ABSTRACT

At Delft University of Technology (DUT) in the Netherlands, multi-disciplinary teams of students collaborate with professionals in living labs to design solutions for real-life complex problems in technological innovation processes. Students are guided by a lecturer through the four phases of design to “cut through” the complexity of the problem. However, in these 'ill-defined wicked problems' nobody has an overall picture of the problem and students face many uncertainties. These uncertainties are often perceived as a barrier for decision-making within the design process.

A reflection tool, based on theoretical insights in transformative and triple-loop learning, is developed to help students critically reflect in action, providing them with options to deal with their uncertainties. We distinguish between task, social, and individual uncertainty. In this study, the central question is: How can the reflection tool help students deal with their uncertainties in solving complex problems in DUT living labs. By means of surveys and interviews we monitored students in two living labs, one with bachelor and one with master students. We focused on what kind of uncertainties they encountered, how they dealt with these uncertainties and how the reflection tool supports them in this regard.

Analysis of the data shows that students perceived all types of uncertainty in the various phases of the design process. By means of the reflection tool students gradually became aware of the many options they have in dealing with uncertainties, and particularly how these pertain to their decision-making in the design process.

1 INTRODUCTION

1.1 Problem

Major socio-technical problems require that many people from different disciplines, angles, and expertise generate new knowledge and solutions together. Living labs have been set up at Delft University of Technology to integrate complex problem-solving in higher education. In the living labs, students work together with academics and professionals. In the minor and master program of Communication Design for Innovation at TU Delft, this is done in the so-called 'C-Labs'. In this, teams of multi-disciplinary students work together with a commissioner and stakeholders (professionals) to analyse and design for complex socio-technical problems. Students do this according to the design-based learning methodology, under the supervision of a lecturer and student teaching assistants.

With these ill-defined, so called 'wicked' problems, neither the students, commissioner, stakeholders or lecturer has a clear view of the problem or what to design for. Following the design process, the actual problem and subsequent design emerges from the collaboration between the different actors. Wherein the commissioner and stakeholders provide in-depth content knowledge, and the lecturer knowledge concerning systems (thinking), collaboration and decision making. The lecturer also provides tools for design and facilitates the process. It is up to the students to combine these different inputs in order to make design decisions. Decisions that on one hand must take into account the design process, and on the other the needs and wishes of their commissioner and stakeholders. This causes students to face a lot of uncertainty, which can be a barrier for their decision-making, and subsequently, their learning process.

1.2 Research goal and question

Since uncertainty is inherent to learning, it is not the intention to resolve or remove uncertainties in the C-labs, but rather to teach students how to deal with uncertainty to prevent that it negatively influences their decision-making and learning process. For that, we started a two-year study (funded by the 4TU Centre of Engineering Education in the Netherlands) with the aim of gaining insight into how students can be supported in solving complex problems in living labs.

Part of the research project is specifically aimed at critical reflection and is divided into three phases: In the first phase, the focus is on the question: To what extent do students experience uncertainties and how do they deal with them? The second phase focuses on the question: How can a critical reflection tool help students with this? and in the final phase, the question is: How can the tool be embedded in living labs such as the C-lab?

In this paper we will discuss the first two phases. The overarching question of this paper is: How can the reflection tool help students deal with their uncertainties in solving complex problems in DUT living labs?

2 THEORETICAL FRAMEWORK

2.1 The C-lab

The concept of the C-labs is based on **authentic learning** and **design-based learning** (DBL). Authentic learning is learning by being involved in real-world problem solving [1]. DBL is described by Gomez Punte, van Eijck, & Jochems [2] as “an educational approach where students gather and apply theoretical knowledge to solve design problems” and rooted in “active learning methods that facilitate students' learning processes" (p.14). Within C-labs, design-based learning is used to approach the problems in a structured way; a creative, disciplined and decision-oriented inquiry, carried out in iterative cycles. Basically, DBL is a teaching approach similar to, and often compared with, problem-based learning; however, in DBL the design process is of main importance. The iterative cycles in design-based learning follow the four stages of the double diamond: discover, define, develop, and deliver [10].

A crucial skill in design-based learning, due to its decision-oriented inquiry nature, is **coping with uncertainty** [3]. We distinguish **three types of uncertainty** that can inhibit the decision-making process of students in design-based learning [4] [5]. First, task uncertainty, wherein the uncertainty is caused by a lack of overview of information necessary or the complexity of the task. Second, social uncertainty, wherein uncertainty is caused by a lack of necessary information exchange or collaborative action. Within social uncertainty we distinguish uncertainty attributed to fellow students, lecturer, and commissioner. The third type is individual uncertainty, wherein uncertainty is caused by a perceived lack of competence of the individual student.

2.2 Critical reflection

As dealing with uncertainty requires students to become aware of how they experience it, it seems necessary for students **to critically reflect** on their uncertain experiences within their learning process. Given this design-based learning process involves many actors from different (technological) backgrounds: diverse students, professionals and lecturer, everyone can perceive uncertainty differently. This research therefore holds a **constructivist view on learning**, seen as using previous interpretations to construct new interpretations of the meaning of one's experience. Both transformative learning [6] [7] and triple-loop learning [8] follow this constructivist view and focus on critical reflection to achieve transformation [7] [8] or profound change [8]. Both theories indicate various levels on which an individual might reflect to deal with a mismatch or disjunction with their current way of viewing the situation. Daalhuizen et al. refer to these situations as non-routine situations wherein the individual experiences uncertainty in the decision-making process [5]. This also warrants a focus on the type of reflection, where this research looks at both reflection in-action: reflecting while doing to change the current situation, and reflection on-action: retrospective reflection to influence future situations [9].

2.3 Perspective Pyramid

This research integrates the above-mentioned theories into a framework for an individual's perspective on which an individual might reflect to become aware of and deal with experienced uncertainty. The framework, called **perspective pyramid** (see figure 1)**,** is grounded in one's perception of knowledge (epistemology), reality (metaphysics) and value (axiology). At the bottom of the pyramid lies one's *frame of reference* - the structure of cultural and psychological assumptions which assimilates past and shapes future experiences. One's frame of reference comprises *habits of mind* - ways of feeling, acting, and thinking based on previous assumptions, which is shown as the second layer from the bottom. One layer above holds the *points of view*, which express the habits of mind. These are constellations of beliefs, feelings, attitudes, and judgments. These are further comprised of *meaning scheme clusters* (the layer above), sets of immediate specific expectations, beliefs, feelings, attitudes,

and judgments. The top layer is then one's *interpretation* of reality – the culmination of the layers into how one experiences a situation.
The perspective pyramid is operationalised as a critical reflection tool used to reflect in-action while students experience uncertainty, by taking the following steps, see figure 1. First, students are asked to classify their uncertainty (task, social, or individual uncertainty). Second, students use the reflection tool to critically ask themselves why they are experiencing uncertainty, going through the different layers of the pyramid from top to bottom. Third, having identified their uncertainty, students are asked to generate options for decision-making in dealing with their uncertainty. The tool was implemented as a paper booklet in phase 2 (see 3.2 Methodology).

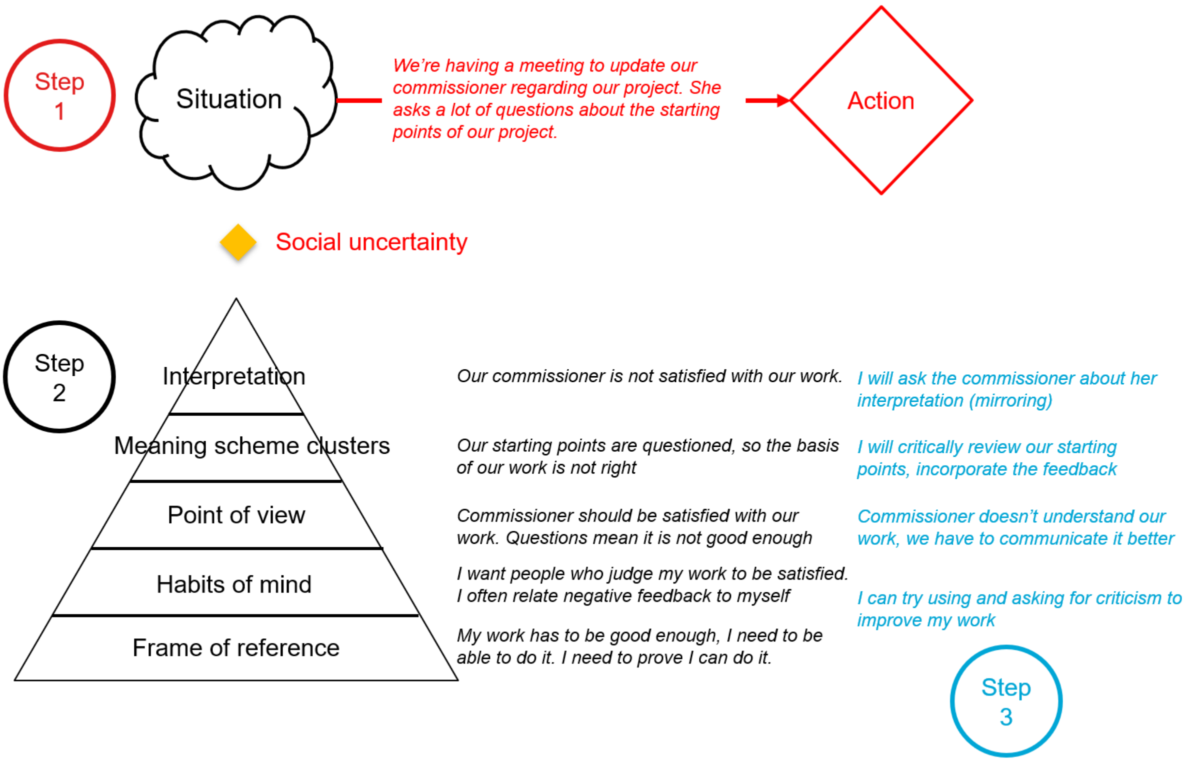

Fig. 1: Example of reflection tool in use

3 METHODOLOGY

3.1 Phase 1

The focus of the first phase was to explore to what extent students experience uncertainties and how they deal with them. In this study, 35 BSc students participated, who all signed the consent form. The students had a wide variety of technical backgrounds, where most came from computer science, mechanical engineering, architecture, and industrial design. Criteria for group composition were based on students' bachelor programs: every team consisted of students with different backgrounds. The students worked in teams of 4-7 and each team focused on a different case; all complex socio-technical problems from practice. The cases were submitted by government, industry and non-profit organizations. These professionals ("commissioners") were actively involved during the entire process, from problem definition to the presentation of the final product. They were available

for input and feedback; at set times and when students had specific questions. The minor included 8 cases with 8 student teams, spread across 9 commissioners.
The C-lab course (15 ECTS) took one semester (September 2021 – February 2022). Students worked on the case from day one. The lectures and supervision by the lecturer and student assistants were aimed at getting students to go through the design process in a systematic way, as explained in section 2.1 of this paper.
During the course students filled out weekly surveys with open- and closed-ended questions. The survey asked participants to reflect on which type of uncertainty they experienced that week, how they dealt with it, and what they would need to deal with such uncertainty throughout the design process. All data was anonymised, and the mentioned uncertainties were coded via pre- and open coding and divided into three categories: uncertainty attributed to the individual, the social context and the task. Additional measurements were used to specify and interpret the data from the weekly student-surveys, like introductory and final student surveys, learning style assessments, and interviews with lecturer and commissioners. Due to the limited size of this paper, this is not discussed in detail here.

3.2 Phase 2

The focus of the second phase was to validate the reflection pyramid as a tool. Four MSc students , all with different technological backgrounds, participated in this part of the research. They took part in a C-lab project in an international context that was compressed in one full week (November 2021). The students filled out daily reflection booklets in which the perspective pyramid was integrated (see figure 1). First students reflected on each type of uncertainty (task, social, individual). Next, each type of uncertainty experienced was further reflected on, using the layers of the perspective pyramid. Lastly students were prompted to formulate potential follow-up actions with respect to their reflections on uncertainty.Students filled out the booklet individually at the end of each day, in a facilitated reflection session.

Retrospective semi-structured interviews on basis of the reflection booklets were held with each individual student: questions related to their process and output of the week, their use and experience of the reflection tool, their awareness and ways of dealing with uncertainty, and possible improvements to the reflection tool.
The 4 interviews with master students in this second phase of the research were transcribed and coded via open coding.

4 RESULTS

4.1 Phase 1

In the monitored living lab with bachelor students, all types of uncertainty were reported. Task uncertainty, social uncertainty regarding collaboration and communication with fellow students, lecturer, and commissioner, and individual uncertainty, see figure 2. Throughout the course, task uncertainty was the most prevalent, and fellow students and lecturer uncertainty were mentioned the least. Individual uncertainty was reported more often, peaking in week 13, where students indicated they were stuck in the design process.

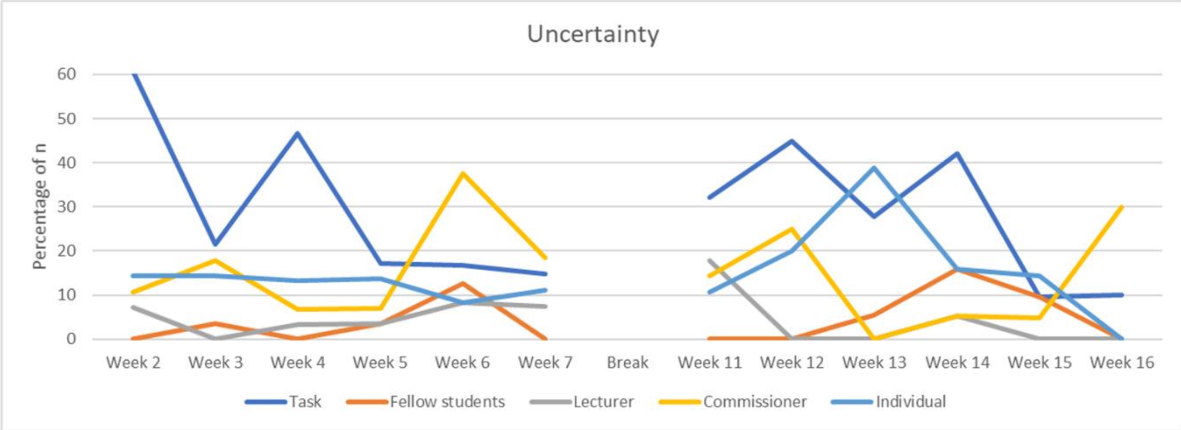

Fig. 2: Perceived uncertainty types throughout C-Lab

To some extent, students were aware of the **causes of their uncertainty**, which changes throughout the course. In weeks 2-4 (discover phase) the cause of uncertainty among most of the students was associated with an unclear task, goal, or unclear next steps to take. They attributed their task uncertainty with causes outside themselves. In weeks 4-7 (define phase), they perceived the cause of their uncertainty having more to do with difficulties in their communication with the commissioners and stakeholders. From week 11 onwards (develop and deliver phases), students took more ownership in dealing with the complexity of the case, basing their decision-making on integrating different perspectives from stakeholders and their commissioner. This required actively asking practitioners critical questions in a practice that is new to most students, causing both task and social uncertainty. Moreover, the introductory survey and interviews with the lecturer showed that bachelor students have little experience with critical reflection, and a limited critical mindset.

> *"Students struggle with developing a critical mindset, to accept different perspectives."* (lecturer)

Students reflected on what they would need to **deal with** their experienced **uncertainty** in continuation of the course. In the first phase of the design process, the following options were mentioned: better task description, clearer goals, (clearer) stakeholder input, better communication with commissioner and stakeholders. These options for improvement all seem to be attributed external to the student. In the later phases of the design process, students suggested more internally attributed options to deal with their uncertainty. The following options were mentioned: improving communication, be open-minded, take initiative, ask for help, improve teamwork. The weekly reflections of students showed that they gradually took ownership of dealing with their uncertainty.

4.2 Phase 2

Results from the retrospective interviews with master students regarding the use of the reflection tool indicate to what extent the tool supports students in dealing with their uncertainties.

In **using the tool**, students were aware of their uncertainties and it supported them in gaining insights into dealing with their uncertainties as learning opportunities. When being asked how a student experienced task uncertainty, she mentioned she had difficulty trusting the design process, finding it difficult to embrace the fuzziness of design. When asked how she reflected on this uncertainty she mentioned:

"The more often you convince yourself it is part of the process, the more it becomes a baseline for yourself. From conscious to subconscious." (#1)

One student mentioned he was very judgmental to his teammates in the beginning of the process. By using the reflection tool, he mentioned the following regarding social uncertainty:

"The tool made me less judgmental to others, first trying to find out how I project things onto others." (#2)

When being asked about how the reflection tool contributed to his learning process, one student replied:

"When you become aware of how input fits in your frame of reference, everything becomes a learning opportunity." (#2)

Students indicated which **conditions** should be prevalent in dealing with uncertainty. The necessity of reflection and reflective discourse was recognized by all students. Two students remarked it especially helped them deal with individual uncertainty. Furthermore, all students were adamant about the importance of creating "common ground" within the respective teams, meaning they had a sense of bonding on a personal and professional level.

"You can reach common ground on both personal and professional level. It can be superficial or deep." (#3)

When asked how to create common ground the following aspects were mentioned: open-minded attitude, sharing vulnerabilities, shared social and informal activities, time and effort to form bonds. Two students mentioned that having common ground helped them to leave their comfort zone.

"Leaving your comfort zone, to not be afraid but open to new things." (#2)

Finally, students provided **recommendations** for improving the reflection tool.
In reviewing the reflection tool, all students expressed enthusiasm in exploring the lower layers of their pyramid:

"It helped me to think about things I would otherwise not think about." (#4)
"I quickly kept asking myself how to get to the bottom of the pyramid. This gave me individual insights." (#2)

This speaks to how the tool facilitates critical reflection through structural questioning. However, they also stressed the importance of how the tool had to be flexible enough to fit individual reflection styles.

"The tool should stimulate reflection in your own way." (#4)

5 CONCLUSION

The central question of this paper was: How can the reflection tool help students deal with their uncertainties in solving complex problems in DUT living labs? This research shows uncertainty is present throughout the design process in DUT living labs. Results from phase 1 show that systematic reflection helps students take ownership of the causes of their uncertainty and internalise options in dealing with their uncertainty. The critical reflection tool tested in phase 2 had similar results. Moreover, the tool stimulated relatively deeper reflection, providing insights and learning opportunities regarding students' habits of mind and frame of reference. Finally, retrospective interviews about the use of the reflection tool indicated certain conditions and recommendations for dealing with uncertainty in living labs.

6 DISCUSSION

Use of the reflection tool can admittedly lead to insights among students about the more personal 'lower layers of their perspective', but (behavioural) changes cannot always be realized within the context of the living lab.This is why attention should also be paid to critical reflection and personal development in other subjects in the students' curriculum, although dealing with uncertainties may play a less prominent role there.

The retrospective interviews with students indicated their desire for a personalised reflection tool. In phase 3 of this research project, our aim is to develop the reflection tool further to both maintain its structural and critical nature, while also being flexible enough to accommodate personal reflection styles.

The extent to which deeper reflection occurs and helps students deal with their uncertainties has been further researched, and will be discussed during the presentation of this study at SEFI 2022.

ACKNOWLEDGEMENT

This research was made possible thanks to funding, input and feedback from the 4TU CEE organization in The Netherlands.

ABSTRACT

There are numerous discourses about competencies of future engineers as well as the challenge to learn, teach and assess them. In particular, this applies for the question of which competencies – besides technical knowledge and understanding – are relevant for future engineers in order to responsibly address the needs of society. This paper contains the initial results of an ongoing research project which aims to investigate engineering students' competencies and their perception thereof. In the context of a recurring engineering master's seminar at RWTH Aachen University the participants conducted interviews with a total of 41 students from outside the course. The interview subjects were themselves master's students from diverse engineering programs. In the interviews, the subjects were asked by their peers, among other things, which competencies they consider relevant for engineers and to what extent they have acquired these in their studies. The answers to those questions are evaluated and discussed in this work. The results show gaps in the acquisition of competencies – from the students' point of view – and in particular a discrepancy

between the perceived relevance of competencies and the acquisition of these in the study programs. Besides problem solving, and technical knowledge and understanding, students pointed out that social competencies, such as communication and teamwork are particularly relevant. At the same time, they saw a lack of acquisition of these competencies in their study. The same applies for missing integration of knowledge into practical application.

1 INTRODUCTION

Research and practice within engineering education are framed by growing discourses about competencies of future engineers. This goes along with the need for both student-centred learning and integrated curriculum development in order to synthesize students' knowledge and to prepare them as future professionals [1, 2]. Moreover, as future professionals, engineering graduates must acquire a broad range of interpersonal and personal competencies that go beyond siloed technical knowledge [2, 3]. This concerns competencies for sustainable development as well as professional identity with regard to responsibility and influence on society. However, those insights are well established. Already, 20 years ago, for example [1, 4] called for a more student-centred and outcome-oriented engineering education. The same applies for the CDIO initiative, which published its first syllabus in 2001 [5].

Several literature reviews focused on competencies engineering programs should emphasize and engineering students should gain [e.g. 6, 7]. Common findings are the need for personal and interpersonal competencies, especially with regard to communication, teamwork and problem solving. At the same time, surveys with engineering students showed that they do not feel well prepared for career entry, as those competencies are lacking in their study programs [8, 9]. Often, this also goes along with an education focused on putting theoretical knowledge before practical applications [10, 11] or a lack of knowing how to integrate knowledge into application [12]. For example, in the study by Miranda et al. [8] civil engineering students emphasized that they primarily learn technical knowledge and perceive themselves in a passive role, rather than having hands-on experience. Applying and integrating theoretical knowledge to real-world problems influences students' perceptions of their engineering profession, thereby reflecting on the need for interpersonal skills, such as teamwork – which surprised several students in the study by Hughes et al. [13]. The results show that students' perception about their engineering profession is often narrow and based on disciplinary and technical knowledge, which is also in line with the results of other studies [e.g. 11, 14].

Building on that and considering the lack of qualitative research about students' perception of their competencies [15], this study focuses on engineering students' perception with regard to the most relevant competencies needed for professional engineers and their acquisition within their study programs. The study aimed to answer the following research questions:

What competencies for engineers do master's students in engineering consider relevant – and why?

To what extent are these competencies acquired in their studies?

2 METHODOLOGY

In the context of a recurring engineering master's seminar at RWTH Aachen University the participants conducted an interview each with a total of 41 students from outside the course. The aim of the course was to find out, through student-led interviews, which competencies engineering students consider relevant to be able to cope with future challenges. The teaching concept is described in detail in [16] and will therefore not be discussed further. Instead, the following is a partial evaluation of the student-led interviews on relevant competencies of engineers.

The interview subjects were themselves master's students from diverse engineering programs (see Figure 1) and recruited by the students from the course. A majority of the interview subjects studied either civil or mechanical engineering. In the interviews, the subjects were asked by their peers, among other things, which competencies they consider relevant for engineers and to what extent they have acquired these in their studies. Here, the interviewed students answered freely without being given a prior choice of competencies. Note that this is a partial evaluation. In a next step, the competencies mentioned will be analyzed further with regard to the students' perspectives on engineering responsibility and identity. A notable limitation is that the interviews were not conducted by one person, but by 41 individual student interviewers. To address this, an interview guide was developed and provided for by the instructor. All interviews were recorded and the original audio files were used for further analysis.

All 41 students-led interviews were then analyzed qualitatively by the authors in order to answer the predefined research questions. In doing so, the interviews were systematically screened for competencies that students deemed relevant.

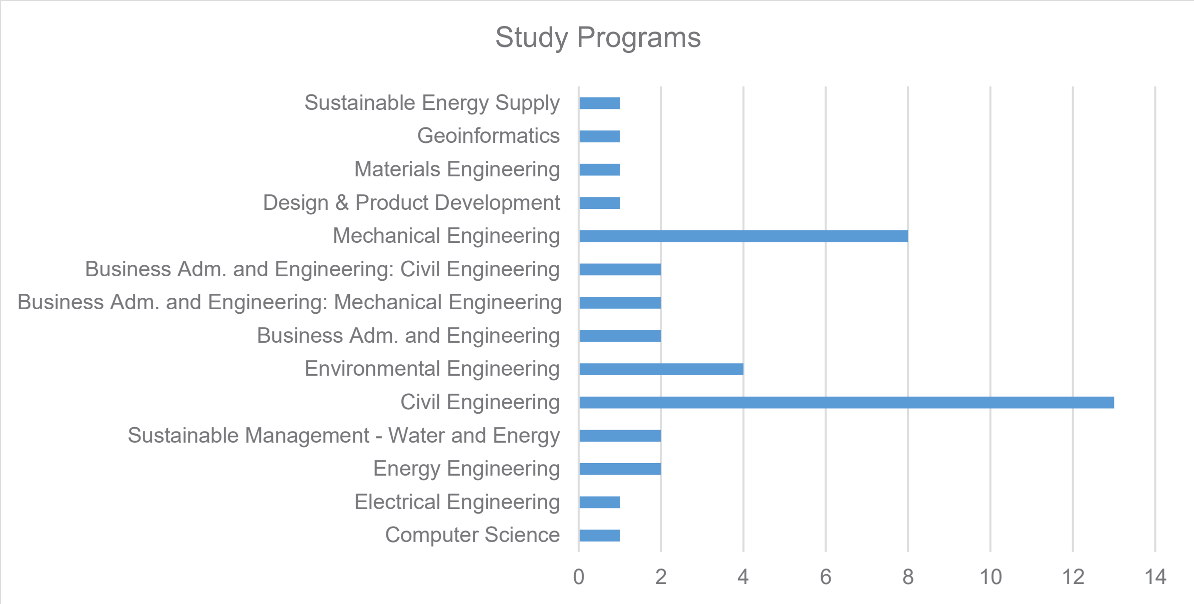

Figure 1. Study programs of surveyed master's students

3 RESULTS AND DISCUSSION

Table 1 provides an overview of both all competencies mentioned by the students as relevant for engineers and all competencies mentioned by the students as perceived as missing in their studies. The number of mentions does not serve as statistical analysis, but is intended to give an idea and to illustrate the respective distribution.

Note that the listed (translated) competencies were mentioned by the students *themselves* [16]. We deliberately did not categorize the competencies in order to transparently present the students' assessment and perception without any biases of the authors. However, there are several frameworks and studies that group teamwork and communication as social competencies, often described as interpersonal skills [e.g. 5, 13]. The fact that students name the respective competencies differently can be attributed to a lack of knowledge about them and the different ways of describing competencies [6, 7, 17].

Problem solving, and technical knowledge and understanding were mentioned most frequently as relevant competencies by students. In general, the students considered these competencies to be central characteristics of engineers, also with regard to their own perceived engineering identity. One student from business administration and civil engineering described that in the following way:

> *"A person who is very independent. A person who is so self-sufficient that when she/he has a problem, she/he has a good solution and can structurally go to this problem and solve this problem by providing certain tools, mainly related to the technical. The implementation of technical problems – this is for me an engineer."*

Note that all quotes were translated from German to English by the authors.

Table 1. Relevant and missing competencies for engineers – students' perspective

Rank	Relevant competencies for engineers (# mentions)

	Recognizing Errors (1)

In general, students' perceptions of relevant competencies for engineers go along with other studies [e.g. 6] and frameworks [e.g. 5]. In their systematic review, Passow and Passow [6] provided a broad overview of engineering competencies with regard to their importance, finding that problem solving, communication and teamwork are the three (ABET-mapped) competencies most important for work. At the same time, they concluded that "technical competence [here: technical knowledge and understanding] is inseparably intertwined with effective collaboration" [6, p. 491], which was also highlighted by the students, as, for example, one environmental engineering student stated:

> *"We engineers will most likely need to continue to work with people to solve problems collaboratively. In terms of that, I think maybe we should work more with each other [in our studies]."*

Moreover, social competence itself as well as teamwork and communication were mentioned frequently by the students as relevant competencies. At the same time, those were mentioned most frequently as missing competencies when asked whether students have acquired these competencies in their studies. To illustrate this discrepancy, these competencies are color-coded in Table 1. One environmental engineering student linked these competencies in the context of communicating technical solutions to the public, but also emphasized the relevance of reflecting on the impact of technical developments:

> *"I would say that social competence should be taken into account even more in education. That you don't just have this extremely specific technical training, but that you also learn a certain way of dealing, especially with people who are not so involved in this technical training. In order to have a better understanding of how solutions affect others, but also how I can present my solution in such a way that others can understand it."*

The competencies that were pointed out as missing most frequently were interpersonal and/or personal competencies. No student mentioned a lack or gap of technical knowledge and understanding, instead they criticized the amount of theory and technical knowledge in comparison to a lack of practical experiences and applications, as one environmental engineering student put it:

> *"Most of the subjects in my study program are far too theoretical and […] I think there is a great lack of practical experience in our study program."*

This goes along with a lack of interaction and teamwork, which was pointed out by a student of design and product development:

> "*I have already had a few bad experiences in the area of my bachelor's study program. On the one hand, there is a lack of any practical reference. A lot of theory is learned, but I missed this practical reference and also teamwork and this whole interaction, which has moved a bit to the back in the study."*

Moreover, students were afraid of not being properly prepared for professional life, as two civil engineering students stated:

"What is particularly difficult is the reference to practice. I don't really feel prepared considering how many theory subjects you've had during your study program and how much theory you retain from it. Although I'm sure these aspects were important, I don't feel that well prepared for later life. Everything I have learned so far and what I can apply are things that a program will do for me later. That doesn't make me very happy, but I can understand why people learn it."

"I don't have the feeling that I, as a whole, already stand in the market and would be ready to be able to solve more complex solutions independently, on my own responsibility. At the same time, I think that's also the competence that you have to have as an engineer: understanding complex situations, analyzing them and breaking them down into smaller packages so that you can then work on them and come up with a solution."

In the last quote, the student voices the feeling of not being able to solve complex problems independently, which students at the same time perceived as one of the most important competencies for engineers.

The lack of practical application and integration of knowledge into practice is a well-known and long discussed problem within engineering education, also regarded as traditional engineering [1, 3, 10, 11]. Thereby students have hardly any opportunity for deep learning experiences which could enable them to solve complex real-world problems [10, 12]. These findings go along with the study by Lermigeaux-Sarrade et al. [9], who asked master's students about their perceptions of gaining conceptual knowledge and professional skills. The results showed that students ask for more practice and interdisciplinarity in their studies, as well as for more teamwork. In comparison to the study by Miranda et al. [8], the results presented here represent students' perception of traditional teaching approaches in civil engineering. Students pointed out the exact lack of integrating knowledge, thereby feeling passive in their role as learners.

4 CONCLUSION

This study showed that there are significant gaps with regard to the competencies students perceive to be relevant for professional engineers and the competencies they believe to gain through their education. Especially, this concerns interpersonal and personal competencies, such as teamwork or communication. This becomes particularly relevant concerning the lack of integrating knowledge into practice, showing that this is still not the "center of their education" [1, p. 7]. The study also revealed that students' perception of relevant competencies is consistent with those discussed in engineering education research. This is novel insofar as qualitative studies from students' point of view are lacking. The results are particularly relevant as the interview subjects did not receive a predefined list of competencies, but answered freely and articulated competencies on their own. Moreover, the respondents were from different study programs, including both traditional technical engineering programs such as civil and mechanical engineering and study programs tending multidisciplinary, such as environmental engineering. However, their perceptions were very similar, especially with regard to the lack of practical application and missing interpersonal competencies. As this study is about students' *perception* of their knowledge and competencies, this does not necessarily imply *actual* gained knowledge and competencies. Therefore, an interesting next approach would be to investigate perceptions of both first-year students and graduates to get a deeper understanding of how the perception of both required and acquired competencies changes during the course of their studies. Even though the results represent the subjective perception of the students, the consistency and similarity to other studies is striking in every way. Therefore, on the one hand, the results confirm the emerging call for new and integrated curricula approaches [2], such as the CDIO approach [5, 18]. On the other hand, the results illustrate that despite existing efforts in terms of curriculum development and innovative teaching approaches, both are – in some areas – not yet applied sufficiently.

