered some calculus in high school. In addition, test scores also influenced practice time, while students coped successfully even with the more difficult tasks.

INTRODUCTION

The transition from high school to university is challenging for students even without the difficulties of the epidemic. In 2020, it was especially difficult for graduates. Knowing that the first-year students had already spent the last months of high school in online education, and due to the epidemic, only hybrid education is implemented at the Budapest University of Technology and Economics, we paid special attention to our students' learning. In the summer of 2020, we created a carefully compiled workbook. During the online lectures, the students were able to fill in the missing parts of the workbook (e.g., proofs, examples) and take notes on it. During the semester, a video was created for each topic weekly, in which we presented a detailed solution to exercises. In the EduBase online education platform, students had parameterized practice exercises for each topic. Thus, each time they entered the platform, they got a different task. The students could do their weekly homework also in this EduBase system. Furthermore, they wrote the first and second midterms and the exam via this same platform. Lectures and weekly consultations took place at MS Teams. Therefore, the whole learning process became easy to monitor. For each student, we could see every day how much time they spend on the calculus subject (e.g. doing homework, practicing), when and how effectively they deal with the material.

We have carried out similar monitoring in previous years [1],[2],[3], while attendance education was still ongoing. The main result of these studies was the following: although students willingly learn using the online platform, towards the end of the semester, when their duties accumulate, they spend much less time practicing. We knew that we need to pay close attention to this in this pandemic and try to prevent this decline. At the beginning of the semester, we tried to assess the students' level of knowledge, skills, and level of thinking with several tests. Thus, we attempted to screen out students who may have difficulties during the semester to help them if needed. We assigned senior tutors to our students. A tutor dealt with 10-15 students, paid more attention to them, and held individual consultations for them. Both tutors and teachers were very enthusiastic and engaged with the students to help them successfully overcome the obstacles of the transition to higher education.

1 DATA AND METHODS

1.1 Investigated group

The students in our study population were admitted to two majors with the highest admission scores of the leading technical institution in Hungary. In 2020, the 433 points were for mechatronics, and 349 points for energy engineering were the inclusion point limit. A maximum of 500 points can be earned [4]. The average admission score of the mechatronics in our study population is 459 points, the standard deviation is 15, while the average score is 421.5, and the standard deviation is 33 points for energy engineering students. A large proportion of students came from a high school where they studied mathematics or science subjects in a higher number of hours. This ratio is 51.6% (32 students) for energy engineering students and 51.1% (47 students) for mechatronic students. 59 (64.1%) of the mechatronics students and 41 (66.1%) of the energy engineering students graduated in advanced level in mathematics. They studied math at an advanced level, which means they had at least 5 math classes a week as a high school student. Furthermore, their high school curriculum included differential and integral calculus, meaning that they had already learned a lot about what is described in the calculus subject.

1.2 High-school learning method during pandemic

It can be seen that 20% of energy engineering students had no part in any education, while this proportion was approximately half in the case of mechatronic students. This is a significant proportion, considering that students come from good ranked high schools for these majors.

2 TEACHING PROCESS

2.1 Course structure and requirements

For first-year energy engineering and mechatronics students, the calculus subject consists of 2x90 minutes of lectures and 1x90 minutes of seminars per week. The condition for participation in the oral and written final exam is successfully completing first and second midterm and tests at least 40%. The final grade is determined as follows: a student can get a maximum of 100 points during the semester, 20-20 points for the tests, 60 points for the written final exam, in addition to 10 extra points for additional optional tasks. Based on their score, students will receive a recommended grade. The final grade is obtained with a maximum deviation of ± 1 grade from the recommended grade based on the student's performance in the oral exam.

2.2 Education method during the semester

The first six weeks of the autumn semester went as so-called hybrid education at Budapest University of Technology and Economics: the lectures were held online, the seminars in the traditional, attendance way. Due to the worsening epidemic situation, the university switched entirely to online, distance education from the second half of the semester (November 16, 2020).

2.2.1 Lectures

The lectures of the calculus course were held online throughout the semester via the MS Teams system. At the scheduled time, the students were able to participate in the lecture together with the lecturer, at the same time. Thus, they could immediately ask their questions and react to the learning material. All lectures were recorded so students could watch them at any time after the scheduled time. A workbook was prepared for the lectures, which already contained the most important definitions and items, thus helping to take notes. However, there were omitted parts (e.g proofs and examples), thus encouraging the students to actively participate and pay attention to the lectures.

2.2.2 Seminars

The seminars were held in the traditional, attendance way with small groups during the hybrid system. Nevertheless, all seminars were uploaded to the EduBase digital classroom in a video format so anyone could watch them again, especially those who were unable to attend the seminars due to the pandemic. At the end of the attendance seminars, the students wrote a small test for one extra point from the material of the given lesson. In the second half of the semester, during the online education, the videos of the seminars had already been uploaded at the beginning of the week, and students had the opportunity to consult in the scheduled time of seminars via the MS Teams.

2.2.3 Homework

Throughout the semester, students had the opportunity to complete homework in the digital classroom for extra points and practice on quiz sets after the submission deadline of homework. In the first half of the semester, while the seminars were also held in attendance, students were able to begin completing their homework after the scheduled time of these seminars. In the second half of the semester, the homework always opened on Mondays after the seminar videos were uploaded into the digital classroom. The EduBase system allowed us to track students' learning processes. The first and second midterms, as well as all the written final exams were also conducted via this EduBase platform.

2.3 Education platform - EduBase

Online education was implemented with the unique testing and examination system of the cloud-based education platform EduBase (www.edubase.net) [1],[5].

3 RESULTS

3.1 Study-time patterns

The figure below (Fig. 1) shows how many seconds students worked in EduBase. Outlier data are not presented. Very short practicing (shorter than 600 s) was not considered. The horizontal axis shows the time of practice in hours and the vertical axis shows the number of entries. The approximately half-hour practice time is the most common. Students often practice for between half an hour and an hour, while practice times longer than 60 minutes are becoming less frequent.

Comparing data from the 2018 pandemic-free semester with 2020, it can be seen that more people practised for longer periods during the pandemic. The detailed analysis of the data also revealed that in 2020 there were 26 students (both populations were made up of nearly the same number of students of the same ability) who practiced more than 40 hours, compared to only 8 in 2018.

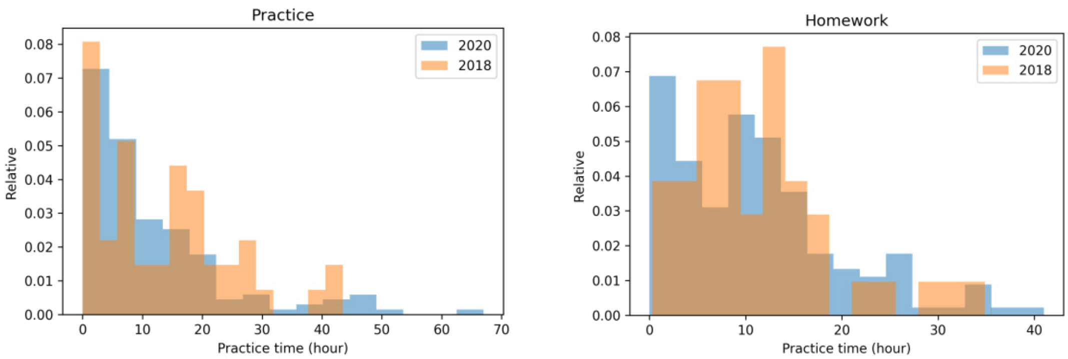

Fig. 1. Distribution of time worked during the semester

Fig. 2 shows how the opening of homework and practice quiz sets developed during the semester. The more intensive preparation for the first and second midterms in the middle of the semester and at the end of the semester is clearly visible with outstanding peaks. In these two cases they practiced more often and more. The peaks seen in late December and January are the preparation peaks for final exams. In these cases, if we compare the peaks to the number of participants in each final exam, we can say that the preparation takes approx. the same for all final exams.

The most remarkable difference between the autumn 2018 semester (left graph in Fig. 2) and 2020 (right graph) is that in 2020, students spent more time practising and solving homework in the second half of the semester. It can also be seen that learning was more even, which has a positive impact on learning efficiency [2], [3]. The data are in accordance with our experience: in pandemic-free periods, in the last weeks of the semester, students are usually so overloaded that many of them are already "struggling to survive", attempting to solve only the compulsory tasks in an acceptable way. Preparing for exams (highlighted in red) during the pandemic is also more characterised by distributed learning throughout the semester.

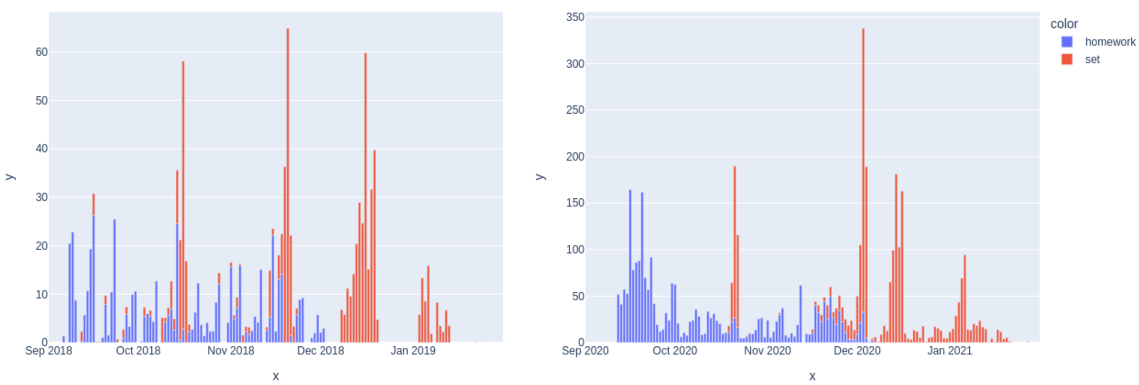

Fig. 2. Distribution of total homework and practice quiz set openings

The homework of the current week was open on Thursdays (after seminar) during hybrid education and on Monday evenings during entirely online education in the second half of the semester. Students had one week to solve their homework. Thus, for the online period, Monday midnight was the submission deadline of homework assignments. Examining the daily distribution of openings, we found that practice began most often on Wednesday, while homework was most often done on Thursday. Weekends were not preferred for practice or doing homework. We consider this fact important as it suggests that the students did not leave the preparation at the last minute, they tried to distribute the practice evenly.

Figure 3 shows the weekly distribution of learning time in 2018 and 2020. The peaks are the days of the week. In 2018, many students were most engaged with the curriculum the day before the deadline (Sunday high peak), while in 2020 the peaks show a much more even spread of learning.

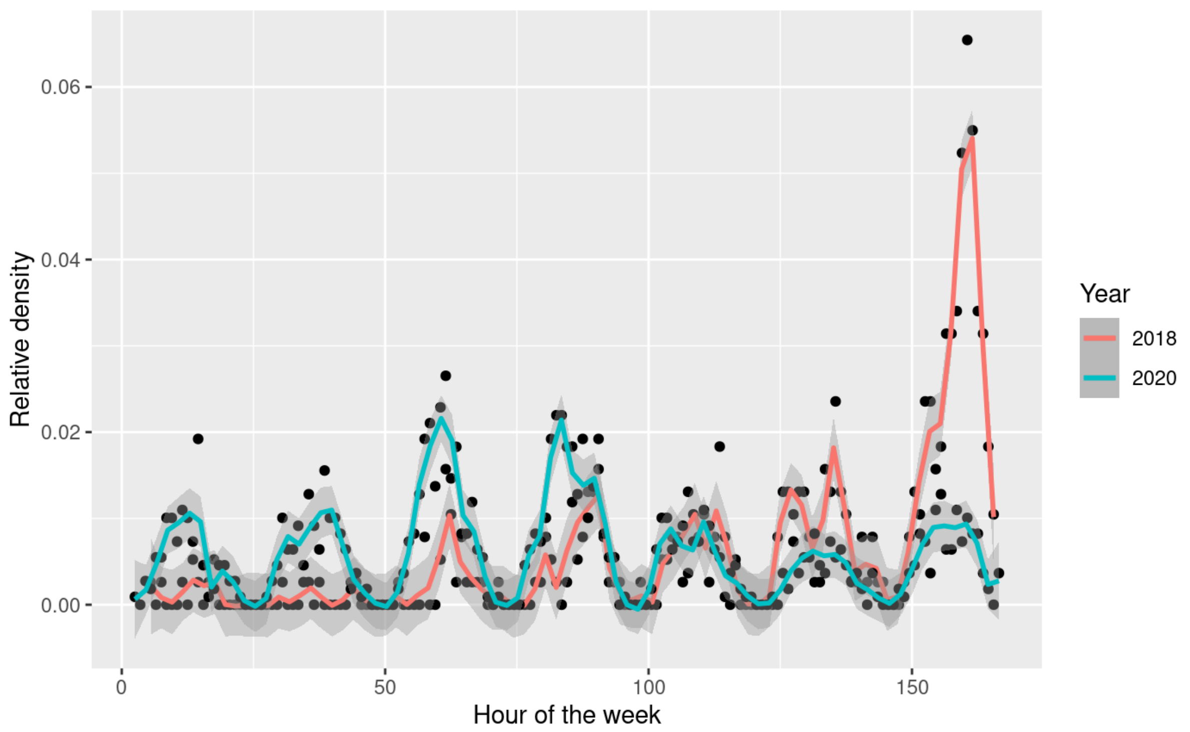

Fig. 3. Distribution of weekly homework and practice time

3.2 Test results

Let's see how students with different study periods performed in the tests in the autumn semester 2020. In the graph, the size of the dots is proportional to the time spent studying, the larger the dot, the more time the student is spending studying. Each dot represents one student.

Figs. 4 and 5 show the relationship between the results of the first and second midterms of the calculus subject and the results of the mathematical-language test written in the first week for each student. The math-language test was written to estimate the level of knowledge of the incoming students. The language part is unusual in technical higher education. The purpose of this section is to compensate for the distorting effect of excessive preparation for mathematics tasks [7]. Each dot in the figures represents one student. The radius of the circle is proportional to the online learning time (outlier data have been filtered out). The students marked with a blue dot attended a special mathematics or science class during high school, so mathematics had a greater emphasis in their high school education. Students marked with a red dot only attended basic maths lessons. Based on the figure for the first midterm, better math-language tests were generally coupled with better first midterm results. Furthermore, those who spent less time practicing and learning, rarely achieved good results. Although, you can see a few blue circles with a small radius and good results. This can be explained by the fact that the material of the first midterm was already discussed deeply in the special mathematics or science classes during high school.

Fig. 5 shows the results of the second midterm. The chart can be divided into 4 rectangles. As mentioned earlier, the second midterm mainly contained material that was not encountered or just mentioned in high school. The light blue rectangle in the lower left contains students with little incoming knowledge who also perform poorly at university. Luckily, it includes only one student who, as the size of the dot shows, didn’t spend much time practicing. In the lower right, light green rectangle, the students did poorly on the mathematics-language test, but apparently practiced a lot during the semester, and the second midterm was already written with good results. Students in the purple rectangle in the upper left, despite writing a good math-language test, practiced little and were not successful in the second midterm. The students in the upper right, yellow rectangle performed well on both measurements, and many of them also devoted a lot of time to practice. Only a few small radius circles can be seen in this range.

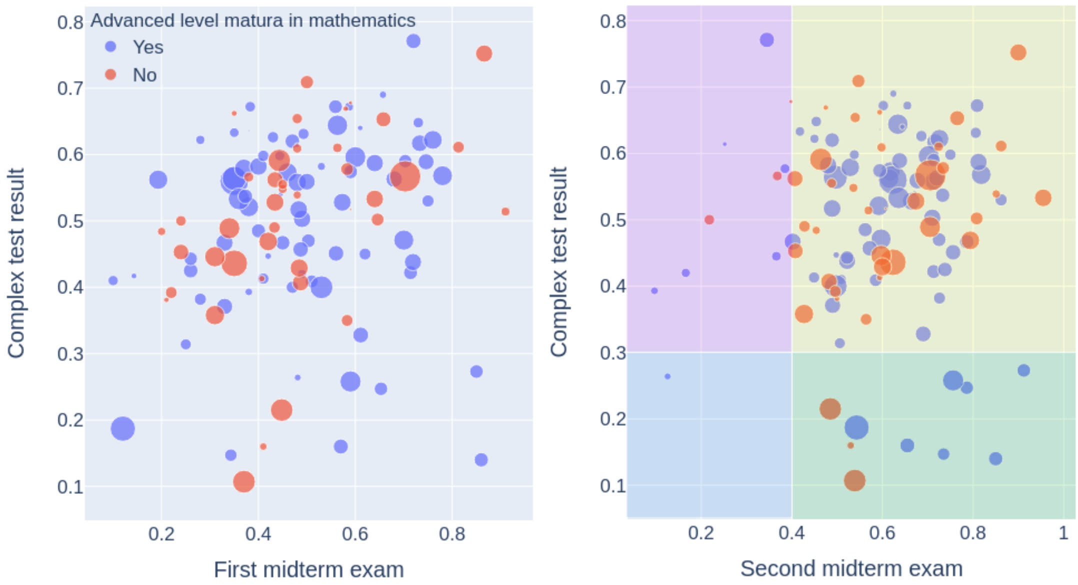

Fig. 4. (left) Relation of student performance on the 1st midterm exam and on the complex test result

Fig. 5. (right) Relation of student performance on the 2nd midterm exam and on the complex test result

4 CONCLUSION

As a conclusion, it can be stated from the detailed analyses of this partly hybrid and partly online semester that first-year students could solve the difficulties of the pandemic situation. Instead of the campaign-like learning that is so common in higher education, providing inadequate knowledge in the long term, students worked evenly, mostly devoting an adequate amount of time to learning. They did the calculus exam well. 20 (13%) students earned excellent grades, 34 (22%) good grades, 51 (33%) fair grades, 31 (20%) sufficient grades, while 16 students failed. The exams consisted of two parts, a 90-minute online written exam with numerical exercises, followed by an oral test on theory. The results were a little lower than usual, but when compared to the results during the pandemic, it was outstanding. In the case of exams with only an online written part, it was common to see better results than before during the pandemic, but much poorer results in the oral part. In calculus, the EduBase fraud detection system did not detect the same bias as in the written exams in other subjects. The slightly weaker results in the oral test could also be explained by the fact that there were no oral exams in Hungary in spring 2020, so that students had their first opportunity to orally test their knowledge of a large amount of material at university. Learning and then orally reproducing a large amount of theory was not easy for many.

For the academic year 2021/2022, education at our university was conducted in-person. For our students, this was more of a start than a return, as it was the first time during their university studies that all their classes were taught in-person format. Calculus 3 is the last regular mathematics course, followed by a comprehensive exam. In the autumn semester of the 2021/2022 academic year, we have tried to implement the distributed learning experienced during the online period. We also monitored the Calculus 3 course in EduBase. The analysis of these data and the comparison with the same subject in the previous academic years is still ongoing, and we intend to publish our results in further contributions.

ABSTRACT

Motivation is an important predictor of ethical awareness; however, it is not easy to assess. The goal of our study is to examine the relationship between motivation and ethical awareness in engineering students. We focus on two personality measures: person-thing orientation and spheres of control and test their association with ethical awareness using engineering scenarios that present ethical dilemmas. We predict that engineering students who score higher on the personality dimension of person-thing orientation will display more ethical awareness than those who score lower. We also predict that students with a higher level of personal control will also display more ethical awareness. Two groups of students were involved in the study. Group 1 was formed by fifty-three first-year engineering students from University in the United States and Group 2 was represented by sixty-four sophomore engineering students in Engineering School in Spain. Students worked individually on case studies that presenting ethical dilemmas; they were asked to write short essays describing how they would respond to each situation. Then the essays were analyzed using an ethical

reasoning and a global awareness rubric. Results revealed that 1) the context/nature of the students' responses to the case study varied greatly, 2) personality traits and global and ethical perspective, all correlate to students' ethical decisions as measured by their responses to the case studies scores, 3) there is an alignment between the SOC and the Global Perspective Inventory (GPI) dimensions that merits further exploration.

1 INTRODUCTION

1.1 Engineering students and ethical reasoning

Since its formalization nearly four decades ago, engineering ethics has made considerable progress, from creating communities of practicing scholars and journals partially devoted to the field, to obtaining recognition, increased emphasis, and formalized courses within the larger engineering community. One of the major goals of engineering education to date has been increasing the ethical sensitivity of students in engineering programs. However, Michael Davis emphasizes three components of the engineering ethics curriculum that are vital for the next generation of engineers that go beyond ethical sensitivity: the history and sociology of engineering, the ability to communicate the complexities and ethical issues of their work to other engineers, and the philosophical knowledge to ground the decisions they make in their work [1].

Codes of ethics, as outlined by many professional organizations of engineers such as ASME and ASCE, have become the commonplace method for introducing collegiate engineering students to ethics education. While the details of these codes of ethics differ across disciplines, some common themes across disciplines include 'acting in the best interests of your employer or client,' avoiding conflicts of interests, and ensuring public safety. In addition to examining codes of conduct, case studies have been the primary pedagogy utilized in ethics education. Case studies can take a complex situation allow students to explore and condense it down to the core issues within the case, which can range from issues of human error to examining competing interests between involved parties [2].

Utilizing codes of ethics, case studies, and various other pedagogical techniques, ethics education has been shown to have an impact of the moral outcomes of students. In a quasi-experimental study conducted on business students at a US university, May and Luth found that students, when exposed to ethics training, whether it was imbedded in other courses or in a stand-alone course, displayed higher levels of moral efficacy (the ability to make ethical decisions), moral courage (the motivation to act on the morally responsible decision), and perspective-taking than students did not have exposure to ethics education [3].

1.2 Personality dimensions and motivation of ethical awareness

Motivation is an important predictor of ethical awareness; however, it is not easy to assess. Multiple scales and theoretical frameworks have been created to examine how to predict ethical awareness and behaviour, with varying success. One framework for understanding how students think about ethical scenarios, presented by Magun-

Jackson, adapts Kohlber's Theory of Moral Development to implement ethics in engineering education. The framework highlights how students, as they develop morally, move from thinking of their own needs to thinking about those related to them (i.e. family) and eventually to how actions will affect society [4]. Another theoretical framework, presented by Bairaktarova and Woodcock, outlines a theoretical framework for predicting ethical awareness and behaviour based off Ajzen's theory of planned behaviour and Harding et al. inclusion of moral obligation [5], [6]. The revised framework included three personality scales to better predict student behaviour, Person Orientation, Thing Orientation, and the Spheres of Control.

Person and Thing Orientation have been used in recent literature to discuss potential reasons for the underrepresentation of women in various STEM fields, including engineering. Su and Rounds , in their meta-analysis of various studies examining gender differences across STEM professions found that women's interests lead to them choosing more people-oriented and less thing-oriented work environments when choosing their career in STEM [7]. Similar work discussing the usage of person and thing orientation in STEM, completed by Graziano, Habashi, and Woodcock (2011), who worked to remodel the PTO model, found that Thing Orientation differed across men and women, but that PO did not [8].

Highlighted in Bairaktarova and Woodcock's proposed framework for predicting ethical awareness and ethical behaviour is the Spheres of Control. Divided into three domains of control, Personal Control (PC), Interpersonal Control (IPC), and Socio-political Control (SPC), which each examine an individual's perceived control, or personal efficacy, within an environment [9]. Each of these Spheres represents an environment in which a student may feel they are in control of the decision-making process. This directly ties to the research of May and Luth which found that ethical teaching directly increased moral efficacy [3].

The goal of our study is to examine the relationship between motivation and ethical awareness in engineering students. We focus on two personality measures: person-thing orientation (Graziano et al.) and spheres of control (Paulhus) and test their association with ethical awareness using five engineering, scenarios that present ethical dilemmas. We predicted that engineering students who score higher on the personality dimension of person-thing orientation will display more ethical awareness than those who score lower. We also predicted that students with a higher level of personal control will also display more ethical awareness.

2 METHODOLOGY

2.1 Study settings & participants

Two groups of students were involved in the study. Group 1 was formed by fifty-three first-year engineering students from Virginia Tech in the United States and Group 2 was represented by sixty-four sophomore engineering students in the Engineering School the Universitat Politècnica de València. Students worked individually on case studies that presenting ethical dilemmas; they were asked to write short essays describing how they would respond to each situation. Then the essays were analyzed using an ethical reasoning and a global awareness rubric.

2.2 Study measurements:

Person and Thing Orientations

We administered Graziano et al.'s Person-Thing Orientation Scale, which taps into the alignment of participants' interests with people and things. The scales consisted of 9 and 5 Likert-like questions for Person-Orientation and Thing Orientation, respectively, with reverse-coded questions. Participants took both the Person subscale (PO) and Thing subscale (TO), which had reliabilities of α = 0.76 and 0.85, respectively.

Spheres of Control

The Spheres of Control (SOC) Scale was developed by Paulhus to measure perceived control in three domains - personal control (PC), interpersonal control (IPC), and socio-political control (SPC) [9]. Each subscale consists of 10 Likert-like questions (30 total), that contained 5 reverse-coded questions. The subscales have reliabilities of α =0.80, α =0.83, and α =0.75, respectively.

Ethical Case Studies

Students were provided with 4 ethical scenarios, each one paragraph long, that asked students to identify if there was an ethical issue within the scenario and to come to a decision based on the information provided. The scenarios described:

- *Scenario 1*: A Material Engineer faces a dilemma of using a cheaper polymer in a biomedical device that carries some risk of damaging human skin or choosing a more expensive polymer that has no known risks that will also take a much longer time to deliver.
- *Scenario 2*: A Mechanical Engineer is asked to by the CEO to change the data of a competitor's product listed on their company website to make their company's products look better.
- *Scenario 3*: After a time-intensive and expensive design process for a new microchip, a microchip testing engineer is asked to lie about a the new products output specifications to the client.
- *Scenario 4*: A Team Lead is left in charge of an underperforming new hire and tight deadlines and are left to decide if they need to be replaced with a hopefully better hire or given enough time will improve.

Each of the 4 scenarios was followed up by questions prompting students to describe the ethical dilemma within the scenarios and the course of action they would take if they were the engineer in the scenario. The student responses to the scenarios were then rated as either 'below competent (0),' 'competent (5),' or 'above competent (10)' across three criteria:

Criteria 1: Explain and contrast relevant ethical theories
Criteria 2: Identify ethical issues in a complex context
Criteria 3: Articulate and defend positions on ethical issues in a way that is both reasoned and informed by the complexities of those situations

Two members of the research team rated each of the student responses for the three criteria listed above. Across all three criteria and all four ethical scenarios, an interrater reliability of 0.8, which is suggests substantial agreement across raters [10].

3 RESULTS

3.1 Scale Reliability

While the results analyzed below only represent those of the students from Group A, the data has been collected for the students in Group B, and is currently being analyzed and will appear in the final version of this conference paper. Additionally, initial analysis of Group B's data corroborate the findings of Group A across many of the subscales scales, from both the PO-TO and SOC respectively. The two groups (VT international students and UPV, Spain) were not significantly different from each other on any of the variables except thing orientation (TO). The first group had higher TO (M = 3.44) than the second group (M = 3.13) and the difference was statistically significant ($p < .05$). This difference will be reflected and explored more in the final draft of the paper.

The first step of the analysis was to ensure the reliability of the various subscales for the Person-Thing Orientation and the Spheres of Control. From these two scales, the PO, TO, PC, and IPC subscales all had acceptable fits, ranging from $0.7<\alpha<0.8$. However, the SPC scale had an unacceptable fit (α=0.342), which may be due to small sample size.

As seen below in Table 1, independent sample t-tests found no significant difference between the Total Ratings (all ratings combined) of the four case studies between males and females. Similarly, for many of the personality scales, there was no significant difference between males and females in all the variables except in the Thing-Orientation (TO) variable. Females had a significantly lower score (M = 2.95, SD = 3.20) compared to males (M = 3.57, SD = 3.60) on Thing Orientation. This was not expected as previous work by Graziano et al. (2012) found that females in STEM reported similar TO scores to their male counterparts while also reporting higher PO scores [8]. This difference may be due to the smaller sample size, which when the data from Group 2 is analyzed may align with previous works.

Table 1. Independent Sample t-tests for all variables by gender

	Statistic	df	p	Mean difference	SE difference	Effect Size
PC_Mean	-0.3576	50.0	0.722	-0.0949	0.265	-0.1214
IPC_Mean	-0.5900	50.0	0.558	-0.1594	0.270	-0.2003
SPC_Mean	0.2982 ᵃ	50.0	0.767	0.0563	0.189	0.1012
TO_Mean	2.4978	53.0	0.016	0.6273	0.251	0.8420
PO_Mean	-0.6424	52.0	0.523	-0.1897	0.295	-0.2171
Case1_Total	0.9645	52.0	0.339	1.5433	1.600	0.3259
Case2_Total	-0.6695	52.0	0.506	-1.4271	2.132	-0.2262
Case3_Total	0.5770	49.0	0.567	1.1341	1.966	0.2035
Case4_Total	0.0762	49.0	0.940	0.1585	2.080	0.0269

ᵃ Levene's test is significant ($p < .05$), suggesting a violation of the assumption of equal variances

A Pearson Correlation Matrix found that with cases 1, 3, and 4 the Total Ratings (all ratings combined) was not significantly related to PC, IPC, SPC, TO, or PO, which is depicted below in Table 2. However, Case Study 2 total score (the sum of a student's scores for the three ethics criteria for a given case study) was significantly related to Interpersonal Control (positive relationship; $r = .315$) and Thing Orientation (negative relationship; $r = -.269$). A positive relationship with IPC indicates that feeling in control of a situation with other people leads to better ethical decision making, which is consistent with the idea of moral courage described by May and Luth [3]. The negative relationship between the case study ratings and TO indicates that students may not have been thinking about how the results of fudging company data would affect other people, and simply saw the issue as a technical one of fixing an error.

Table 2. Pearson Correlation Matrix for all variables

	PC_Mean	IPC_Mean	SPC_Mean	TO_Mean	PO_Mean	Case1_Total	Case2_Total	Case3_Total	Case4_Total
PC_Mean	—								
IPC_Mean	0.272 *	—							
SPC_Mean	0.288 *	-0.050	—						
TO_Mean	0.166	-0.076	-0.034	—					
PO_Mean	0.089	0.076	0.065	0.358 **	—				
Case1_Total	0.224	0.259	0.034	-0.015	0.123	—			
Case2_Total	0.064	0.315 *	0.024	-0.269 *	0.157	0.483 ***	—		
Case3_Total	0.038	0.181	0.031	-0.089	0.054	0.570 ***	0.212	—	
Case4_Total	0.121	0.249	0.001	-0.205	0.155	0.502 ***	0.435 ***	0.479 ***	—

Note. * p < .05, ** p < .01, *** p < .001

Linear regression examinations of Case Study 2 found that both TO and PO were significant in predicting Case 2 total score. Thing Orientation was found to be negatively related to case study rating total score (β=-2.953, p=0.016). Students with higher scores on TO would be expected to have a lower score on the Total Rating on Case Study 2. Dissimilarly, Person Orientation was found to be positively related to case study rating total score (β=2.144, p=0.054). Students who have higher scores on PO would be expected to have a higher score on the have a higher Total Rating on Case Study 2. It is important to note that these trends did not exist for the other case studies. While it may be due to low sample size, which will be remedied with the addition of data from Group 2, it may be that Case Study 2 is unique in and of itself. This may have to do with the fact that Case 2 is the least lengthy of the four, and therefore may not have as much context surrounding it that students needed to identify ethical issues. Regarding the regression scores for TO and PO, Case Study 2 described interactions with people the least, instead focusing on the actor making up false schematics, which might be why people who had higher Thing Orientation scores had lower scores on this Case Study.

Table 3. Linear Regression for Case Study 2 Total Ratings

Predictor	Estimate	SE	t	p
Intercept	-3.494	9.31	-0.375	0.709
PC_Mean	0.152	1.16	0.131	0.896
IPC_Mean	2.099	1.10	1.907	0.063
SPC_Mean	-0.417	1.60	-0.260	0.796
TO_Mean	-2.935	1.17	-2.507	0.016
PO_Mean	2.144	1.08	1.979	0.054

4 SUMMARY AND ACKNOWLEDGMENTS

This research has found that for Case Study 2, Interpersonal Control is a positive predictor and Thing Orientation was a negative predictor of the student scores on Case Study 2. This aligns with previous research and the framework presented by Bairaktarova and Woodcock [6]. However, the research team is continuing to examine why IPC and TO correlations existed for Case Study 2 that did not exist for the other Case Studies and in future iterations may revise the Case Studies to be of similar length, description, and ask similar probing questions to the students. Future research will more closely examine the differences in scores between the first-year students from Group 1 and the sophomore students from Group 2, both in experience within the program as well as cultural differences that may exist.

ABSTRACT

Accreditation bodies such as the Engineering Council of South Africa and the Canadian Engineering Accreditation Board have a group of courses that fall under the umbrella of Complementary Studies. This term is used to describe a set of engineering courses that include knowledge areas other than the more common mathematical sciences, natural sciences, engineering sciences, design and synthesis, and work-integrated learning. Studies have shown that engineering educators sometimes view these courses negatively. They are seen as distracting the focus of the students on the so-called technical courses, which the educators feel are more important. This paper reports on a research study that explored the way that engineering educators make sense of complementary studies courses within an industrial engineering curriculum. The repertory grid technique was used to explore complementary studies courses when compared to other engineering courses within the same curriculum. The relationships between elements and constructs in the grids were analysed using the repertory grid techniques of principal component analysis and cluster analysis. What became clear was that while most of the educators interviewed did recognise complementary studies courses as different to courses considered as core or technical, what made them different was very unclear. Each educator had a very different conception of what defines, differentiates or constitutes a complementary studies course. This range of variation may go some way to explaining why complementary courses seem out of place in engineering programs by educators and students alike.

1 INTRODUCTION

The undergraduate engineering curriculum includes courses which span a range of knowledge areas including mathematical sciences, natural sciences, engineering sciences, design and synthesis, and work-integrated learning. There are also courses which accreditation bodies such as the Engineering Council of South Africa (ECSA) refer to as complementary studies. This is a term used to describe courses that include knowledge areas other than the aforementioned, that complement the practice of engineering (ECSA, 2016). Complementary courses are intended to create, amongst other benefits, well-rounded, socially conscious engineers who are able to work in multi-disciplinary environments (Donald et al., 2017). As with many other universities around the world, universities in South Africa are required to incorporate these courses into their engineering curriculum.

As suggested in the literature (see for example (Donald et al., 2015) and (Dubreta, 2014)), many engineering students appear to face difficulties when engaging with complementary studies courses in the engineering curriculum. They are often perceived as unimportant and an unnecessary hurdle to overcome by both educators and students. Educators often view these courses as distracting from the focus of the students on the technical courses which they feel are more important (Arms, 1993). Navarro et al. (2016) do however argue that if educators are given enough guidance, it should be possible to successfully deliver engineering curricula which include complementary studies courses. This suggests a certain amount of uncertainty around complementary subjects.

The purpose of this study is therefore to explore the way that engineering educators perceive (construe) complementary subjects and their role in the curriculum. Engineering educators in an industrial engineering curriculum that includes complementary studies courses were interviewed to determine their perceptions of these courses. The interviews were conducted using the repertory grid technique, a structured interview protocol associated with Personal Construct Theory (PCT).

2 METHODOLOGY

2.1 The Repertory Grid Technique

The repertory grid technique is a widely applied tool which is associated with Personal Construct Theory (Fransella, 2003). According to this theory, people make sense of the social world around them by creating and recreating implicit theoretical frameworks which become their personal construct system (Fransella, Bell and Bannister, 2004). Any concept encountered is contrasted with concepts within their existing construct system. Each construct has two poles that represent the range that the person uses for ‘sensemaking’ of a particular concept. For example, one of the constructs evident from a participant in the current study was a range from ‘real-world’ oriented courses on one pole, to ‘classroom oriented’ courses on the other. Any course would then be located on the continuum between these poles.

The purpose of the repertory grid technique is to elicit constructs from participants through a structured interview process. The first stage of the interview is to derive a set of elements with which to elicit a participant's constructs. In this present study, the elements were different courses in the curriculum which the participant was familiar with. For example, a course such as Engineering Mathematics could be one element, while Operations Research and Labour Law would be other elements. From a set of elements, a participant would be asked to compare and contrast three elements (a triad) in order to elicit constructs. Participants are asked to group the triad into a set of two that are different in some way to the third. The interviewer then probes the reasons for the distinction the participant is making. A participant's bipolar constructs are elicited from this process.

2.2 The Interview Process

Six engineering educators (referred to as Participant 1, Participant 2 etc.), were identified from the same industrial engineering program as a pilot study for a larger PhD study. Considering that this was a qualitative study, this number of participants proved sufficient in generating rich data for analysis. The repertory grid technique was new to all the participants who expressed both fascination with the unique way of collecting data, and a general appreciation for the benefit of such a study of complementary studies. All six of the educators had knowledge of both complementary and non-complementary studies courses with three of them having recent experience of teaching complementary studies courses in the curriculum.

The interview began with agreeing on the set of seven elements, in this case seven industrial engineering courses, to be used in the discussion. The courses had to cover both complementary and non-complementary studies in order to ensure that a comparison is made between the two types of courses. The interviewer provided a list based on the courses currently offered by the institution in the Diploma in Industrial Engineering programme. From this list, each participant had to pick seven elements based on seven different eliciting questions asked by the interviewer. These questions were asked so that there were at least two complementary and two non-complementary courses in the chosen list which would allow for a comparison to be made.

Once the participants and the interviewer had agreed on the seven elements to be used, different constructs were elicited by using a triad of three elements at a time. For each of these triads, the participants had to state which two were the same in some way and different from the third. Through a laddering process, they then had to state what exactly the two had in common, as opposed to the third. The thing that the two elements had in common was written on the left side of a grid sheet and the reason the third element is different, on the right of the grid sheet. This created a bipolar expression in the form of words or phrases which express a contrast and thereby the person's construct. These three elements then had to be rated by the respondent based on a 5-point scale with each rating being recorded on the same grid. The remaining elements were then also rated based on the same construct. This process was repeated several times with different triads until a set of constructs and ratings were elicited and recorded on the repertory grid. The result was six repertory grids, consisting of elements and constructs with ratings from six interviews.

3 RESULTS

Three kinds of analyses were conducted and are discussed below. Firstly, by thinking back to the interview itself and the participants' responses to particular questions, a process analysis was done. This was then followed by conducting a cluster analysis, which involves highlighting the relationships amongst constructs and elements in a grid so that they become visible at a glance. Finally, a principal components analysis was conducted with the same purpose of highlighting relationships amongst elements and constructs. In the pilot study, the analyses were conducted on six participants. In this paper, the results of two of them, i.e. Participant 1 and Participant 6, are illustrated as examples that show the greatest variety of the responses received.

3.1 Process Analysis

The process of agreeing on the set of seven elements to work with provided some early indications of the perceptions that the participants had towards certain courses. Questions such as, *"Name one course which, if given the opportunity, you would like to teach."* were posed with the aim of eliciting the elements which the participant viewed in a positive light. In all six instances, no complementary studies courses were chosen by the participants as a course that they would like to teach. A question was also posed to each participant with the aim of including a course which the participants felt was the least relevant to the curriculum. The question in this regard was, *"Name one course that surprised you with its presence in the curriculum."* There was only one out of the six instances, where the course that was chosen was from the complementary studies group. The rest of the courses were from the non-complementary group with the second year Engineering Mathematics course surprisingly being chosen more than once.

The process of eliciting constructs from the participants revealed just how varied their initial perceptions were of complementary studies courses when comparing them to the other engineering courses. In most instances, it was necessary for the interviewer to employ the technique of laddering down in order to get to the actual construct and not the initial answer that was provided by the participant. Despite the diversity of constructs, there seemed to be an understanding by the educators that complementary studies courses are necessary in the curriculum even if they might look different and not be the ideal course they would like to teach.

3.2 Cluster Analysis

Cluster analysis is a technique for highlighting the relationships in a grid so that they become visible at a glance. The elements and constructs within the grid are organised so that those with the most similar ratings lie side by side. The extent to which the ratings are similar is indicated by percentage similarity scores with the higher percentages indicating more similarities between the elements or constructs. This is useful for the present study as it can help us to determine the extent to which complementary studies courses are similar to the other courses based on the construals of the participants. Figure 1 and Figure 2 show the cluster analysis output for Participant 1 and Participant 6 respectively with the percentage similarity scores for adjacent elements and adjacent constructs provided. The RepPlus grid analysis software (Gaines and Shaw, 2021) was used to generate this output.

Participant 1 construes the Leadership (complementary) and Industrial Production Engineering (non-complementary) courses as the same with a similarity score of approximately 85% (arrow 1 in Figure 1). Engineering Mathematics and Operations Research, which are both not complementary, have a weaker relationship of approximately 70% (arrow 2). There is one distinct branch which stands out with regards to Participant 1's constructs. This branch comprises the constructs of 'Macro (funnel) vs Micro' and 'Mixed vs Purist' which have a similarity score of over 92% (arrow 3) according to the educator's construal.

On the other hand, Participant 6's highest similarity score is on two non-complementary courses, with Systems Engineering and Industrial Engineering Design being construed to be the same with a similarity score of approximately 87% (red arrow 1 in Figure 2). The complementary courses of Accounting and Leadership are also construed the same with a score of approximately 83% (red arrow 2). With regards to Participant 6's constructs, there is one distinct branch which stands out (red arrow 3 in the diagram). This branch comprises the constructs of 'Industry agnostic vs Closer to industry' and 'Generally applicable vs Specific to IE (Industrial Engineering)' which have a similarity score of over 92% according to the educator.

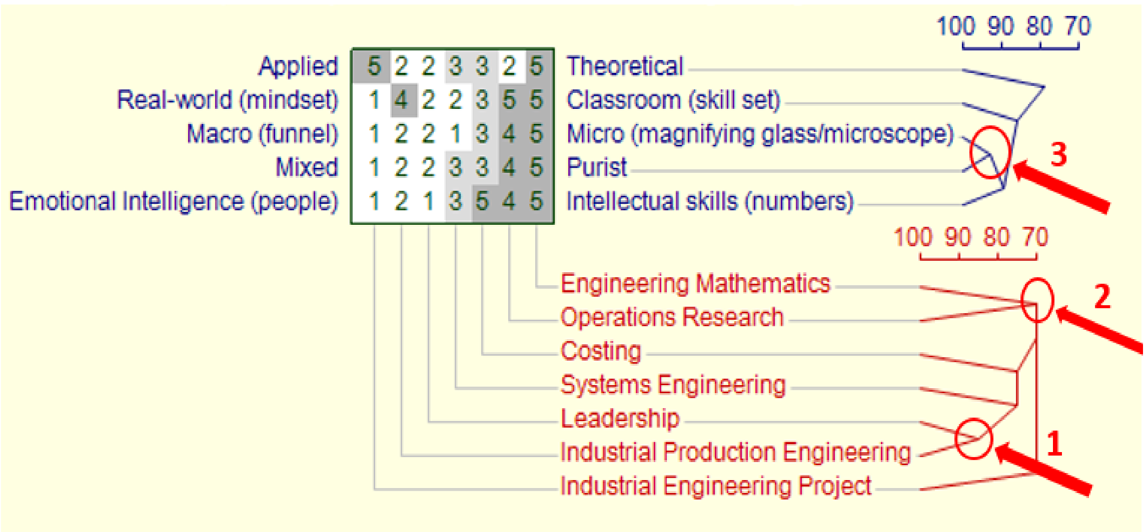

Figure 1: Cluster Analysis Output for Participant 1

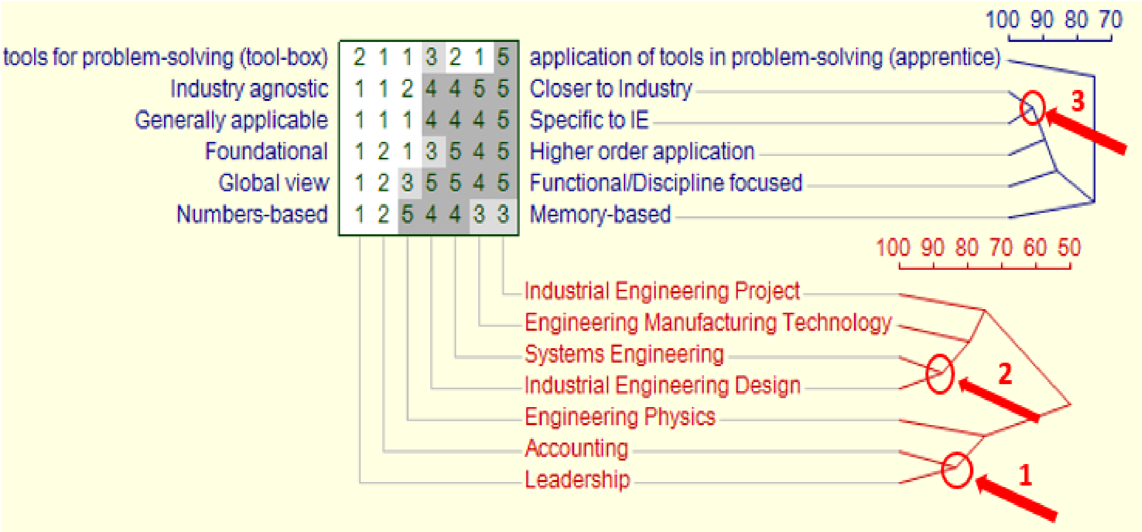

Figure 2: Cluster Analysis Output for Participant 6

3.3 Principal Components Analysis

Principal components analysis identifies distinct patterns of variability from the ratings supplied by the participant. Through an iterative process which is best performed using grid analysis software, the patterns of variability are grouped into components. The two components with the largest amount of variability, that is the principal components, are selected and plotted on the horizontal and vertical axis of a graph with the percentage amount of variability shown (see Figures 3 and 4 where the percentage variability is shown in green). The constructs are plotted as straight lines and the elements are positioned along each principal component. The angle between any two construct lines reflects the extent to which the ratings of elements on those constructs are viewed as the same by the participant, with a smaller angle showing greater similarity compared to a larger angle (Jankowicz, 2005). Similarly, the elements are positioned along each principal component and the distance between any two elements reflects the ratings each element received on all the constructs.

Figure 3 shows the results for Participant 1. Four of the five constructs lie close to the horizontal principal component axis. This means that, according to the educator, these constructs have strong similarities which are distinctly different from the single construct which lies closer to the vertical principal component axis. For example, the 'Mixed vs Purist' construct is seen in the same light as the 'Emotional Intelligence (people) vs Intellectual skills (numbers)' construct. With regards to the elements on the graph, courses such as Leadership (complementary) and Industrial Production Engineering (non-complementary) are construed the same and are distinctly different from a course such as Engineering Mathematics which is not complementary.

The constructs in Participant 6's principal components analysis graph are not as clearly differentiated as they spread evenly all round the plot as shown in Figure 4. There are, however, two groupings of constructs that seem to emerge. The first grouping, which lies closer to the vertical principal component axis, consists of the 'Memory-based vs Numbers-based' and 'tools for problem- solving vs application of tools in problem-solving' constructs. The rest of the constructs fall into the second grouping which is closer to the horizontal principal component axis. With regards to the elements on the graph, the complementary courses of Leadership and Accounting are construed the same and are distinctly different from a non-complementary course such as Systems Engineering.