ABSTRACT

In recent years there has been growing emphasis on the requirement for engineers to contribute toward the complex socio-technological challenges confronted by society. The need for a more holistic understanding of the societal impact of engineering has been highlighted by government, professional institutions and industry, and has strengthened calls for a widening of engineering curricula. Despite this, there is evidence to suggest that the higher education (HE) sector is not producing socially responsible engineering graduates. This study explores potential barriers to the development of socially responsible, culturally aware engineers. In so doing, it draws upon student feedback and reflections from a UK based engineering

design course which makes use of the Engineers Without Borders UK Design for People Challenge, and which focuses on human centered, sustainable design. The findings are discussed in the context of theories of reasoned action and planned behaviour. It is argued that engineering culture and curriculum act to discourage alternative modes of thought which leave students powerless in their ability to enact meaningful change. Alternative modes of teaching and learning are discussed.

1 INTRODUCTION

1.1 Motivation

The need for engineers to solve complex socio-technological problems has been highlighted by government bodies [1], professional institutions [2], [3], [4] and industrial stakeholders [5], [6], resulting in worldwide calls for curriculum changes. Within the UK, the latest edition of the Accreditation of Higher Education Programmes (AHEP) framework (AHEP4) has incorporated language around the social dimension of engineering, with one of the five areas of learning being referred to as “The engineer and society”, this including learning outcomes that refer to mitigation of security risks and supporting equality, diversity and inclusion (EDI), in addition to sustainability, risk and ethics [7]. Elsewhere, the National Academy of Engineering [2] call for engineers to “ethically assist the world in creating balance in the standard of living for developing and developed countries alike” (p. 51).

Despite the apparent consensus that the profession should engage more deeply with societal issues, several pieces of work suggest that higher education (HE) is not preparing engineering students to display social responsibility. For example, Bowen [8] describes “a tendency for engineering, as presently taught and practiced, to prioritize technical ingenuity over helping people” (p. 6). Zandvoort [9], Riley & Lambrinidou [10] and Bielefeldt [11] all note the absence of any clear vision of what serving society means for engineers.

Other work has focused on changes in the way engineering students perceive social responsibility, with both Cech [12] and Rulifson and Bielefeldt [13] reporting an apparent decrease in the value students place upon social responsibility throughout their undergraduate degree. Elsewhere, Smith et al. [14] reported that students taking classes with significant corporate social responsibility (CSR) content tended to express a greater desire to work for socially responsible companies. However, this improvement did not usually translate to their next course. Disengagement with societal issues has been claimed to have direct implications for the diversity of engineers [14], with several pieces of work claiming that women and racial/ethnic minorities are more likely to pursue engineering careers with an explicit sense of social responsibility [12], [15], [16]. It also limits the extent to which we can expect engineers to produce socially just and sustainable engineering solutions.

This mixed methods study explores some of the potential barriers to developing socially responsible engineers. Data is drawn from the Engineering Professional Responsibility Assessment (EPRA) tool [17] and a combination of student feedback and reflections from a UK based engineering course which makes use of the

Engineers Without Borders (EWB) UK Design for People Challenge. The findings are discussed in the context of theories of reasoned action and planned behaviour.

1.2 Theory of Reasoned Action and Theory of Planned Behaviour

The Theory of Reasoned Action, or TRA [18], [19] and the Theory of Planned Behaviour, or TPB [20], [21] are theories used to understand human behaviour, and have increasingly be used in relation to sustainability research [22], [23], [24], [25] as well as energy, green IT technology adoption, environment-friendly energy use, waste management, and vehicle use [26], [27], [28], [29], [30]. TRA (see Figure 1) offers a conceptual framework which proposes that behaviour is influenced by three factors. *Attitudes toward behaviour* and *subjective norms* are both claimed to inform a decision process which results in the deliberate plan to perform the behaviour, or the *behaviour intention*. Within the framework, the attitude toward a behaviour is influenced by two things: *outcome belief* and *outcome evaluation*. Similarly, *subjective norms* are affected by both *normative beliefs* and *motivation to comply*. TPB is an extension of TRA (see Figure 1) which includes *perceived behavioural control*, which relates to the degree to which people feel able to enact the behaviour in question, this being based on opportunity and/or capability. Such theories are of interest given the existence of work which identified a negative correlation between powerlessness and action on climate change [31], [32]. The same work also describes a relationship between action and the commons dilemma, a term originally used by the economist William Forster Lloyd [33], and which refers to a case when the benefit derived from an action accrues to the individual, but the cost is shared within the community.

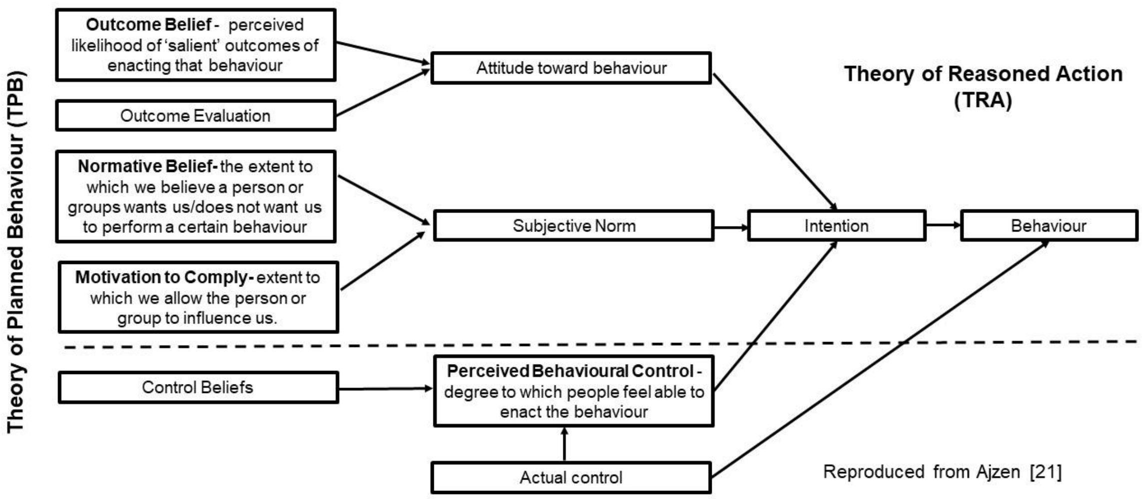

Fig. 1. Schematic showing the dimensions of the Theory of Reasoned Action (TRA) and Theory of Planned Behaviour (TPB) frameworks. Reproduced from [21].

2 METHODOLOGY

Data was obtained from first year (Civil, Electrical and Electronic, Materials and Mechanical) engineering students enrolled on a 10-credit module entitled

‘Engineering for People’. The module ran in the first semester of the academic year, for a duration of seven weeks from late September. The syllabus included: mindset and self-awareness; ethics and professional responsibilities; sustainability; design cycle; teamwork; positionality and personal design perspectives; and reflection. There were 2 hours of contact time per week including lectures and discussion. The module culminated in a week-long immersive design challenge during which all other modules were postponed. Students worked in small groups (5-7 students) to produce a design for the EWB UK Design for People Challenge.

Approval for use of student submissions for research purposes was sought from the Swansea University College of Engineering Ethics Committee. Students were provided with the research information sheet at the start of the module and were asked to complete a consent form to ‘opt in’ to the study. 105 of the 444 enrolled students consented to take part.

A mixed methods approach was adopted with the aim of understanding the attitude of engineering students toward social responsibility. Quantitative data was collected using the EPRA [17] which was administered to the students in the first week of the module. The EPRA has been demonstrated as being a reliable and valid measure of the social responsibility of engineering students and was developed by Canney and Bielefeldt [17] to operationalize their professional social responsibility development model (PSRDM). Their model assumes that, until university, experiences are limited to the personal realm of social responsibility development (realm 1: personal social awareness) when they are heavily influenced by friends and family. It is important to note that data was collected from first year students during their first semester, and it therefore likely that their views and behaviours reflect their personal social awareness. Throughout their degree programme, students learn about the professional realm of social responsibility, this referring to the values of priorities of the engineering profession (realm 2: professional development). The authors claim that students are likely to compartmentalize these two different realms unless they are given opportunity to engage in co-curricular activities that show them how personal and professional experiences can be integrated (realm 3: professional connectedness). The dimensions associated with each realm include: awareness (aw1-aw5), ability (ab1-ab4) and connectedness (co1-co4); base skills (ba1-ba5), professional ability (pa1-pa4), and analyze (an1-an5) and professional connectedness (pc1-pc19) and cost-benefits (cb1-cb4). The original tool therefore had 50 items in total. Following the recommendations of Canney and Bielfeldt [17], the number of items were reduced in the current work. Namely, the number of items related to the professional connectedness dimension were reduced and both the base skills and professional ability dimensions were omitted [17]. Answers were scored with a value of 1 being given for “strongly disagree” and a value of 7 given to answers of “strongly agree”. Negatively worded items (labelled * in Table 1) were reverse scored. For this work, only a basic analysis of data was conducted, and it would be interesting to investigate whether the results varied according to student characteristics, for example by gender, nationality or engineering discipline.

Qualitative data was drawn from several different sources including: written module feedback; lecture discussions; written reaction to the statement "Obsolescence is not only planned but forced and engineered", made by Professor Justin Lewis during a TEDx talk [34]; written reaction to a small extract from [35] which discusses the way in which engineering has focused on the needs of the richest in society, at the expense of other nations. Data underwent thematic analysis [36].

3 RESULTS

3.1 EPRA Results

The mean and standard deviation for each item of the EPRA tool is given in Table 1.

Table 1. EPRA Results

	Item	Mean(s.d.)
Realm 1	aw2: Some community groups within the UK need our (engineers) help	6.11 (0.83)
	aw4: There are members of society who have needs not being met	6.47 (0.97)
	ab2: I can have an impact on solving problems that face my local community	5.79 (1.02)
	ab3: My contribution to society will make a real difference	5.76 (0.99)
	ab4: I cannot have an impact on solving problems that face under-served communities internationally*	5.39 (1.22)
	co1: It is not my responsibility to do something about improving society*	5.80 (1.35)
	co2: It is my responsibility to take real measures to help others in need with problems	5.56 (1.24)
	co3: I feel an obligation to contribute to society	5.56 (1.14)
Realm 2	an1: Cultural awareness/ understanding is important for a professional engineer	6.14 (1.10)
	an3: I would not change my design if it conflicted with community feedback*	5.64 (1.05)
	an4: It is important for engineers to consider the broader impacts of technical solutions	6.26 (0.84)
	an5: It is important to incorporate societal context and constraints into engineering	5.93 (0.99)
Realm 3	pc1: It is important for professional engineers to volunteer and serve others	5.18 (1.14)
	pc3: It is important to me to have a career that involves helping people	5.50 (1.19)
	pc4: Service should not be an expected part of the engineering profession*	4.40 (1.31)
	pc5: I will use engineering to help others	6.05 (0.82)
	pc6: I view engineering and community service work as unconnected*	4.90 (1.45)
	pc7: I feel called to serve others through engineering	4.76 (1.48)
	pc8: Needs of society have no effect on my choice to pursue engineering as a career*	4.45 (1.75)
	pc13: Engineers should use their skills to solve social problems	5.39 (1.12)
	pc14: It is important to use my engineering abilities to provide a useful service to the community	5.70 (0.96)
	pc15: I believe I will be involved in social justice issues for the rest of my life	4.11 (1.61)
	pc17: I think people who are more fortunate in life should help less fortunate people with their needs and problems	5.67 (1.30)
	pc18: I believe it takes more than time, money, and community efforts to change social problems: we also need to work for change at a national or global level	6.10 (0.99)
	pc19: It is important to me to have a sense of contribution and helpfulness through participating in community service	5.27 (1.13)
	cb1: I would be willing to have a career that earns less money if I were serving society	4.48 (1.56)
	cb2: My engineering skills are strengthened through participation in engineering service	5.75 (0.91)
	cb3: I believe my life will be positively affected by the volunteering that I do	5.54 (1.14)
	cb4: I believe extra time spent on community service provides benefits for the community	6.10 (0.75)

The slightly higher values obtained for the awareness dimension, compared to ability and connectedness is perhaps unsurprising given the fact that statements are based on observation and general knowledge, as opposed to obligation [17].

When considering the professional connectedness dimension, the highest value was obtained for pc5, and it is possible that students assume that engineering, by its nature, helps society (e.g., by developing new technology) [17]. Lower values were generally obtained for items which referred to the individual (e.g., pc7, pc8, pc15) as opposed to the profession. One of the lowest values within the dimension was obtained for pc4 suggesting students feel they should have a choice in how they behave as engineers. In comparison, the highest value recorded for the dimension was for pc18. This perhaps indicates that students are aware of limitations in their ability to behave as socially responsible engineers.

It is interesting to note that one of the lowest mean values was obtained for one of the 'discriminating' [17] items, cb1.

3.2 Qualitative Results

Most students considered societal challenges such as climate change, energy security, water availability, over population, and poverty, to be the most pressing issues faced by the profession. Despite this awareness, it was possible to identify several potential sources of resistance to the inclusion of social responsibility in the context of the engineering curriculum. Table 2 presents representative excerpts organized by interpretive theme, alongside associated dimensions within the TPB.

Table 2. Representative excerpts and associated TPB dimensions organized by interpretive theme

	Subtheme	Excerpt	TPB dimension
Tensions between economic and social sustainability	Incentives	engineers focus on "how they can make the most money"; "…if we do not generate a profit then we will lose business and cliental"; if companies are "not releasing new products often enough a different company will"; "…the driving force of the modern world is economic growth and getting things done as quickly and cost-effectively as possible"; "isn't it weird that jobs helping people get paid less?"; "it's like we are being motivated not to help people"; Incentives are "predominately financial"; "…the majority of people will pursue monetary gain rather than social gain"; "…we live in a world where money is a huge factor in our thoughts and decisions making... in an ideal world…perhaps then an engineer would be more willing to pick a lower paying job which benefits the lower class of society"; preoccupation with "monetary gain or personal career development" means "the engineering profession does not attract people with humanitarian interests"; challenges within engineering include "Technology vs. Humanity, Economy vs. Environment, Globalisation vs. Community".	Outcome belief and outcome evaluation (perceived opportunity cost /commons dilemma, and influencing the career path that a student takes).
	Engineering Mindset	"…an engineer should be striving to be efficient in their solution and the cost of the solution" Reduction in financial incentives would lead to "far slower rates" of innovation "… best way to progress is to prove there is profit to be made"	Subjective norm (engineering culture)

	Culture/ "group behaviour"	"…the public's demand for newer things" which engineers don't "have control over". "…society aren't satisfied unless we see progression and improvement" "…a problem many people face is the inward view of success…our view of success drives us to be who we are, thus, in today's society, the brand-new, the fancy, the item everyone 'needs' is the message portrayed by every business, company, and store. We need to be better than we already are, all through physical items and price tags." "…the modern world is so consumed with economic growth and profitability that sometimes we lose sight of real reasons we should be striving to improve what we currently have".	Subjective norm (societal culture)
Sense of powerlessness	Limited impact	"…as an individual there is very little he can do". "…is this challenge one we will be realistically and physically taking action upon and possibly providing to their community or is it just another written assignment sort of thing?".	Perceived behavioural control
	Constraining factors	"…it is up to local governments and charities" "…many engineers…do not have the luxury to fully decide what industry they want to work in" "…empathise with engineers who feel trapped in an industry controlled by profiteering corporations" "…management as they control what products are being sold" "…just carry out orders from people higher up".	Perceived behavioural control
Inter-disciplinary	Respect for other disciplines	"Lads, we are doing engineering not political science" "Bruh, imagine failing an engineering course because you didn't revise social sciences" "RIP those of us that just wanted to build engines"	Subjective norm (engineering culture) Perceived behavioural control (expertise)
	Lack of understanding of systemic social issues	"…with a large population comes large differences…an inevitable inequality" "…the reason most engineering solutions have been developed for the richest people is because they have the knowledge and money to do such a thing… this doesn't mean engineering is only for them, this is just where solutions are developed. That doesn't matter to society though, who cares where or how it is developed?" "…poorer societies also experience large scale engineering…the fact they are poorer (means) they have a limited amount of what they can do.".	
	The self and personal motivations	"…future engineers may have different priorities…international students may focus on the problems facing poorer communities globally" "…the biggest issues I felt, were that many of my peers who have mostly come to Uni straight from school were not engaged in (the module content) the same way" "…the whole looking inside yourself…responsible engineering talks are preaching to the converted…we all know what we can and can't do at this point when it concerns the environment and climate change. University students are all too aware of the risks of climate change considering that we'll be the generation that has to deal with the consequences."	

4 SUMMARY AND ACKNOWLEDGMENTS

This paper has identified several possible sources of resistance to social responsibility. For example, it appears as though some students feel limited control over their ability to contribute towards social issues, something exacerbated by both existing within a consumer society and economic pressures. It therefore seems appropriate to equip engineering students with an awareness of alternative business models and no growth economics. This powerlessness seemed to be emphasised, for some, by the nature of the design challenge which focuses on theoretical solutions for distant communities, and in future it may be suitable to focus more on societal issues within the context of the local community.

In common with the themes identified during this work is a misalignment between personal and professional experiences and a lack of consideration for the ‘whole’ self, something which may not be surprising given both the early specialisation within the school system and valorization of STEM (science, technology, engineering, and mathematics) subjects that takes place in the British context, and the way in which our education systems utilise grades as a measure of student success. As Heywood [37, p.4] reminds us, the person is the base of the engineering process, saying that “Understanding how our beliefs and values (moral and otherwise) are formed is important to our conduct as engineers and individuals but it belongs primarily to the domains of philosophy and theology which are different languages”. In the absence of a ‘well-rounded’ education, students are unlikely to be aware of alternative modes of thought which may allow them to enact meaningful change in the face of complex problems such as climate change and social injustice, and which may allow them to “conceive a way of being outside this neoliberal worldview” [38] and they may, instead, be likely to become agents of cultural reproduction [39].

In what ways can we encourage students to explore their beliefs and motivations in a system, and indeed a society, which values academic success and how much money they make? Perhaps more importantly, to what extent should we try and address these issues? As Pawley [38] points out, as educators, most of us “indoctrinate students into neoliberalism” and fail to make students aware of alternative modes of thought which allow them to “conceive a way of being outside this neoliberal worldview”. Shor and Freire [40] describe how student resistance to liberative pedagogies was rooted in job anxiety and Freire [41] argues for the need to prepare students for the current (neoliberal, capitalist) state of the world.

It is clear we need to help students navigate complex tensions and feel comfortable sitting with uncertainties. This involves allowing ourselves to be vulnerable and admitting we do not know the answers. It necessitates us providing students with space and time, away from pressures of grading, to understand their beliefs and values, and to feel safe to express feelings of anger, guilt or confusion. It also means we need to understand how values and attitudes depend upon cognitive and ethical development [42]. How we best do this in a system which focuses on the cognitive domain over the affective domain, and which encourages disciplinary specialisation, is unclear and involves raising questions about our own learning and development, our own understanding of society and culture and of our selves. This may seem challenging for many of us trained within engineering and involves making choices which affect the way we are perceived by students, colleagues, and management. However, the benefit of the socially constructed nature of engineering is that it does allow us this choice.

ABSTRACT

The growth of Engineering Education Research (EER) has led to claims about it becoming a globally connected field of inquiry. This paper presents data on the development of EER within the UK and Ireland with the aim of contributing towards

[1] *Corresponding Author*

doi:10.5821/conference-9788412322262.1276

our understanding of the field. A computer-aided process was used to extract the names of authors, affiliated with UK and Irish institutions, that had published in a sample of 13 different EER journals in the years 2018 and 2019. We identified 122 UK authors and 17 from the Republic of Ireland.

Selected experts in both countries were contacted to obtain complementary data that were used to build a picture of the research landscape in which EER practitioners function.

Similarities and differences between EER in both geographic contexts were identified. In both there were few institutions listed as having EER centres, and it was more common for participants to refer to individual researchers. There also appeared to be a lack of formal PhD programmes and funding opportunities in EER within both countries. Whilst recognition for EER in the UK was primarily associated with teaching awards and fellowships, in Ireland EER outputs appeared to be as valued as disciplinary research activities.

The overall portrait that emerges from the data collected suggests that in both the UK and Ireland, EER does not benefit from a national support infrastructure but rather, is typically carried out by individuals or small groups of researchers.

1 INTRODUCTION

The last few decades have seen an increasing amount of research which focuses on the evolving nature of engineering education research (EER). The approach to such work varies. For example, Jesiek, Newswander, and Borrego [1] made use of observational data collected at the International Conference on Research in Engineering Education (ICREE) to examine how EER is variously conceptualized as a discipline, community of practice, and/or field. Froyd and Lohmann [2] make use of Fensham's [3] criteria for evaluating the maturation of fields of disciplinary-based education research to describe the state of EER.

Elsewhere, work has considered EER within the global context [4], [5], [6], with some making use of a comparative methodology when considering the approaches taken in different geographical locations. For example, Borrego & Bernhard [7] compared approaches to EER in the US and Northern and Central Europe. They concluded that the growth of EER depends upon understanding the perspectives of researchers within other contexts, as well as valuing diverse views on what constitutes quality.

Several pieces of research focus on the development of EER within different contexts including: the U.S.A. [2]; Portugal [8], [9]; Ireland [8]; Australia and New Zealand [10]; Europe [11]; as well as within three Nordic Countries [12].

More recently, this work has included the use of scientometric analysis to determine trends in the number of EER publications and is thus useful for quantitative comparison. This paper compares the development of EER within the UK (consisting of England, Wales, Scotland and Northern Ireland) and the Republic of Ireland. In so doing, a computer-aided process is used to extract the names of authors, affiliated with UK and Irish institutions. The findings are discussed in the context of complementary data obtained from selected experts within each location. Previous work [8] within the Irish context has described the status of EER, based on Fensham's [3] criteria. In the UK, two different studies have described low levels of engagement in EER, with a lack of peer reviewed articles [13], with most of the published research being single authored, or associated with single institutions [14].

2 METHODOLOGY

2.1 Publication data

This research adopts a case study approach, this being suited to the detailed and complex analysis necessary to answer questions about contemporary phenomena within real-life contexts [15]. We define our cases as the EER landscape within both the UK and Ireland. This includes EER centres within universities as well as national organisations that support, fund, and disseminate EER such as research networks. The research methodology was approved by research ethics committees at both Swansea University and TU Dublin.

A computer-aided process was used to extract the names of authors affiliated with UK and Irish institutions, who had published in a sample of 13 different EER journals in the years 2018 and 2019.

The journals were selected because they were indexed by Scopus and were established journals that had been publishing for at least several years. Related journals which focused heavily on technology aspects were not included (such as Computer Applications in Engineering Education and IEEE Transactions on Learning Technologies), as were journals that did not focus on a tertiary setting (such as Journal of Pre-College Engineering Education Research).

The thirteen selected EER journals were (i) Advances in Engineering Education, (ii) Australasian Journal of Engineering Education, (iii) Education for Chemical Engineers, (iv) European Journal of Engineering Education, (v) Global Journal of Engineering Education, (vi) IEEE Transactions on Education, (vii) International Journal of Electrical Engineering Education, (viii) International Journal of Engineering Education, (ix) International Journal of Engineering Pedagogy, (x) International Journal of Mechanical Engineering Education, (xi) Journal of Engineering Education, (xii) Journal of Engineering Education Transformations, (xiii) Journal of Professional Issues in Engineering Education and Practice (now Journal of Civil Engineering Education).

122 UK authors and 17 from the Republic of Ireland were identified.

2.2 Complementary data

This data was complemented by that obtained from the answers to five questions

1. Are you aware of any research teams/groups in the UK that focus on EER? If so, please name the relevant groups/leads/institutions

2. If there is no recognised EER team, are there individual active engineering education researchers? Can you share their names for the purposes of this study?
3. Are you aware of any institutions that have a structured programme, such as a PhD programme, which specialises in EER?
4. Are you aware of any incentives or recognition at your institution, or others within the UK, for publication within the EER community?
5. Is there funding or support for Engineering Education Research?
   Have any academics/researchers secured institutional, national or international funding for EER? If yes, could you provide source, objective and size of the funding?

In Ireland, the questions were emailed to all 17 of the identified authors. Nine authors who came from five different institutions, as well as one emeritus professor replied. In addition, the relevant deans of engineering and heads of engineering from 16 institutions in Ireland were emailed with the same set of questions. Eight deans/heads of engineering replied. Through this process, a further 17 academics were referred, with three responding. This resulted in a total of 21 individual participants from eight different institutions.

In the UK, where a larger number of authors were identified (122), a purposeful sampling approach was used whereby those contacted were considered to be "actor(s) who have been visible in the dominant EER communities" [12]. 12 individuals were approached, with nine replying. Through a snowball sampling approach, a further three participants were contacted, of which two replied. This resulted in a total of 11 participants who came from nine different universities. 10 participants answered via email, whilst one answered during a video call.

There was also an attempt to understand whether EER projects were funded within the UK. The Gateway to Research (GtR) website, which enables users to search and analyse information about publicly funded research, was used to identify work funded by UK Research and Innovation (UKRI) who are responsible for directing research and innovation funding provided by the governmental science budget. UKRI is composed of 7 research councils, including Engineering and Physical Sciences Research Council (EPSRC), and Economic and Social Research Council (ESRC), the latter being responsible for funding education research, as well as Innovate UK who support business-led research and innovation. Search terms included "engineering education", "engineering" and "education", "STEM education", "STEM" and "education".

3 RESULTS

3.1 Publication data

In quantitative terms we note a difference in the number of authors published from the two national contexts in the years 2018 and 2019 and that there were more from the Republic of Ireland relative to its population, as well as the number of academic staff employed by HEIs.

When considering these findings it is important to note that the computer aided process only considered articles published in 13 different EER journals in the years 2018 and 2019, and the extent to which findings represent long term EER activity within both the UK and Ireland is limited. It is also possible that the most common mode of dissemination is via conference papers as opposed to publications within journal, as has been noted as the case in previous work [13], [14].

Table 1: The number of authors, affiliated with UK and Irish institutions, that had published in a sample of 13 different EER journals in the years 2018 and 2019.

	Authors	Population (million)	Number of HEIs/ Academic Staff	Authors per million population	Authors per HEI/academic staff
Ireland	17	5.2	18/9,977 [16]	3.3	1.1/0.002
UK	122	67.1	214/ 224,530 [17]	1.8	0.6/0.0005

3.2 Ireland

Respondents from Ireland identified a small number of research groups, with the CREATE group at TU Dublin, which is typically made up of 20 individuals, being most commonly identified as directly focused on EER. Other groups noted include the Technology Education Research Group at the University of Limerick, the Sustainable Infrastructure Research and Innovation Group (SIRIG) at Munster Technological University, and the Engineering Education for Sustainable Development (EESD) group that is active in University College Cork. There were pointers to other looser networks and affiliations, such as the Irish Network for Gender Equality in Computing (INGENIC).

One distinguished researcher questioned whether EER is a disciplinary field, as it relies on engineering to exist. This researcher noted that the definition of EER coming from the US was too narrow to be useful, which was taken to mean that generating knowledge of engineering education through research and the EER agenda were not sufficiently broad. Certainly, in looking at the breadth of respondent comments, there were numerous indicators that activities can be interpreted as intending to inform practice, for example preparing students, improving engineering education, changing the nature of engineering, and impacting society [1].

There appear to be no restrictions or limitations on EER activity, and publications in this field count towards research active status, and support promotion applications. There was no evidence of structured PhD programmes in EER. However, a number of institutions clearly support PhD research projects in EER with numerous respondents confirming this. This occurs across the HE sector – within universities, technological universities and institutes of technology.

At a national level there was no evidence presented of targeted funding for EER. However, several funded projects were noted as addressing research questions within EER. At an institutional level, there appears to be some small local support (essentially seed money) for projects within the general definition of EER. One researcher noted receiving significant EU support for international collaborative projects to identify attributes that would inform the practice of educating engineering students.

3.3 UK

A small number of research groups were identified, the most commonly cited being the UK Engineering Education Research Network. UCL, Bristol University and Warwick Manufacturing Group were mentioned as institutions hosting EER groups by numerous participants, with one saying that “the only substantive group would have to be there at UCL. That’s about the only formal one”. There seemed to be confusion around whether some researchers were part of a group, with one participant considering that “because there's nothing formal within the university to promote that it will tend to be a loose, informal coming together of people…if they don't fit within the university structure, then it often it, you know it is built around individuals. So often it will fizzle and die people or move on”. It was therefore more common for EER activity to be associated with individuals within each institution, with one participant describing it as limited to “one or two people. Sometimes they work together, sometimes they don't.” The same participant claimed that it would be beneficial to “mobilize” individual researchers “around a national priority or something…you know, if you've got 50 institutions, you've got 50 contributions to your data set”.

Participants were unable to identify any formal PhD programmes, with one participant saying that this would imply “a more US approach to PhD than the UK individual scholar approach”. They added that “many of the interested academics have one or two PhD students” but that this would not “constitute a programme”. A different participant commented that such PhDs were “done within the typical the institutional PhD frameworks” and were often completed by international students who had financial support from their own governments, or those who had support of the department (especially in the case of candidates who were already staff) or through trusts. Some participants mentioned that the title of the PhD would be associated with the department and therefore, in the majority of cases, candidates would obtain a PhD in Engineering. This has implications for the identity of engineering education researchers, but also how their skills and expertise are perceived and the career opportunities that may be available to them. Other participants identified both UCL’s MSc Engineering and Education and the Engineering Education BSc from the University of Sunderland which both include some elements focused on conducting education research.

Views around incentives or recognition for publication were polarised, with answers being linked to both teaching career pathways and Research Excellence Framework (REF). Those who spoke about teaching pathway (the title given to those on education-focused career paths varied between institutions and included teaching fellows, teaching and scholarship academics or education and scholarship academics), mentioned the need to produce pedagogical research or scholarship in order to achieve promotion. Internal funding for education research and Fellowship of Advance HE and the National Teaching Fellowship awards programme were also mentioned as incentives.

Opinions about the role REF played in incentivizing researchers were mixed. For example, one participant believed “change in terms for 2021 REF enabled EER publications to be submitted for assessment in the engineering panel which gave them a little more status.” In comparison, a different participant believed engineering panels “won't understand what you're doing” and that was assuming that “you've got to get through all the institutional culture that's against it before you can even get to that point”. However, they did add that “REF could be such a facilitator for what we're doing” suggesting “that unless a discipline can demonstrate in the REF it is doing discipline-based education research it should be marked down”. A different participant claimed there were “more disincentives” associated with EER than incentives, which they considered to include a lack of “journals with sufficient rating for REF submission while at the same time being practitioner relevant”, something which they considered made it “difficult for newer researchers to use the field to advance their academic careers” and meant that for more experienced researchers “it can be a part time activity while also pursuing their core engineering discipline”.

Funding for EER was considered to be “very limited”. Some participants had access to internal funds from their own institutions. The Higher Education Academy (now called Advance HE), the Office for Students, QAA, the Nuffield Foundation, and Leverhulme Trust as well as the Engineering Professors’ Council (EPC) and the Royal Academy of Engineering were all named as possible sources of small amounts of money. However, opportunities were sporadic, and organisations were described as not “really properly commit(ing) to something a little bit more like a programme of work”. Obtaining funding was described as mostly “coat tailing on other grants” which looked at “tangential things”. The lack of availability of funding was considered, by one participant, to result in “pigs feeding at a troth (*sic*)” and dispersed efforts, as opposed to the development of a sustainable community.

In comparison, a different participant considered the lack of funding to be a “perceptual problem rather than a real one”, something which they attributed to education research not requiring a lot of funding, and many institutions having small pots of money available. They believed that “the real gap to people doing EER is their own skills and lack of understanding of social sciences research methods, but that often gets masked as lack of funding”.

Funding from UKRI (Identified using Gateway to Research) appeared to take three different forms. In the first instance PhD studentships focused on research within engineering education were funded through EPSRC Doctoral Training Partnerships (DTP), a type of funding provided to UK universities to support multiple studentships. The funding is allocated to universities with significant EPSRC research activity, by means of an algorithm and it is up to the university holding a DTP to allocate studentships within their organisation. This funding source is therefore dependent on the local environment. The second form of funding was for projects that focused on engineering outreach work. The third type of funding was for development of software for education purposes and was typically funded by Innovate UK.