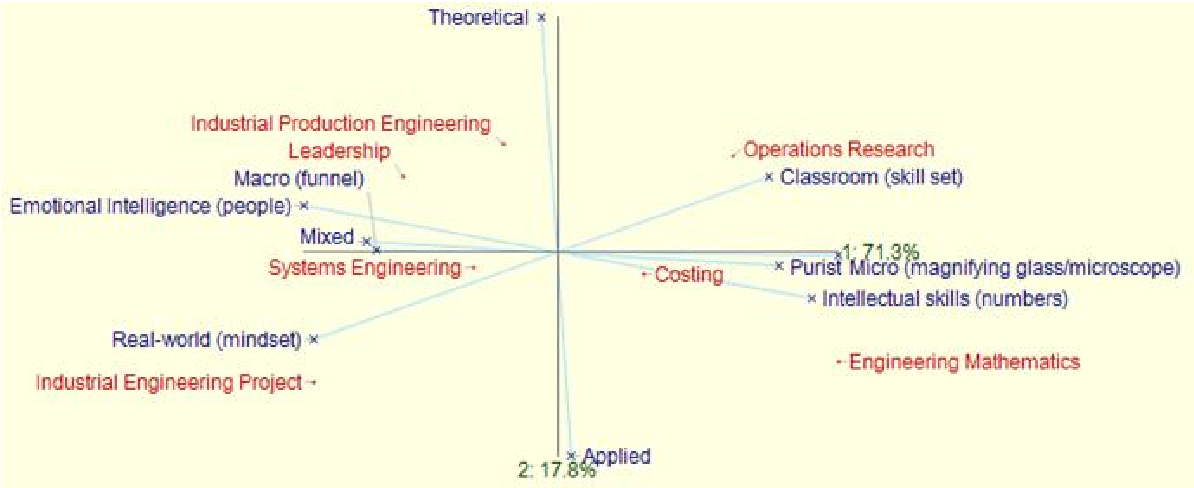

Figure 3: Principal Components Analysis Output for Participant 1

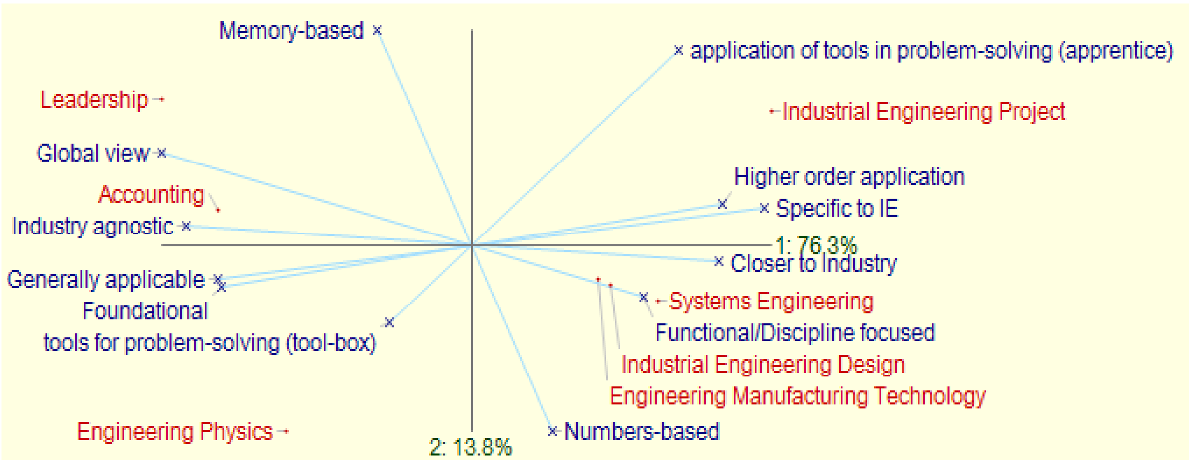

Figure 4: Principal Components Analysis Output for Participant 1

4 DISCUSSION

If, as assumed, complementary courses are different to ‘core’ engineering subjects, one would expect to see them clearly separated from other types of courses when analysed using the repertory grid technique. This is not the case in our present study. For example, Participant 1’s construal of the Leadership (complementary) and Industrial Production Engineering (non-complementary) courses as being similar is very interesting. This is firstly shown by the Cluster Analysis in Figure 1 where the two courses form a distinct branch based on the educator’s ratings. The principal components analysis in Figure 3 then confirms this by showing that the educator was inclined to see both courses as leaning towards the people-focused/real-world constructs. A course such as Costing (complementary) is seen as being less similar to Leadership even though they are both considered to be complementary. This could be due to the fact that Costing involves a lot more numbers and calculations when compared to a course like Production Engineering. This indicates how unclear the distinction between complementary and non-complementary courses can be.

On the other hand, Participant 6's construal of the Accounting and Leadership courses as similar is not as surprising. This is in agreement with the generally accepted classification of these courses as complementary in the curriculum. The educator was inclined to see these courses as being further removed from industry when compared to a course like Engineering Manufacturing Technology, as shown by the principal components analysis in Figure 4. The meaning of 'industry' for the educator was within the context of a manufacturing or factory set-up where most industrial engineering graduates end up working. This closeness to industry is generally seen as an attractive feature of any course as this implies that the graduate can directly use what they learn in the workplace. Another interesting construct that was elicited from the educator was the 'Generally applicable vs Specific to IE ' construct. As can be seen in Figure 4, the educator does not see the complementary studies courses as being specific to industrial engineering (IE) which could make them less attractive as well.

5 CONCLUSION

The aim of this study was to understand how engineering educators understand, or construe, complementary studies courses which have been found to be problematic in the curriculum. This was done by analysing repertory grids that were obtained through interviewing engineering educators from an industrial engineering programme. The most significant finding is just how varied the understanding of complementary subjects is, with the participants having different constructs and ratings that are associated with them. There was general consensus that complementary studies are different from the other engineering courses although there were some unique cases where educators construed them to be the same. It was also interesting to see how when asked to pick a course they would like to teach, none of the educators picked a complementary studies course.

This study does not yet get to the root-cause of why complementary studies courses are found to be problematic by some educators, and students alike. It does however provide a good starting point by first exploring how educators understand, or construe, these courses. In order to get to the root-cause, it might be necessary to go back to the participants with the results of the analysis and confirm if the conclusions are indeed a true reflection of their perceptions. It would also be valuable to carry out a similar study with a group of educators in other engineering disciplines where complementary studies are not as integrated into the curriculum as is the case with industrial engineering.

LEARNING TO LEARN, BOLT-ON, OR INTEGRATED?

ANALYSIS OF STUDENT FEEDBACK FROM A PILOT WITH LEARNING TO LEARN INTEGRATED INTO FIRST-YEAR ENGINEERING MATHEMATICS.

ABSTRACT

Learning to learn is one of the generic skills that are important to becoming an engineer. One outcome of the education is to be prepared for a role as an engineer with lifelong learning. In this paper, I convey experiences gained from two different approaches when implementing “learning to learn” into engineering math courses. The first approach, learning to learn was added to a mathematical course as a “bolt-on” approach in two initial pilots. A second approach was to include learning to learn in the course. In this approach, I wanted to utilize feedback cycles and provide information on learning to learn “as needed”.

Interviews of students and experiences from the pilots have been analyzed using thematic analysis. Two different experiences were described by the students in the two classes that were included in the pilot. In one group, the smallest of the two pilot classes, not a single student dropped out in the remaining three-year of the study program. The program had a major impact. The other group, the biggest class, was more resistive.

In the second approach, I wanted to utilize the role of a mathematics teacher. Here I could use the authority and the relation as a math teacher. However, introducing learning to learn as a teacher conflicted with the role as a teacher. Here I discuss key findings from four focus group interviews, in addition to my experience as a teacher, that can help to plan future course design when learning to learn is included.

1 INTRODUCTION

1.1 Introduction

Higher education requires efficient learning. But learning in higher education is complex, it is a personal development process, and involves a change of perceptions, learning habits, and epistemological beliefs [1]. It is well known that the transition from school to higher education is challenging since students often lack an understanding of the kind of learning that is required [2, 3]. Wingate [1] claims that two things have to be present for efficient learning in higher education. Firstly, students must understand learning and become independent learners that take responsibility for their learning. Secondly, to understand the knowledge and become competent in constructing knowledge within the discipline.

A theory that focuses on what the students can do, and hence is relevant as a toolbox is self-regulated learning [4] and related constructs. Self-regulated learning strives to understand self-regulation, as an active learning process and how it is used to actively pursue individual goals. Self-regulated learning refers to the modulation of affective, cognitive, emotional, and behavioral processes throughout a learning experience, to reach the desired level of achievement [5-7]. Research has shown that self-regulated learners are autonomous, reflective, and efficient learners who have the cognitive and metacognitive abilities as well as the motivational beliefs and attitudes needed to understand, monitor, and direct their learning [8].

Learning to learn (LTL) or developing lifelong learning skills is one of the many generic skills that is envisioned integrated into the study programs at NTNU The question is, how could this be done? A common approach is to hire an expert in learning from outside the faculty, that can teach how to learn. However, these generic, often in separate 'bolt-on' courses [9] are often found to be inefficient. Another approach is to include elements of LTL in the course, challenge the learning process, and provide information according to needs throughout the course.

The results presented here are from two pilot periods. The first period with a bolt-on design, and the second period, with an integrated design where the author integrated LTL in a qualification course in mathematics. Here I discuss results considering my experience gained from the two different approaches to embedding LTL.

1.2 The context

In the first test period, in the autumn of 2014, LTL subjects were integrated into two mathematics courses in a first-year bachelor of engineering mathematics course. Subjects from SRL that were considered relevant to learning, were introduced in a weekly 20 to 40 minutes lecture as a part of the mathematics lectures. The LTL lecture was an additional hour added to the timetable of two math courses, but the subjects were presented by the author and not the math teacher. The concepts introduced to the students were; goals how and why, self-regulated learning in general, work habits, ways of thinking, memory, bulked vs spread practice, self-testing and retrieval practice, implicit theories of intelligence [10], motivation, reflection, self-efficacy, teamwork, and exam preparation.

In the second test period, the author entered the role of a mathematics teacher. Here LTL subjects were initiated by problems that students encountered during their process of learning mathematics. Frequent assessments with integrated reflection forms were used as a source to gather information about the challenges that students faced. No interviews were made and hence the data from this period are only from my own experience as a teacher attempting to integrate LTL in a math lecture. The difference between the two designs was that I changed my role from a bolt-on-teacher to a mathematics teacher. The level in the second design was a qualification course with 12 hours a week of contact. Entering the role as a teacher in the second period was a wish of the author, to establish a closer relationship with the students.

In both periods, learning-to-**learn** was linked to a feedback cycle in what we called classroom assessments, a design inspired by Nicole and MacFarlane-Dick's [11] recommendations on feedback. A classroom assessment consisted of a 1-hour test, where students worked individually to solve problems without any tools. In the last 10 minutes of the test period, students were given alternatives and the results were submitted electronically. After the test, scores were given, followed by an immediate review of the problems, prioritized by the average score on each task. Here the students could correct and pick up immediate feedback. At the end of the assessment, students were given a reflection form, where they were asked to observe reactions to the problem solving, and reflect upon goals and progress. Parts of these reflections were collected and included in the LTL sessions the following week. The second test pilot had a significantly higher frequency of tests than the first and the period lasted for a full year.

2 METHODOLOGY

In the last week of the first test period, four semi-structured focus group interviews were performed by a fellow faculty member. 5 female students and 6 male students participated resulting in 4 hours of interviews that were transcribed. The data corpus, in addition to the interviews, consists of written assessment reflections, student responses in lecture interactions, and evaluations that were available for analysis but were not included in the dataset analyzed. The data set was mainly transcribed interviews.

Interviews were analyzed using a thematic analysis approach[12]. The content was organized in thematic groupings, reviewed, and reorganized according to extracts that essentially describe the student experience. Some relevant codes were structured by the interview guide and some by themes that appear.

In both pilots, every subject was introduced with questions, where students responded through a student response tool iLike [13]. This tool allows for text-based responses in addition to standard multiple-choice questions. As an example, initializing a lecture about motivation text response question "what do you experience as demotivating?" The next question was "What motivated you?" followed by the question "How do you regulate your motivation?" Throughout the lecture series the "what can you do?" was a core concept. The purpose of this initiation was to connect to preexisting knowledge and ideas, for me as a teacher to see how they were thinking, and at the same time, allow students to interact with the content both before and during the lecture

3 RESULTS

3.1 Getting close

Entering a mathematics lecture and starting talking about emotions, does not feel natural for a physicist. There are shifting emotions related to learning mathematics. Emotions change dynamically between confusion, frustration, boredom, engagement, flow, curiosity, anxiety, delight, and surprise. One of the first questions that were asked in the lectures was, how do you agree with this statement "Emotions have nothing to do with learning and should therefore not be mixed with learning" only a few partly agreed 27% and around 60% disagreed. A surprising 17% answered I don't know. In the interviews, this focus on emotions and regulation of emotions became one of the biggest themes and seem to have been easiest to transfer to their own experience. Discussing experiences, emotions, and ways we think opens the door to a personal and private sphere. Allowing students to come closer, and at the same time, coming close to the students.

The superordinate theme of getting closer appears in all interviews in one way or the other. This kind of work with personal development, where thoughts and emotions are discussed, requires a safe space where it appears safe to discuss traits, reflect on learning, and discuss private thoughts. The experience of the students when you succeed is a sense of getting personal.

> *Everything gets more personal. We got a stronger relationship with the school. Instead of a situation where there is a lecturer that we don't even know the name of, is standing there, talking, and babbling about something.*
> - Male student 3 -

Asking questions about well-being and displaying results for the entire class, seem to have influenced individually. But revealing how others are doing also influenced the class environment:

> *It feels like the class environment got better from this.*
> - Male student 3 -

Throughout the semester I allowed students to come close to what I as a teacher was thinking, what I experienced, and the choices I had to make when facing challenges that appeared. Being open about reactions, and insecurity, and allowing for my thoughts and reactions to be bot considered and criticized was interpreted as "down to earth" or honest.

> *The thing is that he is really present and very personal with us. Then you automatically get people interested. He uses examples that we recognize from his life when he was a student, and that is relevant today also.*
> - Female student 1 -

This openness and honest communication lead to a sense of belonging

> *Everything becomes more personal. We got a better relationship with the school. Instead of a lecturer standing there talking and we don't even know his name… I feel that the class environment improved from it too.*
> - Male student 2 -

When the class accepted and created their rationale for why the interventions were there, the perceived effect was a sense of being cared for.

> *It felt like the faculty cared, in a way… because at other schools it's been like, if you fail you fail, bad for you!*
> *- Female student 3 -*

These are all factors that are important in the sense of belonging, an important factor for motivation according to self-determination theory [14]. The establishment of this relation to the class was a key ingredient to opening up for reflections on a private subject like learning.

3.2 Integration in a course vs. bolt-on solution

How do students perceive LTL as a part of the mathematics lecture? When asked about which subject is best suited to include LTL, the students are clear. It had to be entangled in an **important** course.

> *…mathematics is kind of hard for a lot of students, a lot of students have forgotten, and it is — yes it's a lot to remember in that subject, and it is a lot—*
> - Female student 1 -
>
> *And then it's kind of relevant since...*
>
> - Female student 2 -
>
> *But it is, after all, okay that it is given in the connection of a course*
> - Female student 1 -

Another aspect here is that since most students take the subject of mathematics seriously, integrating LTL into the math curriculum will make most students participate. They both appear to share the same experience that since mathematics is demeaning, a course that most students experience as demanding. According to the students, to get a sense of a shared development process, most students must participate. When asked, could it be a part of generic subjects like an introduction to engineering, the students immediately responded "no!"

3.3 Criticism / Resistance

Not all students participated in the lectures and the attendance in the additional lecture dropped throughout the semester. Most students reported that the time of the week, Fridays, was one major reason why they dropped out.

Some resistance lies in the individual beliefs that students hold about learning and how to develop these skills.

> *… I am kind of skeptical to these kinds of self-development-things —my meaning is that these kinds of things must appear from our own experience —*

> *in a way be learned on our own...*
> *My experience is that these kinds of things will appear in a way— and it will appear from the inside.*
> Male student 6

This statement was immediately contradicted by the female friend during the interview. But, there are elements of truth in this statement, you cannot force learning and development on students. Internal motivation is a better starting point than external pressure.

One type of criticism found was on the format. But this is also one part of the resistance you will notice when you introduce LTL without proper integration.

> *Even though I find the subjects interesting, I am very bad at trying them out without having the motivation to do so. I would like to have a challenge or something, just to try it out.*
> - Male student 6 -

Learning activities where students must participate and in learning activities that should be closely linked to active learning situations where the learner is engaged in thinking, learning, and performing.

> *It depends on how willing you are to accept it, I think. I feel that the entire purpose of the project is to get this self-awareness. You cannot sit and listen to someone telling you how your self-awareness should be. … but he has been good at giving us the tools, he has just not given us the chance to use them.*
> - Female student 4 -

This student reported in the interviews, that she had been reading about study strategies and had an interest in developing her skills, which in it selves an autonomous activity. She says she has been given the tools, but given the chance to use them. It is expected that if she was to use the knowledge we had to require and provide a learning activity where she could use them.

4 SUMMARY

There are several known barriers to implementing LTL in higher education [15]. Instead of accepting the responsibility for educating everyone, the easy way out of the challenge is to explain the lack of student success to the student readiness. When the challenge is taken, the easy way to fix the problem is a bolt-on solution that is cheap seen from an economical point of view. One external expert can be hired, to give excellent lectures on learning in general. An expert might have deep knowledge about learning and provide up-to-date information about learning. The other advantage, lectures are released from the responsibility to help students to develop their learning and may spend more time on research. There is a lot to learn when a lecturer starts shifting from a transfer of knowledge model to start feeding and informing students in their process of learning. However, relying on external experts does not shift the institutions' way to teach into a focus on how to facilitate learning.

Picking up the glove and accepting the responsibility for the students learning process, is the first barrier [15]. However, it is worth noticing that facilitating the development of the students learning process is not something that is done without resistance. Priorities at the universities are often directed toward research. The easy way is to initiate a bolt-on solution, where external experts in learning are hired to remedy a need. University teachers as representatives of the domain that we invite our students into are also authorities that make information about how to enter the domain more relevant. The main challenge here is that we repeat what worked for us, lecturing.

> *It's like—what he asks for us to do, is to invest in his ways of thinking...*
> Male student 5

Students prefer to continue to work and do things in the way that they perceive as their model for successful learning, rather than taking the risk to spend time on something that may not work, which requires extra effort. Investing in new ways of working, and experimenting with ways of thinking that might not give immediate results is experienced as a risk. The same is true for teachers that give lectures or facilitate learning.

Who else other than representatives of the domain, the faculty, are more trustworthy of what ways of thinking are needed to enter the domain? However, the faculty must value learner development in addition to the learner's curriculum. In a healthy learning culture, the entire institution should engage in a culture where the students learning process, and experience with learning is in focus. If the faculty use a dialog with students as input for development and learning, students will find an improvement culture more relevant and natural. Keeping the development culture inside the institute is important for continuity in these developments.

Criticism was given on only teaching LTL and not allowing students to "try" techniques. First, it is known that knowledge about the health effects of physical exercise does not automatically create more physically active behavior [16]. The problem of translating knowledge about the benefits of an action does not create a change in what people do. This is known as the knowledge-behavior gap. The same effect might also be present when it comes to the way students learn. Knowing how to study, does not necessarily make students change the way they study. LTL activities have to be integrated into learning activities. In the second period, a stronger link between assessment and reflection schemas was considered more natural. Secondly, learning is more than a technique! Learning to learn is to know and understand oneself and be willing to challenge reactions, patterns in ways to think, and ways to work. It is an agentic search for better ways to interact with the learning process.

The overall purpose was to make students more aware of their learning process. It appeared as an opening ut a safe space where it is safe to talk about how we think, experiences, feelings, and thoughts seemed to be essential to initiating the LTL process. The use of response technology was a key ingredient to picking up information and simultaneously creating a sense of interaction with large groups of students on rather private subjects that LTL is. Technology allowed students to see how other students were thinking about central topics, thoughts, and reactions of others were perceived as an effective element to both inform and create a sense of belonging.

> *We got to know each other through these survey questions, even though we answered anonymously.* - Male student 2 -

Finally, LTL, applying the knowledge, and gaining experience as a learner takes time. For some students, the first exam is real feedback. Then they know for real how their learning worked. This requires constant focus throughout several courses and not just a one-time intervention.

In the second period, LTL lectures were given as a part of a feedback cycle from the author as a mathematics teacher. The feedback cycle was initiated from improved and varied reflection schemas. LTL subjects were chosen according to what students discussed in their reflections about learning. But, here there was a conflict on how to spend the time as a mathematics teacher.

ABSTRACT

In blended learning, students have the opportunity to choose either online or classroom lectures. For higher education institutions, blended learning has many advantages, such as accessibility to students and teachers, cost efficiency, alleviation of the teacher shortage, etc. But what does this mean for the students?

The aim of the study is to find out students' further need for blended learning, its reasons and factors influencing it. An online survey was conducted to answer the research questions. The collected data was analyzed by using statistical analysis methods.

The results of the survey revealed that the technical prerequisites for students to participate in blended learning were met. The biggest problems are related to the self-regulation skills of students. Problems with blended learning are stronger among first-year students. However, the respondents were rather positive about blended learning. Blended learning is most strongly supported by distance learning students who live far from university and are over 25 years old. The least supportive of blended learning are full-time students living near of the university and who are under the age of 25. This is due to the fact that full-time students experience blended learning problems on average more often than distance students because of the weaker learning skills.

The results of the survey help to understand students' views on blended learning, to plan and conduct studies in a student-friendly way, and to plan trainings for teachers to improve the blended learning process.

1 INTRODUCTION

1.1 Aim and research questions

The learning experience of students is influenced by the professionalism of the teacher. It makes it easier to understand what is being learned and diversifies learning [1]. The COVID-19 crisis tested the professionalism of teachers. The contribution to the development of teachers' digital and pedagogical competencies, as well as the continuous development of teaching infrastructure, have made it possible to organize blended learning at TTK University of Applied Sciences (TTK UAS) during the COVID period. In order to find out students' satisfaction and further expectations, the university conducted a survey “How to support learning in blended learning?” The aim of the survey was to find out students' further need for blended learning, its reasons and factors influencing it. In order to achieve this goal, the following research questions were set:

- What are the conditions for participating in blended learning?
- What are the main problems experienced in blended learning?
- How do students evaluate the first blended learning experience in their studies?
- What is the profile of the proponents and opponents of blended learning?

1.2 Background

Blended learning is defined in TTK UAS [2] as a form of study in which it is possible to successfully participate in studies either in the classroom or via the web. Conducting blended learning is a challenge, as it requires the teachers to reshape their approach to teaching and the students to get used to the renewed learning environment and conditions [3]. Issues in blended learning have been studied extensively. One of the aspects that emerges is lack of students' self-regulation skills. Self-awareness and self-motivation have a direct, positive, and significant impact on study habits, but it is concluded that students face higher-than-usual challenges in building study habits in blended learning [4]. According to Susanna et. al [5] there is a positive influence between self-regulation and motivation on student learning outcomes in a blended learning approach aswell. Rasheed et.al states, that the implementation of blended learning in higher educational institutions is increasing due to its perceived effectiveness in affording the benefits of both face-to-face traditional mode and the fully online mode of instructions. However, the leading challenge associated with the online component of blended learning is students' inability to properly self-regulate their learning activities [6]. But, students are obliged to regulate, manage and carry out their study activities and learning tasks independent of their instructor, at their own pace, and also using online technology for in the online component of blended learning, but they encounter here with problems [7]. Kotturi et.al argues that one of the main challenges that students face in an online environment and a more importantly online component of blended learning is self-regulated learning due to the learning flexibility and autonomy granted to students [8]. According to Adnan and Anwar [9] students who have high motivation in conventional learning, do not necessarily have the same motivation for blended learning. According to Lim and Morris [10] and Kassner et al. [11], students' age and preference for the form of study are the factors that differentiate learning outcomes between students either. Based on the foregoing, it can be pointed out that in studies related to the implementation of blended learning, it is necessary to pay attention to these factors.

2 METHODOLOGY

To respond the research questions, the online survey was conducted. The survey form consisted of four parts: conditions for participation in blended learning (6 questions), blended learning experience (8 questions), organisation of blended learning (4 questions) and demographics (6 questions). With the multiple-choice or scale questions the students were asked to evaluate the effectiveness of blended learning, their satisfaction and how willing they would be to learn in blended learning in the future. The open-ended questions identified the factors supporting blended learning, which is not in the scope of this paper. The survey form was made by using Google Forms and it was sent to all TTK UAS students in spring 2021.

In order to analyze the data the following statistical analysis methods were used. The Likert scale was used to weigh the questions, and an overview of the results of the survey was presented in the form of text, figures and tables. The differences between groups were checked by using descriptive statistics on the means and standard deviations. Correlations between variables were examined using the Spearman rho correlation coefficient, and internal reliability was measured using the Cronbach's alpha coefficient [12]. Based on the survey, various statistical hypotheses were formulated and their validity were checked by an appropriate statistical method. The quantitative statistical analysis was performed with MS Excel and statistical softwere R. If there no statistically significant differences were found in some of the groups (eg full-time/distance students), then this group was not considered separately in the analysis.

3 RESULTS

3.1 The structure of study participants

In the 2020/21 academic year, the total number of TTK UAS students was 2931, of which 570 students responded to the survey. Thus, the response rate in the population was approximately 20%. The first-year students responded the most actively (38%), followed by the second-year (32%), third-year (20%), fourth-year (9%) and time limit extension (1%) students. Among the respondents there were more distance students (64%) than full time (35%) and external (1%) students. The respondents came from all institutes (Fig.1), with the largest number of responses coming from students in the fields of transport and logistics (11%), building construction (11%), accounting (10%), social work (9%) and production management (9%).

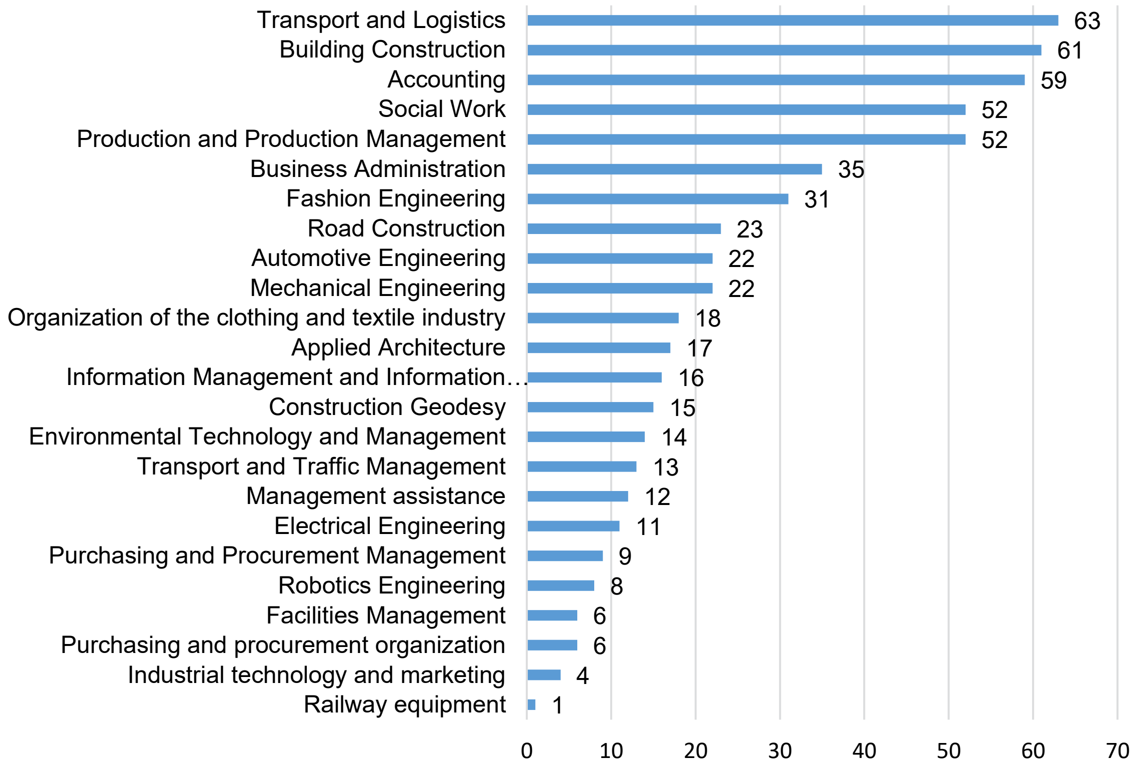

Fig. 1. The structure of study participants

The highest number of respondents coming from the younger age group under 25 years old (47%), with fewer and fewer respondents from each subsequent age group: 26 to 35 years old (27%) , 36 to 45 years old (20%), 46 to 55 years old (5%) and over 56 years old (1%). The highest response rate was among students from Tallinn (39%), followed by learners from rural areas (24%), from other cities (21%), from bigger cities (15%) and from outside of Estonia (1%).

3.2 Technical conditions for remote participation

Based on the results presented in Table 1, it can be concluded that there are no major problems for students to participate remotely in blended learning process due to technical conditions.

Table 1. Technical conditions for remote participation

Technical condition	Yes	No
Private room	82,8%	17,2%
Computer	99,5%	0,5%
Stabile internet connection	92,8%	7,2%
Webcam	94,4%	5,6%
Microphone	98,6%	1,4%

It is a common belief that students use a mobile phone a lot, but only 13% of the respondents used a mobile phone when participated remotely. This is a small proportion, but a potential danger, as it is not possible to carry out all tasks in a high-quality way using a mobile phone alone. For example, if it is necessary to solve tasks with a teacher or view a teacher's drawings for which the screen of a mobile phone is too small, etc.

3.3 Problems in blended learning

The survey revealed that students most often experienced problems in the following aspects: 29% of respondents often experienced difficulties with concentrating, 28% stated that they often felt a decrease in self-discipline and learning motivation, and 26% felt that remote learning often remained superficial. The above results are explained and supplemented by the students' answers, in which problems related to the organisation of studies were seen as barriers for the effective learning (approximately 19% answered “often”), about the same number (18%) experienced a communication barrier with the teacher and other students, and 16% assessed their own learning skills as insufficient for remote participation. The increase in the volume of learning during the blended learning period was felt by 26% of the respondents, and 25% of the respondents also pointed out some technological problems. The remaining problems were mentioned less frequently: the environment is not supportive enough when participating remotly (15%), teacher’s attitude (14%), cannot find the necessary information (11%) and the volume of learning decreases in blended learning (6%).

The analysis showed that first-year students experienced 40% more different learning difficulties than older students.

3.4 Blended learning experience

Students' evaluation of the efficiency of blended learning was rather good (on a 6-point scale the mean is M=4,19 with standard deviation SD=1,08). The students believed that the learning outcomes in the conditions of blended learning were partially achievable (on a 5-point scale M=4,02, SD=0,95). The general attitude of students towards blended learning was rather positive (on a 5-point scale M=4,05, SD=0,96). In the future, students wanted to attend an average of 50% to 60% of the lectures at a distance (on a 7-point scale M=4,24, SD=1,67, mean confidence interval is 4,24 +\- 0,14 with 95% confidence level).

It was also analyzed how the answers to the previous questions are related to the students' form of study, age and distance between the university and place of residence.

Table 2. Mean scores and standard deviations of variables (except for external students and students living abroad)

Variable\Form of study	Full-time students		Distance students	
	mean	SD	mean	SD
Efficiency of blended learning (1…6)	3,77	1,08	4,40	1,01

Achievability of learning outcomes (1…5)	3,68	1,02	4,20	0,87
Attitudes towards blended learning (1…5)	3,67	1,01	4,24	0,87
Problems related to blended learning (14-40)*	27,65	5,71	24,94	5,72
Willingness to participate in studies remotely (1…7)	3,62	1,57	4,59	1,60

* Students were asked to rate the incidence of 14 problems related to blending learning according to the 3-point scale: not at all - 1, rarely - 2, often - 3. The values of the variable are obtained by summing the individual points, where the minimum possible sum is 14 and the maximum possible sum is 42.

In the Table 2 there is a difference between the means of two groups of students. It shows that distance students rate the efficiency of blended learning higher than full-time students. Distance students believe that learning outcomes are achievable in blended learning, they are more positive about blended learning and they are more likely to participate in distance than full-time students. On average, full-time students experience blended learning problems more often than distance students.

There also appear the difference in mean scores depending on age. In the age group up to 25 years the mean scores are lower than in other age groups. This statement is in line with the previous results, becouse the most full-time students are under 25 years old.

There appear statistically significant moderate correlations between pairs of variables from Table 2. Positive correlations show that the higher the students' appreciation of the benefits of blended learning, the more positively they wanted to participate remotely (Spearman’s rho 0,77), and the more they believed that the learning outcomes of the subjects in blended learning were achievable (Spearman’s rho 0,75). The opposite relationship also applies.

The positive correlation coefficients are in range from 0,59 to 0,77, confirming an uniform strong positive relationship between variables. In order to obtain an assessment of the students' first experience in blended learning, a characteristic group of blended learning variables was formed, in which only positively correlated variables were included. The reliability within the group of variables of the flexibility assessment is high (Cronbach's alpha coefficient 0,87), which means that the average correlation between the variables is uniformly strong and there is an internal consistency of the variables.

The negative correlations between variables show that the more often students experienced different problems with the remote participation, the lower they rated the benefits of blended learning (Spearman’s rho -0,64), the less often they wanted to participate remotely (Spearman’s rho -0,49) and the less they believed that the learning outcomes in blended learning are achievable (Spearman's rho -0,54). The opposite relationship also applies.

The further away the distance students live, the more positive they were about blended learning, the higher they valued the benefits of blended learning and the more often they wanted to participate remotely. In the case of full-time students, a statistically significant weak positive correlation has been found between the distance from the educational institution to the place of residence and their willingness to participate in studies remotely.

3.5 The profile of a supporter and an opponent of blended learning

In order to get the answer to the one of the research questions of this study, the profile of the supporter and of the opponent of a blended learning was determined according to the demographic data. The supporter of blended learning is a distance student, who does not live close to the educational institution and is over 25 years old. The opponent of blended learning is a full-time student, who lives close to the educational institution and is under 25 years old.

4 SUMMARY AND ACKNOWLEDGMENTS

The survey showed that the technical prerequisites for students to participate in blended learning are met, as the vast majority have access to a private room, computer, Internet connection, microphone and speakers. Instead, the biggest problems are related to students' self-regulation skills, ie difficulties related to concentrating, self-motivation and superficial learning. Participating in blended learning at a distance requires even more self-discipline and an awareness of how to manage one's own learning so that learning does not remain superficial. Problems with blended learning are stronger among first-year students. However, the respondents were rather positive about blended learning. This shows that students perceived the need for blended learning and also the fact that blended learning has become a so-called new reality that will continue in the future. Blended learning is most strongly supported by distance learning students who live far from university and are over 25 years old. Blended learning helped increase access to the learning process. The least supportive of blended learning are full-time students living near of the university and who are under the age of 25. This is due to the fact that full-time students experience blended learning problems on average more often than distance students because of the weaker learning skills. Thus, the modern learning process requires the university to teach self-regulatory techniques in parallel with the mediation of learning content.

The results of the survey help to understand students' views on blended learning, to plan and conduct studies in a student-friendly way, and to plan trainings for teachers to improve the blended learning process.

ABSTRACT

Educational innovation often builds on existing practices, and focuses on improvement, rather than a radical change. One current example of educational innovation is Challenge-Based Learning (CBL). At university [blinded] the approach is a curriculum wide implementation of CBL based on a integrated programme that combines implementation of bottom-up innovation projects with research. The result of this research contributes to the translation of CBL to practice, thus helping curriculum designers and teachers in designing and executing their courses. In the process evidence is collected about principles of CBL, learning behaviour, learning outcomes, and didactical aspects of CBL, such as coaching and self-directed

learning, assessment, pedagogies, and design of challenges, and facilitating structures.

The goal of this paper is to explore the development of a research agenda, which aligns research and practice, and to contribute to evidence for successful CBL implementation as result. The CBL research agenda shows which topics and aspects of CBL are addressed by research and practice, and which are overlooked. It is a systematic way of collecting strategic and practical problems related to CBL implementation, and how these are translated into research questions, methods, and results. The CBL research agenda leads to dialogue, which in turn guides our CBL programme. This integrated programme, including the research agenda is governed by a Taskforce CBL and supported by programme management, and a university wide research community. This approach enables the curriculum wide implementation and research of CBL as a concept for educating engineers of the future and strengthening on-campus education.

1 INNOVATION IN HIGHER EDUCATION

1.1 Challenge-Based Learning as a case of innovation

Educational innovation often builds on existing practices, and focuses on improvement and renewal, rather than a radical change. One current example of educational innovation is Challenge-Based Learning (CBL) [1]. In CBL challenges are seen as self-directed work scenarios in which students engage [2]. For CBL the objective is to learn how to define and address the problem and to learn what it takes to work towards a solution, rather than to solve the problem itself. The final deliverable can be tangible or a proposal for a solution to the challenge [3]. Central to CBL is that students develop knowledge, skills, and attitude by engaging in real-life challenges, often in interdisciplinary teams.

CBL as a concept allows for flexibility in and experimenting with effective teaching and learning activities, rather than predefining them. The aim of these experiments is to translate CBL as an educational concept to practice, thus helping curriculum designers or teachers in developing their courses and teaching, and in formulating support requirements.

1.2 Curriculum wide implementation of CBL

If universities intend to use CBL as a concept for innovating the curriculum, a developmental perspective is needed, which implies a variety in CBL characteristics across study components, i.e. courses and projects. This developmental perspective helps to align initiatives and bring a sense of coherence to the discussion, rather than anchor and confine research and practice. The result is a flexible approach in what are considered challenges suitable for CBL.

At a university of technology in the Netherlands, the approach is a curriculum wide implementation of CBL based on an integrated programme that combines bottom-up innovation projects with research. This combination leads to evidence about what works in the context of this university, which in turn informs educational design and practice. This approach fits the university's ambition to move towards CBL as a concept for educating engineers of the future and strengthening on-campus education. Implementation of CBL in the university's educational program, allows for a further integration of supporting students to develop knowledge, skills, and attitude, which already was part of the Bachelor's curriculum.

The integrated CBL programme allows for experiments in which teachers explore ways to make their study components more CBL. With an evidence-informed set-up the effects on student learning behaviour of these bottom-up experiments are carefully studied, answering questions about didactical aspects, such as coaching and self-directed learning, assessment, pedagogies, and design of challenges. In addition, staff engages in a range of research projects bridging the concept of CBL and everyday educational practice. The findings of this programme thus guide the design of CBL.The large-scale curriculum approach, in combination with research contributes to the current limited body of evidence for mechanisms that cause CBL interventions to be effective.

Facilitating bottom-up innovation projects implies allowing that teachers can have their own interpretation, which translates the educational concept CBL to educational practice. Furthermore, because educational practice aims to stimulate and facilitate student development, the need arises to allow for different forms of challenges. Hence, a working definition and conceptualisation was applied that supported the developmental perspective and the bottom-up innovation projects [4]. However, to stay in touch with and build on current research in the field, the aim was a definition and conceptualisation that both included commonalities emerging from CBL literature, and that allowed for variety in CBL characteristics between study components or curricula. The resulting framework thus serves as a methodological approach to make engineering education (more) CBL [4].

The framework consists of the higher order concepts vision, teaching and learning, and support, each with subsequent dimensions and indicators that describe CBL in a fine granulated way (please see [4] for a detailed description). These dimensions and indicators together form the basis for an educational view on CBL.

1.3 Organising the curriculum wide implementation

The main body governing the CBL programme, is the taskforce CBL. This taskforce consists of scientific staff, educational programme directors, support staff, and students. The Taskforce CBL will in 2024 advice the University Executive Board on CBL in the university's education. All local research on CBL supplies input for this advice; the university allows itself the coming years to experiment with new initiatives before implementing the initiative at full scale. The aim is to learn how CBL should be shaped to optimize student learning in terms of for instance required fundamental knowledge/skills or combining a deep understanding and a broader view, and what changes are needed to vision, teaching and learning, and support [5]. Furthermore, all researchers involved in CBL at our university grouped themselves in a community of practice [6], with regular meetings to develop and share knowledge.

The variety of research questions on CBL called for a research agenda on student learning behaviour and outcomes, and didactical/pedagogical aspects of CBL with the purpose to:

- make the CBL implementation evidence-informed,
- make the implementation and research projects provide new evidence, which feeds iteratively in the implementation,
- bring together/align all CBL research and projects,
- give direction and guidance to this research and projects,
- support scale and scalability of CLB as a unique selling point.

The aim is a research-based grounding for developing CBL in engineering education. This grounding answers for the university context the basic "what works and why"-question, which in turn would allow teachers and educational leadership to take the next step towards a more systematic less diffuse approach to CBL [7].

The CBL research agenda as part of the CBL programme is the guiding document for research on principles of CBL (vision), student learning behaviour and learning outcomes, didactical/pedagogical aspects of CBL (teaching and learning), and facilitating structures (support). The findings of CBL research form a foundation for evidence informed development of the CBL experiments.

The remainder of this paper explores the development of a research agenda. This agenda aligns research and practice, and contributes to evidence for successful CBL implementation as result. Although the context is a curriculum wide CBL implementation, we believe that the research agenda can be used for a range of evidence informed innovations in higher education.

2 BUILDING A RESEARCH AGENDA

2.1 What is a research agenda?

In general terms a research agenda shows which themes and aspects of a specific topic are addressed by research and practice, and which are overlooked. It is a systematic way of collecting strategic and practical problems related to educational innovation, and how these are translated into research questions, methods, and results. It allows individual experiments and research projects to focus on issues and ideas in a subset of the topic. Yet, it offers an overview of all issues addressed by research. A research agenda is not set in concrete; it naturally changes over time as knowledge grows, practice evolves, and as new research questions emerge.

The research agenda on a larger scale thus guides the governing body - in our case the CBL taskforce - throughout all parallel research processes. Because of the overview, it can also serve as a concept note to advisors and stakeholders including university deans, department deans, teacher education, policy advisors, and teachers, while guiding possible new research proposals.

2.2 How to design a research agenda?

Existing literature gives little starting points for designing a research agenda on a curriculum scale. Especially in nascent fields such as CBL, conceptualisations have not yet been set, and by result relevant themes go in many directions and are only emerging [8]. Our first approach was to follow the lines of a common research plan and report:

- What is the practical/strategical problem to be addressed?
- What is the research area: short problem definition, and possibly description of context (e.g., courses, department)?
- Need to know: research question to be answered, what lack of knowlege can be identified?
- Need to do: research method/approach
- Need to do: what knowledge needs to be implemented? Is additional research needed?
- Need to do: sustainability, dissemination. How to make research less person-dependent. How to add to the researcher community.

Of course, these questions can be extended with organisational aspects:

- Which project addresses this problem?
- Who is involved?
- What is the project's timeframe?

The next step was to answer all these questions for each bottom-up experiment and research project. The result is a matrix with in the columns these questions, and each project filling a row (see also Table 1 for an example). Although this matrix gives a clear overview of projects and how these address practical or strategical problems, it is not yet related to aspects of the innovation topic, in our case CBL.

Table 1. Margins of the page size A4 [mm]

Practical/ strategical problem	**Research area/ problem definition**	**Need to know: research question**	**Need to do: research method**	**Need to do: knowledge to be implemented**	**Need to do: dissemination**	**Project**
Effective teaching	Coaching/assessment	What are effective combinations of coaching/supervision and assessment?	Survey, interview	Starting points for redesign/ design principles	SEFI paper, 4TU innovation map, presentations	Preparing engineering students for the future
How to design effective pedagogies for learning from challenges?	How to structure the process of learning from challenges?	What are effective pedagogical approaches to help students learn from challenges?	Interview, portfolios			CBL pedagogy; Interuniversity
How to integrate disciplinary knowledge and skills acquisition in CBL	1a. - In prior learning and just-time-learning; 1b. - In formative and summative assessment		Interview, observations, course materials		Conference paper, presentations, article, teacher sessions	Modularisation

2.3 The CBL research agenda

To increase our understanding of which project addresses what CBL aspect, the fine granulated CBL conceptualisation presented by [4] was added to the matrix: each dimension and indicator of that framework was placed on a row in the matrix. Next, all experiments and research projects were re-ordered and grouped with the dimensions and indicators. The result is a theory driven overview of all experiments and projects.

Because the input for the matrix came from both researchers and teachers, and from the taskforce CBL, the overview also made clear which practical and strategical problems were considered relevant, but were not yet addressed by any experiment or research project. The research agenda thus serves as a steering instrument for new experiments and research proposals.

3 CONCLUSION

Initial goals for a research agenda can be defined as:

- Themes: Identify guiding themes and setting research questions, crucial for identifying current and future experiments and research,
- Informed decision making: Prioritizing themes with stakeholders (i.e. taskforce, university deans, department deans, teacher education, policy advisors, and teachers),
- Evaluate experiments: Develop a QA system to secure delivering evidence,
- Research community: Build a research community and ensure dissemination,
- Level up experiments: The experiments in the first stage are mainly done on course-level. The timeline for the research agenda also suggest the next phase, once we have had ample time to learn from these experiment.

Each goal consists of multiple actions to reach that goal. Urgency of goals and actions need to be aligned with the CBL programme plan. Furthermore, it is important to tap into existing knowledge and experience from research and experience at our university.

The main outcome of the research agenda is to support the taskforce CBL and the CBL programme in their planning and decision making. The agenda defines the playing field for research resulting in evidence for grounding educational developments. This requires a typology of challenges, including context, which in turn supports developing a shared language among stakeholders, and allows for a local flavour of CBL.

Currently the research agenda shows preliminary results of ongoing projects. Next step is a more elaborate overview of final results. However, even with only preliminary results, the agenda makes clear where the gaps are, which gives starting points to guide research towards those topics.

The strength of a research agenda, as may be clear from this exploration, is an overview of all university wide initiatives on CBL. This informs policy makers, education designers, and researchers alike. The weakness of a research agenda is the effort required to build and maintain it. Furthermore, it requires a culture of sharing and trust: teachers need to be open about the progress and outcomes of their bottom-up innovations, researchers need to be willing to share already at early stages of their project. In our case, the research community helped to overcome this possible weakness.

The main opportunity for a research agenda based on a research plan combined with a theory driven educational view, is that the similar approach can be used on different topics to make innovation truly evidence-informed.

ABSTRACT

Whilst engineering education has primarily focused on providing students with the required technical competencies, new visions emphasise the importance of lifelong learning (LLL). They point towards the need to acquire the necessary competencies for LLL during the study

[1] L. Van den Broeck, lynn.vandenbroeck@kuleuven.be

doi:10.5821/conference-9788412322262.1327

programme. This requires a shift in mindset for both lecturers and students. Other studies have provided some key recommendations on how HEIs should integrate the development of LLL competencies in study programmes such as using authentic discipline-specific learning contexts and explicit teaching of the LLL competencies. This scoping review will provide an overview of which LLL interventions have already been implemented in higher education and aims to answer the question: How can HEIs support the development of students' LLL competencies? The included LLL interventions are categorised based on the type and content of the intervention, the duration, the target audience, the effectiveness, and the efficiency. The outcomes of this review serve a dual purpose: (1) to define research gaps and (2) to provide educators with some general advice regarding the integration of LLL in engineering study programmes.

1 INTRODUCTION

Whilst engineering education has primarily focused on providing students with the required technical competencies, new visions emphasise the importance of lifelong learning (LLL) and point towards the need to acquire the necessary competencies for LLL during the study programme [1]. This requires a shift in mindset as confirmed by [2]: "The educational system will not only have to re-think the content of the curriculum and its function as educator of new professionals but, indeed, to combine engineering education with continuing education in formal and informal learning communities. Individual engineers will become much more responsible for their own personal learning paths, and they will need to learn how to organise and construct their individual learning growth within combined collaborative learning communities."

Resilient students that are ready for the profession and able to pursue a sustainable career, require a HE setting that makes them aware of their professional identity and trains them in continuously re-inventing themselves [3]. The latter is also confirmed by [4] : "Universities play a critical role in promoting lifelong learning through research on the topic, training of teachers to believe in the importance of lifelong learning and serve as role models and providing learning experiences which encourage students to continue learning throughout their lives." Recommendations on how HEIs can integrate the development of LLL competencies in the study programmes are: (1) the use of authentic discipline-specific learning contexts [5], [6] and (2) explicit teaching of the LLL competencies [5], [7].

LLL is, however, a container concept and there is no agreement yet about what lifelong learning entails precisely [7], [8]. The complex nature of this broad concept is also confirmed by knowledge technologists [9] who conclude that lifelong learning is an interesting but challenging concept to capture. Fortunately, there is no doubt about the importance of LLL and the responsibility of HEIs to guide and support students in the development of LLL competencies so that each graduate is prepared for a life full of learning. Literature about LLL is, however, scarce in engineering education and since other disciplines (e.g. medicine) are more evolved in this domain of LLL, this scoping review will not exclusively include studies published in engineering education research. This scoping review will provide an overview of which LLL interventions have already been implemented in higher education and aims to answer the question: How can HEIs support the development of students' LLL competencies?

2 METHODOLOGY

2.1 Defining inclusion criteria

Search terms were created to find papers that met the following criteria:

(1) The intervention involved higher education students.
(2) The intervention was evaluated to a certain extent.
(3) The intervention had a clear connection with lifelong learning.

2.2 Search term

Based on the inclusion criteria and the research question a first search term was used. This search term was refined based on preliminary screening of abstracts and discussions with colleagues. The used search term is presented in Table 1.