Table 2 Comparison of EER landscapes in the UK and Republic of Ireland

EER Landscape	UK	Republic of Ireland
Research Groups	Small number of research groups, with UCL Centre for Engineering Education being the most established	Small number of groups, with CREATE at TU Dublin being the most established.
Degree Programmes	MSc Engineering and Education (UCL) and BSc Engineering Education (University of Sunderland) both include elements focused on conducting education research	PhD at TU Dublin, MSc at DCU
National Incentives	REF (both incentive and disincentive) Fellowship of Advance HE and the National Teaching Fellowship awards. Lack of sustainable sources of funding, with small amounts of money periodically being available from various sources.	No specific funding line for EER, but some relevant projects have received funding.
Institutional Incentives	Some small amounts of funding. Scholarship counts towards promotion for Teaching Pathway Academics.	Some small incentives. Research outputs count towards promotion.

4 SUMMARY AND ACKNOWLEDGMENTS

There do not appear to be any explicit differences between the EER landscapes that would explain the increased number of authors in EER in Ireland compared to the UK. In both contexts there are only a small number of established research groups and formal doctoral qualifications. There is also a lack of external funding with internal incentives consisting of small amounts of funding and progress toward promotion. It is possible that the smaller number of institutions within the Republic of Ireland means that it is easier to collaborate and that there is less competition for the scarce funds available. It is also clear that REF has an impact on the research culture and environment within the UK context and could explain why it is more likely for EER to be considered as research activity for academics within Ireland.

The assumed desire for the UK and Ireland to remain at the forefront of engineering education developments creates the need for clear strategies that focus on national needs and collaboration, something which could be further facilitated by the UK and Ireland EERN, which was mentioned as providing a vibrant community across both of the regions considered. The creation of a research agenda should be facilitated by conversations between all stakeholders including policymakers, professional institutes, as well as academia, industry and engineering students. Such an approach would allow for the critical mass needed to carry out ambitious and well structured projects with wider reaching impact. This, in turn, is predicted to attract interest from researchers from different disciplines, including education and the social sciences, as well as funding possibilities. Researchers within the UK and Ireland should also pursue opportunities to work with international colleagues, particularly those from contexts in which EER is more established. This will allow them develop their research expertise, take part in larger projects and contribute to international developments.

Policymakers should consider funding priorities. For example, as Malmi et al. (2018) point out, whilst the US National Science Foundation support EER, within Europe funding is difficult as it does not align with criteria set out by Horizon 2020 funding [18].

In the absence of external financial support it seems clear, particularly given the increased pressures placed on universities and their staff, that the development of EER within both the UK and the Ireland will be dependent upon both institutional and national recognition for the work involved.

Further work in this area should focus on comparing the trends in publication across a wider timeframe, and comparison with more countries within Europe.

ABSTRACT

A systematic approach was undertaken to locate and analyse empirical research examining the use of technology to support constructivist approaches to learning. In particular, this paper focuses upon Problem, Project and Case Based Learning and consults publications which have employed technology in Science, Technology, Engineering and Mathematics within on campus higher education settings. Four databases were searched and after applying relevant inclusion and exclusion criteria, 56 publications published during 2007–2021 were included in this review. In addition to systematically documenting the landscape of literature associated with this area of research, this paper offers an analysis of the contributions of the research in understanding the way in which technology affects efficiency, team effectiveness and inclusivity as part of the learning process.

1 INTRODUCTION

1.1 Problem, Project and Case based constructivist approaches in STEM

The disciplines of science, technology, engineering and mathematics are collectively and more commonly referred to as STEM. Constructivist approaches such as Problem, Project and Case based learning are often employed within these disciplines and involve students working collaboratively to resolve complex, authentic and real-world problems (Hmelo-Silver, 2004; Graham, 2010; Hanney & Savin-Baden, 2013; Harmer & Stokes, 2014; Kennedy & Odell, 2014). Autonomy in learning, team work, and an active approach to sharing knowledge and understanding as part of a problem-solving process are integrated across the STEM disciplines. The tutor undertakes the role of facilitator to support students when

engaging in carefully selected real-world challenges (Wood, 2003; De Graaf & Kolmos, 2003; Allen, Donham & Bernhardt, 2011).

Distinctions between Problem, Project and Case based learning often relate to the discipline in which they are most often located, for example, medicine and related fields such as healthcare often use the term 'Case Based Learning' (CBL). Cases relate to clinical practice but draw upon features of Problem Based Learning (PBL) such as problem solving in small groups. In some instances, the term CBL can be used interchangeably with PBL (Azer & Azer, 2015) with both involving the ability to collaborate and communicate as key attributes. Such attributes may, in some circumstances, be referred to as graduate skills or attributes of employability (Gunn, Bell & Kaffman, 2010).

For STEM subjects, such an approach would be relevant as the ability to solve problems as part of a team relates to the context in which many of the students will ultimately work and, as such, would be attractive to prospective employers and valued by accrediting bodies. However, there are also potential barriers to PBL-related approaches which often cite resources which include facilities as well as staff time (Graham, 2010; Kokotsaki et al, 2016; Harmer & Stokes, 2014; Frambach et al., 2019) and can be classified under three broad areas, namely, efficiency, effectiveness and inclusivity.

1.2 Constructivist approaches and the use of technology

A wide range of technologies to support campus-based teaching and learning are currently available. These include, but are not restricted to interactive handsets, displays and mobile devices to support, facilitate and enhance constructivist approaches to learning (Ioannou, 2016; Wood & Shirazi, 2020); simulations, games (Vlachopoulos & Makri, 2017), augmented reality, (Ibáñez & Delgado-Kloos, 2018), computer supported collaborative learning environments, (Al-Samarraie & Saeed, 2018) and use of multimedia and video (Noetel et al., 2021).

Existing systematic reviews examine specific technologies in relation to constructivist or student centered approaches to learning, for example, the use of a web-based online environment (Jurewitsch, 2012); cloud computing (Al-Samarraie & Saeed, 2018); audience response systems (Wood & Shirazi, 2020); video (Aronis, 2016; Noetel et al., 2021) or perhaps the use of a specific technology within STEM subjects, for example, augmented reality, (Ibáñez & Delgado-Kloos, 2018); digital case scenarios (Gavgani et al., 2015). There are also studies which focus upon a specific subject or discipline within the overarching portfolio of STEM, for example, Car et al., (2019) and Jin & Bridges, (2014) who respectively examined literature focussing upon digital technologies and interactive whiteboards and virtual learning environments (VLEs) in PBL within health education. The former concluded that there was evidence that digital PBL appeared to be more effective than either traditional PBL or traditional learning in terms of students' skill outcomes and more effective or equal to traditional PBL where knowledge outcomes are concerned. Jin & Bridges' study found that authenticity and 'rich' opportunities for learning facilitated students' growing expertise. Technology offered structured learning and supported engagement in collaborative activities which allowed students to explain, discuss and reflect upon their understanding thereby making their thinking more explicit (2014). Flipped learning in engineering was examined by Karabulut-Ilgu et al., (2018) who concluded that studies generally reported increased effectiveness in student learning. However, Karabulut-Ilgu et al., also highlighted that there was 'a paucity of the report of theoretical frameworks guiding the development and evaluation of the flipped approach' (p. 406), and that quantitative methods of evaluation were favoured above qualitative. Benefits of flipped learning in engineering, particularly 'professional skills and increased interaction' therefore needed further investigation to understand why and how such interventions were beneficial to student learning. A more recent review signalled the potential value of digital games in STEM education and argued that learner types and the effect of different forms and designs of such games on student learning needed to be examined (Wang et al, 2022). The authors also highlighted the need to support students' developing understanding of 'abstract and multi-dimensional concepts' when working within STEM subjects and the potential value of games in achieving this (Wang et al., 2022 p. 10).

Context and Rationale

There is a noticeable rise in the use of blended learning within campuses across the higher education sector. The popularity of PBL and related challenges listed above, calls for a review of the research carried out to date that represents the use of technology to improve the key outcomes for which PBL is chosen. A particular focus is on campus PBL settings as STEM educators now face a high proliferation of technology in their practice. Researchers looking at the how and why technology can enable or enhance the key outcome will also benefit from this review. Rather than selecting a specific technology or subject within the STEM disciplines, this study reviews empirical research which employs digital technologies used within any STEM discipline as part of a constructivist approach to learning and teaching, for example PBL, PjBL and CBL. With constructivist learning providing a central, unifying focus, the findings of this research will be relevant to researchers focussing upon specific or combined disciplines within the field of STEM in higher education.

2 METHODOLOGY

2.1 Research Questions

This systematic landscape review provides an overview of empirical research which examines the use of technologies for CBL, PBL and PjBL in higher education. It focuses upon the meta-discipline of STEM and reports on the landscape of literature which, at the time of writing this paper, sought to present the way in which technology supported and enabled: team-working; the development of graduate skills and student learning.

The PICO framework (Schardt, Adams, Owens, Keitz, & Fontelo, 2007), was employed where key criteria involving Population (P), Intervention (I), Comparison (C) and Outcome (O) provided a means of systematically defining our research question, search clause, inclusion and exclusion criteria in order to identify relevant literature which would allow us to answer the research questions. The population was limited to STEM disciplines in on campus Higher Education (HE) settings and the intervention involved the use of any technology in order to study its impact on the three key outcomes: team-working, graduate skills and student learning.

The following overarching and sub-research questions were developed using the PICO framework:

1. How have learning technology interventions been used to support the key outcomes related to problem, project and, case-based approaches within on campus higher education STEM settings?
    a. What technologies have been used in relation to the identified outcomes?
2. What are the characteristics of these studies?
    a. Which disciplines within STEM education have employed such approaches?
    b. What are the methodological characteristics of the studies?
3. What are the main findings of these studies?

2.2 Search and selection

In order to locate relevant articles undertaking primary research, which corresponded to the area of interest described above, a systematic search of four databases: Scopus (Sco), Education Resource Information Centre (ERIC), Web of Knowledge (WoK) and ScienceDirect (SD), was undertaken.

Table 1

PICO Themes	Corresponding search term
Population: Case / *Problem / Project based*	("Problem based Learning" OR "Project based learning" OR "CDIO" OR or "case based learning")
Population: *Higher Education*	("higher education" or "university" or "graduate" or "bachelor" or "college" or "post compulsory" or "post secondary" or "third level") AND ("engineering education" or "medical education" or "health education" or "science education" or "computing" or "mathematics")
Intervention: *Technologies*	("technology enabl*" or "technology enhanc*" or "video*" or "collabor* technology" or "flip* class*" or "flip* learn*" or "learn* techno*" or "m learning" or "mobile learn*" or "e learning" or "electronic learn*" or "interactive whiteboards" or "forum*" or "Wiki*" or "blog*" or "MCQ*" or "vlog*" or "Network* learn*" or "scale-up" or "blended lear*" or "learning environment" or "interactive learn*" or "handheld" or "active learn*" or "active method*" or "game based" or "Gamifi*" or "Social software" or "CAL" or "Computer assisted*" or "Computer support*" or "CSCL" or "learner track*" or "social learn*" or "Web 2.0" or "authentic*" or "voting systems" or "clickers" or "audience response systems" or "interactive learning tech*" or "simulations" or "augmented reality" or "peer instruction")
Comparator: *Any*	None.
Outcome: *Learning, Team working and graduate skills*	("perform*" or "team management*" or "achievem*" or "pretest" or "posttest" or "team develop*" or "team dynamics" or "collaborat*" or "cooperat*" or "group cohesion" or "team cohesion" or "team work*" or "self-regulated learning" or "SRL" or "team perform*" or "social dilemma*" or "conflict*" or "graduate attri*" or "graduateness" or "graduate skill*" or "soft skills" or "employ* skills" or "learning gain")
Final search clause	Population terms AND Intervention terms AND Outcome terms.

Filters, where available, were applied in order to include articles published from January 2007 to June 2021 and which were written in English. The search was not restricted to journal articles or to those which were subject to peer review in order to ensure the returns encompassed as wide a range of sources as possible thereby reducing the risk of bias across studies (Schlosser et al., 2007). Hand searching and reference checking were undertaken after the screening of full papers had been completed, more specifically, an ancestral search of the reference lists of the 41 selected articles was conducted by the authors, who identified further 15 articles that met the inclusion criteria. The PICO framework, (see table 1), was also helpful in systematically defining search terms within this review.

2.3 Inclusion and exclusion criteria

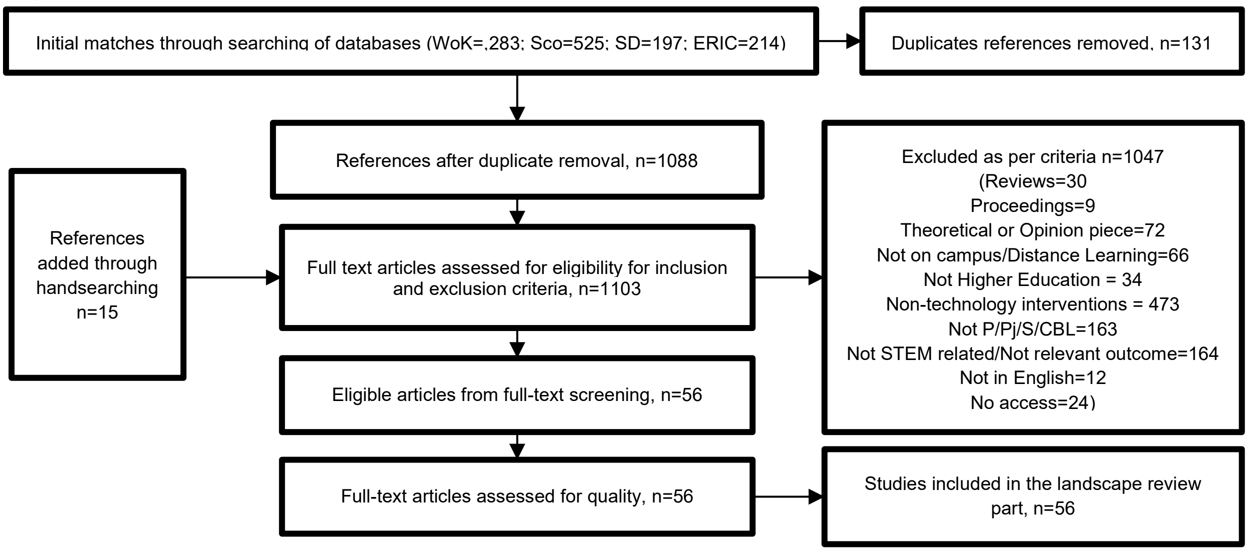
The PICO framework also helped in aligning our inclusion/exclusion criteria in a systematic way with the search terms and research questions. Table 2 shows details of the inclusion and exclusion criteria used.

Table 2

Inclusion Criteria	Exclusion Criteria
Population • HE-STEM Explicit mention of PjBL/PBL/CBL/CDIO. • On campus environments. **Intervention** • Any instance where technology has been used to support the selected population and outcomes. **Outcomes** • Team working • Learning gain • Graduate skills **Time Limit** • Publications between 2007 and 2021.	• All Subjects and Outcome not as stated in the inclusion criteria • Not on campus / Distance Learning. • All non-HE studies. • All studies not written in English. • All theoretical texts/ opinion pieces. • All proceedings • All reviews. • All studies published outside the defined date range. • All Non-Project / Problem/ case-based learning studies. • All Non-technology interventions. • No Access.

Following the recommendations from the Preferred Reporting Items for Systematic Reviews and Meta-Analyses, (PRISMA), (Moher et al. 2009), the landscape review of literature was undertaken through a three-stage systematic process of identifying and screening in order to arrive at the 56 papers included in this study (see figure 1).

Figure 1



During the first phase, a search resulted in 1219 results from the four selected databases. After removing the duplicates, attempts to access the full-text version were made on 1088 articles. To improve the reliability in the use of inclusion and exclusion criteria, each author and a third colleague read the titles and abstracts of 100 randomly chosen articles from the search results. Each researcher examined and assessed the articles independent of the others. A shortlist from each author was used to perform an inter-rater reliability check. The inter-rater reliability scores were calculated using Cohen’s Kappa calculation to consider any chance agreements between the researchers. As there were only 100 data points, the calculation was undertaken using a spreadsheet. Scores between the three pairs of researchers were: 0.70, 0.67 and 0.93 respectively. Scores ranging from 0.61 – 0.80 represent substantial agreement and 0.81 – 0.99 as near perfect agreement (HowToStats, nd). This allowed the authors to identify papers which needed further discussion and refining the use and definitions of the inclusion and exclusion criteria before progressing. The researchers then discussed the differences and agreed on the papers to include before phase two.

The second phase of the review process consisted of dividing the remaining papers from the search results between the researchers who reviewed these independently. This resulted in 41 papers being shortlisted from the search results. Handsearching, (Boland et al., 2017), of reference lists from those shortlisted yielded fifteen articles that met the inclusion criteria which were added to the shortlist. In total, 56 articles were retained for the landscape review.

A shared spreadsheet was used to extract key information, namely; (1) authors, (2) year of publication, (3) type of publication, (4) Population, (5) Intervention type, (6) Comparator / Control use, (7) Outcomes (8) aim of study, (9) country, (10) HE Level, (11) demographics, (8) research design, (9) research instruments, (10) data analysis procedures, (11) length of study and (12) Main findings of study. These are discussed further in the results section.

3 RESULTS OF THE LANDSCAPING REVIEW

The 56 selected studies are summarised in table 3 below. The papers are largely quantitative in nature reflecting the general focus upon the effect of the interventions on student performance. Of the studies that explicitly stated the methodology they had employed, quasi-experimental was the most frequently cited closely followed by randomised control trials. Qualitative data is sometimes employed within studies in combination with quantitative data, however, the emphasis is generally upon the quantitative with qualitative data occupying a minor role. Medicine and other health-related disciplines appear to make the most use of, and undertake research in, the use of technologies for PBL/CBL/PjBL. Alongside engineering and technology, these disciplines appear to contribute the most in terms of research publications. Interest appears widespread across the globe although there is a greater concentration of publications originating from North America and Europe.

Table 3 Landscape review of the findings included in this work

Authors, date of publication and source	**Population, intervention, outcome**	**Methods, instruments and duration**	**Main findings**
Aparicio, F., De Buenaga, M., Rubio, M. and Hernando, A., (2012). *Computers & Education*	medical, ITS, Performance	Quantitative Case study with comparator 90 mins Test and questionnaire	'computer tools created to facilitate and direct information searches on Internet are useful to enhancing the learning process in Health Sciences students.'
Arain, S.A., Afsar, N.A., Rohra, D.K. and Zafar, M.,(2019) *Advances in physiology education*	medical, video, graduate skills	Quantitative Quasi- RCT 1 semester Observations	'The study indicates that inclusion of AV aids improved students' engagement and classroom environment in electronic-PBL sessions, but did not improve diagnostic abilities based on the learned clinical skills'
Balslev, T., De Grave, W., Muijtjens, A.M.M., Eika, B. and Scherpbier, A.J.J.A. (2009*), Advances in health sciences education*	medical, video, team-working	Quantitative Case study with comparator 1 session Interview	An 'enhanced shared cognition through collaborative concept link formation' and 'Co-elaboration of concept formation is stimulated'
Barmaki, R., Yu, K., Pearlman, R., Shingles, R., Bork, F., Osgood, G.M. and Navab, N. (2019) *Anatomical sciences education*	medical, augmented reality, performance	Quantitative RCT 1 semester Test and questionnaire	'time on task, painting outcomes, and level of engagement with statistically significant outcomes' 'Statistical significance was established for most measures except long term knowledge retention.'
Bridge, P., Trapp, J.V., Kastanis, L., Pack, D. and Parker, J.C (2015) *Australasian physical & engineering sciences in medicine*	medical, virtual lab, performance and graduate skills	Mixed Cross sectional 1 semester questionnaire	Greater efficiency (student time and resource access), increased understanding, enjoyable learning, increased opportunity for experimentation and team working.
Chang, S.H., Chen, M.L., Kuo, Y.K. and Shen, Y.C., (2011) *IEEE Transactions on Education*	engineering, simulation and online, multiple outcomes (performance, team-working and graduate skills)	Mixed Case study no control 1 semester Questionnaire and test	Improved student conceptual understanding, design skills and allowed students to learn from one another (team working skills)
Chen, C.Y. and Teng, K.C., (2011), *Computers & Education*	engineering, collaborative system, team-working	Mixed Longitudinal 3 years Survey and interview	The use of a collaborative system introduced a macro-level meeting-oriented group process to guide collaborative work
Cole, D., Rengasamy, E., Batchelor, S., Pope, C., Riley, S. and Cunningham, A.M.,(2017) *BMC medical education*	medical, social media, team-working	Quantitative Cross sectional 1 year Survey and user metrics	Depending on a student's strategy (to use or not to use social media), students used SM to support collaborative learning
De-La-Fuente-	engineering,	Quantitative	Reduction in staff workload, reduction in student

Valentín, L., Pardo, A. and Kloos, (2013) Computers & Education	scripted learning, performance	Case study no control 6 weeks Test	dropout rate, sustained student effort, students valued the scaffolding despite increased workload
Ende, H.B., Lumbreras-Marquez, M.I., Farber, M.K., Fields, K.G. and Tsen, L.C., (2021) *International Journal of Obstetric Anesthesia*	medical, low fidelity sim, performance	Quantitative Quasi RCT 6 months Survey and test	No statistical difference between traditional approach and intervention
Eng, A.J., Namba, J.M., Box, K.W., Lane, J.R., Kim, D.Y., Davis, D.P., Doucet, J.J. and Coimbra, R., (2014), *American Journal of Pharmaceutical Education*	medical, hi fidelity simulation, performance	Quantitative Case study no control 1 semester Tests, survey	Improved confidence, evidence of improved patient care linked to performance, sim environment supported students' recall and skill application
Gisondo, C.M., Weiner, G. and Stanley, K., (2021), *MedEdPORTAL*	medicine (transport), video, performance and graduate skills	Quantitative Case study no control 30 mins to 2 months Questionnaire, pre/post test	Significant improvement in knowledge and confidence
Guariento, B., Al-Masri, N. and Rolinska, A., (2016), *American Society for Engineering Education*	engineering, blended, graduate skills and team-working	Mixed Case study no control 1 academic year Survey	Improved awareness of appropriate communication, processes of teamwork
Gurpinar, E., Zayim, N., Ozenci, C.C. and Alimoglu, M.K. (2009) *Turkish Online J. Educ. Technology*	medical, web-based learning (quizzes, links, search engine), performance	Quantitative Case study with comparison 8 weeks Questionnaire, computer log files and exam results	Significant improvement in exam performance
Hannig, A., Kuth, N., Özman, M., Jonas, S. and Spreckelsen, C.,(2012) *BMC medical education*	medical, game based, performance	Quantitative Quasi RCT 4 semesters Questionnaire and observation	Strong collaboration inspired by the competitiveness of the gaming aspects, increased willingness to learn
Harris, D.M., Ryan, K. and Rabuck, C., (2012), *Advances in physiology education*	medical, hi fidelity simulation, performance	Quantitative Case study with comparison One week 3 x 3 hour Pre/post-test and survey	Increased students' confidence in treatment strategy attributed to active learning involved in simulation
Hoic-Bozic, N., Mornar, V. and Boticki, I., (2008), *IEEE transactions on education*	technology, blended learning, management system, performance	Mixed Case study no control 2 terms questionnaire	Academic achievements were better than expected, dropout rate diminished, but students felt it was time-consuming
Jesus, Â., Gomes, M.J. and Cruz, A. (2016), *11th Iberian Conference on Information Systems and Technologies*	pharmacy, various tools performance	Quantitative Quasi RCT 10 weeks Test	Better exam results than traditional f2f.
Jou, M., Lin, Y.T. and Tsai, H.C., (2016), *Interactive*	engineering, mobile app and cloud computing,	Quantitative Case study with comparator 1 semester	the Mobile Learning APP provided a significant positive effect on learning performance and that most students showed favourable attitudes toward the

Learning Environments	performance	questionnaire	usage of the mobile learning system
Kish, G., Cook, S.A. and Kis, G., (2013), *Anatomical sciences education*	medical, simulation and online content, performance	Quantitative Case study with comparator 11 weeks (8 computer sessions) Exam	Significantly better anatomy curriculum student performance
Kleinert, R., Heiermann, N., Plum, P.S., Wahba, R., Chang, D.H., Maus, M., Chon, S.H., Hoelscher, A.H. and Stippel, D.L., (2015), *Journal of Medical Internet Research*	medical, simulation, performance	Quantitative Experimental 1 year Pre/post-test and survey	Impact shown on knowledge gain- increase in declarative knowledge, students were 'enthusiastic and motivated'
Kourdioukova, E.V., Verstraete, K.L. and Valcke, M. (2011), *European journal of radiology*	medical, computer supported collaborative learning scripting, multiple (performance, team working and graduate skills)	Mixed Survey and case study with comparison 3 weeks and 5 weeks survey and online interactions	Neutral to positive attitude to collaborative learning. CSCL developed students' medical vocabulary and reporting skills
LaRochelle, J.S., Durning, S.J., Pangaro, L.N., Artino, A.R., Van Der Vleuten, C. and Schuwirth, L., (2012), *Academic Medicine*	medical, video, performance	Quantitative RCT 2 years test	Increased authenticity of learning resources- mid level students' performance worsened (attributed to the possibility of cognitive overload)
Lee, M.J., Nikolic, S., Vial, P.J., Ritz, C.H., Li, W. and Goldfinch, T., (2016), *IEEE Transactions on Education*	engineering, video conferencing, graduate skills	Mixed Case study with comparator 2 semesters Test and questionnaire	'students became more confident and honed their presentation skills in preparation for their assessable pitches.'
Lin, J.W. and Tsai, C.W. (2016), *Computers & Education*	technology, scripting, team working	Quantitative RCT 14 weeks questionnaire	In an online PBL environment, GA has positive but temporary effects on low-SR students but positive and sustainable effects on high-SR students. In sum, an online PBL environment with GA support has different time length effects (i.e., temporary or sustainable effects) on different SR-level students.
Lu, J., Lajoie, S.P. and Wiseman, J., (2010), *International Journal of Computer-Supported Collaborative Learning*	medical, scripting, multiple (graduate skills, team working)	Mixed Case study no control 1 semester Observation	'..visualization and argumentation tools which supported goal setting, help seeking, time management, and planning. Students using interactive whiteboards demonstrated more adaptive problem-solving behavior than those using only traditional whiteboards. Interactive whiteboards mediated the teacher's scaffolding by increasing class participation'
Manogaran, E., (2013), *IEEE Fifth International Conference on Technology for Education*	technology, blended technologies, performance	Quantitative Quasi experimental Test and questionnaire	Decreased failure rate by approx. 50% with students performing significantly better
Martinez, M.L., Romero, G.,	engineering, collaborative web	Quantitative Case study with control	'The use of a collaborative Web environment has made it possible for students to work in

Marquez, J.J. and Perez, J.M. (2010), *IEEE EDUCON 2010 Conference*	environment, performance	1 academic year Survey and final marks	multidisciplinary teams' and 'enabled students to approach a problem from four different points of view'
McNamara, J., Sweetman, S., Connors, P., Lofgren, I. and Greene, G. (2020), *Journal of nutrition education and behavior*	agriculture, mind maps and T-Charts, graduate skills	Quantitative RCT 2 weeks questionnaire	'successful at encouraging students to use more CT-DM skills when compared with the control group.' 'better at making a decision and supporting that decision with a greater number of evidence-based reasons.'
Ng, O.L., Ting, F., Lam, W.H. and Liu, M. (2020), *The Asia-Pacific Education Researcher*	maths, interactive whiteboard, performance	Quantitative Quasi RCT 13 weeks test	students in the interactive group had almost twice the normalized gain of the traditional tutorial group.
Pearson, R.J., (2017), *Journal of Chemical Education*	chemistry, clickers, performance	Quantitative Longitudinal 2 years Exam score and survey	students think more deeply in-class and providing instant feedback are essential ingredients when creating an effective problem-based learning environment where students become more inquisitive learners. Combining a team-based model with clicker technology created a perfect blend, thereby allowing students to enter into peer instruction while maintaining a fun, interactive, and engaging environment in which to learn.
Peng, J., Wang, M. and Sampson, D., (2017), *Journal of Chemical Education*	engineering, various tools including visualisation, performance	Mixed Case study no comparison 1 year Survey, tests and interview	the participants made significant improvements on programming task performance and subject knowledge after completing the learning module. Their progress in programming performance was significant in all aspects (i.e., problem understanding, modular design, process design, and coding)
Peng, J., Wang, M., Sampson, D. and van Merriënboer, J.J., (2019), *Australasian Journal of Educational Technology*	technology, visualisation, performance	Quantitative Case study no control 6 weeks Test	the visualisation-based cognitive tool is more effective in improving students' programming performance and better perceived by students in terms of its support for scaffolding and articulating the complex project process.
Poulton, T., Ellaway, R.H., Round, J., Jivram, T., Kavia, S. and Hilton, S., (2014), *Journal of medical Internet research*	medical, simulation, performance	Quantitative RCT 1 semester Test	the use of Dynamic-PBL leads to better midterm learning outcomes than linear PBL (for questions related to D-PBL experiences
Prescott, W.A., Woodruff, A., Prescott, G.M., Albanese, N., Bernhardi, C. and Doloresco, *American Journal of Pharmaceutical Education* F., (2016),	medical, various tools including quizzes, performance	Quantitative Case study with control 1 academic year Exam and survey	improved academic performance and was well-received by students - students enrolled in the blended-learning model scoring better on the final examination and on aspects of the clinical skills examination, and achieving a higher letter and numeric course grade (poss due to watching/rewatching the videos)
Rodrigues Da Silva, A.N., Kuri, N.P. and Casale, A., (2012), *Journal of Professional Issues in Engineering*	engineering, various tools, performance	Mixed Case study with control 4 years Grades, questionnaires and assessments	increased student performance over the four years, evidence of greater knowledge and depth of understanding for PBL groups students took increasing responsibility for their own learning.

Education and Practice			
Sáiz-Manzanares, M.C., Escolar-Llamazares, M.C. and Arnaiz González, Á. (2021), *International journal of environmental research and public health*	medical- nursing, online interaction, multiple, (performance, graduate skills)	Quantitative Quasi RCT 9 weeks Test and questionnaire	Good results have been obtained in all assessment tests in the two types of blended learning. However, the type of blended learning that applied automated feedback and hypermedia resources obtained even better results
Sancho-Thomas, P., Fuentes-Fernández, R. and Fernández-Manjón, B. (2009), *Computers & Education*	technology, various tools, team-working	Mixed Case study with control Up to 2 years Questionnaire	Reduced drop out rate, increased pass rate, positive effect in knowledge acquisition, helped to develop team work skills
Saraç, L. and Ok, A., (2010), *Resuscitation*	medical, video, multiple (performance, graduate skills)	Quantitative Experimental with control 1 semester Test	Students performed less well than traditional approach- attributed to lack of hands-on practice and reinforcement from tutor
Saunder, L. and Berridge, E.J., (2015), *Nurse education in practice*	medical- nursing, simulation, graduate skills	Qualitative Case study no control 1 session Interview	Mostly focussed on design-divided student opinion opportunities to reflect on clinical practice and enhanced sense of competence but lack of realism, possible oversimplification and more student preparation were also listed
Selvi, S.T., Kaleel, D. and Chinnaiah, V., (2012), *International Conference on Recent Trends in Information Technology*	engineering, various tools, multiple (Team working and graduate skills)	Quantitative Case study with control questionnaire	TEL enhanced PBL approach revealed increase in skills (commitment, decision-making, confidence and collaboration) 2. increased competitiveness and 3. team spirit
Spinello, E.F. and Fischbach, R., (2008), *Public Health Reports*,	medical, simulation, performance	Mixed Case study with control 1 year Survey and exam	reported higher levels of cognitive learning in traditional than those in the Sim group, academic performance in sim higher particularly in needs assessment and intervention planning
Splichal, J.M., Oshima, J. and Oshima, R., (2018), *Computers & Education*	technology, scripting, team working	Mixed Case study no control 13 weeks questionnaire, observation	students were likely to self-regulate themselves or co-regulate other members when they encountered socio-emotional challenges such as inactive discussions, students who produced well-organized scripts shared the perceptions of challenges and progressively worked on them and used various regulation strategies.
Sun, C. and Qi, X. (2018), *World neurosurgery*	medical, simulation and scripting, performance	Quantitative Quasi RCT 1 year Test and questionnaire	Increased confidence, sense of accomplishment and individual judgement, the approach visually stimulated students' interest and enthusiasm and increased their self-confidence, pre/post test showed no significant difference between pSBL and non-PSBL
Topalli, D. and Cagiltay, N.E., (2018), *Computers & Education*	engineering, various tools, performance	Quantitative Longitudinal experimental 4 years Test	students' performance in the Senior-projects improved significantly; the game projects improve students' motivation
Tsai, M.H. and Tang, Y.C., (2017), *Library Hi Tech*	chemistry, various tools, graduate skills	Mixed Case study with control 1 semester Questionnaire	the experimental group was found to outperform the control group in terms of problem-solving attitudes, and the difference was statistically significant; authors suggest that lesson plan contents need to be designed based on problem-based learning theory, and reflect real-world conditions

Vivian, R., Falkner, K., Falkner, N. and Tarmazdi, H. (2016), *ACM Transactions on Computing Education*	technology, various tools, team working	Qualitative Instrumental Case study Duration not stated Online discussions	Most students employed content knowledge and discussed the problem- some metacognitive activities- solution focussed, rarely employed monitoring and regulation in favour of leadership and team-orientation
Weidenbusch, M., Lenzer, B., Sailer, M., Strobel, C., Kunisch, R., Kiesewetter, J., Fischer, M.R. and Zottmann, J.M., (2019), *BMJ open*	medical, video, performance	Quantitative RCT 90 mins Test and questionnaire	CCD approach is effective and sustainable approach for clinical reasoning. Higher efficacy of more interactive formats can be attributed to positive effects of collaborative learning.
Whelan, J.J., Spencer, J.F. and Rooney, K., (2008), *Rural and Remote Health*	medical, simulation, team working	Mixed Quasi experimental design 2 years Survey and focus group	1) student understanding of interprofessional practice in relation to quality of patient care increased 2) Broadened student understanding og professional roles-theirs in relatio to others 3) interactivity and authenticity of CNL scenarios well-received. Some not keen on role play but overall the experience contributed to collaborative and team-working skills
Williams, C., Familusi, O.O., Ziemba, J., Lee, D., Mittal, S., Mucksavage, P., Smith, A. and Kovell, R.C. (2020), *Urology*	medical, various tools (synchronous and asynchronous online), multiple (performance and graduate Skills)	Mixed Case study no control 4 weeks Questionnaire	course significantly increases students' scores in: self-perceived urologic knowledge, confidence in naming urologic conditions, comfort with performing urologic evaluations, and confidence placing consults for urologic conditions ($P < .05$).
Woltering, V., Herrler, A., Spitzer, K. and Spreckelsen, C., (2009), *Advances in Health Sciences Education*	medical, various tools, multiple (performance and team working)	Mixed Case study with control 3 years Questionnaire	The students described the blended PBL as "realistic", "descriptive" and "very practical" supporting memorisation and motivation of the students; flexibility the students emphasized the flexibility that was offered by the program, so that they were able to meet when they wanted to and to reconnect to the information after the first meeting; the use of a video was well-received For the tutors; no difference was perceived by tutors
WUa, C.P. and YONG, H.J (2013), *21st International Conference on Computers in Education*	technology, various tools, simulation, web-based resources, performance	Quant Quasi RCT Over 1 month Test	PBL group performed better than the traditional PBL group- authors suggest the worked example simulation of an expert's reasoning process with reasons given for decisions made helped students understand the process and to apply this to similar problems
Yaniawati, R.P., Kartasasmita, B.G. and Saputra, J. (2019), *Journal of Physics: Conference Series*	medical, various tools, online assisted, performance	Mixed RCT 7 sessions Test	The study showed positive impact of PBL and eLearning on Math skills / performance and on SRL to be statistically significant.

Group also made significantly better total score than “Conventional training” Group

4 DISCUSSION

There seems to be a wide distribution of research papers although these are concentrated across European countries, North America and Australia. An inclusive approach was undertaken to allow non-peer reviewed, conference papers and book chapters in addition to peer reviewed journal articles. However, language will have limited the distribution of papers which involve only those written in English and is an unavoidable limitation of this study.

Of the papers included in the final 56, there were variations in quality with some providing relevant theoretical frameworks allowing the author(s) to critically analyse the data collected. In many instances, the findings indicated that the technology had affected some change but this was largely unexplored with some problematic terms such as ‘motivation’ remaining unexplored. In some instances, studies did not articulate the research design or offer detail regarding the intervention which made it difficult to evaluate the quality of the research and its overall contribution to knowledge. Given the use of technology is often seen as innovative and that the range of technologies used is always increasing, the limited number of qualitative or mixed methods studies is certainly a gap in this body of literature. Recognising that there are strengths and limitations in each approach, it would be beneficial to address this imbalance in order to gain greater insight into the way in which interventions using technologies might support student learning and skills development. There were also instances where research was described as mixed methods in its approach but involved limited qualitative data with, for example, a single open question in a questionnaire.

In terms of efficiency, the use of technologies relieved pressures on physical resources such as specialised rooms and equipment and offered opportunities to hone skills and reinforce knowledge and understanding through repetition. There were also advantages in being able to experience events which would not otherwise be possible, for example where it would have been too expensive or unforgiving and offer no opportunity for trial and error; involve challenging logistics in order to bring relevant people together at specific points in terms of time and location or to replay, pause and review content. Student motivation and engagement were also often cited in addition to commitment to their studies. This may not necessarily result in increased efficiency should students commit more time to undertaking the tasks, however, there are arguments that suggest that students might engage more and be more likely to retain what they have learnt and that on campus sessions are able to focus upon exploring and extending learning. Greater flexibility existed where continued access to content, peer discussion and tutor support beyond the campus setting was possible. Individually or used in combination, such interventions provided rich, interactive and extended opportunities to support development of team working skills and collaboration during PBL.

Although there were advantages in engaging students beyond the on-campus setting and in providing greater flexibility in terms of access to people and learning resources, this also raised questions regarding the use of staff time. Their involvement in the development of well-designed and appropriate resources and in the support of small groups as part of PBL approaches would need to be considered although in some instances, technology reduced staff time by encouraging greater student autonomy and offering automatic feedback on student activity to the tutors. In addition to staff time there were also some concerns regarding the expense associated with technological resources and the necessary infrastructure which might include staff and student development in addition to technical support. Beyond the use of the technologies, the approach to learning, including the ability to collaborate and work as part of a team would also need to be considered to avoid inefficiency through unresolved conflict.

The development of team working was integral to some of the research projects including technology supported frameworks and scripting which sought to address what might be viewed as ‘soft skills’ such as project planning, negotiation, collaboration, leadership and team management. Rather than allow students to find their own way in terms of teamwork, such studies guided the students’ learning experience and the outcome was, in most instances, positive and encouraged greater awareness when communicating with others. Automated feedback not only allowed for safe experimentation of ideas but also provided prompts which invited students to reflect individually and collectively upon their learning.
In addition to the cognitive, there were gains in the affective domain where enthusiasm, confidence and enjoyment in the learning provided a stronger impetus for team working. Conversely, where unresolved conflict had been reported in some studies, working relationships had fractured and progress in learning had been slowed or had stalled. This largely hinged upon the ability of individuals within the group to employ appropriate skills to communicate effectively, in order to cooperate in the mediation and resolution of disagreement. In some instances, the technology itself was viewed as a potential distraction to learning with students more closely involved with resolving issues or interacting with the resource than committed to the PBL task.

Inclusivity was given less attention than either efficiency or team effectiveness, however, there were instances where students, by virtue of working with peers from other countries, had gained a sense of cross-cultural awareness. There were also reports of increased sensitivity towards others as part of team-working and the use of visualisation to support the process of scaffolding. Most often, the sense that students were able to regulate their own pace of learning was viewed as a positive contribution and a means of providing a structure and framework to support the intricacies of team working as part of a constructivist approach to learning. This appeared to be more effective in the first year of an undergraduate programme where students were gaining awareness of and developing relevant skills for successful team-working alongside the subject knowledge associated with the relevant discipline.

5 CONCLUSION AND RECCOMENDATIONS FOR RESEARCH

This review highlights that although making efficiency gains often inspire the use of technology within constructivist settings, a focus on the effectiveness of technology in motivating and developing attitudes and skills necessary for team working such as self, co and shared regulation skills, is where future research should focus. The development and qualitative research on computer scripts that repeatedly orchestrate individual learners and teammates to interact with each other and also visualise their interactions can lead to effective and efficient ways to support the development of self, co and shared regulation and team working skills as well as trust the between teammates. Use of scripts can also help and or free up staff from orchestrating interactions between teammates and allow different teams to develop in their own pace. A related work, currently in press and also being presented at this conference, highlights the use of computer scripts in developing trust between neuro-typical and neuro-atypical teammates and in developing their regulation and team working skills (Malik and Sime, 2020; Malik and Sime, 2022a; Malik and Sime, 2022b).

In addition to addressing the imbalance in terms of qualitative, mixed methods and quantitative research approaches, recommendations for further research would include exploration of the design and implementation of technologies which support inclusivity and provide reasonable adjustments to allow all students to participate. Current studies are also restricted to some STEM disciplines and tend to focus more upon student performance as the outcome as opposed to attitudes and skills development. Future research might be extended to provide greater representation from across the portfolio of disciplines in, for example, engineering, mathematics and the sciences. STEM and in particular engineering education researchers, could focus on psychological constructs, such as trust and conflict, that are related to teamworking alongside student performance.

ABSTRACT

Our life is surrounded by digital devices. Engineering education is one of the cornerstones in higher education for future generations and computational thinking (CT) is deemed as a core component in various engineering curricula. The Delft University of Technology (TU Delft), is the largest technical university in the Netherlands and computing; computational concepts and activities have been integrated into curriculum for years at TU Delft. However, there is not a comprehensive investigation on integration of CT into Engineering Curriculum, this paper presents a case study of Master's level engineering curricula investigating: 1) to what extend CT components are integrated; 2) in what way CT is interpreted and integrated in the curriculum; 3) what educational and assessment methods have been used. The results show that CT has been largely integrated into the investigated curriculum mostly with lectures being the educational method and programming assignments as a method for the assessment. Our analysis shows that understanding the context and patterns in problems and solutions was important in different courses and engineering disciplines, indicating possible directions for integration of CT into curriculum.

1 INTRODUCTION

The nature and shape of engineering education is an ongoing topic of debate among engineering faculty members, professionals and practising engineers [1]. It appears to be that the enormous changes in societal dynamics and the development of technology also lead to transformation of the engineering curricula. In both the United States and Europe, an emphasis has been placed on digital skills and literacy. In 2016, Barack Obama launched the 'Computer Science for All' initiative. The aims of this initiative were to allow American students from kindergarten through high school to learn computer science and acquire computational thinking (CT) skills. Computer science was referred to as a new basic skill necessary for economic opportunity and social mobility. As for the European Union, the Joint Report of the Council and the Commission on the Implementation of the Strategic Framework for European Cooperation in Education and Training (ET2020) highlights the importance of digital competences. In addition, the study Developing Computational Thinking in Compulsory Education by the Joint Research Centre, which is the European Commission's science and knowledge service, suggests that CT is a subject of importance within the European Union.

Addressing this emphasis on digital competences and computational thinking, in the Netherlands 4TU has been created to foster the collaboration between the four universities of technology (TU Delft, Eindhoven University of Technology, University of Twente and University of Wageningen). In the vision for Higher Engineering Education written by Kamp (2016), the 4TU Centre of Engineering Education in the Netherlands is mentioned as a "Free-Spirits" think tank which aims to develop suitable higher education scenarios by 2030 by examining the appearance of new engineering profiles in the coming 10 to 15 years. Inspired by the Greek Philosopher Heraclitus stating "the only constant in life is change", its vision states that digitalization is one of the driving forces which makes our world become more uncertain, complex and ambiguous. This does not only impact how people live, but also requires the future generations of students to be empowered with lifelong-learning and general problem-solving competencies including the use of digital and computational tools.

CT was first mentioned by Papert (1980) and then advocated by researchers and practitioners since Wing claimed it as "a must-have skill for everyone" living in the 21st Century rather than solely for computer scientists. Ever since, there has been extensive debate and research on the definition of CT and its relevance for education. Several definitions are used in the field, for example, Wing (2011) defined CT as a set of problem solving skills with which the formulation of solution for problems can be carried out by computing agents (either human or mechanics computing machines). Unlike Wing (2011)'s definition which is descriptive and theoretical, some operational definitions attempt to identify more granular constructs that are more practical. Brennan and Resnick (2012)'s three-dimensional framework consists of CT concepts, CT practices and CT perspectives as well as the four compositional frameworks with problem decomposition, pattern recognition, abstraction, algorithm defined by BBC(2018) are frequently used in research and practices. While efforts on concretizing the definition of CT are still ongoing, the importance of helping people adapt and prepare future generations to live in digital society is widely recognized. As a result, researchers, educators, policy makers and practitioners from both Science, Technology, Engineering and Mathematics (STEM) and non-STEM backgrounds are currently investigating the integration of CT into different fields.

Bearing in mind that fostering students' CT skills is a strategic focus of the 4TU, in this work we aim to investigate their integration in engineering curricula. Considering the effort needed for investigation of all relevant faculties, we limit our case study to the MSc programmes of the two [E1] faculties of TU Delft that incline to integrate CT into their curriculum, and we specifically aim to answer the following research questions:

RQ1. To what extent is CT reflected in the curricula of the TU Delft?

RQ2. In what way does the interpretation or reflection of CT differ per faculty?

RQ3. Which educational and assessment methods are used in CT-integrated courses?

2 METHODOLOGY

2.1 Research Scope and Source Data

The scope of this study was limited to the MSc programmes of two TU Delft faculties: Architecture and the Built Environment (ABE), and Electrical Engineering, Mathematics & Computer Science (EEMCS). As our data source we used the TU Delft study guide, in which we initially performed a keyword-based search and then analysed the course data towards answering the research questions. The search criteria were informed after consultations with faculty members. The TU Delft study guide[2] is the formal collection of all courses and study programmes offered by the different faculties of TU Delft. Each course is listed and described in this database with information such as its overview on course design and general course arrangement. A search functionality offers the opportunity to search the course descriptions per faculty for one or multiple keywords. Hence, the study guide was used as the basis for this systematic research into how computational thinking is reflected across the faculties of the TU Delft.

2.2 Identification of Relevant Keywords

To identify courses that discussed CT explicitly, the keywords "computational thinking", "digital skills", and "digital competency" were applied. Besides identifying courses that explicitly discussed CT, we were interested in identifying the courses that implicitly included CT. To identify those courses, we leveraged the operationalization of CT devised by BBC (2018), which comprises problem decomposition, pattern recognition, abstraction and algorithm design. For each of the four components of CT, keywords were defined that signalled the presence of that step of CT (Table 1 in the Appendix). The asterisk (*) in some keywords ensures courses are found where both words occur in the text, although not

[2] https://studiegids.tudelft.nl/bbDefault.do?SIS_SwitchLang=en

sequentially. In addition, it allows for finding both UK and US spelling in e.g. mode*ing. In addition to these general keywords, after consultation with an associate professor for the faculty of Architecture and the Built Environment, the keywords “parametric”, “computational”, “ algorithm”, and “simulation” were added as ABE-specific keywords.

2.3 Filtering of the Relevant Data

After performing the keyword search, several filtering steps were applied (Figure 1 in the Appendix). First, BSc courses were discarded since we were solely interested in MSc courses. Since a considerable number of courses within EEMCS that included one of the CT components, only the courses with at least two CT components were evaluated. Then, while the presence of one or more CT components under each component in the course description signalled the possibility of CT, it was found that merely the appearance of those components were not sufficiently specific to signal the presence of CT. Therefore, the keywords and its corresponding CT components were applied, and an evaluation of the course description in study guide was performed to identify the courses reflecting CT. The courses were scored on the presence or absence for each of the four components of CT. The course descriptions which at least signalled the presence of two out of the four components of CT were included in our validation set while courses with less than two components were discarded. The validation sets were sent to three CT experts (second evaluators) for evaluation together with the operationalization of CT. The courses that were rated by at least three out of four raters as CT were included in the final selection.

2.4 Data Extraction and Synthesis

The selected courses were analysed with the information extracted from CT courses. Types and categories of the assessment method, educational methods, courses and other categorizations were based on observation from the dataset and aggregated by one of the authors with consultation from experts when necessary. Table 2 in Appendix provides an overview of the extracted information per CT course (with the last row presenting the information aggregated based on descriptions of the courses).

3 RESULTS

3.1 Inter-rater Reliability on the Identification of the Relevant Course

A low Fleiss’ kappa inter-rater reliabilities of 0.33 and 0.17 for the courses of the faculties ABE and EEMCS, respectively. These low values indicate that, although the operationalization of CT of this study was provided to the raters, their interpretations of CT were still divergent. Apparently, the provided operationalization left room for interpretation, which led each rater to use its specific background knowledge on CT. Zooming in on the ratings, we observe e.g. that one expert utilised a broad perspective and considered almost all courses of the test sets to be CT, while another expert utilised a narrow perspective and only scored about half of these courses to be CT. Clearly, their interpretations of CT differ greatly.

3.2 CT in the Curricula

A total of 15 ABE MSc courses under two MSc programmes (Geomatics and Architecture, Urbanism and Building Sciences (AU&B)) were designated as CT courses while a total of 27 EEMCS MSc courses were designated as CT courses (an additional filtering step was applied compared to ABE). The keywords that were found in the course descriptions of the CT courses are visualised in Figure 2a and Figure 2b (can be found in Appendix), with the font size correlating to frequency. Compared to the keywords from ABE, we can see "algorithms" and "algorithm design" were much more frequent for EEMCS. Meanwhile, Of the three MSc programmes analysed, unsurprisingly, Computer Science contained the highest number of CT courses. Due to the set-up of the EEMCS MSc programmes, all courses were compulsory choices courses.

Figures 3 and 4 demonstrate the different types of CT courses within ABE and EEMCS respectively. Most courses at ABE were about learning to use a computer program or a modelling task that contributes to analysing the environment or the design of new buildings. For example, in Digital Terrain Modelling students were taught to use datasets to reconstruct a terrain and use these for applications related to the built environment, and in Geomatics as support for energy applications students are taught to build 3D city models. Another type of CT courses at ABE were courses that comprised large projects with a computational component of varying extent. For example, in MEGA[3] students designed a special big building in multi-disciplinary teams. Within this team, just one of the students was responsible for the computational design. On the other hand, in Earthy the design of the building is completely computational. Finally, the course Operations research methods was specifically on teaching research methods and using mathematical modelling to make decisions.

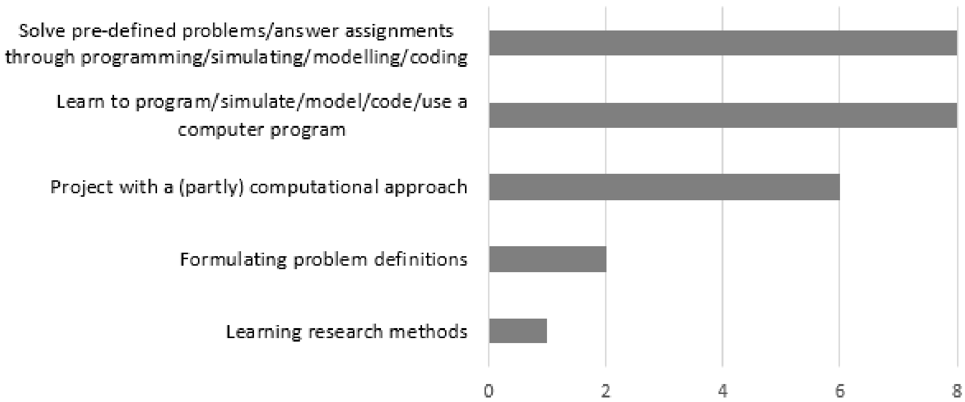

Fig. 3. ABE – Types of reflection of CT in courses

As for EEMCS, the largest part of the courses includes learning about the context and patterns in problems and solutions; frequently in the form of students being taught to recognise which algorithms to use for which problems. For example, in Object Classification

[3] MEGA is a collaborative integral multi-disciplinary design of a special big and/or tall building.

with Radar two of the four learning goals specifically refer to recognizing patterns in the data and the type of problem and deciding on the approach dependent on these patterns: 'Analyse and compare the different domains of radar data that can be exploited for objects classification, and the convenience of use of one rather than the other in different situations' and 'Propose and evaluate possible approaches for given classification problems based on radar sensors data'. Furthermore, more than half of the courses involved a larger project with a (partly) computational approach. Interestingly, whereas the ABE faculty always started out with a problem (e.g., I want to design a building and I need to know the terrain) and then took a computational approach to solve the problem, the EEMS faculty also frequently took the algorithm as a starting point and then went looking for a problem to be solved, sometimes looking at other faculties of the TU Delft to provide problems to be computationally solved.

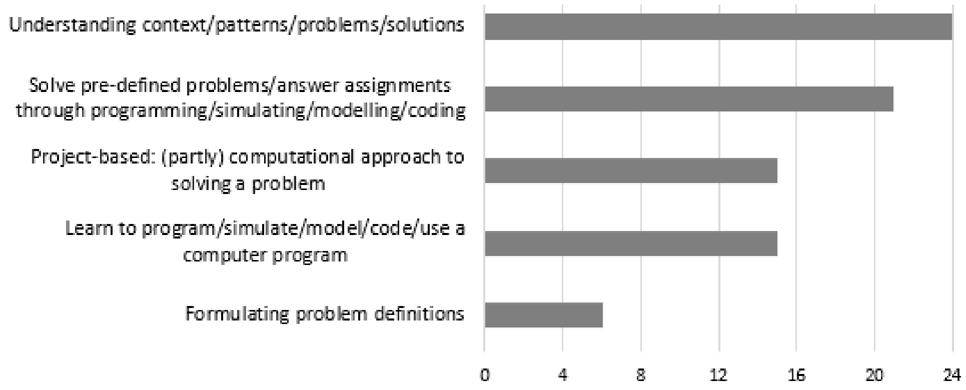

Fig. 4. EEMCS - Types of reflection of CT in courses

To conclude, these courses illustrate how CT is important also at a design faculty and the EEMCS faculty provided many CT courses. In a design faculty, there are many problems to be solved (e.g., how to best design the building) and in some of the courses a (partly) computational approach is taken to solve these problems. Meanwhile, understanding the context and patterns in problems and solutions was important in almost all courses; demonstrating the importance of this step of CT.

3.3 Educational Methods

Zooming in on the different educational methods, we see that a wide variety of methods was used in CT courses at ABE (See Figure 5). Contrary to what one might expect given the practical nature of CT, lectures were the most common instructional method. However, within one course on approximately 4 educational methods were used, signalling that lectures were often used in conjunction with different educational methods. For example, in the course Geomatics as support for energy applications three education methods are used: lectures to provide the theoretical background, practicals to allow the student to practice building models while supervision is present, and self-study to further dive into the theoretical background and do more modelling. Besides lectures, practicals and self-study, computational assignments were a common educational method, which is in line with expectations: computational assignments allow the student to apply their CT skills in practice. In addition, notable is that a fair number of courses included tutoring sessions. These sessions are a common way of teaching in the ABE faculty, during which a tutor provides feedback on the work or design of the student or students.

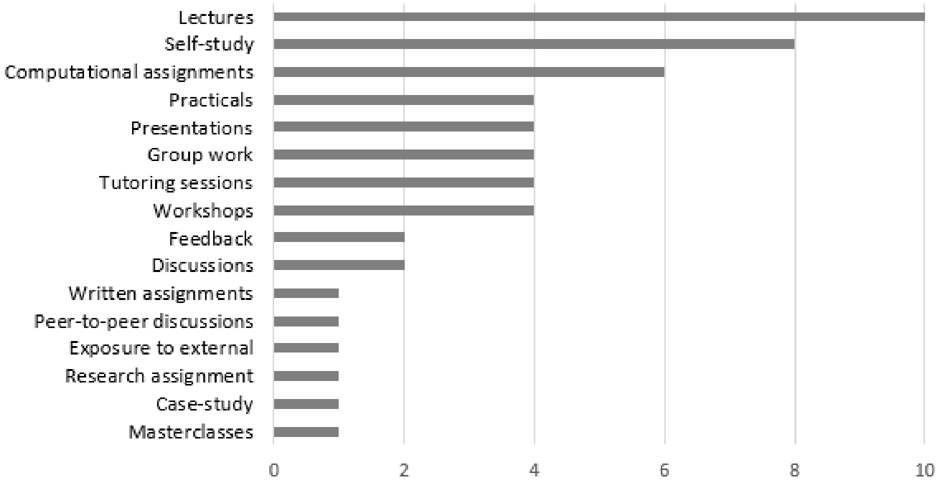

Fig. 5. ABE - Occurrences of different educational methods in CT courses

Figure 6 demonstrates the utilised educational methods at EEMCS, with on average 3 educational methods per course with lectures being the most used educational method. In 37% of the courses, practicals and/or computational assignments were used as educational methods. Larger computational groups or individual projects were more common in the EEMCS faculty. For example, in the course Crowd Computing students are working throughout the entire course for six hours per week in a group on an extensive computational project. Besides this group project, the other utilised education methods are lectures and computational assignments. Notable is the occurrence of some more innovative instructional methods like recorded lectures for the course Applied Machine learning and lectures by students for the course Machine Learning in Bioinformatics.

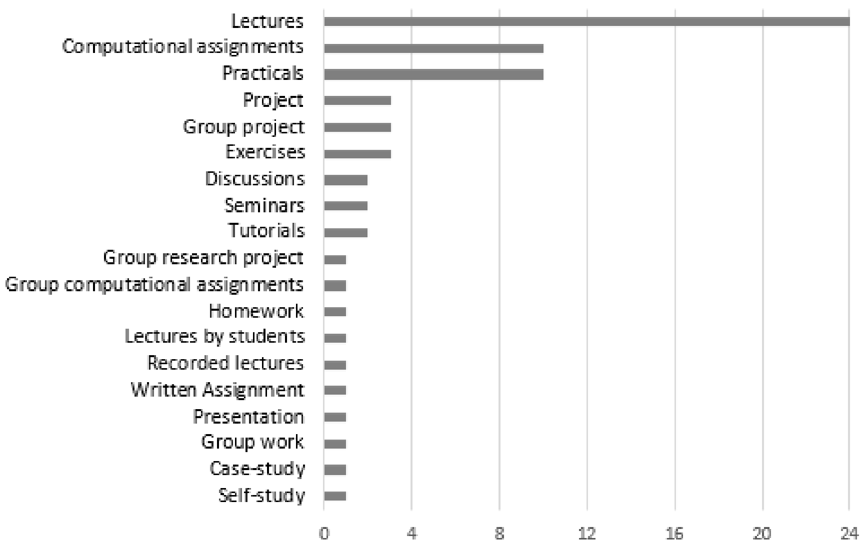

Fig. 6. EEMCS - Occurrences of different educational methods in CT courses

3.4 Assessment Methods

For the assessment at ABE and EEMCS, most courses used more than one assessment method and overview of assessment methods being used for both faculties are presented in Figure 7 and Figure 8 respectively, with computational assignment (s) being the most common assessment method. The more traditional written exam was also frequently used, often in combination with computational assignments as in e.g. Geoweb Technology, Geographical Information Systems (GIS) and Cartography and Python Programming for Geomatics. Group presentations, group reports and individual reports were also common; it should be noted that often these reports were about the developed computational model. For example, in Operations Research Methods the assessment was based on a written assignment and on a report on two mathematical models. In addition, they were often used in parallel (e.g., Algorithms for Intelligent Decision Making, Artificial Intelligence Techniques and Evolutionary Algorithms). Oral exam is also used as an assessment type; though it might be labour intensive.

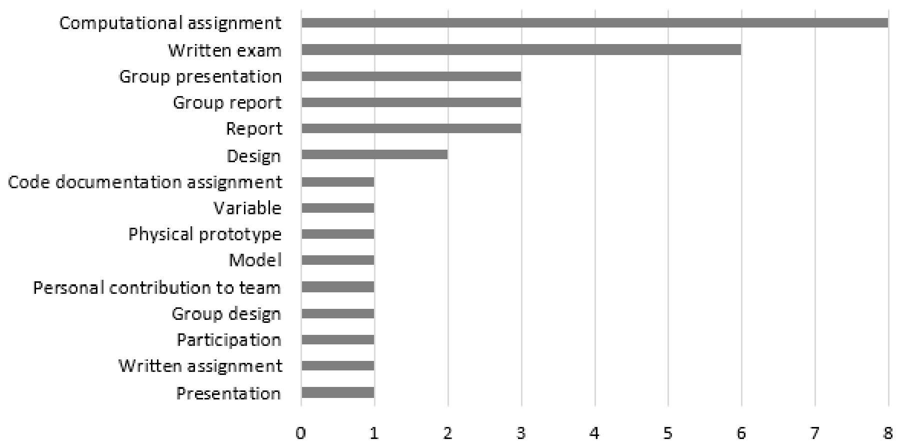

Fig. 7. ABE - Occurrences of different assessment methods.

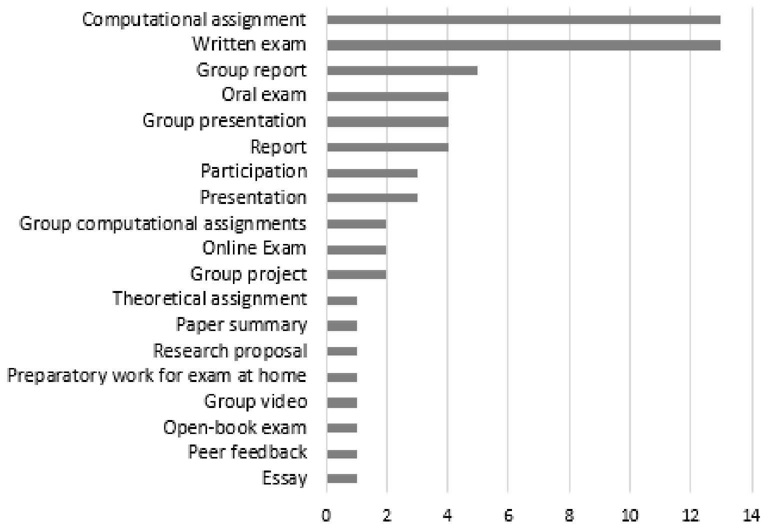

Fig. 8. EEMCS - Occurrences of different assessment methods.

4 CONCLUSIONS, LIMITATIONS AND FUTURE WORK

With the preliminary results of this work so far, several conclusions can be made: First of all, aligned with the findings of the group concept mapping study from Specht et al. (2019), this work finds that agreement on definitions and the relations between different competences and skills under computational thinking is still vague even for experts. For developing an embedding of CT skills in an engineering curriculum necessary definitions and focus should be aligned. Secondly, the examples from the two different faculties of TU Delft show different approaches and embedding CT concepts into the curriculum. On the one hand fundamental developments or algorithms and computational abstractions need to be developed extending CS curricula and there focus, on the other hand more design oriented engineering disciplines embed computational tools and skills often in concrete design and project work. Last but not the least, we observed course designs in which computational tools and digital skills can be linked to specific subtasks of design challenges but also more generic courses which integrate computational tools as a base element of engineering design.

However, the authors spotted major limitations of this work regarding its methodology and its scope, mainly being: this is a case study on specific faculties of one university and, even though both are large and well established faculties, they might not be representative of engineering faculties in other countries. Also, that the study was based on the information on the study guide which, even if it is a requirement that it is updated yearly, might not fully reflect instruction methods that the instructors apply. Furthermore, the course descriptions used for this work was limited to academic year 2020-2021, which indicates that effectiveness of the findings in this study is time delimited and engineering education is changing with the technological and societal dynamics, which indicate that longitudinal observations and investigations are needed. Regarding the methodology, though this work follows certain level of systemacy and considers the potential bias caused by individual work, several aspects should be noted: Information coding and data synthesis was weak regarding the verification of the validity; the conclusions were made merely with observation and analysis from course descriptions, making it weak as actual situations may differ from the course descriptions.