Table 1. Search term

TITLE-ABS-KEY (*"lifelong learning"* OR *"lll"*)	AND TITLE-ABS-KEY (*"train"* OR *"empirical"* OR *"effectiveness"* OR *"intervention"* OR *"pilot"*)	AND TITLE-ABS-KEY (*"competenc*"* OR *"skil*"* OR *"attitude*"*)	AND TITLE-ABS-KEY (*"universit*"* OR *"higher education"* OR *"HEI"* OR *"student"* OR *"undergraduat*"*)

In addition, it was decided only to include journal articles, written in English, and published in the last 20 years. Via Scopus 247 records were returned, which were sorted on relevance. Since this is only a scoping review it was decided to stop screening abstracts when only 2 out of 20 consecutive hits were retained. As a result a total of 169 abstracts were screened, of which 31 full papers were retained [10]–[41].

2.3 Analysing the included studies

To analyse the included studies, a spreadsheet was created to provide the following information for each study: (1) Type and content of the intervention, (2) Duration of the intervention, (3) Target audience, (4) Used research design, (5) Effectiveness of the implemented intervention, (6) Efficiency of the intervention, and (7) the link with LLL competencies. These seven aspects will be discussed in the results section.

3 RESULTS

3.1 Link with LLL

A third of the included studies (n=13) linked the intervention (a method or tool) directly to lifelong learning competencies. Whereas other studies clearly defined the underlying competencies, related to LLL. A majority of the studies made a clear link with Self-regulation, Self-reflection, or Self-directed learning (n=12). Other, less frequent, underlying competencies were information literacy (n=2), clinical reasoning (n=1), and self-efficacy (n=1).

3.2 Type and content LLL interventions

When analysing existing LLL interventions in HEI, four main types can be identified: (1) Focus on self-regulation via (e)Portfolios, personal development plans, specific sessions, online material or personal learning environment & network (n=8), (2) Reflective journals or practice (n=3), (3) Student-centred teaching methods such as Problem/Project Based Learning (PBL), flipped classroom, team based learning, networked learning, work integrated learning (n=11), and (4) Use of Peer and Self-assessment (n=4).

3.3 Duration of the interventions

Most interventions are relatively short. A couple of studies (n=4) have a very short duration ranging from one session to two months. More than a third of the studies included the LLL intervention during a specific course (n=15). One study implemented PBL in four courses during one year, and six studies implemented their interventions in one or two semesters.

3.4 Target audience and discipline of the interventions

The target audience, if specified, of most LLL interventions are older students (n=23), ranging from second year students to final year students. Only two studies focused on first-year students. Both of these studies implemented an intervention for first-year students focusing on reflective behaviour regarding their study results or approach.

Half of the studies (n=16) focus on students in health care related study programmes (e.g. medicine, nursing, midwife, and dental). Other, less frequent disciplines are accounting & economics (n=4), teacher education (n=3), and engineering (n=2).

3.5 Used research design to measure effectiveness

In general, most of the studies adapted a mixed method approach, combination of e.g. interviews, focus group discussions, self-designed surveys, and validated surveys, to measure the effectiveness of the interventions. If quantitative measurements were used, a pre and post-test set-up was very often selected. Some of the studies also used a quasi-experimental design and thus used a control and treatment group.

3.6 Effectiveness of LLL interventions

Overall, almost all the studies have the potential to lead to successful and effective LLL interventions. Their conclusions are not always inconclusive, however, students' perceptions were positive.

3.7 Efficiency of LLL interventions

Only a few studies (n=3) mention something about the efficiency of the implemented interventions. The ones that do mention it, state that the interventions or methods used are more time consuming (e.g. PBL and reflective journal). Only one study sees an improvement in efficiency, because thanks to the use of technology it is possible for every student to learn where and when they want at their own pace.

4 DISCUSSION AND CONCLUSION

LLL is very often used as a buzz word or key word, even when the study does not focus on LLL at all. This was the case in many of the excluded studies. There is no clear agreement yet about what LLL exactly entails and how it should be assessed. A coherent framework would therefore be an added value in both research and practice.

Overall, when looking at the types and the content of the LLL interventions there is one major common feature: almost all interventions focus on a student-centred approach, either via a specific teaching method, or via the focus on self-regulation and reflection, or via the use of peer and self-assessments. This is not unusual, since being prepared for lifelong learning is indeed a personal matter which starts from the individual. It is the task of the HEIs to support their students during this journey.

Most of the interventions are rather short and longitudinal interventions are scarce [8]. Longitudinal interventions and studies are particularly interesting since competency development is a continuous process, where knowledge, attitudes, and skills become more and more intertwined [42].

It is also no surprise that most of the research is related to the medical field, since this field already has a large and explicit emphasis on LLL. These studies are an important source of information for engineering programmes. Most of the LLL interventions focus on older students, however [10] argue that LLL should be included in the curriculum as early as possible.

Measuring effectiveness of educational interventions is not easy, especially since there are many confounding and uncertain variables. The most preferable set-up is a quasi-experimental design with a control and treatment group, using a pre and post-test setup with validated measurement tools and a mixed method approach to capture both the quantitative as the qualitative results. Some authors also mention that there is a gap in the research about how to foster and measure LLL to obtain a deeper and more detailed understanding of students' LLL competencies.

Sustainable interventions, not only have to be effective but also efficient. An intervention is efficient when the observed outcomes are produced at the lowest cost in terms of resources. Existing literature about educational interventions, does not focus on this aspect [43] . Indeed, of the included studies only a few mention something about efficiency. This is an important aspect, that should be given more attention in future intervention studies.

When linking the intervention to lifelong learning competencies, many studies just make the statement that the used method or tool is important to improve LLL. It is, however, even more interesting to look at the underlying competencies of LLL. According to the included studies self-regulation is a very important one. Based on the literature around LLL, it can be concluded that self-regulation is a core competency of LLL. Longitudinal interventions, starting in the first-year and focusing on self-regulation, have the potential to be effective for engineering students.

ABSTRACT

To adequately prepare engineering students for their professional career, educational institutions offer projects in which students collaboratively solve engineering design problems. It is known from research these projects can lead to a variety of learning outcomes and student experiences. However, studies that provide insights in the influence of different features of an educational design are rare. In the current study we use Cultural Historical Activity Theory (CHAT) as analytical framework to understand how different elements of an educational design affect students' experience. Additionally, we use the notion of contradictions to identify opportunities

for structural course improvement. Focus groups were conducted with 12 Master students in Aerospace Engineering, that participated in a collaborative engineering design course. During the course, students applied Systems Engineering (SE) and Concurrent Engineering (CE) and worked in the Collaborative Design Laboratory (CDL), which is a state-of-the-art facility that holds a variety of industry relevant tools. It was found that students valued the guidance of their coach and experts, co-located collaboration and the freedom to structure their own process. However, they perceived challenges with regard to adoption of tools in the CDL, sharing their progress with their supervisor, coordination of collaborative efforts and scheduling issues. An analysis using CHAT revealed what contradictions caused these challenges. Finally, recommendations are given on how course structure can be structurally improved.

1 INTRODUCTION

Engineering problems grow increasingly complex, and the ability to design solutions to these problems in a team environment is essential for 21st century engineers [1], [2]. To adequately prepare future engineers for industry, educational institutions adopt pedagogical approaches, such as Project- or Challenge-Based learning, in which students collaboratively solve open-ended problems. However, only providing students with the opportunity to engage in collaborative engineering design activities, does not necessarily lead to effective learning and can lead to varying experiences. According to Cultural Historical Activity Theory (CHAT) [3], an educational activity can be described in terms of interrelated elements that influence outcomes. Contradictions within and between these elements explain how an activity develops over time. Still, studies that reveal how specific elements of an educational design affect students' learning trajectory are scarce [4]. We aim to add to the body of knowledge by conducting focus groups to investigate the impact of different elements of an educational design on student's learning trajectory. We use CHAT to perform a systematic analysis as it not only enables us to outline the elements that mediate an educational activity, but also addresses the complex interrelations between these elements. Additionally, its notion of contradictions provides a tool to identify areas for improvement in a course design.

2 THEORETICAL FRAMEWORK

2.1 Collaborative engineering design

Engineering projects grow increasingly complex [2]. In order to systematically manage this type of problems, Systems Engineering (SE) has been widely adopted in industry. SE can be defined as "*an interdisciplinary approach and means to enable the realization of successful systems*" [5, p. 21] and offers processes, methods and tools that can be leveraged to manage the design and integration of a system thereby taking into account a variety of realistic constraints, such as economic factors, safety, and reliability. In traditional process models, experts design sub-sets of a system relatively independent, while using stand alone tools. However, this separated approach makes it more difficult or even infeasible to integrate the system and find optimal solutions which include insights of the multiple technical and non-technical disciplines involved [6]. To overcome these limitations, industry increasingly makes use of Concurrent Engineering (CE), which is "*a system design practice that encourages immediate collaboration between groups working on interrelated subsystems, so that the whole system can be integrated seamlessly and quickly"* [7, p. 1]. Additionally, tools have been developed to support the continuous integration of a system. Examples are in the Concurrent Design Facility of The European Space Agency (ESA) [6], which provides tools that support the creation of a model that integrates different sub-sets of a design, enable experts to share and present work, and facilitate co-located as well as distributed collaboration.

Educational institutions have to prepare the next generation of engineers for industry by developing education in which they simulate (parts of) professional practices. They increasingly adopt team-based design courses in which students solve complex problems while using industry relevant approaches and tools. In our research we aim to support the design of these courses based on CHAT, which provides a framework for understanding how collaborative engineering design activities can lead to learning.

2.2 Cultural Historical Activity Theory

In CHAT learning is conceptualized as an improved ability to participate in existing cultural practices [8]. For this, learners (subjects) engage in an activity that already exists in a community, because they have a common motive (object). The actions of subjects cannot be understood without the cultural context in which they take place [3]. While acting on the object, the subjects' actions are mediated by interrelated elements. First, there are tools, which are the means that subjects use to work on the object. Furthermore, subjects are mediated by implicit and explicit cultural norms and rules (rules), responsibilities, tasks and power relations (division of labour), and the community that shares the same object (community). These elements and their relations form an activity system (Figure 1). The mediational structure of an activity can be leveraged to promote learning, for example, through letting learners interact with more knowledgeable others [9] or through implementing tools that provide support [10].

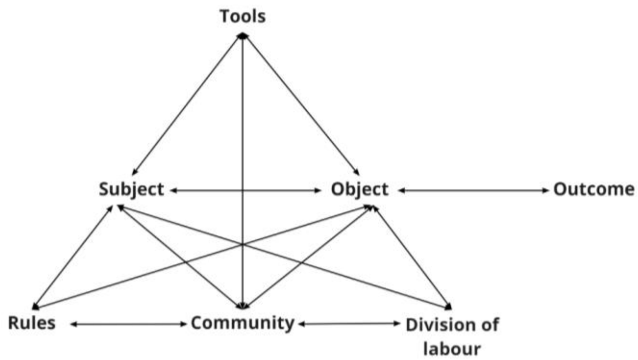

Figure 1. Activity system adapted from Engeström [3]

Activity systems are dynamic in nature and change over time. The source of these changes are contradictions, which are defined as "*historically accumulating structural tensions within and between activity systems*"[11, p. 173]. Analysing contradictions is an essential step toward understanding how activity systems evolve. Moreover, disruptions in the activity systems that are caused by contradictions provide fertile ground for structural improvement. There are four types of contradictions:

1. **Primary contradictions** exist within an element of an activity system, for example, a conferencing tool that cannot be used because the sound bar is not working properly.
2. **Secondary contradictions** emerge between different elements of an activity system for example, when CE rules require experts to integrate their sub-sets of a system in an early stage, but the tools they use do not allow for such integration.
3. **Tertiary contradictions** occur when the object of an activity is more culturally advanced than the dominant form of an activity. For example, when students go to

class their object might be to obtain a good grade, while their teachers instil the more culturally advanced object of skill development.

4. ***Quarternary contradictions*** exist between the central activity system and its neighbouring activity systems. For example, when the learning objectives of a certain course do not match the skills required by industry.

CHAT provides advantages for research on collaborative engineering design education. First, features of an educational activity cannot be examined in isolation as it is a system with complex interrelations. CHAT provides a framework that can help to understand an entire activity system and the interrelations between its elements. Second, the notion of contradictions can be used to trace opportunities for structural improvements in a course design.

In the current study we aim to first identify the benefits and challenges that students perceived during a collaborative engineering design project. Next, we trace back which elements of an activity system are central to challenges and which type of contradiction caused the challenge that was perceived by students. Our study is guided by the following research questions: 1) What benefits and challenges did students encounter during a collaborative engineering design course? 2) What contradictions underlie the challenges that students perceived?

2.3 Study context

The study was conducted within an elective course for Master Students in Aerospace Engineering at Delft University of Technology coined the Collaborative Space Design Project (CSDP). CSDP is a 5EC course that takes place within a period 8 weeks. A mid-term review in week 4 and a final review in week 8 form two major milestones. In this section the activity system of the course will be described (Figure 2).

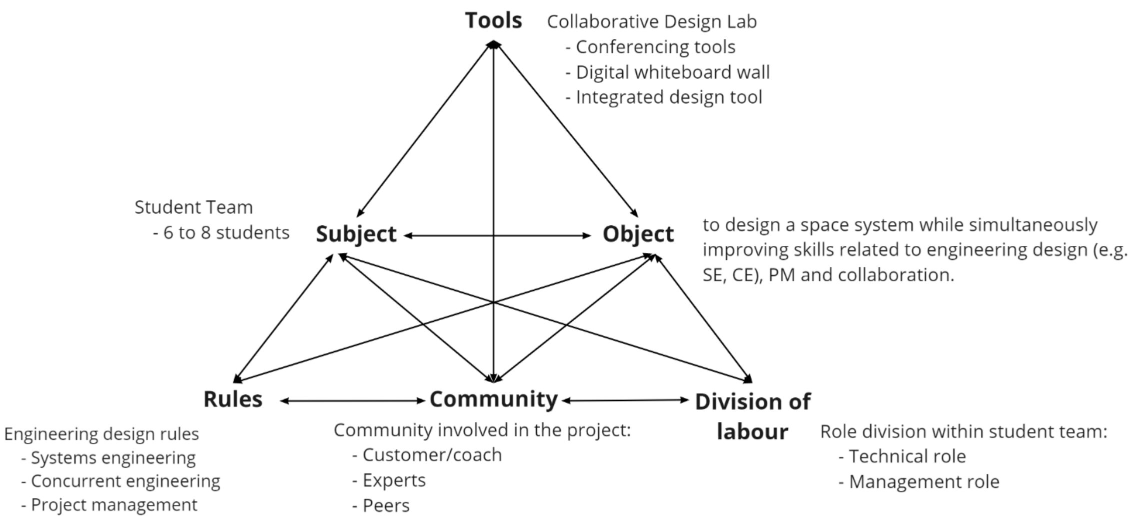

Figure 2. Activity system of CSDP

The ***subjects*** of the activity are three teams of 6 to 8 students. In the CSDP the object is to design a space system while simultaneously improving skills related to engineering design (including SE and CE), project management (PM) and collaboration. Teams work in the Collaborative Design Lab (CDL), which is an environment inspired by ESA's Concurrent Design Facility [6]. It holds a variety of industry relevant ***tools*** that facilitate CE, including: 1) conferencing tools, that allow hybrid meetings, 2) a digital whiteboard wall, which can be used for collecting, organizing and presenting information, and 3) an integrated design tool that allows for the creation and continuous integration of different sub-sets of a design. Teams were offered workshops on CE, SE, and PM, to support the application of these ***rules*** that are used in professional collaborative engineering design practices. Students were free to choose their approach to **division of labour**. However, they were encouraged to assign technical and management roles to each team member. During the process, students interacted with a **community** in several ways. Each team had one or two coaches who also fulfilled on the role of customer. Additionally, experts from industry and peers were invited to the mid-term and final review.

3 METHODOLOGY

3.1 Study design

We conducted focus groups, which are focussed discussions with a small group of people to provide qualitative data to help understand a certain topic [12]. Focus groups can guide the development of an educational program, as it provides insights from the perspective of the target audience.

3.2 Participants

In the academic year 2021-2022, three teams engaged in the CSDP. All teams were invited to participate in the study and 12 out of 21 students enrolled, respectively 3, 4 and 5 for each team. All students were Master Students in Aerospace Engineering, but there were variations in prior experience, study background and nationality.

3.3 Instruments

A semi-structured interview protocol (Appendix A) was constructed. The first part was based on Mwanza's Eight-Step-Model for interpreting the elements of an activity system [13] and addressed the role of each element of CHAT in students' design process. The second part addressed the benefits and challenges that students' encountered during their process, in order to explicate possible contradictions.

3.4 Procedure

Participants engaged in two focus groups; one after the mid-term review and one after the final review. Focus groups were conducted with members that were in the same project team. This led to a total of 6 focus groups. All focus groups were conducted by the first author of this paper and had a duration between 50 and 70 minutes.

3.5 Analysis

Our analysis constituted of two phases. In the first phase, we mapped development of students' activity by identifying features of the course they valued as well as the main challenges they encountered. For this, all focus group recordings were transcribed and analysed in Atlas.ti. We coded all interviews using a coding scheme based on CHAT elements (Appendix B). Next, we collected all benefits and challenges and performed a thematic analysis to cluster them. Only the ones that were mentioned during multiple focus groups were included in the results. In the second phase, we used CHAT as a framework to understand why challenges have emerged. We connected the elements of CHAT that were associated with a certain challenge and assessed what type of contradictions caused the challenge.

4 RESULTS

In this section, we provide an overview of the features of the CSDP that are perceived as beneficial and challenging. Next, we use CHAT's notion of contradictions to understand why these challenges emerged and to identify opportunities for structural improvement of the course.

4.1 Benefits

The design of an activity system can be leveraged to improve learning. In this section, an overview is given of elements of the educational design that were perceived by students as beneficial for learning.

4.1.1. *Freedom to make mistakes*. All student teams appreciated the freedom they were given during the CSDP. This not only gave them the opportunity to pursue a direction that was aligned with their own interests, it also created a valuable learning environment. Students had to choose their own directions and structure their own work processes. They felt that this led to making 'mistakes' that were in hindsight the most important learning moments. One student explained: "*I still think that making the mistake was a learning experience. Tripping over the stone is like: 'Hey, this stone is there*.'" As such, students perceived the way rules were embedded in the activity as positive, as they were given the freedom to choose, try and evaluate their own approach rather than having an imposed set of rules.

4.1.2. *Communication with coach and experts*. Teams mention that they benefitted from the interaction with their coach and experts. One team indicated that they especially valued the informal character of the conversations they had with their coach. It was also mentioned that the mid-term and final review that were attended by the coaches, experts and the other project teams were very useful for collecting feedback. Involvement of the community gave them the opportunity to learn from others that were already more advanced in collaborative engineering design practice.

4.1.3. *Co-located collaboration*. Two teams mentioned that working co-located in the CDL was beneficial for their collaboration. Being together in one room smoothened communication and coordination of tasks among team members. Students perceived that the facilities that were offered positively influenced the division of labour.

4.2 Challenges

The design of a learning activity can also be sub-optimal and elicit challenges for learners. This section provides an overview of these challenges and connects them to CHAT elements.

4.2.1. Technological issues. Two teams mentioned that technological issues made it difficult to use some of the tooling available in the CDL: “*you have to fix problems, they don't work the way you want them to (…) and it slows down things and it is frustrating*.” This challenge applies to the tools element of the activity system.

4.2.4. Coordinating cooperative efforts. The process of dividing and integrating work was perceived as challenging by all teams. Team 2 and 3 both indicate that it was difficult to monitor group progress, as there was no formal process for coordinating and organizing work. “*We didn’t really have a formal way of tracking tasks. (…) I think the problem was we didn’t really have somebody in charge of running these meeting in which you ask: ‘how are you doing on this task? And how can we move it forward and all?’.*” This shows that there was a lack of rules on how to organize the division of labour. Team 2 attributed the difficulties in convergence to the fact that they did not have a shared goal in mind: “*The biggest challenge for me during this course was, we split work at the beginning and then that was it for me. So I had the things I said for myself in relation to my part of the thing, but I didn't have a common goal of which I said: ‘Okay we need to get there because we are all coming here’.*” This indicated there was division of labour without having clarity on the object of the activity.

4.2.3. Interaction with coach. Teams had the freedom to organize the interaction with their coach. Team 2 struggled with talking about ‘the bigger picture’ rather than separate issues. Their coach saw their complete design only short before the mid-term review and initiated major revisions: “*I think updates were not exhaustive in that sense, right? (…) I must say, we never showed her what we were actually doing and then she saw everything at once and then she said so many things.*” Team 3 indicated that they had not been pro-active in approaching their coach in the early stage of the project. As a reaction, their coach visited them on his own initiative and asked questions they had not prepared for. Both teams mentioned it was a challenge to provide an overview of their work in early stages of the design. This indicates that teams (subjects) struggle to communicate their work in relation to the project goal (objective) to their coach (community). This challenge disappeared after the mid-term review, where teams presented an overview of their work that provided common ground in later stages.

4.2.2. Adoption of tools. The tools that were available in the CDL were not used extensively by teams. Teams mention that learning to use the tools is a time intensive process and that investing the required time did not feel worth it. In particular the concurrent engineering tool had a steep learning curve and it was more attractive to use familiar tools: “*We haven’t really used [the integrated design tool], because we felt it was easier to use Excel. Learning a new software cost time, and we needed more time to focus on our design options and selecting the optimal design*”. Meanwhile its application felt inappropriate in early stages of the design, because the number of calculations that needed to be performed and integrated were limited: “*(…) the more in-depth we go in the design, the more useful [the integrated design tool] gets. At this moment we are that shallow that a special tool has no use.”* Elements of the activity system, might not resemble the ways of working that are employed in industry and allows subject to rely on familiar tools and rules they know from previous practices.

4.2.1. Course schedule. All teams mentioned that the time frame for the CSDP was tight and the workload was high, especially in combination with other courses. Also, there was overlap between workshops and other courses, which made it impossible for students to attend some of the workshops. The cause is beyond the CSDP activity system and involves activity systems of other courses.

4.3 Contradictions

Challenges that were identified in the first stage, are now understood more thoroughly through the notion of contradictions. For each challenge we have identified an underlying contradiction. Moreover, insights are provided on how to change the activity system in order to improve the course design. A mapping of challenges, contradictions and suggestions for improvement can be found in Appendix C.

First, tools in the CDL did not always work. This is a primary contradiction, thus a solution can be found within a single element, for example replacing malfunctioning software. Second, there is a secondary contradiction between division of labour and rules or object, as some teams have not agreed on rules related to work division or clarified the object of the activity. In addition, there appears to be a secondary contradiction between subjects, community and object, as students struggle to provide an overview of overarching work and goals to their coaches. Solutions to these secondary contradictions should target the interaction between elements. In this specific case subjects should be supported in explicating rules on division of labour. Moreover, the object should be clarified within the group as well as to their coach. A solution is to provide scaffolds that help students to explicate rules and goals. Students indicated that the mid-term review helped in integrating and showing their work. To establish this in an earlier phase of the project, a baseline review can be added in the beginning of the course. Fourth, during the CSDP tools were offered to enable students to simulate (parts of) CE practices from industry. However, students perceived that these did not have sufficient advantages over tools that students were already familiar with, while learning to use them was time consuming. As such, a tertiary contradiction emerged by the activity system of the course and the more advanced activity system in industry, where similar tools are deeply embedded in engineering design practices. Solutions should aim to make the activity system of the course better match the more advanced activity systems of industry. For example, by choosing an object that requires more in depth analysis with elaborate calculations, an integrated design tool could offer more advantages. Finally, a quarternary contradiction emerged as there was overlap between courses and a high combined workload at certain times. A solution requires coordination between multiple activity systems. However, if this is not feasible, it would be possible to record workshops and make the content available for students who could not attend.

These suggestions for improvement can provide support to students to overcome the challenges they perceived during the CSDP. However, it should be taken into account that these attempts should not interfere with the features of the educational design that are currently perceived as beneficial by students. Specifically, students indicated that being able to make mistakes contributed greatly to their learning process. Providing students with more directions, such as scaffolds, could also take away the opportunity of 'tripping over the stone'.