To further advance this work, the authors plan to conduct focus group study or interviews to gain more insights about the integration of CT into Engineering curriculum and establish more solidate coding schemes and verification standards to improve the validity of the extracted information in future work.

ABSTRACT

Remote Learning and Examination based on Augmented Reality (RELAR) is a European Erasmus+ project (2020-1-NL01-KA226-VET-083043) that aims to create a crisis-proof resilient education environment, enabling remote coaching and digital skills training based on AR. RELAR integrates seven European partners –Vocational Training Institutions and Higher Education Institutions– all linked to the maritime industry. The industry itself is also represented.

With the help of a reference group, a set of learning outcomes has been defined to develop three demo scenarios to test and demonstrate the RELAR system, which is based on the RealWear HMT-1 assisted reality hands-free computer. All scenarios are scaffolded on the same framework that integrates active learning pedagogy, curriculum requirements and technological integration.

This digital active learning process pedagogy incorporates two processes for instruction: a remote instruction process called ‘Expert Coaching’ that gives the students the possibility of receiving instant feedback while taking actions and decisions; and a remote assessment process named ‘Digital Workflow’ that incorporates formative assessment to consolidate learning. The curricular aspect focuses on the professional competencies students will acquire, the expected learning outcomes, the required knowledge, and the transferable skills required by students to perform professionally. Finally, technological integration describes how and when the assisted reality system should be incorporated to add value to the learning process.

This paper describes the work in the learning spaces currently under development by the partnership based on the same methodological and pedagogical foundations.

1 INTRODUCTION

RELAR project aims to create a crisis-proof resilient maritime educational ecosystem by enabling remote learning and examination using Augmented Reality (AR). The project addresses the difficulties of the maritime and port education ecosystem caused by the situation unearthed by COVID-19 and any other crisis that may affect face-to-face education and training. In this context, new digital technologies such as AR can make it possible to transfer the expertise and knowledge of industrial organisations while improving security, safety, and efficiency by empowering frontline connected trainees and workers with remote technology. The RELAR consortium partners will identify and adopt a joint architecture and framework for future interoperability, scalability and sustainability of remote learning. The core concepts of the architecture will be inspired by the background and experience of functional design approaches for remote learning and assessment developed by STC Group for maritime education [1].

RELAR is formed by a consortium of seven European Vocational Education & Training (VET) Institutions and Higher Education Institutions (HEI), and industry organisations, all linked to the maritime industry.

The consortium –listed below– is coordinated by a lead partner, which is currently the STC Group.

- Shipping and Transport College Group, STC Group.
- Malta College of Arts, Science & Technology, MCAST.
- Šolski center Nova Gorica.
- Romanian maritime training centre, CERONAV.
- Satakunta University of Applied Sciences, SAMK.
- Universidad de La Laguna, ULL.
- University of the Aegean, Aegean.

This work is possible thanks to the consortium members and the following Industry associated partners:

- Knowledge Insight.
- KOTUG International.
- WeAR.
- WinNova.
- ONEX Syros Shipyards.
- MarineTraffic.
- Creative Solutions.
- Palumbo Shipyard Malta.
- Cassar Shipyard.
- Romanian Naval Authority.
- Tenerife Shipyards.
- Hidramar Shipyards.

RELAR project will deliver two Intellectual Outputs (IOs):

- *Architecture and framework* (IO1) contemplate technical development aspects.
- *Commons* (IO2) incorporates the pedagogical aspects of the project.

Given the focus of this conference on Engineering Education, this paper describes the development of IO2, which consists in the development of shared resources that will be integrated into three different demo scenarios that will incorporate pedagogical content. The idea behind these demos is to show how common resources developed by the consortium can be integrated with the RELAR ecosystem and how researchers, the educational community and even businesses and industry can use them and develop them further.

Three partners with experience in maritime education are building the above-mentioned demo scenarios for learning and examination purposes for the following use cases: *Marine Engineering* (developed by ULL), *Shipyard Technician* (developed by MCAST), and *Logistics/Fleet Technician* (developed by Šolski center Nova Gorica). All three demo scenarios will share the same pedagogical framework named in RELAR as Digital Active Learning process, which is described in detail in next section.

2 METHODOLOGY

The development of each demo scenario needed a shared structure to make them comparable, so it was necessary to define the common requirements, showed in Table 1:

Table 1. Common requirements for demo scenarios

Definition	Requirement
Level for qualification and learning outcomes, based on the European Qualification Framework (EQF)	4
Total learning hours, based on the European Credit Transfer and Accumulation System (ECTS)	1 ECTS (25 hours)
Assessment of the learning outcomes	Up to partner's decision
Providing of formal certification	Up to partner's decision
Cost of the contents	Free of charge
Delivering language	English

2.1 Designing Demo Scenarios

As much as possible, the development of the scenarios would follow a Scenario-Based Learning (SBL) methodology. This strategy uses an active learning approach, using real-life situations for exposing the learners to a relevant learning experience. This methodology will help learners in critical thinking skills training and communication skills training. Learners would also be able to understand the cause-effect in relation at the workplace [2].

Each scenario's methodology is based on three components that facilitate the adoption of active learning in Engineering Education: Curriculum, Pedagogy, and Technology (see Fig. 1) [3].

Curriculum. The curricular aspect is built-in base on the descriptors proposed by EQF level 4, *Knowledge, Skills,* and *Responsibility and autonomy* [4]. From these descriptors are extracted four aspects that feed each other and are used to determine the final outputs for the RELAR scenarios: *Professional competencies*, *Learning* *outcomes*, *Subject knowledge*, and *Transferable skills*. Those are interrelated in such a way that the learning outcomes are dependent on the professional competencies, the required knowledge is set by the learning outcomes and transferable skills are determined by the professional work environment (see Fig. 2).

This loop in the curricular aspect guarantees to select all aspects related to the subject and how it connects to future application in learners occupation.

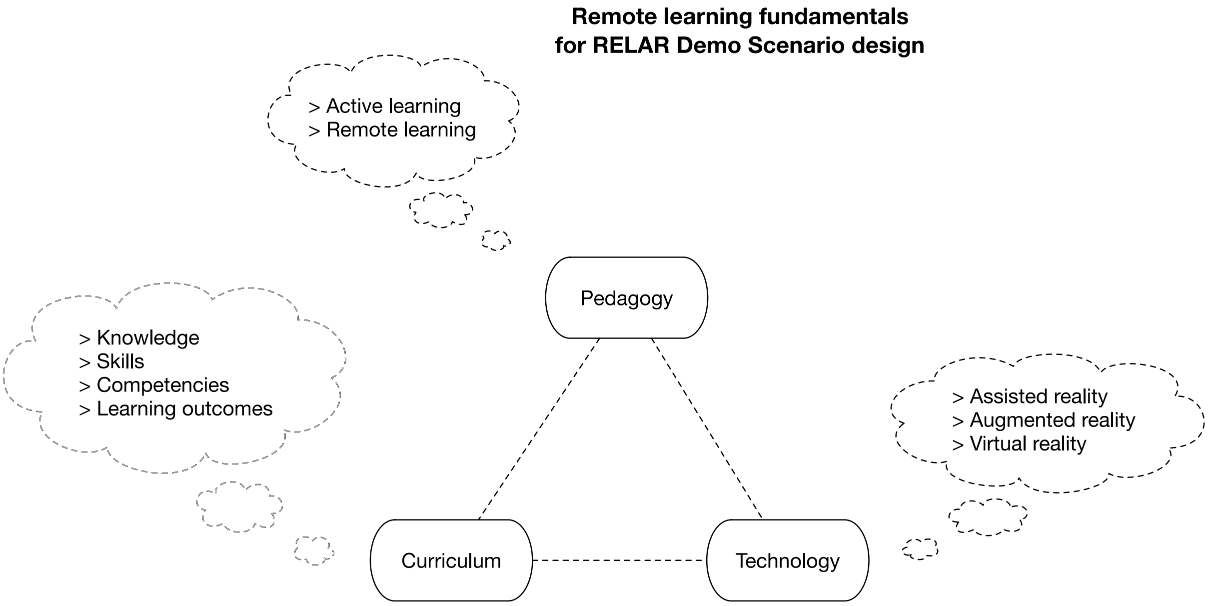

Fig. 1. Learning fundamentals for RELAR Demo Scenario design

Pedagogy. Pedagogical framework for Demo Scenario design is based on active learning and remote learning. The instructor's role during the process is to guide and facilitate the learners through their actions and to give feedback when it's needed. Considering it necessary for proper active learning, the activation of previous knowledge is fundamental, where wrong concepts and misconceptions are corrected and helps to relate previous experiences to a new situation. Creating new knowledge and competencies, and consolidating them are the next steps, always considering the learner's motivation for its optimal autonomous learning process (see Fig. 3).

The *Digital Active Learning process* incorporates two different actions for remote instruction called *Expert Coaching* and *Digital Workflow*.

During Expert Coaching, learners receive instant feedback through selected technology while they are taking their own actions and decisions. Digital Workflow contemplates asynchronous formative assessment to consolidate learning.

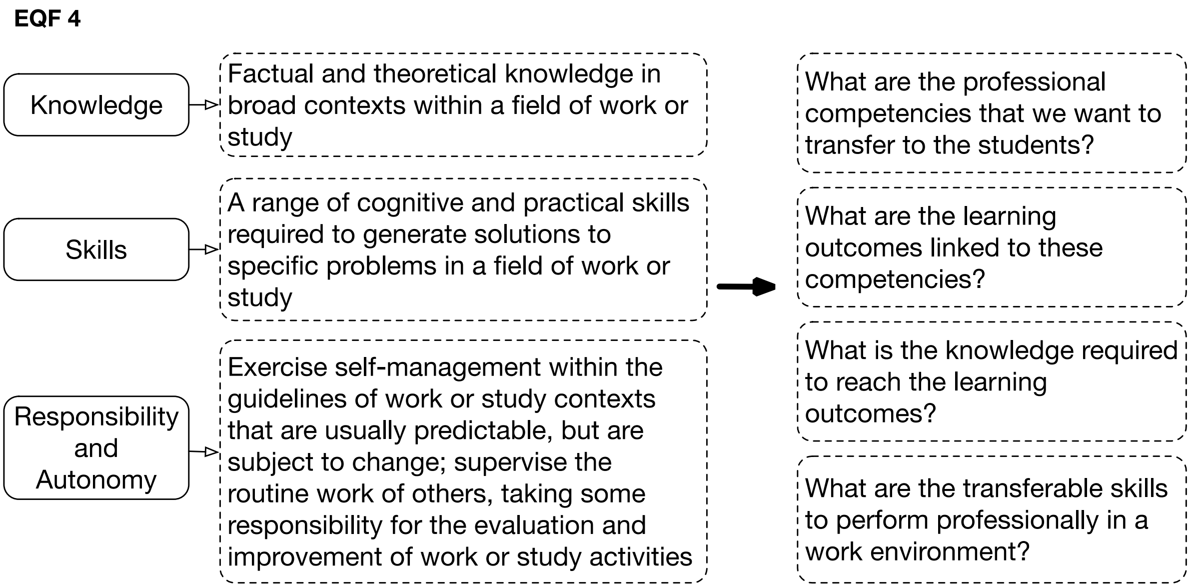

Fig. 2. RELAR curriculum aspects

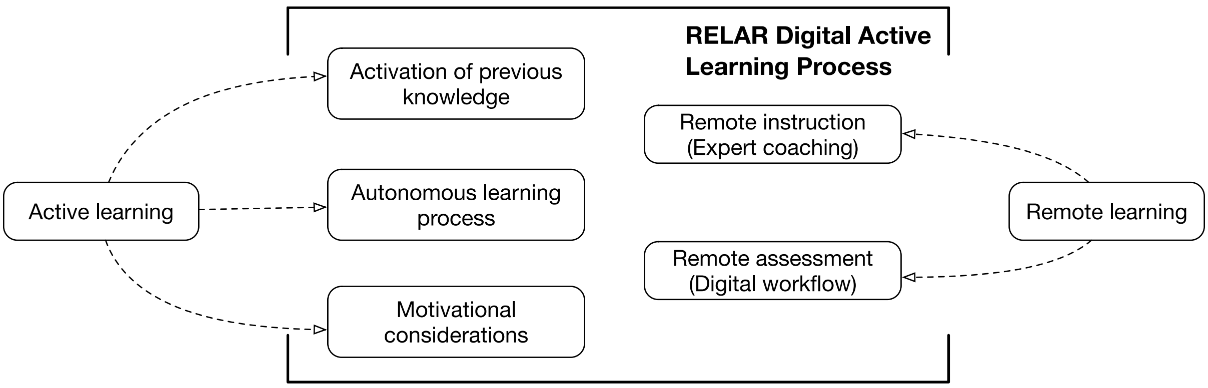

Fig. 3. RELAR pedagogical aspects

Technology. Technological integration describes how and when assisted reality system should be incorporated into the learning process. For this purpose, HMT-1 device is the chosen tool by the consortium, leaving other devices based on AR and VR as feasible options for similar scenarios (see Fig. 4).

HMT-1 device is a wearable computer that is designed to be used in industrial and commercial environments. It is a rugged device that can be worn on the head, and it includes a display, camera, microphone, and speakers. The device runs on the Android operating system, and it has been designed to be used with a variety of applications [5].

Its features allow the instructor to follow the user's view using a video call, capable to maintain a synchronous connection for immediate feedback or recording the action for asynchronous review, helping in Expert Coaching and Digital Workflow, respectively.

From the learner's point of view, the device can be used as a tool for viewing documentation related to their actions or as a guide to follow previously generated workflows.

Learning Management Systems (LMS) and videoconferences are useful tools to use in the digital active learning progress, to follow and share between learners and instructor in asynchronous or synchronous ways, respectively.

Technological integration into the digital active learning process is possible by the collaboration between lead and support partners, iterating with the possibilities and limits on software or hardware.

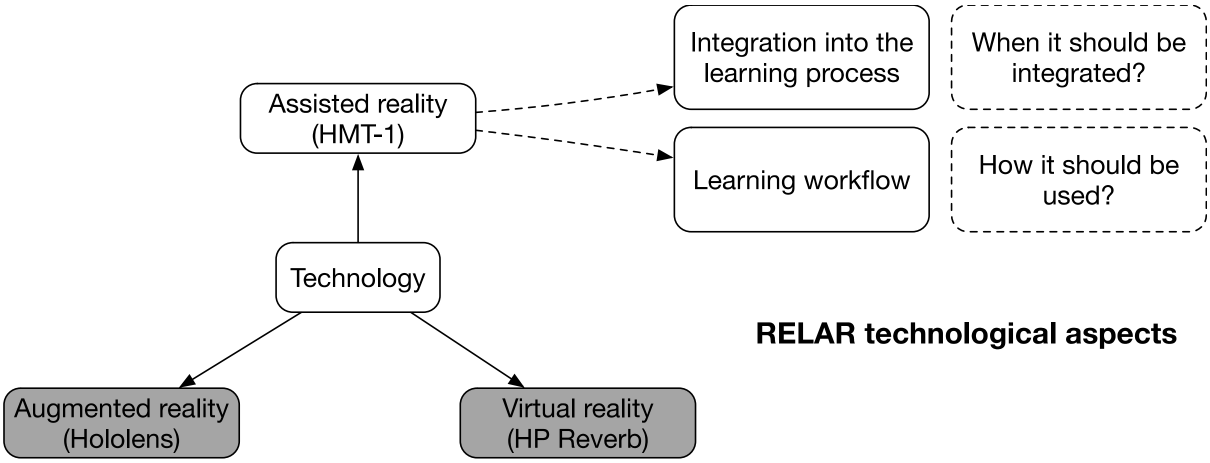

Fig. 4. RELAR technological aspects

2.2 Demo scenario workflow

In general words, RELAR demo scenarios are divided into 3 phases (see Fig. 5). 1st phase focuses on the activation of previous knowledge, where students can be exposed to the topic knowledge that they already should know. Using self-evaluation tests and having an open discussion between classmates and instructor is a proper way to know and understand lack of knowledge or misconceptions from the learners, facilitating flexible variations during the learning experience.

2nd stage's aim is to create new knowledge and competencies. Learners themselves must work as teams to investigate digital content about the topic and elaborate their own content to take action in training. During this stage can receive instant feedback from the instructor via HMT-1 (expert coaching).

On 3rd stage, the knowledge has to be consolidated, expecting that it can be transferred to new situations in learners' future professional environment. For this stage, learners may build their own workflow to follow in the expected problem. The learner action can be recorded by the HMT-1 device to receive asynchronous feedback from the instructor (digital workflow). This final stage could be used as an assessment of the topic.

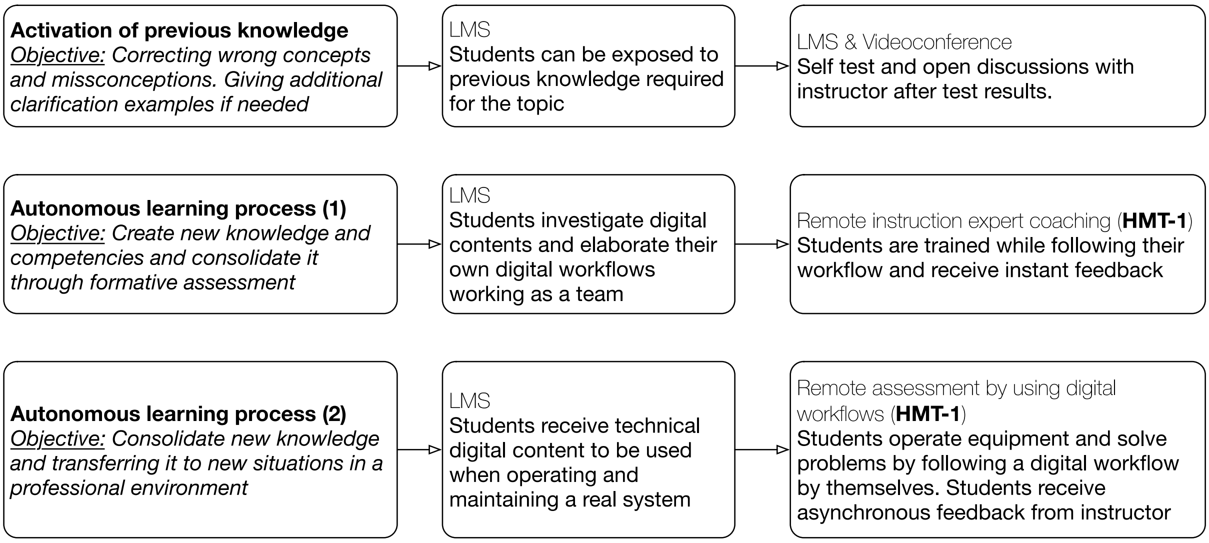

Fig. 5. RELAR digital active learning process

3 EXPECTED RESULTS

In future Intellectual Outputs scheduled in RELAR actions, the scenarios created by the consortium will be tested, ensuring that demo scenarios are correctly build in its three aspects, optimizing them if needed. The experience must be validated by the reference panel, through a series of meetings where product will be showcased.

As part of the dissemination activities, the partners will organise nine Transnational Meetings in total, of which four will be Training Events. During the Transnational Meetings teachers, students and experts from maritime industry and other sectors get familiar with RELAR and receive the necessary information on how to use it to educate and examine students and professionals on-the-job remotely.

During ‘train the expert’ sessions the partners ensure that the level of technical knowledge, the digital skills and understanding of concepts among teachers and trainers is sufficient for using RELAR in their daily work.

During ‘train the trainer’ sessions teachers and trainers get familiar with using RELAR scenarios for learning and examination using RELAR scenarios.

By the end of the project’s schedule, a RELAR Trainers’ pack must be developed by various partners. This trainer’s pack will include standard procedures with hardware and software and scenario specific info.

RELAR is a project under development with expectations of improving learning outcomes in engineering by using devices that are becoming common in the industry 4.0. With the backup of institutions and industry, future RELAR editions could have a vague expansion on the use of other devices and technologies and incorporating and testing over other environments.

4 ACKNOWLEDGMENTS

Remote learning and examination by using AR in maritime VET education, RELAR, is a European Erasmus+ project with agreement number 2020-1-NL01-KA226-VET-083043. This project is scheduled between May 2021 until April 2023.

ABSTRACT

To address the need for more responsible research and innovation, there is a growing call to integrate ethics education across the science and engineering curriculum. Accordingly, ethics education must not be limited to the avoidance of scientific misconduct but rather be oriented toward addressing the complexity of planetary challenges and realizing social good. Designing curricula to accommodate the ambition of integrated ethics, however, remains a great institutional and epistemic challenge. In this paper, we introduce the *Berlin Ethics Certificate* (BEC) at the Technical University of Berlin, to demonstrate how this challenge can be addressed by using interdisciplinarity as a core building block of integrated ethics education. The BEC's unique approach to ethics education enables the positioning of ethical issues in all study programs within the university by designing future-oriented interdisciplinary courses open to all students, be they from the humanities, natural or engineering sciences. The paper outlines the BEC's conceptualization of interdisciplinarity, ultimately arguing that interdisciplinary ethics education must be built upon the epistemic practice of situating knowledge. Methodologically, we show how the BEC approaches integrated ethics education through three iterative steps: 1) situating disciplinary knowledge in relation to other forms of knowledge, values and experiences (by focusing on multidisciplinary learning experiences), 2) establishing a common epistemic practice of collaboration (by focusing on interdisciplinary learning experiences), and 3) actively engaging with non-academic stakeholders to create responsible technology and take ethical action beyond the university (by focusing on transdisciplinary learning experiences). Examples of how the BEC implements this methodology are shown, which may serve as suggestions of best practices in integrated ethics education.

1 INTRODUCTION

In face of the many planetary-scale crises faced by societies today, dealing with ethics and figuring out how to shape responsible futures is becoming an urgent matter. We are arguably more dependent on science and technology than ever before, and thus also more vulnerable to associated risks. To meet the demand of these challenges, teaching ethics to engineers has become common practice, as ethical, social and environmental considerations have been widely recognized as critical for engineering, computer and data science education. In the European context, the call for responsible research and innovation has placed further emphasis on ethics education in the technical sciences to steer processes of technological development toward socially desirable effects and mitigate downstream harms.

However, in the growing body of research on ethics in engineering education, there is considerable debate regarding proper course content and learning objectives, best teaching methods, and effectiveness of outcomes [1][2]. Most discussed is the question of how to best incorporate ethics into engineering education. The dominant paradigm, stemming from a lineage of professional and business ethics, has focused on the avoidance of individual scientific and moral misconduct (e.g., Responsible Conduct in Research in the US), and siloed modes of ethical reasoning taught in appendix "applied ethics" modules [3]. There is increasing recognition of the limitations of this paradigm, namely its failure to teach ethical reasoning skills beyond individual compliance and its subordination of ethics to dominant motives of technological progress and economic growth [1][3]. To address these limitations, there is a growing call to integrate ethics education across the science and engineering curriculum [2]. Accordingly, ethics education must not be limited to codes of conduct but rather be oriented towards addressing the complexity of current and future local to planetary-scale challenges and bringing about positive societal change. A key element of such an approach involves integrating ethical reflection across the curriculum so that ethical questions can be addressed from the perspective of many disciplines. Designing curricula to accommodate the ambition of integrated ethics, however, remains a great institutional and epistemic challenge, primarily due to the difficulty of cross-disciplinary activity.

In this paper, we present a response to this challenge in ethics education: the Technical University of Berlin's newly established certificate program *Reflection and Responsibility—Berlin Ethics Certificate*. The certificate program integrates ethical reflection across all study programs by using interdisciplinarity as a core building block of ethics education. In section 2, we first outline the basic structure of the certificate and its setting at the Technical University of Berlin (TUB), where ethics and the humanities are granted a special status due to the history of the university. In section 3, we propose interdisciplinarity as a building block of integrated ethics education with the Berlin Ethics Certificate (BEC). In section 3.1, we conceptualize interdisciplinarity as an epistemic practice, focusing on the dynamics of knowledge production in interdisciplinary collaboration and the epistemic requirements for actors involved. In section 3.2., we argue that interdisciplinary collaboration must be founded on the practice of situating knowledge, which allows for students to perceive their disciplinary and non-disciplinary knowledge as partial and gain an awareness of their values and moral intuitions, thereby enabling them to successfully enter a process of joint reflection. In section 3.3, we then show how this practice of situating knowledge is used by the BEC to ultimately generate socially responsible and epistemically robust knowledge. Finally, in section 4, we provide concrete examples from the BEC to demonstrate how integrated ethics education is implemented by focusing on multi-, inter- and transdisciplinary learning experiences.

2 THE BERLIN ETHICS CERTIFICATE AT TU BERLIN

Today, numerous German and international technical universities have humanities departments and offer affiliated study programs. However, the presence of different disciplinary cultures at the TUB is special in this respect, as it has had a humanities faculty since 1950. The reference to humanistic-oriented values through the humanities as well as a civil clause are special characteristics rooted in the TUB's historical responsibility accepted for the atrocities committed during the era of National Socialism in Germany.[4] In line with this, the present mission statement states that "research and teaching in the natural, planning and engineering sciences are inextricably linked with the humanities and social sciences" [4]. According to its mission statement for teaching, academic education should "enable students to develop as individuals". Furthermore, they should "learn to place their knowledge and actions within a broader historical, social, and cultural context and to reflect on the ethical consequences of their actions" [5]. With its focus on social and ethical responsibility on one hand, and interdisciplinary community building on the other, the BEC realizes these principles. Within the program, students are educated to take responsibility for the future by orienting their scientific and technological practices toward desirable visions for society and to practice interdisciplinary collaboration.

Reflection and Responsibility—Berlin Ethics Certificate offers students the opportunity to develop a specialization in ethics, science theory and technology reflection as a complement to their disciplinary studies. Students from all study programs, including the humanities, social, natural and engineering sciences, may volunteer to register for the certificate program, which is completed by attending courses of their choice offered by the BEC. The BEC was launched in 2021 and is coordinated by a working group of the *Berlin Ethics Lab* at TU Berlin and an interdisciplinary advisory board of the *Berlin University Alliance*.

[4] Between 1933 and 1945, numerous Jewish scientists were expelled from the formerly *Technische Hochschule Berlin*, while its remaining researchers played an essential role in maintaining a network among science and military actors and participated in National Socialist armament research. Following the war, the partially destroyed university was reinaugurated in 1946 as *Technische Universität Berlin* by the British allies with a new humanistic orientation and educational mission, instantiated by the founding of the Faculty of Humanities in 1950.

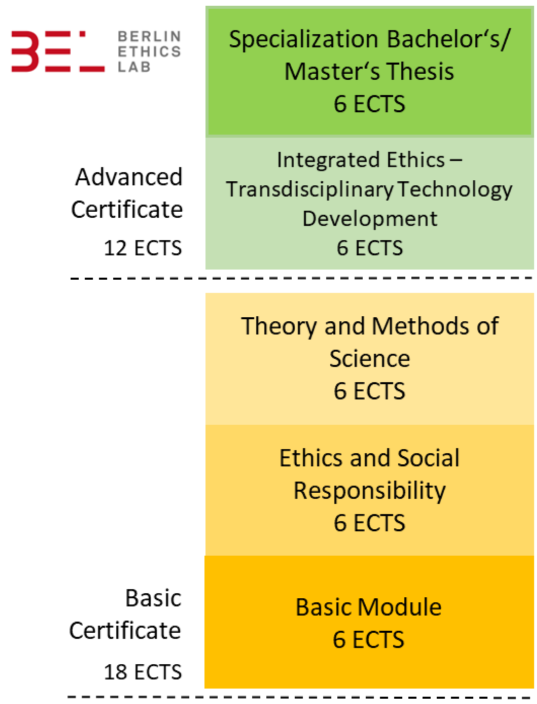

Fig.1 *Two-stage structure of the Berlin Ethics Certificate*

The BEC's two-stage structure enables the acquisition of a foundational *Basic Certificate* and optional supplementary *Advanced Certificate*, whereby required credit points can be distributed over bachelor and master's degree programs and completed within the standard period of study [Fig. 1]. The qualification can be acquired via compulsory or elective courses, which upon completion are accredited within BEC "container modules". Corresponding courses are accredited based on their thematic and credit point conformity to BEC container modules and are primarily drawn from the existing rich curriculum of TU Berlin. In addition, supplementary interdisciplinary courses have been created, including a compulsory *Basic Module* for all participants of the BEC, which lays the groundwork for ethical reflection on a personal level as well as for interdisciplinary cooperation.

3 INTERDISCIPLINARITY AS A BUILDING BLOCK FOR ETHICS EDUCATION

Although the question of how interdisciplinarity can contribute to ethics education is not new [6][7] and there is wide agreement that interdisciplinary collaboration is necessary for addressing real-world problems [8], there exist few examples of best practices. Before we explain in more detail how the BEC employs interdisciplinarity as a core building block, we want to outline the BEC's conceptualization of interdisciplinarity. This is important as concepts of interdisciplinarity in academic teaching and research vary due to a multitude of approaches, and reaching a uniform general definition seems difficult [9]. A common delineation, however, distinguishes interdisciplinarity as a form of synergistic interaction between disciplines rather than a mere combination of disciplines as in the case of multidisciplinarity [7]. In the field of possible interaction between different disciplines, a rough distinction can be made between multi-, inter-, and transdisciplinarity. While these three kinds of interaction share the aspect of bringing together different forms of (disciplinary) knowledge, they differ in terms of how actors are involved in interactive processes and in which ways various forms of knowledge interact to respond to different problems.

3.1 The Berlin Ethics Certificate's conceptualization of interdisciplinarity

The BEC understands interdisciplinarity as a temporary, collaborative process of knowledge production, where diverse epistemic actors with different disciplinary backgrounds come together in a common working environment by collaborating on project-based work. By bringing in their different expertise, namely their prior knowledge and disciplinary methods, actors enter a joint epistemic process, which unfolds in a milieu of reflection—a joint arena of thinking and reasoning [10]. A successful interdisciplinary process leads to an epistemic ascent (in the form of new knowledge or insights) through knowledge generation by knowledge integration. This contrasts with multidisciplinarity, where no integration of knowledge takes place, and transdisciplinarity, where non-academic actors enter the joint process of knowledge production.

From an epistemological point of view, interdisciplinary knowledge production can be characterized by how the various actors are involved in the joint epistemic process of project work. Firstly, actors have only partial (disciplinary and non-disciplinary) knowledge and are ignorant in other domains relevant to the joint project and must therefore develop strategies to deal with limited knowledge as well as known and unknown unknowns (given their epistemic perspective). Secondly, epistemic actors must integrate bodies of knowledge from other disciplines into their own knowledge horizon and must therefore develop strategies to deal competently with knowledge without understanding it in depth. Thirdly, none of the epistemic actors involved in the process have total knowledge in the sense of being able to fully understand the initial knowledge basis of the project (such as initial assumptions or methods) as well as the emerging knowledge. Therefore, new strategies for collaborative testing and validation of emerging knowledge are needed.

Interdisciplinary collaboration places high demands on the design of the resulting milieu of reflection (based on the framework design and process design of the project) as well as on the persons participating in the joint process. As epistemic actors they must bring specific competencies and epistemic values including humility in recognition of the knowledge of others. This recognition of other modes of knowledge production presupposes a recognition of one's own epistemic boundaries, which is based on honest and clear communication of the limits of one's disciplinary knowledge, methods, and worldview (e.g. "here I am stuck", "here I am uncertain", "here I need help", "here I made a mistake"). Curiosity and openness towards other points of view and towards unknowns as well as an eagerness to learning from others are crucial for interdisciplinary collaboration. This, in turn, presupposes an agility to taking another perspective and a readiness for change. Furthermore, trust is necessary to rely epistemically on the expertise of others in areas where one might have none. Lastly, the willingness to share (knowledge, methods, failures) and ability to actively listen are also vital to the epistemic success of the joint process.