5 SUMMARY

In the current study we aimed to investigate how elements of an educational activity affect students' experience during a collaborative engineering design course using CHAT. It was found that students valued the freedom of choosing their own approach (rules), having a room for co-located collaboration (tools) and interacting with their coach (community). However, students also perceived challenges. Technological issues occurred, which indicated a primary contradiction within the tools element. Other challenges were caused by contradictions between elements. This included difficulties with explicating rules on division of labour and the object within the team and between the team and the coach. Support should target the interrelations between the elements involved. Additionally, tertiary contradiction between the activity system of the course and the more advanced activity system of industry caused hesitance among students in adopting tools in the CDL. A solution should be found in aligning elements of the CSDP's activity system with professional practices. Finally, challenges with conflicting schedules were caused through contradictions between activity systems of multiple courses, and should be solved through coordination between these activity systems.

The current study has some limitations. First, conclusions are based on the redescriptions of events by participants. This is useful for the collection of perspectives, but might not give an accurate reflection of the actual activity. To investigate the impact of different features of an educational design in more depth, methods such as observations could be used to complement focus group results. Second, the results of this study are tied to a specific course and therefore highly context dependent. Similar features in a different course design, might lead to different experiences for students. Therefore, it is important to expand this research to different collaborative engineering design courses, to see if generalisations can be made. Finally, some recommendations are given for course improvement. However, these suggestions are not yet tested in practice. It is important to follow up on these suggestions in order to assess whether they have the desired impact on students' experience.

Despite these limitations, we have shown how CHAT can be used as conceptual framework to address complex interrelations of elements in a course design. Moreover, the notion of contradiction can be used to understand the challenges that are perceived by students and to systematically trace opportunities for course improvement.

APPENDIX A – INTERVIEW PROTOCOL

Question	**CHAT element covered**
- Which Bachelor degree did you finish before starting this Master - For which Master's track you are currently enrolled? - How much experience do you have with projects that involve both collaboration and engineering design?	Subject
- What did you expect to learn from the CSDP? - What have you learned during the CSDP?	Object

- What phases did you distinguish in the design process? - What activities did your team perform in each of these phases? - Why did you perform these activities? And why this order?	Rules
- How was the work distributed during these activities? - How did you keep up to date with eachother's progress?	Division of labour

- Where there people involved in the project from outside of your team?
    o Who where those people?
    o How did they contribute to the project?
	Community

- Did you use tools during the project?
    o When did you use those tools?
    o For what purpose did you use these tools?
	Tools

- Which parts of the course did you perceive as beneficial? o Why was this beneficial to you?	Activity system
- Which parts of the course did you perceive as challenging? o Why was this challenging to you?	Activity system/ contradictions
- How could you be supported during these challenges?	Activity system
- Do you have any other recommentions to improve the course? - Is there anything else you would like to share that we have not yet discussed?	Activity system

APPENDIX B – CODING SCHEME[2]

Code	**Applies to quotes that relate to:**	**Example**
Subject	characteristics of one or more students that participate in the project (i.e. the subjects)	"And for another, for me this is a completely different country, with completely different communicative cultures."
Object	the motive to participate in the activity. As the activity is an educational activity, the motive can relate to learning objectives as well as project objective.	"For me it was more about the software and the facilities we could use. So I thought it was nice we could learn something about concurrent facilities that is also used in industry and get experience in it."

[2] Version of coding scheme dated 2022-04-29

Tools	the means that students have used to achieve their objectives.	"We haven't really used [the integrated design tool], because we felt it was easier to use Excel because learning a new software cost time, and we needed more time to focus on our design options and selecting the optimal design"
Rules	the implicit and explicit rules in a community that mediated the activity.	"Yes for example for the orientation [phase],there is of course a certain structure to it when it comes to systems engineering."
Community	the community members that were involved in the activity.	"We invited a couple of other people to the review so at the review those people helped us and we've also scheduled meetings with them this week"
Division of labour	how work and responsibilities were divided among students during the activity.	"In the planning phase we gave each of us, how do you call it? A role, so (..) I was the cost person and [another team member] was the propellant management guy, so each had a subsystem or technical role, so later in the design we picked up those roles"
Contradiction	the indication there might be a contradiction	"the biggest challenge for me during this course was, we split work at the beginning and then that was it for me. So I had the things I said for myself in relation to my part of the thing, but I didn't have a common goal of which I said 'Okay, we need to get there because we are all coming here".

APPENDIX C – CHALLENGES, CONTRADICTIONS AND IMPROVEMENTS

Challenge 1: Technological difficulties when using tools		
Examples of evidence	**Contradiction type**	**Suggestions for improvement**
Team 2. "Yeah I mean because it is hardly even an intuitive thing" (…) "Some of the screens you have no idea where the control comes from" "Yeah, sometimes it is that pc, sometimes it is that pc, you don't know" Team 3. "you have to fix problems, they don't work the way you want them to (…) and it slows down things and it is frustrating."	Primary, tools	Replace malfunctioning software.
Challenge 2: Teams struggle with coordinating cooperative efforts		
Examples of evidence	**Contradiction type**	**Suggestions for improvement**

Team 1. "I think, where we are at this moment working on, is that it [work] is a bit hard to track, to back log so to say." "Yes when we were working on our presentation (…) that gave a good overview. I do not have that overview in our [Google] Drive." Team 2. "The biggest challenge for me during this course was, we split work at the beginning and then that was it for me. So I had the things I said for myself in relation to my part of the thing, but I didn't have a common goal of which I said: 'Okay we need to get there because we are all coming here'." Team 3. "We didn't really have a formal way of tracking tasks. (…) I think the problem was we didn't really have somebody in charge of running these meeting in which you ask: 'how are you doing on this task?"	Secondary, between division of labour and rules or object	Scaffolds by tools or community
Challenge 3: Teams struggle with showing an overview of their work to coaches and experts		
Examples of evidence	**Contradiction type**	**Suggestions for improvement**
Team 2. "I think updates were not exhaustive in that sense, right? (…) I must say, we never showed her what we were actually doing and then she [coach] saw everything at once and then she said so many things." Team 3. "So that is something we probably should have done better, actively communicating with him [the coach] a bit more." (..) Yeah, there was this dynamic that we certainly didn't reach out to him as much as we should have and what i think that happened is that he showed up to our working sessions which was actually nice to get that communication going. But then, because we weren't actually reaching out we could control how and when we actually wanted to have these feedback sessions."	Secondary, subjects, community and object.	Implementing a baseline review
Challenge 4: Teams do not adopt tools that are offered in the CDL and stick to familiar tools.		
Examples of evidence	**Contradiction type**	**Suggestions for improvement**
Team 1: "(…) the more in-depth we go in the design, the more useful [the integrated design tool] gets. At this moment we are that shallow that a special tool has no use." Team 3: "We haven't really used [the integrated design tool], because we felt it was easier to use Excel. Learning a new software cost time, and we needed more time to focus on our design options and selecting the optimal design"	Tertiary, between activity system of current engineering design courses and more advanced engineering practices in industry	Restructure activity system of course so that it is more similar to engineering practices in industry.

Challenge 5: Courses overlap with each other and combined workload is high.		
Examples of evidence	**Contradiction type**	**Suggestions for improvement**
Team 1. "For me it was also a very big challenge that there was an overlap with other subjects." Team 2. "In my case I had a lot of classes at the same time as the workshops and they were important classes." Team 3. "I think the workshops on the tools, they are great to expose us to these tools and these ways of working, but in a way I felt a little overwhelmed by some of them. Especially with [the concurrent design tool] I actually missed the first one [workshop] and then it felt like there was no point in trying to get it now and catching up because we had to manage all our other classes."	Quarternary, between CSDP and other courses' activity system	Coordination of schedules between courses, record workshops

DEVELOPING FUTURE WORKING LIFE COMPETENCIES WITH EARTH-CENTERED DESIGN

ABSTRACT

Integration of sustainability in the curriculum of higher education creates a demand for bringing the theme into concrete development projects. Sustainable and proactive development have been identified in Finland as key generic competences in higher education. Capability to innovate and create sustainable solutions and services for future are key skills in producing novel sustainable solutions. We experimented with master's level students the use of a novel design method, Planet Centric Design (PCD), to create sustainable system and service concepts for the future. The trialed method combines systems thinking with service design to solve sustainability related challenges. It has been developed by a software company to support practical sustainable solution development jointly with their customers. Companies have

doi:10.5821/conference-9788412322262.1436

recently been active in developing their own approaches to support design related activities. Trialing, benchmarking, and learning the use of the topical industry-lead methods during their studies, provides students practical hands-on experiences of using the methods and confidence to use the methods. The participating students found using an industry-developed design method valuable. Learning about sustainability was perceived to be applicable both for working and personal life and have impact in both areas. In the student's self-reflection reports on their learning and experiences, the collaborative teamwork in multidisciplinary teams and the creative confidence gained through the learning to use a novel design approach, were the most most often described positive themes.

1 INTRODUCTION

1.1 The need for new sustainable future related working life skills

Sustainable development related working life skills are increasingly part of competencies of software engineering curricula. This development is driven by, e.g., the UN 2030 Agenda for Sustainable Development [1].

In Finnish universities of applied sciences generic sustainable development competence related skills on bachelor's level include familiarity with the principles of sustainable development, ability to promote their implementation and acting responsibly as a professional [2]. For graduating bachelors, ability to find sustainability related information and solutions, and apply them in practice, as well as understand sustainability related challenges and issues are described as possessed skills. On master's level sustainable development compentences call for ability to develop and manage sustainable and responsible operating methods in work, and support sustainable change in work community and society [2]. Furthermore, the abilities of graduating master's level students include creation of sustainable solutions and analysing and assessing systemic dependencies of complex challenges.

Future competencies include also proactive development. On bachelor's level a graduating student seeks and implements solutions that anticipate the future and can apply existing knowledge and methods [2]. On master's level student can manage the development of new solutions that anticipate future by using various research and development methods to create new knowledge [2]. In addition, creative problem solving collaboratively in multidisciplinary teams, design thinking related customer centricity, sustainable and viable solution seeking and development, as well as future anticipation are needed skills for proactive development [2].

This pair of competencies calls for novel approaches to integrate the skill acquisition into the curricula and course implementations. Concrete development projects, where development methods used in industry are applied in practice to solve real-life problems have proven fruitful in learning the status quo industry practices [3]. Software companies are increasingly digital agencies providing not only software development, but also consultation and collaboration based on design thinking and service design. They provide as services not only solution identification, design and development, but also strategic planning, e.g., including business model innovation. Therefore, companies are active in developing approaches that support their wider spectrum of provided services.

1.2 Design approaches to solve sustainable future related challenges

As sustainable development goals increasingly drive innovation activities in organisations, new practice-oriented design approaches have emerged. As Papanek [4] in 1972 called for design that is revolutionary and radical to be ecologically responsible and socially responsive, Design for Sustainability as an approach emerged to address the sustainability and responsible design activities [5;6].

Designers themselves have recently globally joined to create an initiative and community around so called Earth-Centered Design [7]. The idea is to move from starting the design process from individual level to planetary ecosystem level. Earth-centered design has sparked practical design approaches, some of which are called planet-centric design. They are offered as consultative services for organizations to create sustainable solutions and business models. As the approaches are novel and industry-developed for practical purposes, the research on earth-centered and planet-centric design is still practically non-existent at the time of writing this article.

Design Council has also been active in creating a new framework for designing for the planet. Design Council's well-known Double Diamond model [8] for innovation is originally based on practitioners' design thinking approaches and has been widely applied in software engineering projects in industry as well as by academia. Recently Design Council has published for sustainable design a Systemic Design Framework [9] that combines the Double Diamond model with systemic thinking and puts planet and people in the center of design activities.

The Systemic Design Framework has six principles that guide the design activities [9]. These include the following: 1) People and planet centred to focus on shared benefits of all living things, 2) Zooming perspectives in and out - from a human to the wider system, from present to future, from root cause to vision, 3) Testing and growing ideas, 4) Inclusive and welcoming difference by creating safe and shared spaces to include various perspectives, 5) Collaborating and connecting as a project is one element in a wider system, and 6) Circular and regenerative by re-use, nurturing and growing existing physical and social assets. Systemic design includes the following activities: 1) Exploring throughout the design process, 2) Reframing the problem in different ways to support the creation of new ideas, 3) Creating bold, radical or provocative ideas as well as interventions at different levels of the system, adopting a circular mindset and prioritising most valuable actions, and 4) Catalysing by testing prototypes and consequences, by measuring by created metrics the environmental and social impact, by using sustainable business models to avoid negative consequences, and identifying similar ideas to create a bigger movement for change. The methods used in the Systemic Design process can be applied, e.g., from service design or from organisation's own or other suitable toolkits.

As an example of a planet centric design (PCD) toolkit developed by a company, a Finnish technology company Vincit openly shares their PCD toolkit to be used in sustainable design activities [10]. The approach combines systems thinking with design thinking to support creation of sustainable service or product concepts as well as business models. Design is done collaboratively and using a creative mindset. Toolkit consists of 19 canvases and a handbook to support the design process. The canvases are used to analyze, design, and evaluate different aspects of the sustainable solution development and the outcomes of the design process. The approach consists of five phases, with each phase having 2-6 canvases to support the design activities. The five phases of the PCD process are prepare, understand, envision, create, and release. We chose this method to be used in our course implementation, as it was at the time of planning the course implementation one of the few openly available toolkits and provided both the handbook as well as the canvases to be used in a concrete design project.

2 TRIALING PLANET CENTRIC DESIGN APPROACH

2.1 Learning goals

Problem-based learning (PBL) as a pedagogical approach emphasizes working on open-ended real-life problems to enable acquisition of desired skills and transferring learning to real-life [11]. We found it fitting as an approach to acquisition of competencies in sustainable and proactive development. To enable the development of the two competencies, we searched for novel approaches and practical methods that supported developing and trialing new pedagogical implementations. To address the goal of our master's level course "Creation of Future – Out of the Box" where sustainable development goals (SDG) were set as the driver for design and innovation activities, we decided to utilize an openly available industry-developed approach and toolkit for sustainable design, that is, the previously described Planet Centric Design (PCD) approach by Vincit.

As problem-based learning was chosen as the pedagogical approach in our course, we chose seven business fields in which the students as teams explored the sustainability challenges in their business field and chose the challenges to address in their team work. The learning goals of the course included understanding sustainability and sustainable development goals, mastering skills needed in creative collaboration and working as multidisciplinary teams, as well as applying design and systemic thinking related principles and development skills in practice.

2.2 Preparation and used learning technology

At the time of starting the planning of the course implementation and using PCD as the design approach, we contacted the technology company who had developed and openly shared their PCD approach and the related toolkit. The company experts, who had been designing and developing the PCD approach, gave the teachers support in planning the use of the toolkit and choosing suitable canvases (i.e., templates supporting design activities) from the toolkit to be used in the course implementation.

Materials of the course for self-study prior to and during the course were selected, created, and shared on a learning platform (Moodle) on the PCD toolkit, SDGs, creativity, systems thinking, as well as on business model design. These were chosen to support the students' self-paced learning. Miro boards containing the chosen canvases from the toolkit were created for each of the student teams to work on. Miro (miro.com) is an online collaboration tool that provides support for distributed cooperation synchronously and asynchronously by providing a whiteboard as a workspace. A group was created in MS Teams for the course and channels for each of the student teams were created to support their team work in terms of joint meetings and workshops, communication, and creating the team assignment outputs. The teachers of the course followed up and gave mentoring support in the design process by following up the activity of the teams in Miro, and on MS Teams channels, by the chat function of the channels.

2.3 Course implementation

35 master's level students enrolled to the course. Students were simultaneously actively working in their own organizations and primarily worked on the team assignment after work in the evenings or during weekends. The learning activity consisted of following parts. First, in a pre-assignment they chose on first come, first serve basis one of the seven business fields to work on as five (5) member teams: 1) Buildings and homes, 2) Green energy, 3) Tourism, 4) Transport and mobility, 5) Health and wellbeing, 6) Food, and 7) Online shopping. After choosing the theme, the students were asked to explore digital services or products in their chosen business field individually. Each of the students reported online intheir joint discussion forum in Moodle their findings on the exploration of solutions and identified gaps related to sustainability. This pre-assignment was aimed at supporting further working as a team during the first joint contact session online as well as during the later phases of the design process.

Three experts from a technology company facilitated an ideation workshop in Zoom for the student teams in the first contact session. This activity was based on the findings of the pre-assignment and self-study materials on SDGs. Student teams ideated solutions using a Planet Centric Ideation canvas in Miro to a question "*How might we deliver [value] responsibly, systemically and transparently by 2030?*" related to their business field. "*How might we*" questions are typical questions used in service design processes as the question to which solutions are ideated for.

First, the student teams needed to identify for the question the "value" to be delivered. Then the value to be delivered was asked to be brainstormed taking into account each of the three viewpoints. The students were encouraged to ideate in this phase freely, without criticism, to generate as many ideas as possible. The three viewpoints – responsible, systemic and transparent - were defined as follows. Responsible covers causing harm to the planet, systemic refers to collaboration between different partners, organizations, and other collaborators, and transparent stands for opening up the processes to end users and providing sustainable choices when using the service or solution.After ideation all the teams came together to discuss the ideas. The company experts discussed with the students the identified problems and value propositions, and the ideas for the three sustainability related areas. Experts also raised questions and helped the students in formulating and refining the value propositions and ideas.

After this session, each student team continued their PCD process online at their own pace during a one-month period. Miro board was used as the ideation and development platform, and MS Teams as the communication and collaboration channel synchronously and asynchronously. The process required the students to work as a collaborative team synchronously when brainstorming and developing solutions on the Miro board. This differed from many of the earlier course implementations during their master's degree studies where they could do group work asynchronously and divide the work between the group members for independent working. The details on the used eleven canvases from the total of nineteen PCD canvases in the design process are reported elsewhere [12].

In the end of the course, the students were asked to report their design process with its phases and outcomes with a short 10 min video and write a blog post on the learnings on the creative process, the use of the method as well as reflect on the ideas and thoughts on applying the learnings and methods in their worklife. In the second, final joint 4-hour learning session in Teams at the end of the course, each student team was asked to moderate a 15-minute discussion based on the 10-minute video presentation by one of the other teams. Instructions for how to prepare and run moderated discussions were given to the students to help them prepare their moderation. The moderation included introductions to the theme and the presenting team members and their video, preparing questions to the presenting team, and leading the discussion based on the video using the prepared questions.

2.4 Questionnaire for students on learning process and learning experience

In the end of the course, students were asked in a self-assessment questionnaire to reflect their own learning process focusing on skill development related to creative thinking, sustainability development, and future readiness. They also were asked to describe their learning experience – what was easy, what was hard for them, as well as what skills they would like to develop further, and how they could apply what they learned during the course and while applying the PCD process. The collected data was qualitative, and it was analysed by thematic analysis.

3 RESULTS

3.1 Design outcomes from the PCD approach

As outcome of the PCD process in its fourth phase, i.e., the Create phase, each of the seven student teams created one digital service or an IoT solution concept taking into account the sustainability aspects and using the results from the earlier phases of the process, including the third phase, i.e., ideation of solutions. The Planet Centric Concept canvas was used to transform ideas into concepts and identify what makes the concept sustainable. Idea was analysed with the following questions: What does it do? What is the planet positive impact? How can you measure success? What are the risks? How can it be improved?

For the created concept teams also analysed the systemic touchpoints by considering the positive and negative impact from the point of view of economy, society, and environment. For economy the question to answer was: How does the concept change the value of key resources? From the point of view of society, the questions to consider were: How do lifestyles change? Do new behaviors emerge? Who are the winners and loosers? Finally, for the environment, the impacts on environment were collected with the question: How does value of resources and new behaviors impact nature?

To enable concrete business to emerge, a business model canvas was used to address what the business model would be like with sustainable goals. Specific questions related to sustainability related issues guided the creation of the business model. As in traditional business model canvas, customer segments and value proposition were the starting points of filling in this canvas. Furthermore, the key strategic partners were identified that would enable the concept to develop into a real service. These were identified in terms of amount of influence, and on the other hand, who is in favour and who is resisting and holding back the initiative. These could be both internal and external partners.

Finally, in the fifth phase, i.e. Release, teams were asked to address how they could get their message across about the sustainability of the created solution to their target audience using the Sustainability Storytelling template. Teams considered first, what would be the metrics, i.e., the facts, related to sustainability that are communicated to the target audience. Teams then picked the tone of their message, that would represent the brand personality, and created the message to share the facts. Teams reflected on the possible perceptions of the target audience on the message, and impact of the message on their behaviour. Also risks related to the created message were analysed. If risks emerged, message could be iterated.

The concepts created by the teams included the following. A mobile application concept for mobile phones was created to support saving energy in buildings. Another team created a concept platform for green energy market for those selling energy and for consumers. Team focusing on food, identified sustainability related gaps in the current model of food delivery service Wolt, and created new features to the service based on their findings, thereby renewing the concept and business model. Online shopping platform Wish was analysed by one team, and they found a number of sustainability related issues in the operation model to address, including the returning of products. The new concept addressed several SDG's to create a more sustainable online shopping experience. The team focusing on tourism created a novel mobile application concept to support sustainable travel and related choices. New requirements were also idenfitied for developing smart watches, including materials and batteries, and related digital services. One of the teams created a novel digital service concept for sustainable citybikes.

To address the quality of the outcomes of the process, the following can be concluded from the perspective of the teachers. Firstly, quality of the outcome was affected by how the team committed to working as a team synchronously in joint workshops, and how well organized the planning of the joint team workshops were. If someone took charge of planning and facilitating each of the team workshops, this affected positively the quality of the ideas, the created concept, the business model, and the message to be delivered to the audience. Secondly, the more focused the problem to address was by the teams, how many SDGs were chosen, and how clearly the value could be identified, the more desirable and viable the concept and business model appeared, and the more clearly the message could be conveyed.

3.2 Fun and inspiring – Student experiences from the trial

The most often mentioned positive theme in the students' reflection of the course and using the PCD approach in the questionnaire was collaborative teamwork to solve the problems together as a multidisciplinary team. Furthermore, students described the creative nature of the PCD process, and many described that their creative confidence was boosted while learning and using the PCD approach collaboratively. Focusing on sustainability was considered challenging, but the canvases were mentioned to help in taking it into account in the process. Most of the students mentioned spontaneously that they took after the course more into account the different aspects of sustainability in their own working and personal life, although they noted that making the choices was not always easy. In addition, the systemic approach of the method that revealed the complexity and interconnectedness of issues, was described as valuable. Learning to use the industry-developed PCD approach and gained knowledge of sustainability issues was described as an asset and giving practical skills to be applied not only in the worklife, but personal life as well.The challenges of using the method raised by the students were primarily related to understanding the use of the canvases or the process itself, but as the process advanced, this was described to become easier. Overall, the students reflection revealed that the learning and experiences were positive.

4 CONCLUSIONS

We described the use of a novel Planet Centric Design method in higher education while using problem-based learning approach in a course implementation. The collaboration with the software company that had developed the method and applying the method was perceived fruitful and valuable by the students. In order to ensure both work-orientation and value of acquired competencies in studies for working life, experiments with new methods should be carried out as well as trialing the use of industry-standard methods in higher education. This would also allow a further comparison of the methods and the results obtained in these experiments in terms of competence and skill development as well as their applicability in working and personal life.

Conference Key Areas: Theme 12 *(Physics and Engineering Education),* Theme 14 *(Challenges of new European Universities)*

Keywords: *student selection, mathematics skills, physics skills, advanced mathematical skills, engineering education*

ABSTRACT

Higher education institutions assess applicants with entrance examinations as a way to identify and rank those applicants with adequate ability to proceed in their studies. Engineering students form a significant group of higher education students, both in Europe and Finland. Finnish universities of applied sciences (UASs) developed and harmonised their student selection in the Development Project in 2017–2020. In the Development Project, a new national digital universities of applied sciences entrance examination (UAS Exam) was developed. In the current study, a cross-sectional design was used to assess advanced mathematical skills and related factors of the bachelor-level engineering applicants performing the newly developed UAS Exam. The advanced mathematical skills exam section contains mathematics and physics problems. The data were collected via the digital exam system. Altogether, 1205 engineering applicants consented to the study and performed the exam section. The data were statistically analysed. The applicants' mean scores were 4.8 (SD 5.2, median 3.9, range -4.9–20 pts) out of 20 maximum points. Over 20% of the applicants failed. Some of the background variables explain the applicants' exam results, indicating that older applicants scored better than younger ones, males better than females, and high school graduates and applicants with previous higher education degrees better than those with vocational diplomas. The results indicate that engineering applicants' advanced mathematical skills were rather poor, indicating that it may be possible that engineering applicants lack the basic skills in mathematics and physics, but this may vary between applicants.