3.2 These demands clearly show that interdisciplinary collaboration does not come without the effort of those involved. To make this kind of project-based collaboration work successful and satisfying, specific education of the persons involved is needed. In addition, the process design should aim at targeted interventions to raise awareness and sensitivity towards

the above-mentioned prerequisites. Finally, of equal importance is the framework design, which implements a culture of interaction. Essential here is the fostering of values which trigger a positive and stimulating mutual learning environment, such as social and moral (non-epistemic) ones. Specifically, an interdisciplinary learning environment should foster treatment with dignity over disrespect; empowerment rather than intimidation; encouragement rather than discouragement; independence and personal responsibility instead of overdependence; recognition of differences instead of discrimination; and allowing for learning from mistakes instead of (public) shaming. Practices of situating knowledge

As the BEC's conceptualization of interdisciplinarity shows, a high degree of reflexivity on the part of all actors involved is required. Thus, to provide the foundation for interdisciplinary collaboration, BEC draws on epistemic practices of situating knowledge in multidisciplinary learning environments. Our approach is inspired by Donna Haraway's concept of *situated knowledge* [11], which expresses the fundamental conditionality of all scientific knowledge, by highlighting the social location of the researcher and the historical, political, and disciplinary constraints that condition the production of knowledge. Situated knowledges serve to create "a more adequate, richer, better account of a world, in order to live in it well and in critical, reflexive relation to our own as well as others' practices of domination and the unequal parts of privilege and oppression that make up all positions" (p. 579). Through learning that knowledge is always situated, students are prepared to engage in inter- and transdisciplinary collaboration to address ethical issues. Educational approaches of the BEC allow students to situate their knowledge in four respects, which exist in an iterative process and do not correspond to an explicit order.

Firstly, one's own disciplinary knowledge is situated within a broader academic knowledge framework. Students get an understanding of the scope and limitations of their respective disciplinary methods by being exposed to differing approaches. Examining the similarities and differences of their own disciplinary approach relative to others allows them to become aware of their epistemic blind spots and "disciplinary goggles", which frame how they address the world.

Secondly, one's own disciplinary knowledge is situated within one's broader non-academic knowledge stemming from their life experiences. Rather than leaving their life experiences "at the door" and engaging with topics on a purely intellectual or abstract basis, students are encouraged to understand their academic practice through the lens of their own personal and non-academic experiences.

Thirdly, one's own disciplinary knowledge is situated within one's personal values and moral intuitions. Students are encouraged to see their emotions, values, customs and background as a resource for collaborative practices. The emphasis on a holistic perspective on the self enables students to carry ethical reflection taught inside the classroom beyond their academic experience.

Lastly, one's own disciplinary knowledge is situated with respect to one's social positioning as means of gaining a reflexive awareness of power relations and their ethical consequences in process of knowledge production. In this sense ethics is approached from perspectives that account for the actual non-ideal conditions that inform our realities, including those of oppression and difference. Such a critical theory-informed approach to ethics is not only concerned with analyzing the impact of emerging technologies on society, but also affecting change.

Through these practices of situating knowledge, students explore resonance and reciprocity at the intersections of their knowledge opening up new lines of affinity and common ground while allowing for epistemic pluralism. In addition, community building, as a key aspect of the BEC program, is achieved by students gaining an awareness of the interdependencies amongst each other and their environment and developing a sense of collective responsibility for improving societal conditions. Situating knowledge in such a way prepares the ground for an interdisciplinary reflection of ethical issues in order to generate socially responsible and epistemically robust knowledge.

3.3 Interdisciplinarity for socially responsible and epistemically robust knowledge

Based on the practice of situating knowledge, the BEC employs interdisciplinarity as a core building block for integrated ethics education. Social and ethical responsibility and technology reflection are taught in interdisciplinary learning environments whereby students from engineering, science, the humanities and social science work together on common projects. Thereby, the BEC's ethics education goes beyond merely "ethics for engineers" so that ethical questions and problem framings can be sought simultaneously from many disciplinary perspectives. We concur that practicing ethics can be seen as "an inherently interdisciplinary endeavor" [6] (p. 259), ethical problems in society are multifaceted and arise from the intersection of different knowledge domains. Students of the BEC experience how knowledge is generated mutually through a guided collaboration of their respective disciplines, practices of disagreement and compromise, and exploring alternative perspectives. By this, interdisciplinary collaboration contributes to the generation of socially responsible and epistemically robust knowledge, with the aim of directing scientific and technological processes towards beneficial outcomes for society and the environment, as emphasised in approaches of technology assessment (TA) and responsible research and innovation (RRI) [12][13]. Accordingly, robust knowledge is crucial for effectively addressing the complex problems of the 21st century, including in the context of emerging technologies, which can no longer be adequately addressed by isolated disciplines. Robust knowledge stems from epistemic processes which bring together a multiplicity of disciplinary and societal perspectives, across many time scales and spatial contexts. Crucially, robust knowledge is not only about integrating diverse disciplinary knowledge, but also considering the social positions and power relations of the actors involved or affected, along with their diverse values and experiences, with the goal of protecting and promoting human emancipation in the scientific process. In the following, we show how the BEC enables students from different disciplines to come together in an interdisciplinary learning environment, thereby demonstrating the BEC's approach to integrated ethics.

4 HOW INTERDISCIPLINARITY IS TURNED INTO A TEACHING CONCEPT: EXAMPLES FROM THE BERLIN ETHICS CERTIFICATE

The BEC implements integrated ethics education through three iterative steps: 1) situating disciplinary knowledge in relation to other forms of knowledge, values and experiences (by focusing on multidisciplinary learning experiences), 2) establishing a common epistemic practice of collaboration (by focusing on interdisciplinary learning experiences), and 3) actively engaging with non-academic stakeholders to create responsible technology and take ethical action beyond the university (by focusing on transdisciplinary learning experiences).

As mentioned in section 2, the BEC qualifications can be acquired via compulsory or elective courses that are open to all students of TU Berlin and can be accredited upon completion within the BEC modules. Corresponding courses are accredited based on their thematic and credit point conformity to the BEC modules. Due to the character of the interdisciplinary "container modules", the BEC allows students a high degree of freedom in the choice of course content. At the same time, the structure of the certificate (basic and advanced) reflects the close connection between ethics, epistemology and inter- and transdisciplinarity, as conceptualized by the BEC.

The BEC's mandatory module, "Reflection and Responsibility — Basic Module," lays the foundation for ethical reflection at the personal level through multidisciplinary learning experiences which focus on situating knowledge. The overall structure of this module includes a total of five workshops (corresponding to themes of responsibility, ethics, philosophy of science, inter- and transdisciplinarity), which provide the thematic and methodological foundation for all other modules (i.e. "Ethics and Social Responsibility", "Theory and Methods of Science", "Integrated Ethics — Transdisciplinary Technology Development") of the BEC [Fig. 1]. Drawing on their own disciplinary as well as everyday experiences, students learn to situate their knowledge within a multidisciplinary learning environment. For example, in the philosophy of science workshop, students are grouped by discipline and explore the epistemic possibilities and boundaries of their own disciplinary methods in relation to those of other disciplines. Over the course of the module, students are tasked with developing an ethical question on a self-elected topic, where the idea is that they reflect their own knowledge, values and experiences to critically engage with a relevant societal issue. Through the method of situating knowledge, the module ultimately teaches the relevance of individual and collective responsibility to epistemology, and interdisciplinarity to ethical reflection on real-world problems.

The course "Ethical and Social Challenges of Emerging Technologies: Automation, Robotics, AI" — which can be accredited under the container module "Ethics and

Social Responsibility" — serves as an example of an interdisciplinary learning experience. In interdisciplinary teams, students develop in-depth proposals for responsible technology design by establishing a common epistemic practice which progresses in a milieu of reflection. The selection of their own case study gives students the opportunity to seek personally and ethically relevant connections between technology, science, environment, society and each other. This bottom-up approach also allows students to think beyond mere technological problem solving and tech-solutionism by assessing technology in a wider socio-technical framework. Interdisciplinary methods are developed in joint workshops on systems thinking and framework analysis, value assessment, and critical design thinking. Ethics thereby is not taught as mere theory ready to be applied, but is actively experienced as an interdisciplinary epistemic practice, one that is tangible and practicable through project-based learning.

Finally, the BEC specialization module "Integrated Ethics — Transdisciplinary Technology Development", which is still under planning, aims at transdisciplinary learning by addressing real-world problems through action-oriented engagement with stakeholders. By exploring ethical questions in a practical project, students learn methods of participatory technology design and integrated technology assessment. They experience directly that technological futures can be shaped in cooperation with societal actors towards mutually desirable outcomes.

Based on the epistemic practice of situating knowledge, participating in the BEC enables students to trace a process from reflection to action, that is, to engage in processes of ethical reflection within multi-, inter- and transdisciplinary learning experiences, thereby making knowledge production more reflexive, responsible and robust.

4 SUMMARY AND ACKNOWLEDGMENTS

While there is a growing call to integrate ethics across engineering curricula and broaden ethical reflection beyond individual compliance, there is no standard curriculum or agreed upon methodology of how to do so. The Berlin Ethics Certificate presents a novel curriculum structure and epistemological approach for integrated ethics, which employs interdisciplinarity as a core driver of ethical reflection.

In this paper, we have argued that crucial to the integration of ethical reflection into science and technology education is the conceptualization of interdisciplinarity as an epistemic practice, which draws on situating knowledge. The epistemic practices of situating knowledge address the call for ethics education to be more emotionally engaging, critically reflective, grounded in real-life experience, and responsive to the complexity and inherent interdisciplinary nature of real-world problems. Situating one's disciplinary knowledge in relation to other disciplines, as well as one's personal experiences, values, and social positioning, allows one to engage in interdisciplinary joint reflection. In this joint process of interdisciplinary collaboration, new knowledge is generated by the integration of partial perspectives and the common search for novel methodologies to test and validate emerging knowledge. Through the BEC's approach to ethics, which upholds the necessity of robust knowledge stemming from a diversity of standpoints, interdisciplinary collaboration is oriented toward taking ethical action. In this sense, students learn to associate ethics with broader societal engagement rather than the simple prevention of scientific misconduct. Through the BEC's emphasis on community building, the shared practice of ethics not only fosters mutual understanding in the disciplinary sense but also allows for students to experience collective responsibility for the future.

Beyond its theoretical contribution of understanding interdisciplinarity as an epistemic practice based on situating knowledge, this paper has outlined a new structural approach for integrating ethics across the curriculum. Rather than teaching "ethics for engineers", the BEC's structure allows for ethical problem framings to be investigated simultaneously by students from a range of disciplinary backgrounds. We have outlined several concrete examples and courses, which may serve as examples of best practice for interdisciplinary and integrated ethics education. Only when ethical reflection becomes integrated into the education of students dealing with science and technology, can we begin to address the complexity of the societal challenges we face.

ABSTRACT

The rapid pace of change in technology, business models, and work practices is causing ever-increasing strain on the global workforce. Companies in every industry need to train professionals with updated skill-sets in a rapid and continuous manner. However, traditional educational models — university classes and in-person degrees— are increasingly incompatible with the needs of professionals, the market, and society as a whole. New models of education require more flexible, granular and affordable alternatives. MIT is currently developing a new educational framework called Agile Continuous Education (ACE). ACE describes workforce level education offered in a flexible, cost-effective and time-efficient manner by combining individual, group, and real-life mentored learning through multiple traditional and emerging learning modalities.

This paper introduces the ACE framework along with its different learning approaches and modalities (e.g. asynchronous and synchronous online courses, virtual synchronous bootcamps, and real-life mentored apprenticeships and internships) and presents the MIT Refugee Action Hub (ReACT) as an illustrative example. MIT ReACT is an institute-wide effort to develop global education programs for underserved communities, including refugees, displaced persons, migrants and economically disadvantaged populations, with the goal of promoting the learner's social integration and formal inclusion into the job market. MIT ReACT's core programs are the Certificate in Computer and Data Science (CDS) and the MicroMasters in Data, Economics and Development Policy, which consist of a combination of online courses, bootcamps, and global apprenticeships. Currently, MIT ReACT has regional presence in the Middle East and North Africa, East Africa, South America, Asia, Europe and North America.

1 INTRODUCTION

Emerging global challenges are adding to already intensifying demands for national and international competitiveness, and across the world many point to the urgent need to speed up innovation and modernize organizations [1]. STEM is a key pillar in the modern innovation-based economy, though by no means the only [2]. Rapid innovation requires an innovative workforce, and yet there is a global shortage of skilled workers [3] in the STEM field and beyond. All this while thousands of already highly skilled professionals get forcibly displaced every year, without knowing a formal carefully designed mechanism to support them in being able to demonstrate their skills, continuing their education, and actively getting back to work.

Traditionally the main avenue towards expertise building has been graduate-level programs. These are usually based on traditional practices – classes and in-person degrees, for example – which are increasingly incompatible with the learner, societal, and market needs. They are monolithic and often inconvenient for full-time employees balancing personal, professional, and financial obligations.

As companies in every industry feel the need to train professionals with updated skill-sets in a rapid and continuous manner, the industry is working on adjusting their corporate training programs to meet current market needs, including university-industry collaborations [4,5]. However, the vast majority of these programs are developed with the company's needs, rather than employees' professional goals, in mind. Furthermore, corporate training is an extremely heterogeneous field without clear quality standards, skills accreditation or standardized assessment.

Workforce education today needs a new model to complement traditional graduate education: one that is more agile, continuous, granular, incremental, convenient and affordable while still ensuring and assuring high quality. Additionally, this new agile model needs to be attuned to the needs of employers and learners, apply the latest developments from the science of learning, use modern educational technology and pedagogy, and present content in a fluid, flexible and digestible way to ensure student success. We introduce a model that we refer to as Agile Continuous Education (ACE), a philosophy and framework to standardize this new and emerging –though fluid– paradigm of upskilling.

1 THE ACE FRAMEWORK

The ACE framework that the Massachusetts Institute of Technology (MIT) is proposing focuses on providing education in a flexible, cost- and time-efficient manner by combining a broader range of modalities: online, on-site on campus, and at-work. As presented in Figure 1, the ACE framework is built on 3 pillars: *individual* learning, *group* learning, and *real-life mentored* learning. A complete learning path should include experiences combining all 3 modalities. As an example, based on current MIT offerings and opportunities, a learner can start with individual coursework online or in-person and build a digital academic portfolio of credentials at their own pace. However social aspects of learning are equally important, particularly considering that most workers will need to work in teams. For this reason, the second pillar of the framework is a group learning component. We cite the example of MIT Bootcamps, which are "guided hackathons" – intense, facilitated, hands-on, project-based, online or on-site activities – as an example of a group activity in which learners can firm up their skills in a team setting. Working with others has the additional benefit of identifying and rectifying possible blind spots from individual activities; coaching in MIT Bootcamps further brings about the exercise of deliberate practice [6]. The third pillar in the ACE framework, we argue, must be a mentored, real-life learning experience (e.g. through apprenticeships, or a collaborative university/industry project), where learners set specific skills development goals at the beginning of at-work engagements. This third phase, we argue, gives the learner the opportunity to apply their new skills and to firm them up in the context of the real world by participating in carefully structured and mentored experiences.

ACE provides new degrees of freedom to workforce learners by:

- Encouraging them to try new courses and content, and earn credentials along the way;
- Offering them the possibility to use credentials and to be subsequently accredited in a full-time academic program (e.g. the MIT Micromasters programs);
- Making content and certification available in smaller bite-sized chunks when and where it fits best to work and personal-life;
- Allowing them to customize their path based on personal preferences, rapidly-evolving industry needs, or personal future career goals;
- Allowing them to apply learned skills and knowledge in more rapid cycles (in a more agile way) in real-world projects;
- Enabling these benefits to be delivered in a more cost-efficient manner;
- Facilitating exposure to the real work environment so they better understand work and culture in potentially unfamiliar fields and roles; and
- Exposing them to career choices via smaller engagements designed for both learning and experience, allowing their career decisions to follow a discovery driven path. Learners are consequently equipped to make informed decisions about the role and industry that will best fit.

Fig. 1. The 3 pillars of ACE

The ACE framework combines known educational approaches that have been developed and tested at MIT and elsewhere; it does so in a way that systematizes what is otherwise unstructured, in keeping with the discipline of the three pillars we have described: *individual* learning, *group* learning, and *real-life mentored* learning.

To ensure speed and relevance in ACE delivery, we sought a use case that would put the ideas to the test amid an urgent need: the MIT Refugee Action Hub (ReACT). We present ReACT below as a "case study" to illustrate the potential for ACE to revolutionize lifelong learning.

2 MIT REFUGEE ACTION HUB (REACT)

The MIT Refugee Action Hub (ReACT) is an institute-wide effort to develop global education programs that target the needs of underserved communities, including refugees, displaced people, migrants and economically disadvantaged populations. MIT believes that education is a critical tool to help underserved learners achieve their personal and professional goals, by giving them a platform to recognize and leverage their talents, access a professional career, and create positive change in their lives and communities.

ReACT launched in May 2017 as a response to the MIT SOLVE call to find creative solutions to the problem of refugee education. It focused on the creation of a center at MIT to design and deploy new learning opportunities for displaced populations around the world. Driven by his own experience as a refugee, Prof Admir Masic has since led a collaborative effort with internal partners including MIT Bootcamps, MITx, MISTI, the MIT Enterprise Forum Pan-Arab Region, and external partners around the world to address the complex problems of this growing crisis and offer programs with the potential to change the narrative of the refugee experience.

With 79.5 million forcibly displaced people around the world, and only 3% of them able to access higher education, there has never been a greater need for the kind of globally focused educational innovation offered by MIT [7,8].

2.1 ReACT cohorts, learners and hubs

ReACT's global cohorts connect to a worldwide network of universities, nonprofits, organizations and companies committed to serving underserved communities and connecting them with relevant learning resources, professional development opportunities, and meaningful employment.

The first ReACT cohort was established in 2018 to support mostly Syrian refugees resettled in Jordan (the first ReACT hub) and refugees from Palestine and other nearby regions. Their learning path focused on skills development in computer programming, entrepreneurship and innovation, using curriculum drawn from MIT courses, MIT Bootcamp workshops and maker activities. After the two week in-person Immersion and Acceleration workshop, learners completed two MITx MOOCs on basic Python programming and computational thinking as well as a third elective course of their choosing. Since then two more cohorts have completed the Certificate in Computer and Data Science program, and a fourth one is currently undergoing activities. In all, 90 individuals have completed ReACT training, and 65% found employment in the field within 6 months.

Throughout these four cohorts, the ReACT learning path has evolved to better respond to the learners' professional, socio-academic and personal needs as well as external factors, including the COVID pandemic. COVID forced the ReACT programs to be completely virtual but created opportunities for the program to extend and accept more learners globally. From one hub in Jordan in 2018, ReACT programs currently take place in 6 different Hub locations, supporting learners from more than 29 countries. Table I presents a summary of the ReACT cohorts, its number of learners per cohort, their location and overall completion rates. The location of the currently active ReACT hubs all over the world is summarized in Fig. 2.

Table 1. Summary of ReACT cohort data (dates, learners, locations and completion rates)

Cohort number	Learning journey dates	Number of locations	Total # learners enrolled
1	May 2017- Oct 2017	1 (Jordan)	17
2	January 2018 - January 2019	1 (Jordan)	22
3	September 2020 - Sept 2021	3 (Jordan, Colombia, Uganda)	50
4	Jan 2022 - present (currently ongoing)	6 (Jordan, Colombia, Uganda, Uruguay, Afghanistan, Greece, USA)	136

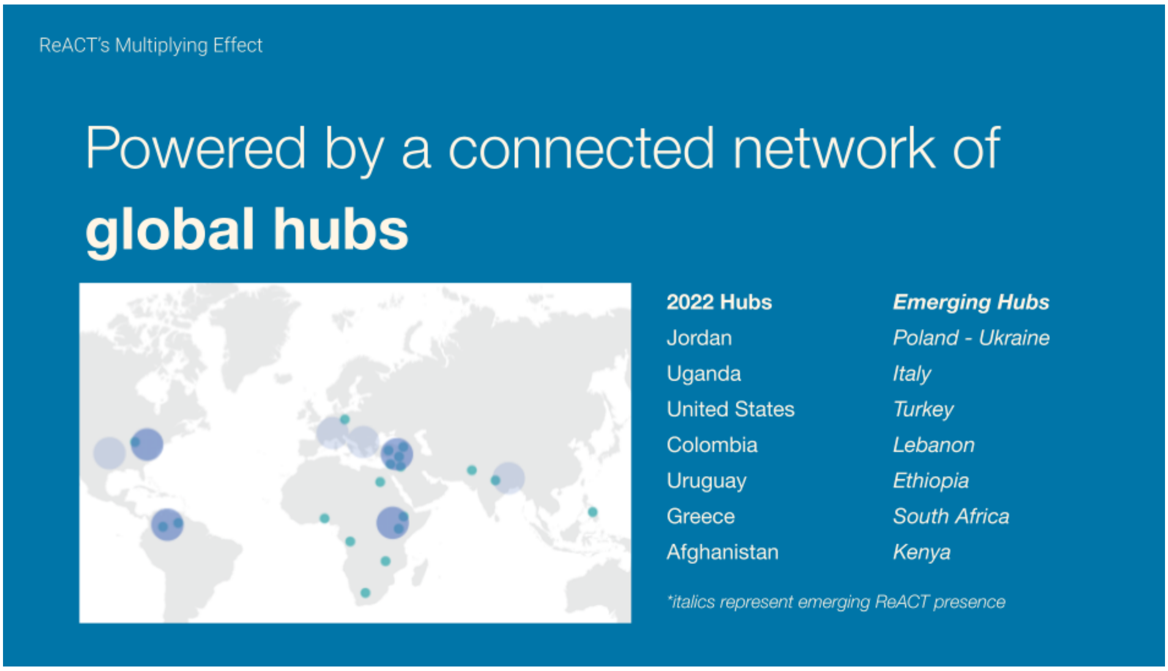

Fig. 2. Location of MIT ReACT hubs around the globe (updated April 2022)

2.2 Implementing ACE through the MIT ReACT Computer and Data Science (CDS) Certificate Program

ReACT's cornerstone program is its Certificate in Computer and Data Science (CDS), a yearlong online program in which participants hone the skills needed for success in the 21st-century economy. The CDS is a high-touch ACE program, consisting of online courses, bootcamps, and learning through internships. In CDS learners study computer programming and data analysis, while also focusing on cross-cultural collaborations and work readiness, innovation thinking and entrepreneurship.

The CDS learning journey is structured around the 3 main ACE pillars. As learners progress through the program, they advance capacities in academic and technical skills using *individual*, *group* and *real-life mentored* learning:

- *Individual* learning through online MIT courses in computer and data science,
- *Group* learning through participation in the MIT Innovation Leadership Bootcamp, synchronous online workshops focused on human skills development, peer communities through study groups supported by community Teaching Assistants and online social gatherings, and
- *Real-life mentored* learning supported by mentored activities that cover paid internships or mentored learning projects. Learners are also matched 1:1 with a mentor with professional experience in the tech sector.

Individual learning: Learners complete three online instructor-led asynchronous MITx courses in computational thinking, coding, programming using Python, and data science, as well as their choice of electives on the edX catalog to allow specialization in data science for healthcare or economic development policy.

Group learning: The cohort starts with an orientation workshop, where learners participate in visioning and goal-setting activities, strengthen their skills in virtual networking and interactive information and communication technologies, are exposed to opportunities to improve their English, and begin developing an online community.

ReACT partners with Na'amal, which aims "to pave a way for accessible remote employment for refugees and other vulnerable populations" [9] and leads several interactive workshops on planning, success in remote work, communication, data compliance and digital security, and self-management.
Current cohorts also participate in the intensive 10-week online MIT Innovation Leadership Bootcamp, where learners collaborate across cultures and time zones to build new entrepreneurial ventures. The ReACT cohort is integrated within the MIT Bootcamp's larger class of several hundreds of aspiring global entrepreneurs, creating opportunities for ReACT learners to be meaningfully immersed in wider networks while developing their leadership capacities.

Real-life mentored learning: ReACT develops computational thinkers ready to enter high-skill careers as full-stack engineers, software developers, business planning analysts, and data and information management at various companies. MIT ReACT staff connect learners to local and remote paid internships. Priority is given to high-skill, meaningful internships within the tech sector and with companies that indicate interest in hiring full-time after a successful internship. MIT uses its institutional networks through the MIT Alumni Association, the J-WEL, and MISTI program to connect ReACT learners with internship opportunities in locations where these refugees live. Alternatively, some learners are given the option to pursue real-life mentored learning completing specific projects either within their current place of employment or independently as individuals or small teams. These experiences are especially important for learners who do not have prior work experience but can use what they learn from ReACT to build Github or Linkedin portfolios or personal websites that showcase their job-ready skills.

Preliminary evaluation research on the implementation and efficiency of the React program is scheduled to begin in August 2022.

3 THE FUTURE OF ACE

Although MIT ACE developed this framework with existing MIT courses, programs, and learning experiences in mind, it is our aspiration that it will be adapted and used by other institutions as well, and possibly at different educational levels. To further shape and promote ACE authors would like to connect with professionals seeking to advance their knowledge and skills in the field of education; learning & development leaders at companies; education policy makers; MIT and other university scholars conducting research in ACE and ACE-like models; and those interested in the current development of education and its future. Together we are aiming to further explore:

- Efficient and scalable coaching and mentorship for learners as they are building their own learning pathways and progress toward career goals.
- Better practices to inform how “human skills” [10] such as critical, creative, and ethical thinking, could be best integrated in the content.
- How the global education community can guide the ACE framework standardization, including discussions about accreditation, digital credentials, unified transcripts, and record achievements.

4 ACKNOWLEDGMENTS

The MIT ReACT team thanks the support of the ReACT learners and their families, all the communities surrounding and supporting them, as well as Na’amal, the humanitarian organizations, organizations, and governments aiding refugees. ReACT is made possible through the generous support of the Western Union Foundation, Berger Charitable Foundation, J-WEL and the support of a number of individual donors.

ABSTRACT

There has been a rising awareness in recent years of the gender inequalities within STEM-related programmes and the need to overcome them and so bridge the gender gap in these academic disciplines. Different initiatives have arisen, among which there are gender equality policies, regulations and programmes. In line with this, the Catalan University Quality Assurance Agency (AQU) promoted a regulation for the incorporation of the gender perspective in all the bachelor's and master's degrees in tertiary education in Catalonia by 2021. To comply with this regulation and also to promote a culture of equity and equality of opportunities for women, the Universitat Politècnica de Catalunya (UPC) fostered different projects within its community. One of these projects has been developed by the Gender Equality Commission at Barcelona School of Nautical Studies and consists in the development of a web platform with resources for lecturers to incorporate this new transversal competence of gender perspective in the nautical, marine and naval engineering study plans. The main objective of this teaching innovation project is to aid teachers with the incorporation of this competence not only by providing online tools and resources but also gender-focused teacher training to allow them to design tailor-made activities and strategies. Some tests were also administered to assess the effectiveness of the implementation of these newly-designed gender equality teaching practices and some sample study plans and activities were developed to serve as a model and example of good practices for the incorporation of gender mainstreaming in the disciplines of nautical, marine and naval engineering.

1 INTRODUCTION

1.1 Framework

In order to promote gender mainstreaming in all Catalan Universities, the Catalan University Quality Assurance Agency (AQU) published in 2018 the General Framework for the incorporation of the gender perspective in university teaching [1], following the Resolution 693 / XII of the Official Gazette of the Parliament of Catalonia (BOPC number 505, of 9 January 2020) [2] on the recognition and guarantee of women's rights. To foster a culture of equity and equality of opportunities for women at the Universitat Politècnica de Catalunya (UPC), and also to comply with these recommendations, the Governing Council of the UPC, which establishes the University's strategic and programmatic lines, approved on 1 April 2020 the incorporation of the new transversal competence on gender perspective (Agreement CG / 2020/02/13) [3]. According to point 2 of this UPC Governing Council Agreement, "All bachelor's and master's degrees taught at the UPC must gradually incorporate the new competence on gender perspective."

The Commission for Gender Equality of the Barcelona School of Nautical Studies was created to promote actions and address issues aimed at ensuring and achieving gender equality within the school community. In accordance with this, and in order to assume the mandate of the Governing Council of the UPC for the incorporation of the new competence of gender perspective in teaching, the commission, constituted as a work group, presented the proposal for an innovation teaching project for the development of a web platform with resources for the incorporation of the gender perspective in the Nautical, Marine and Naval engineering bachelor and master's degrees. This proposal was approved in July 2021 and developed during the academic year 2021-2022.

1.2 Objectives

The incorporation of gender mainstreaming in education improves the quality of instruction and the social relevance of the contents taught while avoiding partial and androcentric interpretations of society and knowledge. Gender-sensitive teaching also encourages students' critical thinking capacity and provides them with tools to identify gender bias, stereotypes and roles. All this gender awareness is essential to cater for diverse roles and needs and to avoid gender blindness not only in university teaching but also in students' future careers, which may aid with the transformation of present unequal gender relations [4]. This is one of the reasons why gender mainstreaming in education is promoted by national and international institutions and organisations, as a strategy towards combating discrimination and realising gender equality.

In keeping with this, the main goal of the innovation project presented here was to provide resources to teachers for the progressive incorporation of the gender perspective in the curricula of all the studies of the Barcelona School of Nautical Studies. This main goal fostered different types of actions to encourage teaching staff participation in addressing gender equality issues in teaching, such as specific teacher training to empower them with respect to the implementation of this new gender perspective. The final aim was to provide training and resources on gender-sensitive pedagogies and innovative teaching methodologies that reduce inequalities, biases and stereotypes. This way we may also address the current gender gap in nautical, marine and naval engineering studies, which the 2021-2022 academic year only recorded 16.9% of female students enrolled according to the Planification, Evaluation and Quality Office (GPAC[1]) data.

2 METHODOLOGY

According to AQU [1], "when applied to teaching, the gender perspective implies a process of reflection which affects the design of the competences and skills in the programme's curriculum, the design of courses, including learning outcomes, the content taught, examples provided, the language used, the sources selected, the method of assessment and the way in which the learning environment is managed. To ensure the successful mainstreaming of the gender perspective, teaching staff need to acquire this skill through the training provided by universities' teaching innovation

[1] GPAC: Gabinet de Planificació, Avaluació i Qualitat

units and the specific courses organised by gender equality units and observatories." In consonance with this, the innovation project attempted to aid teachers to assess gender inequality, transform their curricula, develop sex- and gender-sensitive content, include more gender-balanced references, foster a more inclusive learning environment and apply gender-sensitive teaching methods and assessment.

2.1 Project areas

In order to design solutions that could help teachers assess inequality and develop the necessary abilities to transform their curricula, course contents and teaching methods, along the lines of the definition above, the innovation project provided different types of resources and training, which were organised around the five main areas described below:

AREA 1. Development of gender-sensitive curricula

This area contemplates the development of gender-sensitive curricula incorporating the gender perspective at different levels, namely, in terms of inclusive vocabulary, gender-sensitive goals and content, gender-balanced references and inclusive evaluation activities. Teaching content should be inclusive, avoid gender bias and stereotypes, and incorporate female references as role models for students. On the other hand, including women in the bibliographic references with their full name would also help to give female researchers more visibility. Finally, it has been demonstrated that the different types of exam questions and teacher's performance may also affect students' answers according to gender, which should also be taken into consideration.

AREA 2. Guide of resources and good teaching practices to promote gender equality

The guide of resources and good teaching practices should be used as a tool to promote the incorporation of the gender perspective in teaching not only in terms of content and assessment but also in terms of teaching methodology and classroom management. The teaching methodology should take into account the different learning styles and allow students to reflect on social issues relative to gender equality. Classroom management should consider assigning roles in classroom interaction so as not to fall into gender biases, offer a balanced participation, and a variety of experiences that address diverse gender needs.

AREA 3. Teacher training on gender and feminist pedagogies

The two areas above in isolation would not prove effective if they do not go hand in hand with some gender-specific teacher training. Therefore, to help and empower teachers with tools to effectively incorporate the gender perspective in their teaching, training courses and seminars were held to cover and address all the issues described in areas 1 and 2.

AREA 4. Development of diagnostic tools

In order to assess teacher performance and the general sensitivity of the different community groups towards gender equality, different diagnostic tools were developed and incorporated in the platform to diagnose the degree of gender-sensitivity of the school and management, teaching materials, teaching and administrative staff and students. These tools, generally with a survey or checklist format, were designed to assess the extent to which gender mainstreaming is supported and promoted by the school, the community and the curricula with the aim to provide suggestions and encourage community members to progress in this journey.

AREA 5. Dissemination of the project

The work carried out during the project has been disseminated both internally, within the university, and externally, in conferences and journals, with other practitioners within and outside the discipline so as to share some insights on issues relative to the incorporation of the gender perspective in university teaching.

2.2 Teacher training

As it is essential to train students to work on projects, assignments, bachelor's or master's degree projects with a gender perspective, it becomes equally essential to train teaching staff to help them in this endeavour. Departing from the premise that all courses can mainstream gender, teachers need to be provided with the necessary tools and knowledge to incorporate the gender perspective effectively in their teaching. In order to acquire this required knowledge, practitioners should be encouraged to participate in training courses so that they can identify aspects that can be improved or reinforced and so transform their curricula and develop gender-sensitive teaching methodologies and materials accordingly.

The teacher training course on gender mainstreaming was based on the framework of feminist theory and, more specifically, feminist pedagogy, which according to Crabtree, Sapp and Licona (2009 p.4), can be defined as follows: "Feminist pedagogy is a set of assumptions about knowledge and knowing, approaches to content across the disciplines, teaching objectives and strategies, classroom practices, and instructional relationships that are grounded in critical pedagogical and feminist theory. It is an ideology of teaching inasmuch as it is a framework for developing particular strategies and methods of teaching in the service of particular objectives for learning outcomes and social change."[5] Thus, the incorporation of feminist pedagogy in teaching is more a way or rethinking teaching and learning than a methodological perspective [6]. In an attempt to simplify and choose some fundamentals of feminist pedagogy applicable to our teaching context, which undoubtedly falls into an oversimplification, the following were selected to be implemented in the development of the course activities:

- reorganising the relationship between students and teachers to break with the traditional hierarchy in the classroom and question the traditional structural assignment of the principle of authority from a critical perspective.
- creating a shared and collaborative learning environment where students' experiences and knowledge are valued, thus empowering students based on the recognition of their knowledge.

- respecting different identities, rhythms and learning processes.
- developing pedagogical proposals that gather this diversity of knowledge and break with the idea of single, absolute and reductionist thinking.
- transforming learning to allow students *and* teachers not only acquire new knowledge but to shift their thinking in new directions so that their personal interpretations of experience and knowledge can be re-read in new, critical ways.
- creating a safe space in the classroom that tries to overcome prejudices, stereotypes and discrimination, thus enhancing the sense of community.

In keeping with this philosophy, the innovation project described here incorporated some gender-specific training for the teachers of Barcelona School of Nautical Studies. Fifteen teachers participated in a specially-designed course to learn about gender-sensitive pedagogies and innovative teaching methodologies to transform their curricula. The course consisted of three theoretical sessions followed by some individual guided work and two final sessions to discuss with the whole group the activities developed. The feedback received in these final sessions served to refine the activities and a final version of the valuable materials produced was included in a repository on the project platform to be used as a guide and example for other teachers.

3 PROJECT OUTCOMES

3.1 Web Platform

The main outcome of the project was the development of a web platform with resources for the incorporation of gender mainstreaming in the discipline of nautical, marine and naval engineering, encompassing the five project areas described in section 2.1. This platform constitutes a flexible tool to generate a comprehensive and dynamic virtual learning environment, which allows interaction between users to share experiences and knowledge. This platform, which is linked to the Barcelona School of Nautical Studies website, has three major sections, as illustrated in Figure 1:

- Section 1. Gender equality observatory
- Section 2. General resources on gender equality
- Section 3. Resources for the incorporation of gender mainstreaming in teaching and research

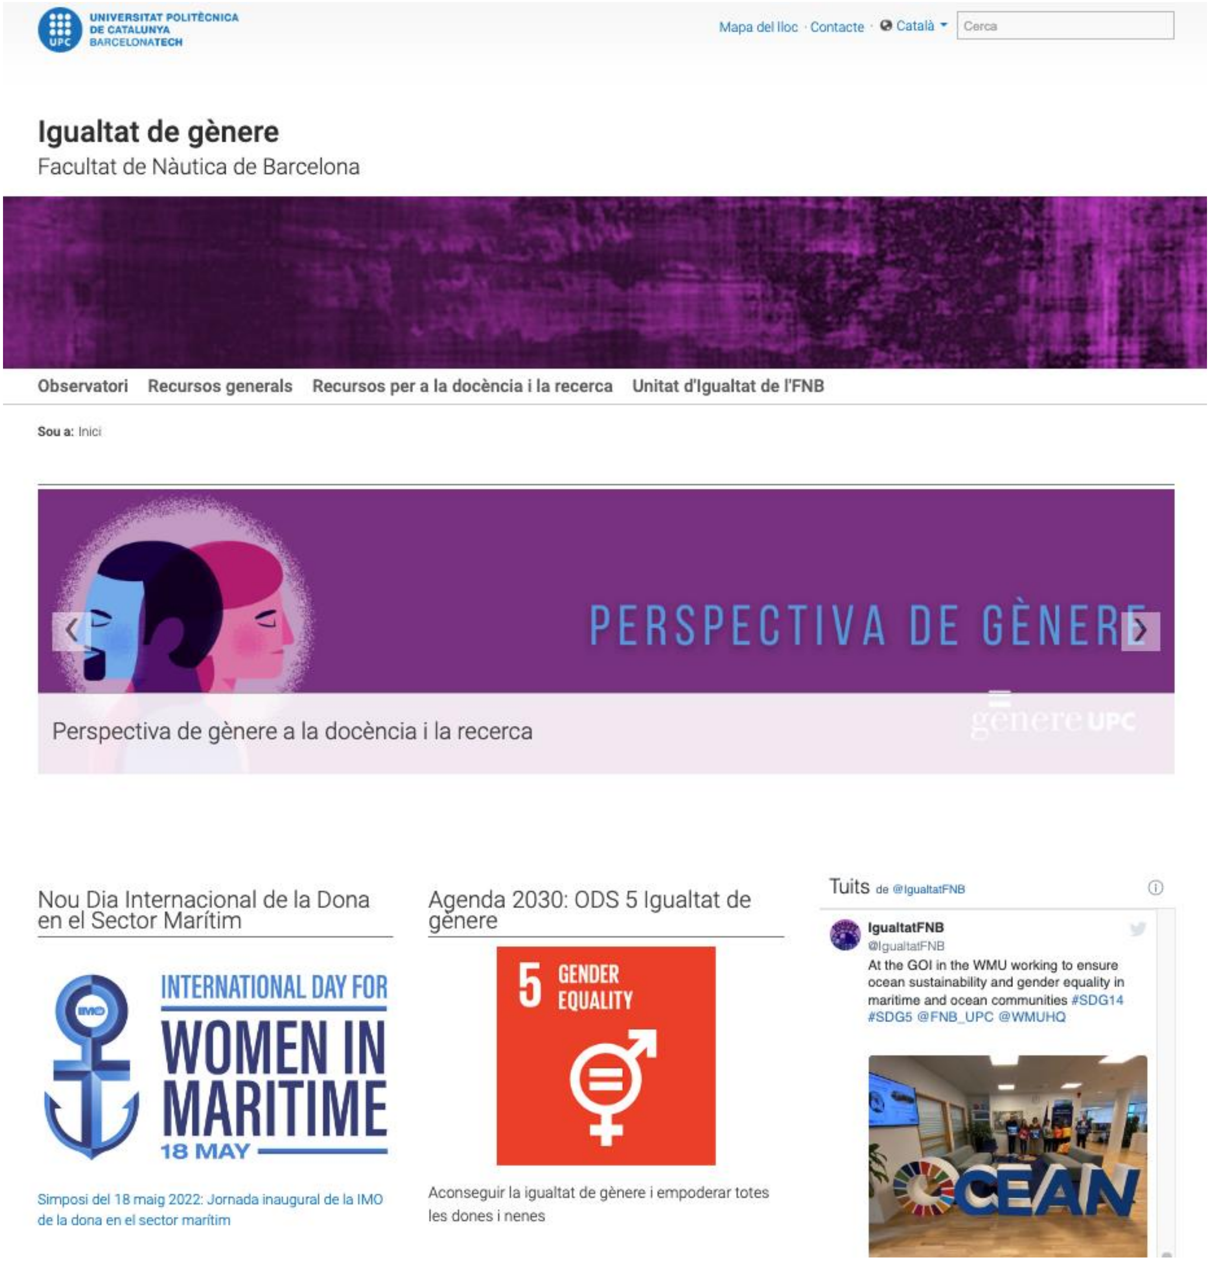

Fig. 1. Web platform homepage

All the resources provided in the different sections are specifically addressed to students, teaching and administrative staff of the discipline of nautical, marine and naval engineering. Below is a description of the resources available in each section:

Section 1. Gender equality observatory

This section includes gender-disaggregated data and statistics to allow the community learn about the reality of the maritime sector and studies. In addition, different diagnostic tools have been incorporated to determine the extent to which gender mainstreaming is supported and promoted by the school and its programmes, and the teaching staff. Also, the degree of gender-sensitivity of the different groups of the community is gathered and analysed with the aim to detect gaps, deviations and difficulties and so identify the aspects that can be improved or reinforced.

Section 2. General resources on gender equality

The resources in this section are divided into two main groups. The first group includes some basic gender literacy to learn about the different key concepts associated with gender and guides on the use of a gender inclusive language. The second group contains resources on gender equality for the maritime community such as programs, organisations and associations involved in promoting equality in the sector.

Section 3. Resources for the incorporation of gender mainstreaming in teaching and research

This third section includes resources for the incorporation of gender mainstreaming in university education and research with a special emphasis on the maritime field. The resources in this section are mainly addressed to teachers and researchers and consist of relevant bibliography, guides and specific practical resources for classroom use. A valuable collection of resources in this section is the repository of gender-sensitive syllabus proposals generated in the teacher training course as explained in section 3.2. below.

3.2 Repository of gender-sensitive curricula

The gender-specific teacher training course offered to the teachers of Barcelona School of Nautical Studies served not only to empower teachers with the necessary tools to effectively incorporate the gender perspective in their teaching, but also to generate a repository of gender-sensitive curricula to be used as guide of good teaching practices by other teachers. The activities developed involved transforming the existing course syllabuses with respect to objectives, content, assessment, methodology and references. To develop the activity teachers could focus on one or several of these aspects depending on their needs and interests. The result was a collection of syllabus proposals with an enhanced gender mainstreaming approach. This was an important output of the project in itself as it allowed teachers to reflect on different questions relative to gender pedagogies, confront the challenge of resisting a single, dominant, institutionalised narrative and look for and find ways to transform their teaching and study plans. The proposals stemming from the course were incorporated in section 3 of the platform.

4 SUMMARY

This innovation teaching project constitutes a step forward towards the incorporation of gender mainstreaming in the disciplines of nautical, marine and naval engineering. The resources and tools incorporated in the web platform developed may serve to enhance curricular design and content, learning outcomes, teaching and assessment methods and consider student diversity. At the same time, these resources may prove useful to detect and avoid gender blindness, bias and stereotypes in teaching and so avoid the production of future professional outputs and projects based on androcentric patterns. Finally, the participation of teaching staff in the project has been key to empower them with the tools and knowledge to incorporate the gender perspective effectively in their teaching while becoming a valuable asset to develop gender-sensitive materials.

ACKNOWLEDGMENTS

This innovation teaching project has received funding from the UPC Teaching Innovation Projects 2021 Call Resolution (Agreement CG / 2021/02/34, of 9 April 2021) and Barcelona School of Nautical Studies. This support is gratefully acknowledged.

ABSTRACT

Spatial skills have been shown to strongly predict STEM attainment and can therefore be a determining factor in choosing to pursue high-paying engineering careers. This strong reliance on them particularly limits students with low spatial skills – a group over-represented by girls and students of low socioeconomic status. It has also been demonstrated that spatial training leads to meaningful improvements in skill development. In Ireland, as in most countries, spatial thinking is not explicitly taught at the pre-college level, even though it could influence students' eventual career paths. Currently, only a person's previous experiences outside the classroom influence skill development. In order to increase the number of students who select engineering and other STEM occupations as a career path, an explicit emphasis on training spatial thinking is likely to be very beneficial in pre-college education. An established spatial intervention course was selected for delivery to secondary schools in Ireland. Through training and ongoing support, teachers' spatial skills, and pedagogical content knowledge for spatial thinking are being developed to be shared with their students, leading to an increase in students' spatial skill level and future employment opportunities.

1 SPATIAL SKILLS

Spatial skills can be defined as spatial visualization, which includes the ability to imagine and mentally transform spatial information [3]. Wai, Lubinski, and Benbow [9] examined the importance of mathematical, verbal, and spatial skills in high school students using measures of spatial visualization and how they affected their later career choice and success in STEM fields. They analyzed the data from Project TALENT, which included students' assessments of cognitive skills (mathematical, verbal, and spatial skills) from the 9th until the 12th grade. The sample included approximately 50,000 males and 50,000 females per grade level. After 11 years, they gathered follow-up data and found that most STEM graduates came from the group of students whose spatial skills were highly developed at age 13. This skill has shown to be the best indicator for future STEM success (especially for engineering) – even more so than the level of mathematical and verbal development.

1.1 Spatial Intervention

Findings from large-scale studies such as Project TALENT highlight the need to investigate the extent to which spatial skills training can facilitate improvements in performance in a range of STEM tasks. Motivated to explore the connection between spatial skills and success in engineering majors, Sorby and Baartmans [8] developed a spatial visualization course for first-year engineering students, which emphasized sketching and interacting with 3D models of geometric forms. Their data showed the course developed students' spatial skills, which were correlated with improved performance in graphics courses and an increase in the engineering major's retention rate (especially for female students) [8]. These very encouraging results led to another three-year study conducted with middle school students which showed that students who took part in the training significantly improved their spatial skills compared to those who did not [7].

Spatial skills are a primary factor of intelligence that is viewed as a combination of several separately measurable subfactors. Some of these, mental rotation in particular, typically reveals gender differences in favor of males. Since mental rotation and related factors are so highly correlated with performance in many STEM tasks and girls are often under-represented in STEM courses, improving spatial skills might play a significant role in reducing this gap in representation. One interesting result that emerged from the middle school intervention study was that female participants who improved their spatial skills through the training subsequently enrolled in more math and science courses than girls in a similarly identified comparison group [7]. This could suggest that the training reduced their spatial and math anxiety levels. A study from 2019 [8] demonstrated that spatial anxiety relates to spatial strategy avoidance in solving mathematical problems which negatively influences math success, math anxiety and math avoidance. There is also some evidence that girls who perform lower in maths may be at higher risk for developing math anxiety than are similarly performing boys [1]. Therefore, systematic development of spatial skills in the education system is needed and can be successfully implemented with middle school students where it still influences their choice of high school subjects and future career opportunities.

1.2 Rationale for the Study in the Irish Context

Results from a recent national study in Ireland [5] highlight the underdevelopment of spatial skills in grade 7, which is the 1st year of post-primary students, and that a relatively small gap in spatial skills in favor of males exists at this stage but grows quite significantly over the subsequent years in the second level through to grade 12. Also, the Irish STEM Education Policy Statement 2017–2026 emphasized the necessity to ensure that students' learning in STEM disciplines significantly improves and that more young people (especially females) choose and sustain their involvement in STEM education. To accomplish this goal, continuous efforts in initial Teacher Education and teachers' ongoing professional development (PD) are needed [2]. Since the Developing Spatial Thinking course yielded positive effects on middle school students' subject choice and STEM engagement, it has been chosen to be adapted for the Irish transition year (TY) students aged ~ 15 years.

2 METHODOLOGY

The purpose of the current small-scale pilot study is to test a project plan and research design that will be refined and used in a large-scale pilot study that will commence in September 2022 involving approximately 60 teachers in several secondary schools in Ireland. The data for the entire project are being collected from students and teachers – focusing on teachers' needs and requirements, and how to design the professional development (PD) to address these. The project is being designed and delivered in collaboration with the national in-service teacher training organization in Ireland, Professional Development Service for Teachers (PDST). After 2 years of gathering and analyzing teacher and student data on the effects and the structure of the intervention, the course and the PD will be refined and implemented on a national scale for the TY students.

2.1 Participants

Schools were canvassed by the PDST for interest in participating in the project and a small number of these schools were approached for participation in the small-scale pilot project. A total of 10 teachers were recruited as shown in Fig 1. One teacher did not complete the post-test and the post-interview, so their data cannot be included in the final pre- and post-differences examination process.

Participants	SMALL-scale pilot study 2021/22	LARGE-scale pilot study 2022/23
maths teachers	10	~ 40
TY students	~ 250	~ 1000

Fig. 1. *The small-scale pilot and large-scale pilot study participants.*

All participating teachers teach mathematics in grade 9 which is called transition year (TY) in the Irish school system. This is the year in which students undertake a wide variety of non-academic activities such as work experience and community care. However, much of their time is spent in school which gives teachers the flexibility in their timetable to trial novel educational experiences and interventions.

Description of the Spatial Course

The spatial course comprises 10 modules:

1. Surfaces and Solids of Revolution
2. Combining Solids
3. Isometric Sketching and Coded Plans*
4. Orthographic Projection*
5. Inclined and Curved Surfaces
6. Flat Patterns
7. Rotation of Objects about a Single Axis*
8. Rotation of Objects about Two or More Axes*
9. Reflection and Symmetry
10. Cutting Planes and Cross Sections

The four modules (marked with an asterisk) focus on developing students' sketching skills with the use of manipulatives (snap cubes). They require students to build a shape and sketch it from different perspectives. The importance of hands-on experiences for learning originates from Piaget's theory of cognitive development [4]. His theory claims that students need physical references to understand mathematical concepts, hence this element is an important feature of the course. In addition, sketches provide external representations of the visualizations formed by students which can then be examined and reflected on to check for accuracy and provide feedback on how they are visualizing. For this study, a website with online resources for individual modules was created, that includes:

- brief lectures with video demonstrations,
- interactive software,
- supplementary online teacher resources, and
- optional videos with additional exercises.

Physical workbooks with sketching exercises for each module were prepared for students. Teacher guides with lesson plans and pedagogical implications were arranged for teachers. Provided materials for fostering hands-on learning included:

- snap cubes to build and manipulate 3D shapes, and
- K'nex to represent the x, y, and z axes for demonstrating the rotation of objects around one or multiple axes.

2.2 Project Overview

The entire spatial project consists of three major steps. The first step (in the academic year 2021/22) is devoted to the small-scale pilot study, the second to the large-scale pilot study (the year 2022/23), and the third (from 2023/24) to the implementation of the spatial course in the transition year curriculum as shown in Fig. 2.

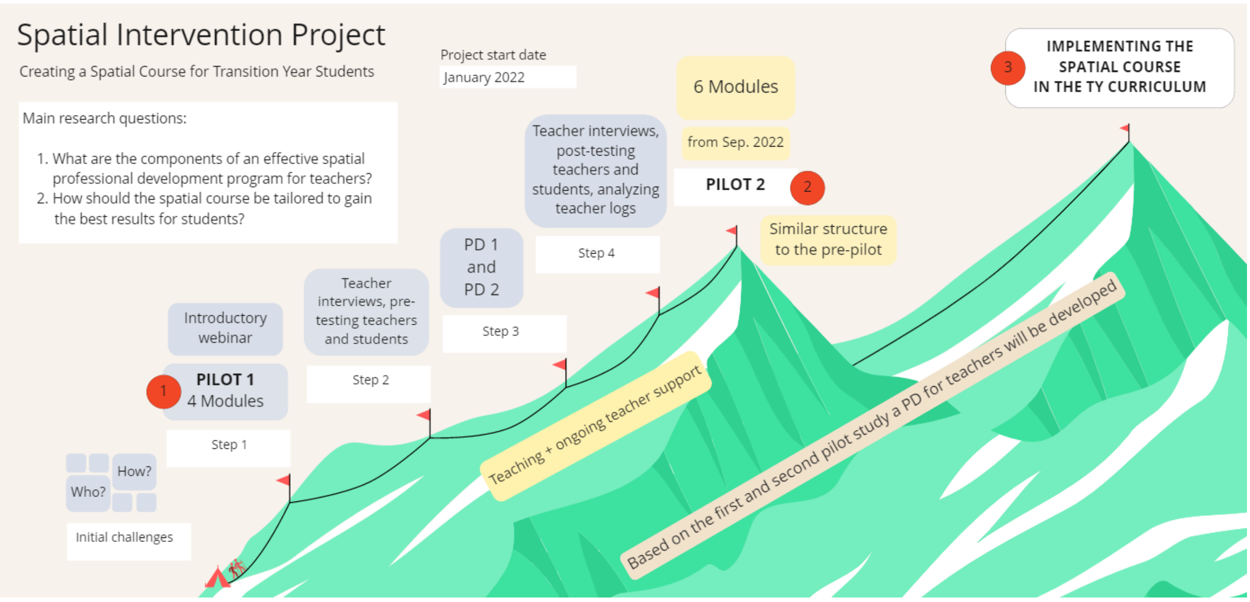

Fig. 2. *The structure of the Spatial Intervention Project: small-scale pilot, large-scale pilot study, and the nationwide implementation in the TY curriculum.*

Small-scale pilot structure

In January 2022, the small-scale pilot began. The initial challenges revolved around selecting which schools and how many teachers of which subject were going to be involved, which modules from the spatial course were going to be taught and how the entire process of the intervention was going to be organized. The purpose of the small-scale pilot was to assess all instruments and the quality of the PD for teachers to refine them and use them on a larger scale during the second pilot study.

Step 1 included the decision on which modules will be taught and the introduction of the study with the whole timeframe to the participants (teachers).

Step 2 describes the activities between the initial introduction and the first professional development day. Teachers were asked to take part in a pre-intervention interview where the researcher asked questions about their perception of spatial skills within the curriculum and their expectations of the spatial training. Teachers signed the consent forms for participation and completed the spatial test (PSVT: R Visualization of Rotations Test) with the incorporated feedback questionnaire on their experience of solving spatial tasks. Also, students were given the PSVT: R test to assess their skill level prior to the intervention.

Step 3 combines the two separately performed professional development days. The first one created a safe space for teachers from different schools to get to know each other and explore the fundamental module 3 (Isometric Sketching and Coded Plans) and module 7 (Rotation of Objects about a Single Axis) with an emphasis on pedagogy and on their content knowledge development through hands-on manipulation and sketching activities in student workbooks. After that, they started teaching the modules in their classroom. The second PD occurred a month after the first. Teachers shared their experiences of introducing the spatial course to their students and the students' initial reactions to the spatial tasks. During the PD, they worked on module 6 (Flat Patterns) and module 8 (Rotation of Objects about Two or More Axis), again with the emphasis on pedagogy and the use of multiple manipulatives.

The professional development days centered on fostering teachers' pedagogical content knowledge by improving their understanding of the skills' importance in STEM, and their skill level, and actively exploring ways of supporting their students in the future. Examples of student support discussed during the PD are:

- Use concrete examples to explain the isometric view by observing the corner of the room from different perspectives.
- Use the manipulatives (snap cubes, K'nex). Students who struggle must build the shapes first before sketching them. Start with the easiest examples and

give them time to explore the materials. Make sure they understand the isometric sketching and coded plans of module 3 before moving on.
- Students can cut out different shapes and fold them to get a better understanding of where the edges align.
- Make use of the online resources. Students can watch the videos and build along, solve additional examples and work with the interactive software.

While teachers were teaching the course, classroom observations and ongoing support were provided by the PDST. Teachers were also required to fill in a teacher log document after each lesson to reflect on their experience.

Step 4 describes the current and final stage of the small-scale pilot study. The researcher will conduct another set of teacher interviews regarding the implementation process, their recommendations for improvement, and their overall experience of teaching the course. The teacher logs will be collected for further analysis, and spatial tests will be given to teachers and students to measure the effects of the course on their skill development. Teachers will also answer questions on the questionnaire regarding their experience taking the test to compare the results with the first set of tests.

3 RESULTS AND DISCUSSION

The initial teacher pre-test spatial scores presented in the left graph in Fig. 3. show that the teachers' spatial skills before the intervention were relatively good. Seven participants out of nine scored from 65 % to 95 %. When observing their perceived difficulty level (from *very, very easy = 1*, until *very, very difficult = 9*) it is revealed that they all experienced it as difficult (*6 = rather difficult*, *7 = difficult*, and *8 = very difficult*), regardless of their skill level. An explanation for this could be the unfamiliarity with the spatial tasks. Perceived difficulty can influence teachers in spatial skill avoidance, where they are not actively seeking ways of incorporating it into their teaching. This provides a strong incentive to organize an effective PD to familiarize them with spatial activities and assessments with the goal of reducing the perceived difficulty level.

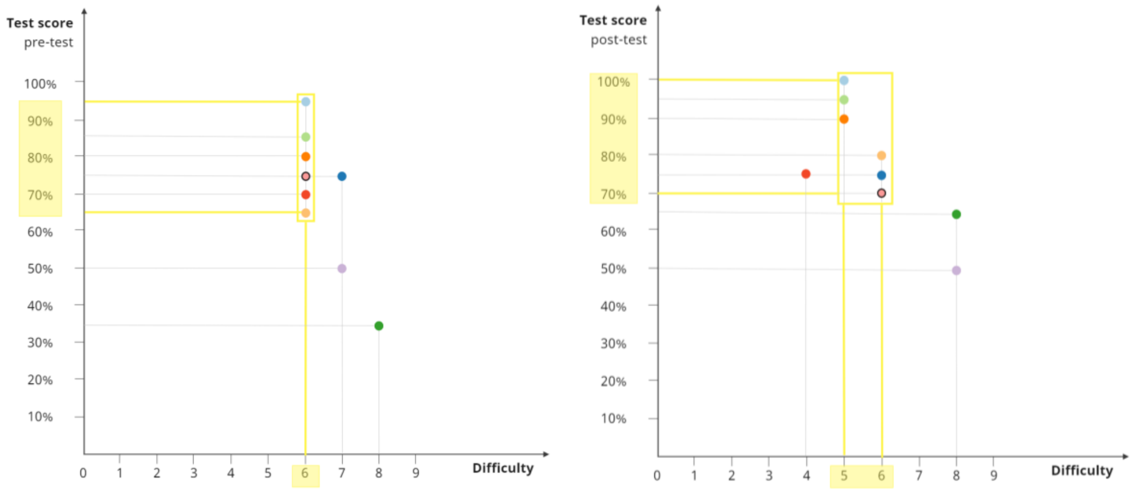

***Fig. 3.** The pre- and post-test results with the perceived difficulty level.*

The right graph in Fig. 3. shows the post-test results and perceived difficulty level after the spatial PD. The majority scored from 70 % to 100 % and experienced the difficulty levels 5 (neither easy nor difficult) and 6 (rather difficult). One teacher experienced it as rather easy (difficulty level 4), and two as very difficult (difficulty level 8). Four teachers (presented in colors: light blue, light green, dark orange, and red) improved their test scores and felt it to be less difficult compared to their pre-test experience. Two teachers (dark green and light orange) improved their test scores but experienced the post-test to be as difficult as the pre-test. Two teachers (purple and dark blue) received the same score but experienced a difference in the difficulty level. The first one (purple) experienced the post-test to be more difficult and the second one (dark blue) as less difficult than the pre-test. One teacher (light pink with a black circle) received a lower score on the post-test and experienced it to be as difficult as the pre-test. During the post-interview, it was discovered that this teacher took the time to focus on the pre-test but rushed through the post-test due to personal time restraints. Based on the teachers' pre- and post-test scores we can observe a general increase in their spatial skill development and a decrease in perceived difficulty level. This suggests that direct training of the skill through the spatial course and having the opportunity of teaching it to students can improve their skill and confidence level in teaching it.

Pre- and post-intervention teacher interviews are currently being analyzed and will be presented in the future. So far, they reflect the potential of this spatial intervention in secondary education based on teachers' experience of the small-scale pilot study. Teachers generally felt their spatial skills improved and gained a better understanding of how to develop them in their students – suggesting an improved pedagogical content knowledge for spatial thinking. It will be interesting to compare the effects of the small- and large-scale pilot study to find if these benefits improve with longer exposure to the intervention.

4 SUMMARY

Spatial skills have been linked to success in engineering. Since they are currently not being systematically developed in Irish pre-tertiary education, their development is being left to chance. Students with better developed spatial skills tend to choose more math and science subjects, which affects their career opportunities. To increase the number of students who could engage in engineering, a spatial intervention in Irish secondary schools is needed. The small-scale pilot study included teachers who wished to incorporate spatial skills in their lessons but needed guidance and support in the form of professional development to accomplish this goal. So far, the training proved to be beneficial in improving teachers' spatial skills and reducing the experienced difficulty level when working with spatial problems on the test. Through a small-scale and a large-scale pilot study, data on the quality of the PD for teachers and the effects of the spatial course on students will be gathered and used to improve it. Future work in Ireland will involve the implementation of the refined spatial intervention in transition years.

cycle, a seminar on sustainable development is offered. It is held in the second semester and lasts two full days. The first objective is to make them aware of corporate social responsibility (CSR) issues in companies. The second is to build on the knowledge acquired during the last 6 months to develop the life cycle of a garment and understand the associated impacts. Finally, it is to highlight the different possible strategies based on eco-design, fair trade, taking into account the regulatory constraints. This seminar is based on active pedagogy, where students work in teams and compare their results with each other. It also aims to provide the minimum tools to understand ecodesign strategies and to be an informed fashion consumer, and to become a textile engineer capable of participating in and technically supporting companies' CSR initiatives.

1 INTRODUCTION

The Ecole Nationale Supérieure des Arts et Industries Textiles (ENSAIT) is a public institution of a scientific and professional nature located in the heart of Roubaix. It is one of the few schools specialised in materials and processes for the textile industry. Each year, it trains around 110 engineers whose role will be to meet the challenges of the sector while respecting the values of the companies and environmental standards.

The ENSAIT engineer's training lasts three years and is available either through a full-time study course or through a block-release program. In the first year, the courses include engineering sciences and the basics of textile processing. Specialisation is then progressive, first with a range of 'majors' offered in the second year (technical textiles; fashion and luxury) and then with a range of application areas in the third year (supply chain, connected business, composites, smart textiles, and sustainable materials and processes).

Also, given the social, ethical, environmental and economic issues raised by the textile industry, the training program provides for all engineers to be aware of and prepared to meet the needs of companies on these subjects. For this purpose, and for more than fifteen years, courses related to the various aspects of sustainable development have been given at ENSAIT. Initially proposed in lecture form and practical work, the educational reform of 2015 has enabled them to be divided between a seminar given in the first year and the specialisation offer of the majors and application areas proposed in the third year. Initially, the lectures were disseminated through the year. However, given the volume of time dedicated to sustainability, this approach was not constructive enough to enable students to develop a sufficient skill. Thus, the solution was to concentrate the dedicated lectures time into a single seminar event. Finally, the aim of such an organisation is to enable all students to become aware of sustainability issues and, for those who wish to specialise, to deepen methodological and critical thinking issues.

In the following, we will focus on the seminar, named “Sustainable development awareness seminar”, and its pedagogical objectives, detail the programme (section 2) and go through its content (sections 3.1, 3.2, 3.3).

2 METHODOLOGY

2.1 Sustainable development awareness seminar

The Sustainable development awareness seminar is designed for about 90 students. It is held from the first year of the engineering cycle with the aim of raising awareness of corporate social responsibility (CSR) issues in companies.

By combining group and individual activities with expert presentations, the seminar aims to ensure that students:

- develop a critical mindset when faced with environmental claims,
- learn about the tools that are useful for addressing CSR issues (social audits, labels, environmental standards, environmental assessment methods),
- know how to understand, criticize and use the results of these tools,
- are fully aware of the regulatory and legal issues,
- understand the complexity of social issues and not making judgements.