1 INTRODUCTION

The admission of new students to universities can be described as a process of matching, guidance and selection enabling the graduation of students with the adequate skills needed in their future working life (1). Therefore, higher education institutions (HEIs) assess their applicants using entrance examinations and other selection methods to identify and rank applicants with a high probability of programme completion (2). The assessment of applicants should aim for equity and fairness, which challenges HEIs to use objective and valid selection methods (2; 3). However, student selection practices vary within and between countries (1; 2).

In Europe, engineering students form a significant group of higher education students. In 2019, there were 10.9 bachelor-level engineering graduates per thousand inhabitants in the European Union (EU) area. In Finland, there were 15.6 engineering graduates (bachelor level) per thousand inhabitants in 2019, which was the second highest number of graduates on the Eurostat list of the European countries (4). However, engineering educational systems differ across the world (5). In the Finnish educational system, higher education has a dual model consisting of science universities and universities of applied sciences (UASs) (6). In science universities, the basic degree is a master's degree, whereas UASs offer more pragmatic education and in where the basic degree is a bachelor's degree. Both university sectors offer engineering education programmes in Finland. In UASs, the duration of bachelor-level engineering education is four years, covering 240 ECTS (7).

In Finland, higher education is free of charge for citizens in EU member states and the European Economic Area (5). However, entry to Finnish HEIs is limited, so there are more applicants than study places available. Until 2016, entrance to the bachelor-level engineering education to Finnish UASs was based on success in earlier studies (matriculation examination scores) or work experience (concerning applicants with vocational diplomas) and entrance exams testing applicants' basic skills in mathematics and physics or chemistry. To be qualified as an eligible applicant, the applicants had to get enough points from the entrance exam (about one-third of the total). The final selection decision was based either on a combination of certificate scores/work experience scores and entrance exam scores or only on the entrance exam scores. Since 2017, entry to bachelor-level engineering education in Finnish UASs has been possible with certificate-based selection as well.

Finnish UASs have developed and harmonised their student selection in the Development Project for Student Selection in Finnish UASs 2017–2020. A new digital national universities of applied sciences entrance examination (UAS Exam) was developed and used for the first time in autumn 2019 (8). The UAS Exam is intended to be used in all study fields, and it includes exam sections common to all applicants and those common to applicants in specific study fields. The exam section of advanced mathematical skills is performed by all bachelor-level engineering applicants.

The purpose of the current study was to assess the advanced mathematical skills and related factors of the bachelor-level engineering applicants (to UASs). The research questions were: 1) What is the level of advanced mathematical skills of engineering applicants? 2) What factors are related to advanced mathematical skills of engineering applicants?

2 METHODOLOGY

2.1 Design, setting, participants and data collection

A cross-sectional study was conducted. Altogether, 20 UASs that were geographically spread out and that used the UAS Exam in autumn 2019 participated. Engineering applicants (bachelor level) who answered the advanced mathematical skills section in the UAS Exam and gave their consent were included. The collected data comprised the applicants' automatically calculated exam scores from the digital exam system and background variables of age, gender, previous education, socioeconomic background (according to mother/father), place of birth (own/parent) and study programme/field of an applicant. The applicants performed the UAS Exam under supervision at the participating UASs using their own devices between 29 October 2019 and 1 November 2019. Approval to undertake the study was granted by the UASs, and ethics committee approval for the study was obtained (27 September 2019).

The advanced mathematical skills exam section assesses applicants' abilities in mathematics and physics. The problems concerning mathematics involve simplifying algebraic expressions, solving equations and problems involving plane geometry and trigonometry, for example, a right-angled triangle. Physics problems involve conclusions and calculations based on the given physical models or basic knowledge related to physical phenomena, as well as interpreting charts and graphs. Unfortunately, the more specific presentation of the concrete exam questions is beyond the scope of the current paper. In autumn 2019, there were altogether seven exam questions (multiple choice). The maximum scores were 20, the minimum pass score was 1, and penalty scores were used to avoid guessing behavior.

The validity evaluation of the advanced mathematical skills exam section was conducted as part of a larger research project (8). In the research project, the exam questions were evaluated by an expert panel and pilot tested, and psychometric testing utilising both classical test theory and item response theory methods was conducted (8).

2.2 Data analysis

The data were analysed using the Statistical Analysis Software (SAS 9.4®). Descriptive statistics were used to describe the applicants' success in the advanced mathematical skills section (exam scores) and describe the demographic characteristics. The relating factors were analysed from two perspectives: by analysing the associations between the background variables and exam scores and between the background variables and failed exam results (i.e., the applicant scored below the minimum pass score limit). Analysis of variance with Tukey's test in post hoc multiple group comparisons was used to analyse those factors related to the applicants' exam scores. Logistic regression analysis was used to explain applicants' failed exam results and related factors. The data were analysed as part of a wider research analysis focusing on the exam results for the entire UAS Exam and its sections. Therefore, all the background variables were included in our analysis. However, the variable of 'study field' is not reported in the current study because its practical importance was considered minimal because only the engineering applicants performed the advanced mathematical skills exam section.

3 RESULTS

3.1 Applicants' demographic characteristics

Altogether, 1205 out of 1756 engineering applicants participated in the study (response rate 68.6%), thus performing the advanced mathematical skills section in the UAS Exam. Most of the applicants were 20–24 years old, and less than 10% of the applicants were younger than 20 years old (Table 1). Two-thirds of the applicants were male. Most of the applicants were high school graduates or had a vocational diploma. Applicants' parents were most often manual workers by their socioeconomic background. Most of the applicants were born in Finland. (Table 1.)

Table 1. Demographic factors of the participants (n=1205).

Demographic factor	**f**	**%**
Age		
< 20	108	9.0
20–24	479	39.8
25–29	261	21.7
> 29	357	29.6
Gender		
Male	866	71.9
Female	339	28.1
Previous education		
High school	469	38.9
Vocational school	431	35.8
Double qualification (high school and vocational school)	43	3.6
Higher education degree	93	7.7
Other	169	14.0
Socioeconomic background (father)		
Self-employed persons	215	17.8
Upper-level employees (with administrative, managerial, professional and related occupations)	202	16.8
Lower-level employees (with administrative and clerical occupations)	193	16.0
Manual workers	417	34.6
Students	27	2.2
Pensioners	114	9.5
Others (Unemployed)	37	3.1
Socioeconomic background (mother)		
Self-employed persons	115	9.5
Upper-level employees	154	12.8

(with administrative, managerial, professional and related occupations)		
Lower-level employees (with administrative and clerical occupations)	297	24.6
Manual workers	476	39.5
Students	25	2.1
Pensioners	73	6.1
Others (Unemployed)	65	5.4
Place of birth (own): born in Finland		
Yes	1107	91.9
No	98	8.1
Place of birth (parent): one parent or both parents born outside Finland		
Yes	156	12.9
No	1049	87.1

3.2 Applicants' advanced mathematical skills and related factors

The applicants' mean scores in the exam section of the advanced mathematical skills were 4.8 (SD 5.2, median 3.9, range -4.9–20 pts) out of 20 maximum points. Over 20% (n=299, 24.8%) of the engineering applicants failed (scored less than +1 points). The score distribution of the applicants is presented in Figure 1.

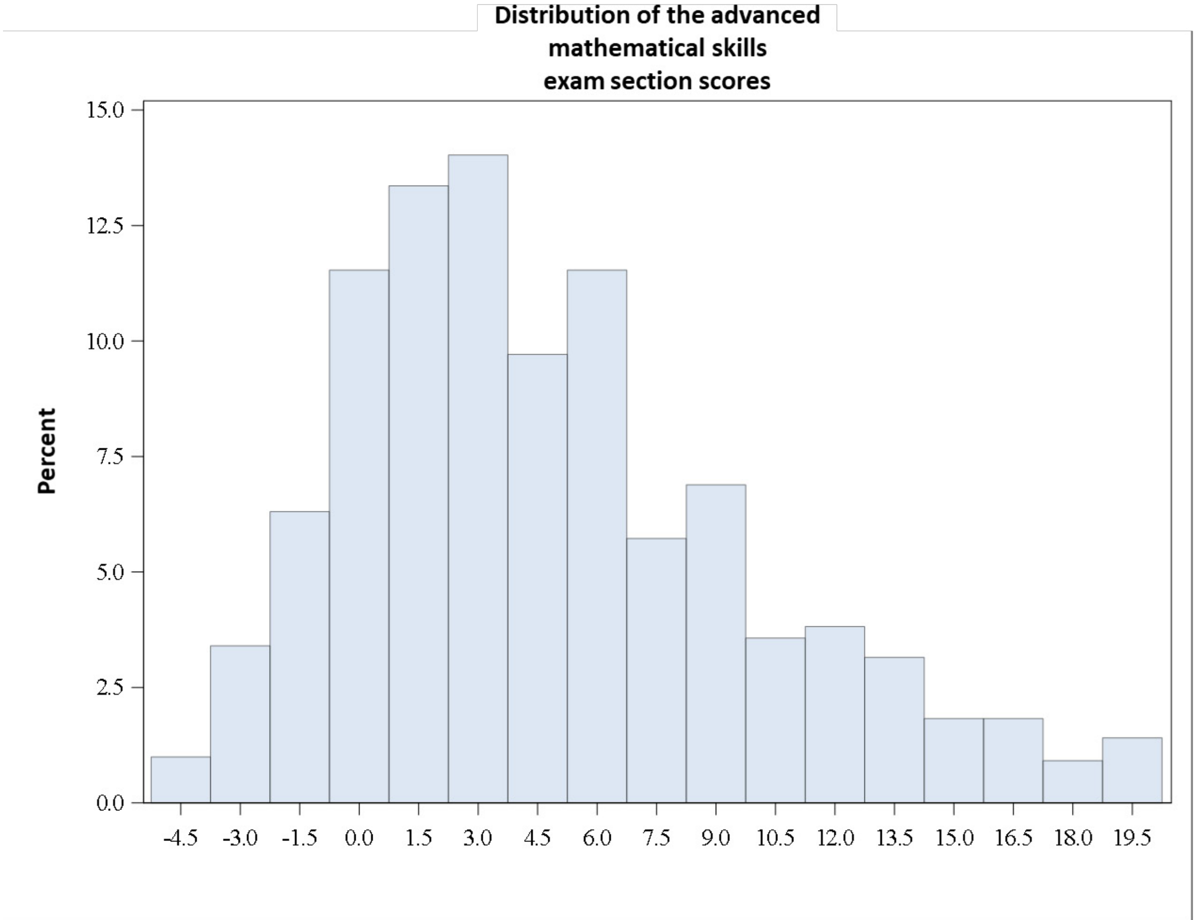

Figure 1. Score distribution of the advanced mathematical skills exam section.

Age, gender and previous education explained the applicants' success in the advanced mathematical skills exam section (Table 2). The oldest applicants (> 29 years) scored better than the youngest age groups (< 20 years and 20–24 years), and male applicants scored better than female applicants. Concerning previous education, the main result was that those applicants with previous higher education degrees and who graduated from high school scored better than the applicants with vocational diplomas. (Table 2.)

Table 2. Factors related to engineering applicants' (n=1205) advanced mathematical skills.*

BACKGROUND VARIABLES	**TOTAL SCORES** Difference between means (95% confidence interval), **p-value**/NS = not significant
Age	
20–24 vs. > 29	-1.44 (-2.41– -0.46), **0.0009**
< 20 vs. > 29	-1.64 (-3.09– -0.18), **0.0201**
Gender: Male vs. female	1.79 (1.13–2.44), **<.0001**
Previous education	
Vocational school vs. higher education degree	-3.75 (-5.37– -2.12), **<.0001**
Vocational school vs. high school	-2.69 (-3.63– -1.75), **<.0001**
Higher education degree vs. other	3.54 (1.70–5.39), **<.0001**
Other vs. high school	-2.50 (-3.78– -1.22), **<.0001**
Socioeconomic background (father)	NS
Socioeconomic background (mother)	NS
Place of birth / own	NS
Place of birth / parent	NS

*Only the statistically significant results in group comparisons are presented.

Gender and previous education were the only background variables explaining the failed exam results (Table 3). Female applicants were more likely to fail than male applicants. Applicants with vocational diplomas were more likely to fail than those with previous higher education degrees and high school graduates. (Table 3.)

Table 3. Background variables explaining engineering applicants' failed exam results in the advanced mathematical skills section (n=299/N=1205).

	OR*	**95% confidence interval**	**p-value**
Age	-	-	NS
Gender: Male vs. female	0.48	0.36–0.65	**<.0001**
Previous education			
Higher education degree vs. vocational school	0.39	0.21–0.71	**0.0024**
Other vs. vocational school	1.06	0.71–1.59	NS
High school vs. vocational school	0.54	0.39–0.75	**0.0002**
Double qualification vs. vocational school	0.64	0.30–1.37	NS

Socioeconomic background (father)	-	-	NS
Socioeconomic background (mother)	-	-	NS
Place of birth / own	-	-	NS
Place of birth / parent	-	-	NS

**OR = Odds Ratio. When the OR is higher than 1, there are more failed exam results in the group on the left than in the right one. When the OR is lower than 1, there are less failed exam results in in the group on the left than in the right one.*

4 SUMMARY

The purpose of the current study was to assess advanced mathematical skills and the related factors of the bachelor-level engineering applicants (to UASs). A new objective and digital assessment method (UAS Exam) was used. The results indicate that engineering applicants' advanced mathematical skills were rather poor and that a considerable number of applicants failed the exam section. In Finland, advanced mathematical skills, such as mathematics and physics, have been assessed for years in engineering student selection. Previously, it has been reported that entry-level engineering students lack the basic abilities in mathematics and physics, and the failure percentage in engineering entrance examinations can be very high (9). According to recent educational statistics in Finland, the number of UAS applicants who have included the physics test on their matriculation examination (a national examination taken at the end of Finnish upper secondary school) is rather low (10). Based on the results of the present study, it is possible that many UAS engineering applicants lack the basic skills in mathematics and physics, but there may be a large amount of variation between applicants and, thus, between prospective students' skills. These results should be acknowledged both in the upper secondary level when preparing students for higher education studies and in the entry/first semester of the UAS studies to find solutions that can help in filling the gap in new students' skills. Overall, it is not ideal to fail a high number of applicants in student selection. However, it is possible that the applicants' low exam scores may also relate to the difficulty level of the exam and use of penalty scores. Therefore, the scoring technique and difficulty of the advanced mathematical skills section should be further evaluated. The study results indicate that some background variables may explain engineering applicants' success and failed exam results. Male applicants scored better than females, but men were the major applicant group. An important result is that high school graduates scored better than applicants with vocational diplomas. Upper secondary education (11) should prepare students for higher education studies, but it seems that high school graduates are better prepared than those applicants with vocational diplomas. The results of the current study highlight the importance of preparing upper secondary students for higher education studies, especially in vocational education. The results can be used in further development of the UAS Exam and of fair and objective student selection practices. Furthermore, the results have international implications because HEIs are encouraged to develop their student selection practices (3).

ABSTRACT

This is a position paper presenting the scenario and main conditionings that delimit approaching the technological and digital (re/up)skilling problem by also enhancing the role of the university as a regional ecosystem key player. This is the main objective of COMPASS, an initiative initiated to face actual challenges on the labour market related to the digital skills mismatch. COMPASS goal can be stated as the development of a regional ecosystem-based training platform and associated methodologies for effective and efficient skilling pathways. COMPASS as a guiding tool is conceived to a) guide individuals and companies to get a closer idea of the skills-gap they need to cover, as well as to b) help universities as training providers to elaborate their offer on the basis of the detected regional needs. This will definitively help to make the overall ecosystem more efficient. On the other hand, COMPASS is also conceived as a learning & training environment, in the sense of a) dynamic micro-learning environment providing easy and mobile interaction between the learners and the content and b) micro-credential system linked to the achieved skills.

1 INTRODUCTION

Today we are experiencing what has come to be called the Fourth Industrial Revolution or Industry 4.0, in which digitalisation is one of its most important pillars, while at the same time we are on the verge of a green transition towards a decarbonised and environmentally friendly economy. This is the so called Twin Transition to a green and digital economy firmly grounded in the objectives of the European Green Deal. Digitalisation can go further than is currently planned by facilitating the shift to a more sustainable production. Technologies such as blockchain, automation, machine learning, additive manufacturing, digital design, digital twins allow additional degrees of freedom for designers and engineers to create products that emit less CO2 during their manufacturing phase, use (and re-use), and more value creation across the whole value chain, including wide based manufacturers. This twin transition is imposing urgent challenges to individuals and companies that need to face nowadays on the labour market. However, are companies prepared for this twin transition? What enablers they need? These facts, jointly with the COVID-19 pandemic have put a renewed focus on the core question: What will be the future of work, workers and workplaces? [1]

In this communication we present the drivers that motivated out university to face the technological and digital (re/up)skilling problem, specifically for adult population, as well as the conception of COMPASS as a platform to enhance the role of the university as key player on its regional ecosystem. On that respect, COMPASS, an initiative lead by the university but with the engagement of different societal players. Main purpose is to face some of the needs society 4.0 is facing for adult learning specially with respect to the engineering education related to technology ans digital skills. Those needs are basically related to the skills needed to surf the Twin Transition; for an appropriate career guidance as well as an effective and efficient upskilling & reskilling formation offer. Career guidance can facilitate re-employment by identifying new job opportunities and proposing relevant training. However, coordination of the many actors involved in such career guidance is a challenge. Career guidance is a fundamental policy lever to help adults successfully navigate a constantly evolving labour market through advice and information on job and training opportunities. Most adults who do not train say that there was no training offer that they wanted to take up. This may reflect a lack of understanding of the importance of training in today's labour market, or difficulties in identifying suitable training opportunities. The concept of adult himself is changing, who are today's decision makers and voters sustaining or influencing change in Europe. Their knowledge, capacity and learning build the groundwork to address the urgency of recovery, to decrease the burden for next generations and to pave the way to the future that Europe anticipates.

The rest of the communication is intended to present the elements that constitute the scenario as well as the proposal approach for the COMPASS platform. The scenario includes considerations about the future-proof education, the role of the universities and the considerations about a platform for appropriate reskilling/upskilling. Finally the components of COMPASS are presented. It is worth to say that in its actual stage, COMPASS is a project under development that is focused on the digital skills

FUTURE-PROOF EDUCATION

One of the indisputable consequences of the covid19 pandemic crisis is the acceleration of changes that were on the agenda of almost all universities but remained at the horizon. The crisis has motivated an urgency for teaching online and this has brought new ways of teaching and learning, look for innovative uses and new ides with respect to the adoption of technology as a key educational tool. Much of those changes have proven to be really useful and will definitively stay as the crisis is remitting. Therefore, modernizing the on-campus learning.

The mass adoption of technology has clear benefits, as it will allow universities to reach more people, provide new communication channels and the use of a wide variety of educational resources. However, personalization and human interaction are important, too. Those are key aspects to consider when looking for a future-proof education.

In his communication *on a European strategy for universities* (Strasbourg, 18.1.2022),[2] the European Commission clearly delivers the message that Universities have to adapt to the rapidly evolving situation regarding skill needs: *The green and digital transitions require future-proof education, research and innovation, in close cooperation with the related industries and stakeholders and the significant disparities in digital skills across the EU must be overcome*. Therefore, universities need to be put at work to tackle those needs as a societal challenge. The reference to future-proof education is not a minor issue and introduces some considerations (constraints?) to highlight for universities to face educational needs for the coming future. So whatever the adopted solution, the educational approaches should take into consideration:

- **Embrace technology:** The adoption of technology has made possible the continued delivery of education even the challenging situation we faced during the last two years. This fact has lead digital transformation of educational tasks at an incredible pace. Among them, the hybrid learning approach has opened new doors and made students' expectations to grow because of added flexibility.
- **Optimize human interaction:** Even technology provides means for a distance learning of improved quality, it is needed to put special attention to the added value of student and teacher meet face to face and spent time together, interacting. This time window should be focused on probing questions, look into student understanding, finding areas needing more clarity and having meaningful discussions and dialogue. Students can use recorded videos. Those are now a well-established resource (widely used, for example,

in the flipped classroom approach). They can review it at their own pace, on an asynchronous way, but they will not completely replace in-person time

- **Personalize content:** The use of online learning based on Learning management systems (LMS) either as a complement to presential on-campus education, hybrid-based approaches or on full on-line education, constitutes an unprecedented opportunity to use data analytics to understand individual learning and to tailor education for that learning. This allows learning and content to be adapted to evolve with the learner much more quickly. The use of interactive elements such as polls or questions, with informed, tailored personalized support can accelerate learning. As data reveals content that students find most challenging, the lecturer, tutors, and teaching algorithms can focus instruction in these key areas to improve learning outcomes.
- **Reach more people:** This has been one of the clear benefits the adoption of technology has put on the table during the pandemic crisis: being able to reach larger audiences than on pure presential formats. There is no discussion on this. The world's population is shifting, internationalisation is increasing, and in a closer future, our students will be coming from different places than they are now. We expect to see increasing demand for higher education from students in places such as India and Africa and it is becoming much easier to reach those students and make further learning more equitable.

All the presented factors, put on the shelf considerations that should be taken into account when desgining training and learning approaches. Specifically for specific targets such are, in this case, adult people. Therefore, by combining our use of technology, optimizing our human interactions and personalizing our instruction will allow us to stay relevant and in demand through the changes ahead.

2 THE ROLE OF UNIVERSITIES

Future jobs will be more diverse, demanding, flexible. There will be more entrepreneurs and more people working in small and medium size enterprises. This complex future is driven by the new roles that will be (in fact are being) created by the Fourth Industrial Revolution, shifts in the global economy and industrial transitions towards sustainability. Those shifts are the drivers for the EU Skilling Agenda. How will University prepare himself for this complex future? Whatever will be the adopted strategy, there is no doubt in that this preparation will need to take place in coexistence with the complex world to which people is being prepared for. What is the role of university in this new ecosystem? [3]

There are clear positionings at governance level that points the central role of higher education systems in this new panorama. The World Economic Forum, The World Economic Forum launched in 2021 the *Reskilling Revolution* [4], an initiative to provide people with better education, skills and jobs by 2030. The scheme aims to future-proof workers from technological change and help economies by providing new skills for the Fourth Industrial Revolution. This is reinforced by the European

Higher Education Area (EHEA) Rome Communiqué 2020 [5] that has already brought reskilling and upskilling to the forefront of the debate on changing the tertiary educational offer. This excerpt from the EHEA Rome Communiqué is a clear statement of this positioning "*higher education institutions have the potential to drive major change – improving the knowledge, skills and competences of students and society to contribute to sustainability, environmental protection and other crucial objectives. They must prepare learners to become active, critical and responsible citizens and offer lifelong learning opportunities to support them in their societal role*."

The report *Upskilling for Shared Prosperity* [6] finds that dual vocational training systems are particularly effective in emerging and developing countries – by combining theory and training embedded in a real-life work environment. Despite these encouraging trends, the global education and training sector remains fragmented and would benefit significantly from the emergence of a more comprehensively interconnected ecosystem.

The previous situation is reflecting the starting point of a changing higher education landscape where some fundamental questions, not appeared nor raised before, are appearing. With this perspective in mind, learning demand is shifting to a fundamentally new paradigm. What is the best way of tackling this uncertain and complex future is a question with no answer. However, for these situations it is worth to devise plausible scenarios that stimulate university leaders to formulate appropriate questions, to analyse global trends and detect opportunities and threats. There will be the need for a continuous criticism regarding the resilience of current strategies regarding new patterns and emerging trends.

One of the clear positionings that the University should redefine himself is that of collaboration with local or regional social, cultural and economic stakeholders. This is usually seen less significant than research or international collaboration. Too often also, about associating university with the world of work. There is therefore the need for a shift in perspective from the university governance with regard to the societal compromise of the university. This applies specially for what matters to lifelong learning for adult people when we refer to technology and digital skills.

3 MICROLEARNING AND SKILLING PLATFORM CONSIDERATIONS

The constant and rapid evolution of knowledge, specially within the technological domains, requires workers to adapt to this new context in order to maintain their productivity. Therefore, increase opportunities within a new more dynamic labour market. Micro-learning comes into play to facilitate this process to potential learners by breaking down new concepts into small fragments or pills of content, also called micro-content. These small learning units are given to learners progressively and in a way that is suited to them [7].

The combination of several factors has stimulated the development and the positive reception of the micro-learning paradigm: i) the human capacity to stay focused on a single item, avoiding distraction and inattention, has decreased; ii) very quick changes in all areas, especially in technology, have resulted in workers needing to update their training constantly; and iii) traditional training is not proving to be a good method to train workers effectively and efficiently.

In any case, offering adequate environments that can be totally integrated into the working processes is not a trivial aspect. An inappropriate training environment may result in high drop-out rates. This is clearly reflected in the use of MOOCs (Massive Open Online Courses) as a complement to daily work activity, with more than 90% of dropouts in this context, due to a range of reasons [7]. Accessibility is the main motivation of many students, who use the platform at their convenience for training without following the guidelines of the course in an exact way. Definitively this puts a very interesting challenge on the table of trainers, specifically at HEI. In fact, the difficulty in designing training content that is adequate for learners is not constrained to the field of continuous training for adults/employees, but it can also be used in other areas such as the university. Therefore, it is clear that the university itself will experiment a clear benefit of dealing with continuous learning as a direct multiplier effect.

These small lesson plans are gradually given to students in a way that is tailored to their needs, with the aid of telematics devices. For those employees who must be trained as an indispensable process in their professional career, micro-learning perfectly fits in by introducing short units of content, usually in audiovisual format, which can be digested in downtimes between activities. According to the main recommendations found in the literature, we consider that each unit of micro-content must be composed of three elements: a brief introduction or description, the development or explanation of the content and a small section to assess knowledge acquisition.

In order to support a micro-learning approach, it is necessary to provide activities and to facilitate the design of adequate training sequences. The Microlearning materials should be able to draw attention to very specific and clear aspects; besides, there should be complementary materials which enable learners to directly participate in their generation, assembling and modification. It is important to find a balance between brief format and complementary information. Finally, it is especially interesting to promote the micro-learning for communities, where materials derived from the training activities themselves are accessible for the student community in a manner that they can serve as a basis for debate, as support material for new activities or simply as a reference to consult.

The composition of micro-content to elaborate or define training sequences requires a system which can provide solutions to store, to locate and to compose micro-content. The cloud computing paradigm fits in perfectly with the concept of micro-learning, since if the latter is characterized by the use of brief educational resources upon request, the cloud computing paradigm is also supported by the flexible use of resources (hardware, software, storage, computation, etc.) whose amount dynamically varies depending on what is needed at each particular moment. Consequently, the application of this paradigm to the provision of micro-learning environments can be considered as a natural evolution from the first platforms based on web environments, which would allow the availability of storage, backup services and computer services, elastically provided depending on the needs at each moment, and at a more affordable cost.

There is a wide range of options when deploying a micro-learning platform. In spite of the difficulties they must face, some proposals have proved successful in this context. The appearing of some commercial solutions providing the explicit characteristics that, especially for corporate training, workers do need because of the difficulty of combining training and their normal work. On the other side, Universities do conduct formal education lying on Learning Management Systems (such as Moodle, edX, etc). Those environments where not initially been designed to support the features needed to develop, manage and deploy micro-content and implement micro-learning solutions.

At this point is where a hybrid solution comes into the table to be explored. In a similar way such as formal education is not considered an appropriate option for the corporate context, a hybrid approach that combines formal training, work experience and informal training has proven to be effective, why not to analyse an integration of micro-learning activities in traditional distance learning frameworks?

The advantages of using an existing learning platform include (i) familiarity with the environment on the part of both technicians and professors, (ii) a range of tools to manage users, profiles, permissions documents, etc. and (iii) continuous updates and improvements in terms of security and functionality.

There are however some of the essential features of micro-learning that deal with the interaction between the learners and the content. This needs further analysis and, probably, some developments. For example, since one of the relevant aspects of micro-learning is the active participation of learners in the process of co-creation and distribution of micro-content there is the need to ensure the environment is providing the mechanisms to allow both students and professors to have a more collaborative role in the creation and learning processes.

4 METHODOLOGY

From the methodological point of view, COMPASS as a skills guiding tool will be elaborated incorporating regional ecosystem activity, sector-based skills taxonomy and introducing technological trends as a source for pointing at the near future needs. Therefore, the tool is conceived from the regional ecosystem detected needs and from a transnational point of view for what matters to implementation of the learning platform. This approach will foster expertise synergies among EU HEI that will collaborate in the joint micro-learning offering. The development is conceived in terms of the following steps and activities.

4.1 Skills Taxonomy

Methodological approach to skills characterization in the technological, digital and green domains from a taxonomical point of view. This encompasses some steps forward in the characterization of skills. The elaboration of a detailed skills taxonomy is intended to allow for a statistical monitoring of brain circulation and to establish a set of indicators to allow monitoring and statistical analysis of training needs to properly redefine current offer. For example, defining a taxonomy of skills for the green transition, which will allow the statistical monitoring of the greening of our professions. This skills taxonomy should be developed jointly with the complicity of the regional ecosystem. Therefore, regional industry associations have been contacted and will take part on the skills taxonomy definition. This is a key point because ethe establishment, denomination and definition of the skills should be understood from both sides of the equation, academy and potential recipients.

4.2 IT Tool for Skills Taxonomy Management and Data Gathering

This It tool is intended to feed a database defined in terms of the previous taxonomy. The data will be collected from the regional ecosystem and will provide a data base to enable decision making regarding training offers. The fact of facing training offers in terms of a skills-based approach will enable new pathways to employment by allowing a more tailored training offer in terms of the detected gaps (actual skills map, technological trends, regional job market, etc)

4.3 Ecosystem Engagement

Once the Skills Taxonomy is established and the IT tool for management implemented, ecosystem engagement will be worked out by means, for example, of a series of sessions organised by umbrella assciations and joining companies, work placements, regional governments, adult organisations, etc. Main purpose is to present the faced problem on career guidance as well as the prospective for the COMPASS tool will be presented. These sessions will contribute to elaborate a radiography of the skills status of a region/economic area/company/etc. Allowing for trends in economy and technology to be introduced, skills gaps will also be reflected, and skilling pathways based on similarity profile.

4.4 Ellaboration of the Carreer Guidance tool

This career guidance tool will be elaborate to operate on the skills taxonomy dabase that refects the state of the region. On the basis of actual challenges, desired skills, individuals as well as companies can test heir position with respect to the needed skills. The detected gap will suggest the most appropriate training. As per the university concern, what is relevant is the picture of the detected skill gaps at regional level. This should drive the university on what is the more suitable offer on lifelong learning if it has to impact on the region.

5 COMPASS CONCEPTION

COMPASS is conceived as the development of a regional ecosystem-based training platform and associated methodologies for effective and efficient upskilling and reskilling.

COMPASS as a platform is conceived as integrated by two key elements: a) skills guiding tool and b) a dynamic micro-learning based training offer. COMPASS as a skills guiding tool will be elaborated incorporating industrial activity, sector-based skills taxonomy and introducing technological trends as a source for pointing at the near future needs. COMPASS guiding tool is conceived to:

- Guide individuals and companies to get a closer idea of the skills-gap they need to cover.
- Help universities as training providers to elaborate their offer on the basis of the detected regional needs. This will definitively make the overall ecosystem more efficient.
- Provide a skills monitoring dashboard to facilitate a dynamic micro-learning based offer to cover the actual and forecasted needs.

On the other hand, COMPASS as a micro-learning based training environment:

- Dynamic micro-learning environment providing easy and mobile interaction between the learners and the content.
- Micro-credential system linked to the achieved skills.
- Incorporation of a challenge based system to help drive the learning pathway to the appropriate micro-modules

The tool is conceived from the regional industrial ecosystem detected needs and from a transnational point of view for what matters to implementation of the learning platform. This approach will foster expertise synergies among EU HEI that will collaborate in the joint micro-learning offering.

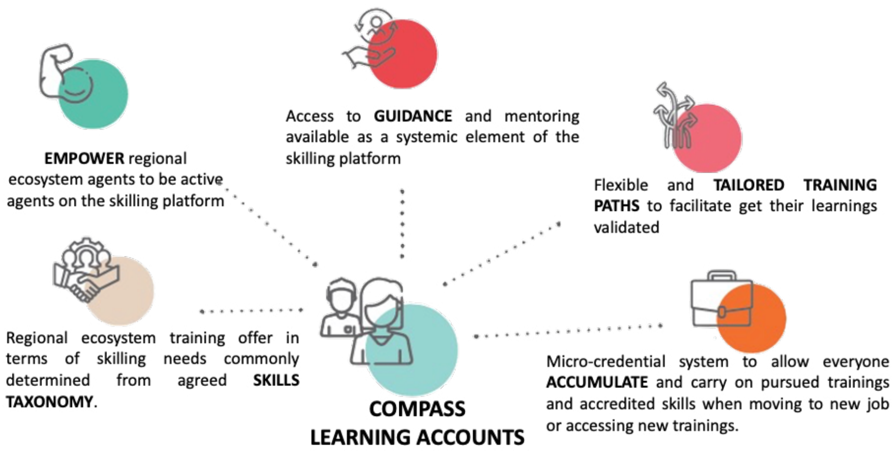

Fig. 1. COMPASS

6 SUMMARY AND ACKNOWLEDGMENTS

This communication has presented the scenario that drives an higher education institution to be involved into the training activities oriented to increase the labour effectiveness of the surrounding ecosystem. The settings are the ones linked to the COMPASS initiative that is focused on the technological, digital and green skills. The overall picture has been presented and the key role universitie should play into those regional ecosystems highlighted. The point of introducing a shift into the perspective of better valorising education in front of just doing research will by sure have a mid-long term impact on a more global level.

ABSTRACT

Ethics is considered an essential aspect of tertiary computer science and engineering education and forms a core part of professional accreditation for degree providers. The authors have been unable to locate a study in New Zealand on computer science and engineering students' ethical beliefs, making this study an important exploration in this field. This study investigates the incoming first-year

doi:10.5821/conference-9788412322262.1247

cohort's beliefs and understanding of ethical issues across three areas: students, future employees and members of society. We conducted the study over two consecutive years to investigate cohort beliefs. For most questions, the students provided high ethical responses, except in the areas of "software piracy and copyright" and "misuse of computer resources". In one year a small but significant number of female students indicated very low agreement that plagiarism is unethical. This research identified the importance of gaining an insight into student ethical beliefs as cohorts can differ in opinions. The findings challenge the common practice of teaching the same material over multiple years with the recommendation that teaching is adapted to address differences in students' ethical beliefs.

1 INTRODUCTION

1.1 Background

In both engineering and computer science education there is a recognised need by professional bodies and tertiary institutions to educate students in ethical responsibility and reasoning [1]–[3]. Despite this goal, the international literature indicates that there is widespread differences in approach and limited evidence on the effectiveness of many existing curricula [4]–[5]. In the New Zealand case there is no significant body of literature that looks at effectiveness of teaching, students ethical beliefs, or relevant context.

Our School of Engineering and Computer Science programme at Victoria University of Wellington, New Zealand (VUW) teaches a Bachelor of Science (BSc) and Bachelor of Engineering with Honours (BE) in digital technology fields. There is no instruction on ethics in the first-year programme and both degrees share many technical courses. Ethics education within our programme is primarily delivered via second- and fourth-year professional engineering courses in the BE.

2 METHODOLOGY

2.1 Survey, Data Collection and Analysis

This study aims to identify the strength of ethical belief of our incoming BSc and BE students from three perspectives: as students, as employees and as members of society - asking from different viewpoints allows identification of features in the responses indicative of the character of student understanding of ethical issues. We used a modified version of the survey instrument developed to assess ethical perceptions by Omosalewa Aderonmu, Cheryl Aasheim, and Paige Rutner, from Georgia Southern University, USA [6]. The full survey can be found here: https://bit.ly/35wjty4. The VUW ethics committee approved this research (ref. 0000027448). Questions are grouped into the three perspectives and responses are requested on a 5 point Likert scale where 1 is "strongly disagree" and 5 is "strongly agree". Table 1 in section 3 lists the survey questions. The surveys were distributed in paper form in the courses COMP103 "Introduction to Data Structures and Algorithms" in trimester 2 of 2019 and in COMP102 "Introduction to Computer Program Design" in trimester 1 of 2020, within the first three weeks of the courses.

These courses were chosen because all BE and BSc students are required to pass both of these courses. The response rate was 45% in both years and the results were manually entered into Qualtrics [7]. In our analysis we divide responses into "buckets" with scores of 4 and 5, indicating positive agreement with the ethical position described in the questions, while grouping responses in the range 3 – 1 into a "bucket" indicating the student needs ethical education ("needs education").

3 RESULTS

3.1 Average responses on the Likert scale

How a student answers the survey questions, as a student, employee or member of society, reveals their ethical understanding. The overall results indicate generally high (> 4.0) average agreement with the ethical statements, but differences between responses within each viewpoint reveals evidence of ethical relativism on issues which should be important for students studying toward careers in digital technology. Table 1 shows the average response to each survey question in 2019 and 2020 surveys; the full results of the surveys are available online.

Table 1. Average responses to questions in 2019 and 2020

Question	Text	2019	2020
As a student I believe it is unethical to:			
Q6.1	Take credit for someone else's work	4.5	4.5
Q6.2	Hire someone to write an essay	4.5	4.3
Q6.3	Purchase or submit a research or term paper from the internet to a class as one's own work	4.6	4.5
Q6.4	Cheat on a graded assignment	4.5	4.5
Q6.5	Cheat on an exam	4.5	4.5
Q6.6	Plagiarize other people's work without citing or referencing the work	4.4	4.4
Q6.7	Add the name of a noncontributing person as an author in a project/research study	3.9	4.0
Q6.8	Copy and paste material found on the Internet for an assignment without acknowledging the authors of the material	4.1	4.3
Q6.9	Deliberately provide inaccurate references for a project or research study	4.2	4.3
Q6.10	Knowingly permit student work done by one student to be submitted by another student	4.2	4.4
As a student I believe it is unethical to			
Q7.1	Surf the internet for personal interest and non-class related purposes during classes	2.4	2.6

Q7.2	Make a copy of software for personal or commercial use	3.2	3.2
Q7.3	Make a copy of software from a friend	3.0	3.1
Q7.4	Download pirated software from the internet	2.8	3.4
Q7.5	Distribute pirated software from the internet	3.2	3.7
Q7.6	Buy software with a single user license and then install it on multiple computers	3.6	N/A
Q7.7	Share a pirated copy of software	3.3	3.6
Q7.8	Install a pirated copy of software	3.2	3.3
As an employee I believe			
Q8.1	Providing unauthorised access to other people's personal information to be unethical	4.7	4.7
Q8.2	I have an obligation to respect and protect the integrity of intellectual property and confidentiality agreements	4.5	4.6
Q8.3	Using social media networking as a tool for cyber bullying to be unethical	4.6	4.6
Q8.4	It is unethical, and potentially unlawful, to take an unathorised copy of someone else's work	4.5	4.5
Q8.5	Ethical behaviour is better understood by students in your major than students in other majors	2.8	3.0
Q8.6	Education has an influence on one's ethical behaviour	4.0	3.8
Q8.7	Being ethical is important in the information technology sector	4.4	4.4
As an employee I should			
Q9.1	Not disclose confidential organisational information to co-workers without authorisation	4.6	4.6
Q9.2	Uphold and abide by the laws, code of conduct, ethical and moral principles of my organisation	4.6	4.6
Q9.3	Not violate the privacy and confidentiality of information entrusted to me to further personal interest	4.7	4.7
Q9.4	Not surf the internet for personal interest and non-work related purposes at work	3.3	3.4
Q9.5	Not involve in the act of phishing (unathorised stealing of people's valuable data)	4.8	4.8
Q9.6	Not involve in the act of email spoofing (deformation of email phishing purposes)	4.7	4.8
Q9.7	Not violate other people's privacy with the use of internet	4.7	4.7

	monitoring devices		
Q9.8	Not use technology to infringe on other people's privacy rights	4.7	4.7
Q9.9	Adhere to strict confidentiality rules regarding privacy and proprietary matters	4.7	4.6
As a member of society, I should			
Q10.1	Advise in an honest and trustworthy manner to enable people to behave ethically	4.5	4.4
Q10.2	Be ethical in my behaviour in all aspects of life	4.3	4.3
Q10.3	Protect fundamental human rights	4.7	4.6
Q10.4	Respect the diversity of all cultures	4.7	4.6
Q10.5	Abide by and not violate the laws of the country and community	4.4	4.5
Q10.6	Not misuse computing or technology resources	4.3	4.3
Q10.7	Report and violations of ethical regulations to an authority	4.1	4.2
Q10.8	Protect against the act of piracy (downloading or copying copyrighted music/video/books/software or any electronic materials)	3.4	3.5
Q10.9	Take action if I catch someone involved in unethical use of computing resources	3.6	3.8
As an employee, I believe			
Q11.1	Establishing an organisational code of ethical standards encourages employees in that organisation to behave ethically	4.2	4.3
Q11.2	Establishing a code of ethics for professionals encourages professionals to behave ethically	4.3	4.3
Q11.3	Students acquire and develop their ethical standards by taking ethics as part of the curriculum	3.6	3.6
Q11.4	Ethical standards are important in programmes. Ethical standards should always be included in the curriculum	3.8	4.0

Questions 6 and 7 ask, from the perspective of a student, for an assessment of matters related to academic integrity and software piracy and copyright violation. The contrast in responses is stark: most Q6 responses are greater than 4.1 while most Q7 responses are less than 3.7; the distributions are explored in detail in section 3.2.

Questions 8 and 9 ask for the ethical perception from the perspective of an employee, regarding obligations to society and their employer with respect to privacy, confidentiality, copyright, intellectual property, and ethical behaviour. These two questions consistently received the highest average responses. Both cohorts rate the ethical understanding of their peers in other majors as neither better nor worse than their own (Q8.5 “neutral” 3.0 average.) The influence of employment vs.

academic context may also be seen in the results of question set 11 regarding codes of ethics, where higher average responses are given to organisational importance (Q11.1, Q11.2) than academic importance (Q11.3, Q11.4).

Question 10 is asked from the perspective of a member of society regarding personal behaviour. The majority of responses to these questions indicate a sentiment of high ethical obligation to society from both cohorts. The exceptions are questions 10.8 and 10.9, regarding copyright violation and the unethical use of computing resources, and are notable because they are consistent with context-sensitivity displayed in the lower average responses to Question 7.

Ethical relativism is where ethical belief is attributable to context, be it cultural or social norms while in contrast, ethical absolutism holds that ethical situations have definitive answers regardless of context [8]. The absolutist response to the survey would be "strongly agree" to every question. We find in the results consistent ethical relativism related to the personal identity as a student, reflecting the students understanding of social norms in their peer group. This relativism is most pronounced in question set 7 but also discernible in several other questions, for example, a reluctance to report peers visible in the response to Q10.9, or the different average responses to Q6.1 and Q6.7 which ask the same fundamental ethical question. The dichotomy seen in the average responses to question set 11 is also consistent with a relativist interpretation that ethical understanding is acquired in the context of employment rather than learned in an academic context.

3.2 Distribution of ethical sentiment within the Likert scale

Question Q6.7 was identified receiving the lowest average response in the Question 6 set regarding academic integrity, despite its close relationship to Q6.1. Question Q6.1 asks whether it is unethical to take credit for someone else's work while Q6.7 effectively asks whether it is unethical to give credit for someone else's work. Both are violations of academic integrity by the misrepresentation of authorship. The distribution of responses for these two questions is revealing and are shown in Table 2. In both years 90% of students agree, with around 80% strongly agreeing, with the statement that taking credit for someone else's work is unethical. In contrast, around only 37% – 43 % of students strongly agree with the statement that giving credit for someone else's work is unethical and 26% – 30% are neutral or disagree. Question Q6.7 provides an example of clear differences in response between the 2019 and 2020 cohorts, with a shift of around four percentage points toward stronger sentiment that "gift authorship" is unethical in the 2020 cohort.

Table 2. Distribution of responses for Questions 6.1 and 6.7 in 2019 and 2020

Question 6 As a student I believe it is unethical to:	Bucket	2019	2020
Q6.1 Take credit for someone else's work	Needs education	10.8%	11.0%
	Somewhat agree	8.9%	11.0%

	Strongly agree	80.4%	78.0%
Q6.7 Add the name of a noncontributing person as an author in a project/research study	Needs education	30.4%	26.0%
	Somewhat agree	32.9%	31.5%
	Strongly agree	36.7%	42.5%

This is perhaps the single strongest result pointing toward ethical relativism by first-year students and indicates that further education is required for both cohorts on this specific aspect of academic integrity, particularly in degrees such as the BE which place emphasis on group project work.

Question set 7 received consistently low average responses compared to all other question sets, and the distribution of responses is shown as Table 3.

Table 3. Distribution of responses for Question 7 in 2019 and 2020

Question 7 As a student I believe it is unethical to:	Bucket	2019	2020
Q7.1 Surf the internet for personal interest and non-class related purposes during classes	Needs education	82.8%	80.2%
	Somewhat agree	14.0%	12.7%
	Strongly agree	3.2%	7.1%
Q7.2 Make a copy of software for personal or commercial use	Needs education	56.4%	63.2%
	Somewhat agree	26.9%	20.0%
	Strongly agree	16.7%	16.8%
Q7.3 Make a copy of software from a friend	Needs education	62.6%	60.8%
	Somewhat agree	27.1%	22.4%
	Strongly agree	10.3%	16.8%
Q7.4 Download pirated software from the internet	Needs education	65.4%	50.8%
	Somewhat agree	24.4%	27.8%
	Strongly agree	10.3%	21.4%
Q7.5 Distribute pirated software from the internet	Needs education	60.5%	43.7%
	Somewhat agree	19.7%	21.4%
	Strongly agree	19.7%	34.9%
Q7.6 Buy software with a single user license and then install it on multiple computers	Needs education	40.8%	N/A
	Somewhat agree	24.8%	N/A
	Strongly agree	34.4%	N/A
Q7.7 Share a pirated copy of software	Needs education	51.0%	43.7%
	Somewhat agree	24.8%	27.0%
	Strongly agree	24.2%	29.4%

Q7.8 Install a pirated copy of software	Needs education	58.3%	56.3%
	Somewhat agree	21.2%	23.0%
	Strongly agree	20.5%	20.6%

Almost every question received a response indicating neutrality or disagreement with statements that software piracy is unethical from more than 50% of respondents. The only exception is Q7.6 in the context of licensing – a legal term – where only 40% or respondents are neutral or disagree that violating the terms of a software license is unethical. In 2019 only around 10% of respondents indicated strong agreement with the statements "as a student I believe it is unethical to download pirated software from the internet" and "as a student I believe it is unethical to make a copy of software from a friend."

These sentiments are incongruent for students to hold, whose career pathway is employment in the software industry in which their livelihood will depend on compliance with legal and ethical obligations to observe software copyright and licensing. Some awareness of this issue is revealed in the responses to questions Q8.2, Q8.4 and Q8.7 as employees while apparently not applying to themselves in the academic context [9]-[10]. Identifying this manner of ethical reasoning in the students indicates that significant classroom discussion of ethical relativism [8] should be incorporated into the professional engineering courses for these cohorts.

A trend of a small but significant number of female students responding with very low scores on the ethical understanding of "plagiarism" was observed in the 2020. For example, Q6.6: in 2019 there were 115 respondents identifying as male and 39 identifying as female, of whom 6.7% and 5.1% "strongly disagreed" with the ethical statement. In 2020, 84 respondents identified as male and 40 as female, of whom 3.4% and 17.1% "strongly disagreed" with the statement. Other questions in this set showed a similar relatively high "strongly disagree" response from female students in 2020, with differences statistically significant at the $p=0.05$ confidence level. A complete statistical analysis of this trend is unfortunately beyond the scope which can be accommodated by this Research Paper.

4 SUMMARY

We find evidence in the survey results consistent with relativist ethical reasoning [8], particularly in relation to software piracy and copyright violation [9]-[10]. Our professional engineering courses teach the same ethics material over multiple years from a predominantly absolutist perspective – which student relativist reasoning perceives as less effective (Q11.3; Q11.4). We recommend, and will implement in our courses, that teaching is adapted to address incoming students' surveyed ethical beliefs. It is clear from the data that our courses need to address the idea that ethical understanding is equally important across the three boundaries: student, employee and member of society. Our courses must address the connection between being a student and an IT professional and in doing so it may be possible to utilise the discussion around ethical relativism as a means of exploring ethical case studies.