2.2 Seminar structure

The seminar is held over 2 consecutive days and is awarded by 2 ECTS. To be awarded, students are evaluated on both, an individual basis and on a group activity:

- the individual evaluation consists in a quizz evaluation which cover the thematics addressed during the lectures and during the parallel workshops;
- the group activity assessment consists in a presentation of the work done during the self-directed activity which is further presented in section 3.3.

The seminar is mainly made of in class activities and is structured as follows:

- an introduction, given during the first half-day, provides a context for sustainable development with its many perspectives,
- learning the tools of CSR, carried out in groups over two half-days,
- a project to be carried out in groups and in autonomy during the last half-day.

In practice, it is as detailed in Table 1:

Table 1: Seminar structure

Duration	Content	Session type	Number of students
15 minutes	Academic introduction and program detail	Plenary session	90 students
45 minutes	Company's introduction about CSR	Plenary session	90 students
2 hours	Classroom lectures	Plenary session	90 students
1 hour	Exercices	Group sessions	45 students/group
4 * 1 hour and half	Parallel thematic Workshops	Group sessions	23 students/group
1 hour	Evaluation (quiz session)	Individually	90 students

Half a day	Self-directed activity	Group	6 to 8 students
From 20 to 45 minutes	Thematic interventions	Plenary sessions	90 students

In class activities This structure mixes lectures and active pedagogy. As discussed by Jouquan et al. [1], active pedagogy create the right conditions for students to engage and persist in learning situation. As mentioned by Jouquan et al. active pedagogy requires a high level of commitment from both, the students and lecturers. Thus, to engage students before the beginning of the seminar, a first out of class activity is committed. Students have to work in groups on the CSR policy of companies in the clothing sector. The companies are pre-selected to cover the field of possibilities: from mass market to luxury, including new brands "born from sustainable development values" (i.e. Bonobo, Burberry, C&A, Carrefour, Mudjeans, SKFK, ...). This activity, delivered in the form of a report, must be returned before the start of the seminar and is intended to provide an initial snapshot of the distance that students are able to stand back from the environmental claims made by companies. Such an exercice corresponds to a role-playing exercise that Lemaître mentioned [2]. The aim is to use observable practices from professional contexts into a training one. The training situation is as close as possible to a professional life situation, which should enable the student to project into a future activity. Such a learning situations supports meaning for the students, unlike courses centred on knowledge content seen as disembodied.

3 RESULTS

3.1 Seminar introduction

The beginning of the seminar is marked by an introduction which allows explaining the programme and most of all to set the scope of this course.

In the context of textiles, it highlights the variety of themes behind the term "sustainable development". As an illustration, professionals, consultants or companies are given the opportunity to present their views. The aim is to benefit from the experience of these players, to appreciate the existing dynamics and for the students to become aware of the expectations of the sector. Regarding these presentations, it is also interesting to notice that a more systematic use of video-conferencing has allowed more actors to intervene and therefore to cover more perspectives. As an example, during the 2020/2021 seminar, these presentations enabled both an approach to CSR, its meaning in companies (with the aim of showing the diversity of themes: social, societal, ethical, legal, environmental or even image) and to deal with specific topics, in this case the environmental labelling of textile clothing products (a topical subject that these engineers will be confronted with as soon as they leave school).

Alternating with these presentations, a first session of courses is held on eco-design, its principles and objectives, its tools and their advantages and limitations.

The aim of eco-design being to reduce the environmental impacts related to the life cycle of a product or a process, it is essential that the students understand these impact indicators. To do so, the students are actively involved in a group exercise. Each group has 1 impact indicator to choose between a list of 16. As an example, they can investigate the global warming potential or the eutrophication or the ecotoxicity and so on. The time dedicated being 20 minutes, they have to understand describe and prepare 2 slides maximum for presenting to all the students. At this stage, it is not requested to make any link with the textile value chain but rather to describe the impact indicators used in LCA.

3.2 Evaluation tools

The following two half-days are dedicated to developing students' skills regarding the tools that will enable them to monitor and respond to the social, environmental and legal aspects of sustainable development with:

- an initial exercise to familiarise themselves with single-criteria quantitative tools for the energy and carbon footprint of a textile product, the exercise being individual,
- four successive workshops dealing specifically with (1) social impact assessment tools, (2) environmental labels, claims and obligations, (3) the legislative and legal aspects of sustainable development and (4) life cycle assessment.

3.2.1. Energy and carbon footprint assessment of a product

A first individual activity is proposed before starting the four workshops. For one hour, students are divided into two groups and are asked to draw the outlines of a first eco-design case study. At this stage, the product (a cotton shirt) is virtual and relatively simple. The idea is to give concrete form to some of the statements made in the first part.

In practice, the approach consists of conducting an energy and a carbon assessment of the life cycle of this shirt. Using their skills in textile processing, the students are responsible for determining the manufacturing cycle of the shirt and its use.

As these two evaluations are single-criteria assessments, this exercise is an initial awareness-raising exercise and introduces the interest of Life Cycle Assessment (LCA) as a multi-criteria tool.

3.2.2. Social impact assessment tools

After a first sensitization to the social problems of the textile industry, the students are given a definition and an illustration of what a social audit is. They thus become familiar with the objective of the tool and its possible uses. Indeed, it is a tool for evaluating the conformity of practices, and the outcomes are part of a wider diagnostic and continuous improvement process. They can be used to meet the requirements of standards, for example in relation to responsible purchasing.

The audit practice is explained by covering the audit criteria (management system, transparency and traceability, minimum age, forced labour, non-discrimination ...) as well as the role and behaviour of the auditor.

A case study is included in this workshop. It gives the students the opportunity to experience a situation where they have to map the "supplier risks" on social impact maturity. The approach is to be validated by the construction of a rating scale and an example of a questionnaire to cover part of the audit criteria outlined earlier.

3.2.3. Environmental labels, claims and obligations

Standards and labels are abundant in the textile sector. They enable buyers to be informed about the environmental and/or social performance of a product or service. Thus, they are widely used. However, it is not easy to distinguish between a promising logo and the reality of the specifications.

To this end, this workshop enables students to:

- understand the principles of environmental communication and thus be able to better assess the transparency, relevance, credibility and clarity of a given communication
- to know the communication methodologies, specifically the categories of declarations developed in the ISO 14024 standard.

An additional exercise is to investigate and report on different labels. This teamwork should enable students to investigate the governance and the origin of the label, its objectives, the certification criteria and their link with the textile sector.

Attention is also paid to the REACH directive, which aims to regulate the use of chemical substances in Europe. As the list of substances is constantly being updated, it is crucial for students to be aware of it and to know how to find and relay such information.

3.2.4. Legal contribution to the sustainable development seminar

During this workshop, students are introduced to the legal instruments that support CSR. Indeed, CSR is framed by a number of national, European and international standards.

While the previous workshop (Environmental labels, claims and obligations) focused on voluntary labels and standards, this workshop focuses more on mandatory standards and the legal consequences of non-compliance.

Thus, binding tools such as the Commercial Code, the OECD principles, children's rights, the law on duty of care, the REACH regulation, the anti-waste law for a circular economy (AGEC) etc. are presented. This latter is also covered in an exercise to better understand the obligations of companies with regard to the regulation and what the penalties are in case of non-compliance.

In addition, the restrictive nature of the various legislative measures is illustrated with various case studies from forced labour to misleading advertisements to the non-respect of the right to strike in the textile value chain.

3.2.5. Environmental assessment tool: Life Cycle Assessment (LCA)

The last workshop focuses on life cycle assessment, a multi-criteria quantitative environmental assessment tool.

The aim is to enable students to grasp the LCA methodology, its vocabulary and what it requires.

The approach is similar to this presented by Viere et al. [3]. The teaching starts with an introduction and the positioning of LCA in a wider context. It is followed by an explanation of the principle, purposes and steps of LCA, regarding the ISO 14040 and ISO 14044. It is followed by the use of the simplified LCA software, EIME proposed by CODDE Bureau Veritas. This online tool corresponds to the students' area of study and benefits from textile-specific databases. Practice is carried out individually on a common case study, the cotton shirt mentioned above, whose life cycle has been determined. The purpose of this exercise is to enable students to identify the "hot spots" in the life cycle of a garment, to be able to monitor future design choices and to understand the concept of life cycle thinking.

3.3 Ecodesign - Self-directed project

The final phase of the seminar is devoted to a student-led project. Entitled "CSR and eco-design strategies", it allows students to put into practice the tools they developed during the seminar. In groups of 6 to 8 students, they are asked to represent the same company whose main product is a cotton shirt, produced in a globalized manner. The company's objective is to improve its CSR strategy, particularly in terms of environmental and social issues. The statement is given as a problem situation more than an exercice. As mentioned by Fayolle et al. [4], it enables to provide a more open but also more realistic context for empowerment and reflection.

An eco-design wheel and guiding questions are provided to assist students. They are expected to choose improvement strategies and to describe how they will implement, monitor and control the success of the strategy.

This experience is punctuated by thematic interventions given by professionals, consultants or companies. The themes covered include end-of-life textile management, the circular economy and the economy of functionality. They are proposed in short formats, 20 minutes long, and should stimulate reflection in the framework of the self-led project.

4 REFLEXIVE FEEDBACK

As previously mentioned, the current seminar format aims to replace previous lectures which were disseminated through the year. This previous approach was not constructive enough to enable students to develop a sufficient skill. Given the volume of time dedicated to sustainability, this approach required constant revisiting of course material as a reminder. By concentrating the sustainability related lectures in two consecutive days, the seminar approach enabled us to better engage students in an intensive learning process and to add some active pedagogy practices. However, by working over two consecutive days, we are experiencing the advantages and disadvantages of such an approach. It is quite clear that the concentration of topics and content is high and it requires a quick involvement of students. However, as some students will not pursue a specialization in sustainability, it is an opportunity for them to deal with diversified topics. It also enable them to increase their critical mindset from regulatory aspects to environmental and social assessment methodologies and communication. As future engineers, whether specialised or not, it is essential they gather knowledges so that they can think constructively about the issues of sustainability.

As lecturers, the preparation workload is quite similar to the one required for traditional lectures. The additional steps are spent on organising and on meeting with companies, specific organisms and NGO to get them involved. It appears that these external interventions are particularly appreciated by students and require our full attention.

During the seminar, we also have:

- To play as a time keeper. The agenda of the seminar is full of activities, some of which may run over. Thus, in order to tackle the whole of the planned programme, it is important to be careful with time management.
- To deal with a diversity of students profiles. The students arriving at ENSAIT come from relatively varied backgrounds and for this reason, the skills are relatively heterogeneous. Facing new activity and knowledges, this diversity of profile is remarkable and requires adaptation and, as far as possible, individualisation.

As mentioned above, the students work individually or in sub-groups. So far, the students groups were made relatively to an other project. Since the students well know each other, we noticed different dynamic nature of each group. At the moment, it is up to us to compensate the weakest dynamic going from group to group. There is probably a way to make it more efficient, perhaps by assigning roles to the students or by setting a time for exchange per group.

This seminar format is led for more than five years. After each, a survey is conducted to know more about the students opinion. It appears that the satisfaction level is quite high with more than 75% of satisfied students. Compared to a traditional lecture, students highlight the changes in the rhythm of each activity, the interactivity and the group activity, the self-directed one specifically. Regarding students opinion, the strongest elements of this seminar are:

- The involvements of companies and association;
- The diversity of intervention methods.

Regarding students' opinion, the areas of improvement are about the time, more time should be spent on the topic in general and on the different activities. This would help them to better appropriate the tools. The imposed nature of the groups was also discussed. Indeed, group work remains a challenge and it is sometimes difficult to involve 6 to 8 students in the same activity. The activity we are proposing is no exception and students would like to be grouped by affinity. This is a choice that we have already experienced with in other situations and which also has its drawbacks (group harmony, heterogeneity of skills, etc.)

5 SUMMARY AND ACKNOWLEDGMENTS

In order to address the sustainable development issues of the textile-apparel sector, a sustainable development awareness seminar is provided in the first year of the ENSAIT engineering course. This seminar covers more than just environmental aspects, it also introduces social issues and social impact assessment tool, environmental labels and communications, vigilance towards claims as well as legal aspects behind sustainability. Students are frequently put into active situations, either individually or in groups, in order to better understand the tools, their implementation and their limits. This format enables a positive group dynamic which is supported by strong individual motivations.

Students learn to step back from sustainable development issues, and sharpen their critical eye. They become aware of how the textile industry is involved in sustainable development actions, and that they have a crucial role to play in transforming the textile industry.

ESTABLISHING A NEW SEMINAR TO COMBINE LEARNING ABOUT TECHNOLOGY AND SOCIETY

U. Berbuir [1]
Ruhr-University Bochum
Bochum, Germany
ORCID: 0000-0003-4451-0128

Conference Key Areas: *Sustainability and Ethics in Engineering Education, Teaching methods*
Keywords: *Problem Based Learning, Public Participation, online collaboration, Interdisciplinarity*

ABSTRACT

For the transformation we face in industry and society, a broad societal consensus and collaboration between different stakeholders are vitally important. With this in mind, the Environmental Engineering program focuses on environmentally relevant technical developments and the consideration of systemic interrelationships while incorporating societal frameworks.

The recently implemented course Technology – Dialogue – Society was developed as an introduction to these complex tasks for first-year students. It focusses on topics of the energy transition sector and public participation. The learning objectives of the course are the acquisition of methodological competencies as well as the promotion of communication, teamwork and the ability to reflect. An overarching goal of the course is also onboarding of students in the program.

A wide set of teaching-learning methods is used to achieve this broad objectives. In addition to lectures, collaborative and dialogue-oriented teaching-learning methods such as problem-based learning, peer review of student work, conversational simulations and reflection assignments are used. A particular challenge of

[1] *Corresponding Author*

ute.berbuir@rub.de

doi:10.5821/conference-9788412322262.1337

implementation was the course size of approximately 100 students and the need for online teaching due to the Covid-19 pandemic.

The structure of the course is described and the evaluation results of the first run are presented.

---

1 INTRODUCTION

1.1 Background

In light of the climate crisis, issues of sustainability and rapid decarbonization of our energy supply are becoming increasingly urgent. The changes required go hand in hand with fundamental social and technical transformations that can only succeed if technical developments are also socially viable. Precisely because engineers are the ones who develop and implement technology, awareness of societal problems and interrelationships is also of particular importance to them and should be integrated into engineering curricula.

As part of the restructuring of the Environmental Engineering program (formerly Environmental Engineering and Resource Management), a new module was developed and intergrated in the curriculum to address these challenges in the program. A particular goal of the module is that students are confronted with this kind of profession-related topics from the very beginning and experience the consideration of societal concerns as belonging to the subject.

The module consists of two parts: The first part, the course *technology - dialogue - society (TDS)* deals with challenges and methods of public participation in industrial and infrastructure projects. The construction or reconstruction of infrastructure as well as the use of technologies is always accompanied by questions of acceptance. In Germany (as in many other countries), there are increasingly massive disputes about the realization of energy transition projects like wind turbines and transmission grids. Finding viable solutions and creating acceptance is a task for society as a whole [1] and this challenge is a well-suited topic to promote the necessary attitudes and competencies in an engineering course.

The second part, the course *environmental ethics for engineers*, focuses on philosophical methods and the analysis of environmental ethical issues. This paper presents the design of the TDS-course and discusses the results of the first run.

1.2 Goals of the TDS-course

The TDS-course deals with environmentally relevant technical issues and social application references. Solving such complex problems requires a variety of knowlege as well as personal and social skills, such as communication skills and the ability to work together in an interdisciplinary manner. These personal and social competencies should be fostered in the course and the development of values and attitude should be stimulated.

The content-focused learning objectives are the acquisition of technical and methodological skills for public participation. The Association of German Engineers (VDI) has developed a guideline that provides support for organisations in the planning, organisation and execution of early public participation, as well as recommendations in the form of a structured process [2]. The methods taught in the course refer to this standard.

This broad set of learning objectives aims at developing competencies based on the T-shaped model [4] and the Future Skills concept. "*Future Skills* are competences that allow individuals to solve complex problems in highly emergent contexts of action in a self-organised way and enable them to act (successfully). They are based on cognitive, motivational, volitional and social resources, are value-based and can be acquired in a learning process." [5] Obviously, these competencies cannot be covered comprehensively or at a high level in such an introductory course, but serious engagement can be initiated and an awareness of the approaches and importance of these competencies and topics can be fostered.

With regard to the observation, that students who do not have a positive experience with social transition at the university have greater difficulty coping with the challenges of the first year of study [6], this course is also intended to promote arrival at the university. This aspect became particularly important in the first run due to the Corona contact-restrictions and limited opportunities for social interaction on the campus.

2 STRUCTURE AND DIDACTIC ELEMENTS OF THE TDS-COURSE

The objectives explained above were transformed into a course concept under the following framework conditions. The TDS-course is a required course in the first semester of the Environmental Engineering degree program and encompasses a workload of 2 credits. The number of expected participants, based on the number of new students, has fluctuated between 50 and 120 in recent years.

The development of the TDS-course is based on the experience with the topic of public participation from interdisciplinary seminars for advanced students and the successful use of problem-based learning (PBL) and conversational simulations therein [3]. The PBL-method forms a core element in this new course as well and the case work drives the thematic discussion and structures the weekly sessions. Problem-based learning (Maastricht model) is process-oriented, promotes communicative skills and collaboration, encourages reflection, and is very well suited to deal with interdisciplinary tasks [7]. Case studies from everyday (work-) life are the starting point. These are worked on in groups and the PBL-process takes place in predetermined steps:

- Case analysis and derivation of research tasks in the group
- Research phase (usually until the next session)
- Presentation and discussion of the results in the group,
  development of solution approaches and feedback [8, 9]

Experiences with the use of PBL with student groups that are not familiar with this form of learning show that it is very helpful for students to receive a relatively high level of content support and reflection. Therefore, basic knowledge is conveyed in short lectures (30 min) or instructional videos and the results and solution approaches from the group case work are also reflected on again in the plenary.

Since students in the first semester have little experience with scientific work, feedback on their writing is very important. Therefore, a peer review of the students' research questions was introduced as an additional step. This is handled via the Moodle learning platform. The peer review offers the great advantage that the students also change into the role of the commentator. They see the work of their fellow students and have to give feedback on certain criteria. Furthermore, they receive feedback on their own work.

The problem-oriented approach is continued during the two seminar sessions, the format also encompasses. These seminars serves as an exemplary application of learned methods. It is also a deep dive into communication situations that occur in public participation. In the second seminar a participation format will be carried out as a simulated conversation (role play). The structure of the course is shown in Figure 1.

Fig.1. Structure of TDS-course

In line with the methods, different types of written performance are required:

- - Elaborations on the "own" PBL research questions.
- - Peer reviews on elaborations by other students
- - Written reflections on findings, processes, or discussions.

In the run-up of this course it was intensively discussed in which form the learning process can be secured and wether and how the performance of the students could be measured. The learning objectives focus on the development of personal and social competencies. Measuring such competencies is generally demanding and time-consuming. Taking into consideration that the course is also about raising awareness for complex issues and stimulating personal development, testing and grading seems counterproductive. Like Reimann says, rather "*potential educational spaces"* are needed: "However, these can only unfold if not every performance shown (and not shown) is recorded and evaluated" [10]. In addition, the course is also intended to support onboarding. Therefore, the course does not include a traditional exam or grading. The workload is secured by checking and documenting the weekly work assignments.

3 IMPLEMENTATION

The first run of the course took place under two special conditions. First, a high number of students from the third or fifth semester of the former study program, who had switched to the modified program, were obligated to attend according to examination law. Their share of the total number of student paricipants was about 50%. The second special condition is that, due to the pandemic, it had to be conducted entirely as online-remote teaching.

About 100 students participated in the course. They were divided into 14 groups of 6-8 participants. As shown in Figure 1, the weekly Zoom Online sessions consisted of different phases. They usually began with a short plenary lecture. Then, students worked on PBL cases in breakout sessions in their groups. At the end of the group-session, there was another plenary phase in which the results were reflected on together and the work assignments for the following week were concretized.

At the beginning of the course, the objectives and methods were made transparent and in particular the PBL method was explained and practiced. Extensive templates were provided in the online whiteboard Miro for collaborative processing of the tasks. With the help of the pre-structured templates, the students were able to work autonomously in the group phases, i.e. without tutorial guidance. In case of questions, tutors were available in the plenum. Students had a work assignment to complete by each of the weekly deadlines during the current semester. The assignments were uploaded to or worked on in the accompanying course on the learning platform Moodle.

In addition to the weekly meetings, two seminars took place. The first seminar was conducted with one group and lasted two hours each. In the second seminar, three groups were combined. In this four-hour seminar, students assumed specific stakeholder roles and simulated participation situations.

4 EXPERIENCES, EVALUATION AND DISCUSSION

Overall, the implementation of this methodologically complex and organizationally extensive course worked well. 104 people registered and 99 successfully completed the course. From the teachers point of view, it was possible to create a good working atmosphere in which an intensive exchange was possible. On the basis of the submitted work assingnments, the documentet work processes and results in the Miro-Boards and the high level of commitment in the two seminars, we can conclude that a comprehensive examination of the topics took place. Basic knowledge and methods were acquired, which all groups were able to demonstrate, especially in the two seminars. Nevertheless, the level of goal achievement varies on the individual level.

Student evaluation of the course was assessed using a standardized questionnaire of the faculty of mechanical engineering. A total of 92 students participated in the evaluation and the course was rated good to very good overall. (mw: 4.5 on a scale of 1-5 (5 = very good) N=92)

The students' responses to open-ended questions are particularly revealing. More than 50 students described in their own words what they particularly liked about the course and where they see potential for improvement. For a differentiated analysis, the students' responses were split into individual statements and these were then assigned to thematic categories. The numbers of mentions per category are shown in Figure 2.

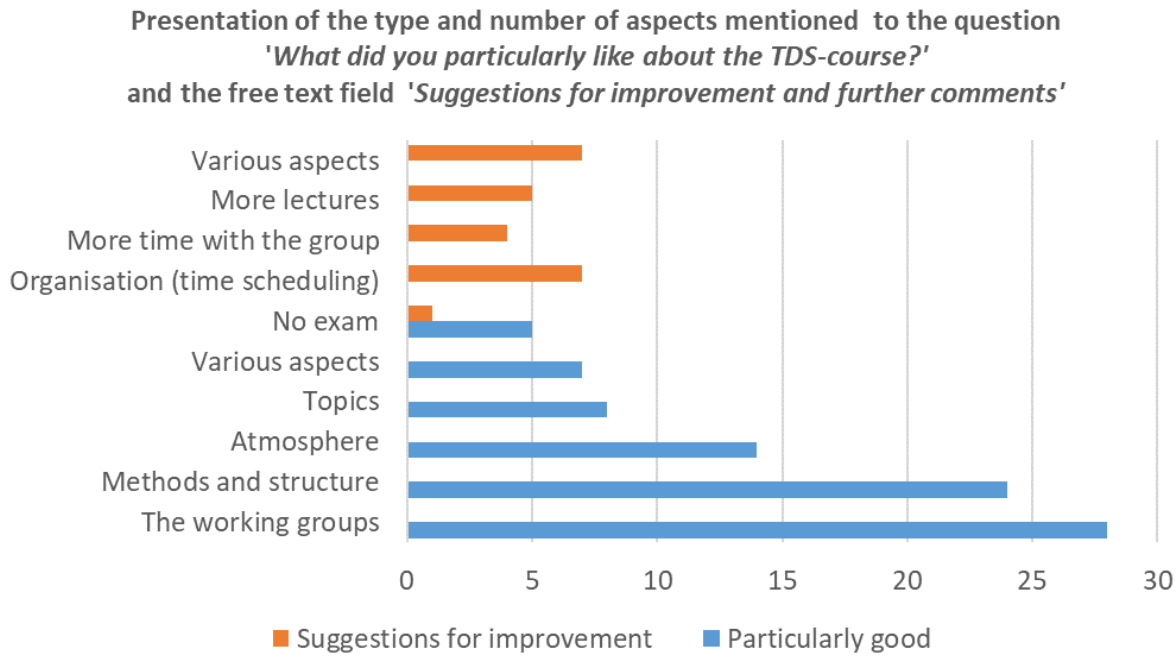

Fig. 2 Evaluation outcomes: Number of mentions per category

The high number of comments suggests that the course has succeeded in engaging students well and that a good level of ownership of the course has emerged. This is also matched by the observation that the comments on the potential for improvement were all constructively formulated and appropriate in terms of content.

The analysis of the free text fields shows that many participants especially liked the group work in the course. More than a quarter of the students explicitly name the group or the group work as *"a highlight of the course"*. The good and open atmosphere in the course is also mentioned as particularly positive.

Suggestions for improvement often relate to organizational aspects, such as the scheduling of seminars or implementation problems in the Moodle course, which should be improved in the next run. Further suggestions concern the wish that the seminars should take place face-to-face on campus - which hopefully can be realized in the future.

About a quarter of the participants explicitly described the methods of the course as particularly good. Students frequently remark that a good mix of methods was used and that this type of teaching was inspiring. The topic of public participation and dealing with societal challenges such as the acceptance of the energy transition are described as interesting and important.

However, individual differences are also apparent from the comments. While some participants would have liked clearer guidelines, less group work and more input, others call for the exact opposite, i.e. less input and more group work. These different assessments can be attributed to personal preferences on the one hand, and group effects on the other hand. Depending on the composition of the group, different dynamics can develop that have a significant impact on cooperation and learning. This is also evident in the individual responses. While some students regret that there was sometimes little talk in the group, others say that they *"had a lot of fun"*, *"rarely met such dedicated people"* and had a *"very motivated and friendly group"*. But even with a less motivated group, the course was considered to be successful: *"Unfortunately, my group wasn't very communicative ... but it worked out anyway"*.

Special condition: no written exam. There were also comments on this topic. These were mostly positive, such as *"I felt like I was attending the course to learn something and not, as in other courses, just to get my certificate of achievement... "*. Two comments criticized the fact that there was no written exam at the end. The lack of the self-disciplining effect of an exam was referred to as a negative one, and another student pointed out a danger of *"cheating through"*.

Particulary interesting is students' view on the amount of work. With regard to the amout of credit points this was seen as appropriate by most students, but is estimated as too high by some. In particular, the extensive research tasks are criticized for being too time-consuming. It is clear that in this course students' own motivation is of great importance. But this can also be seen as an opportunity. The question is whether the majority of the students worked continuously and used this opportunity. In this regard the comparison with other courses is interesting. From the faculty's area-wide course evaluation aggregated comparative data is available. In the answers to the question *"I regularly prepare/review the session/work units"*, the TDS-course actually scores slightly better with a value of 3.6 (agreement on a scale of 5) in comparison to the average in the mechanical engineering courses value of 3.3.

What also became clear in reviewing the feedback is that for some students participation in the course helped quite explicitly in arriving at their studies in dealing with distance teaching: *"I was part of a really motivated and sympathetic group that I will continue to work with. In this Corona time, this has been very helpful for me.", "The TDS-course has also been an anchor point for me in an otherwise spongy asynchronous semester and has helped me structurally as a result."*

5 SUMMARY

This paper describes the structure and experiences of the first run of a course for first-year students in environmental engineering. Using the example of acceptance problems in energy transition projects, technical and societal issues are discussed and methods of public participation are addressed.

The teaching concept has proven to be viable for a group of around 100 participants and was conducted entirely online in the first run. Through the use of various coordinated collaborative teaching methods, it has been achieved that the students have intensively dealt with different perspectives of energy transition projects. The students have systematically worked together in groups and comprehensively reflected on their work results. The openness of the course, which was also due to the fact that there was no assessment and grading at the end, was very positively received and engaged by the vast majority of students. The course was also able to make a valuable contribution to students onboarding.

ABSTRACT

The interest in programming in schools has the last decade increased, and many countries have introduced programming as part of the school curriculum. Teaching of programming to students in primary and secondary school is often focused on the computer sciences aspect of programming. The current study is a part of the recently initiated research project "Programming for understanding mathematics" which has a different emphasis; the project investigates how the mathematical competence of the students are affected by actively using programming in mathematics lessons. In this paper, a recognized analytical framework for analysing the cognitive demand of mathematical tasks is presented. We extend the framework to include the analysis of tasks that utilize programming, allowing us to distinguish between tasks that are demanding due to the mathematical content, but the programming aspect of the task is trivial, and tasks that are cognitive demanding due to complex programming, but the mathematics is simple. We use the extended framework to analyse tasks in four mathematics textbooks written for 16-17 year old students by two major publishers in Norway. The results show that the tasks provided in the textbooks mainly focus on elementary programming skills, and the tasks give limited experiences with cognitive demanding programming tasks.

1 INTRODUCTION

We have entered the era of computation. High speed calculations have become such an integral part of our life that we do not even notice; path finding algorithms show us the direction on our phones, assisted driving increases the safety on the roads, and the weather forecast allows us to know if it will rain next weekend. Behind these features, are complex mathematical models and algorithms that are solved by computers. In the professional world, especially in Science, Technology, Engineering, and Mathematics (STEM), this can be seen as a rapid change in the use of computers and computing over the last decades.

As a response to this shift in technology, programming has been introduced in the school curriculums of most European countries [1]. Most countries that introduce programming in schools argue that programming enhances logical skills and problem-solving skills [1]. For mathematics, programming is often claimed to enhance computational thinking, which can be defined as a thought process and problem-solving approach that can provide the means to translate problems into formulations that can be solved computationally (either by a computer or human) [2]. The set of skills learned from computational thinking can be promoted when tackling difficult problems. It includes decomposition (breaking a problem into smaller parts), pattern recognition (analyse and find connections in data), abstraction (identify relevant information and eliminate the extraneous details), and algorithmic thinking (develop step-by-step processes) [3], which are concepts also related to programming.

The introduction of programming in schools will change the competence of students starting at engineering education. To take advantage of the changes, it is necessary to understand how these changes are in practice implemented in schools. In this paper, we present initial results from the recently initiated research project “Programming for understanding mathematics”. The project focuses on programming at primary through secondary school, and the aim of the project is to investigate how programming can be used to enhance mathematical understanding.

While programming is introduced in schools on a higher level based on developing the computational thinking and 21st century skills of students [1], it is interesting to see how these new curriculum changes are implemented in practice. Thus, in this paper we take a closer look at how programming is introduced in the Norwegian upper-secondary school. There are mainly two different approaches that are taken when programming is introduced in schools. In many countries, programming is either introduced as a separate subject or part of an information technology course [1]. However, increasingly programming is introduced as part of traditional school courses, usually mathematics. In Norway the second approach is taken; programming is treated in several subjects, but mathematics has been given a key role in developing the students’ competence in programming. Similar tendencies can be seen in other Scandinavian countries, see e.g., [4] for an overview.

From a long tradition in mathematics, the textbook is important as a curriculum resource for teachers [5]. The tasks and how they are presented in the textbooks impact how teachers and students work with the subject. When introducing a new topic in mathematics lessons, which many teachers also are feeling unconfident about, we suppose that the textbooks may be even more important, and the content of the textbooks lay the foundation for the students' outcome of mathematics courses. Although tasks can be used differently by teachers, the way it is presented in textbooks are anyhow important for how challenging the tasks will be.

2 METHODOLOGY

In this paper we analyse how programming is treated in two different Norwegian textbook series, Mønster [6,7] and Sinus [8,9], for upper-secondary mathematics. The textbooks cover the mathematics courses of 11th and 12th grade students (age 16-17) aiming towards STEM programs at university.

2.1 Analytical framework

Boston & Smith [10] present a framework for analysing mathematical tasks. Tasks are assigned a number 0-4 based on the mathematical potential of the task. Level 0 is a task that does not contain mathematics, level 1 or 2 is given to a task that requires the execution of known routines or procedures while level 3 or 4 is given to highly cognitive demanding tasks that require the student to do mathematics.

In this work, we are interested in analysing tasks that include both mathematics and programming. A task can be cognitively demanding both in terms of the programming aspect and the mathematical aspect. Another task can be demanding due to the mathematical content, but the programming aspect of the task is trivial, e.g., running provided programs. Yet another task can be cognitive demanding due to complex programming, but the mathematics is simple. Thus, we extend the framework of Boston & Smith [10] to include a second axis that specify the programming potential of the task, shown on the right side of the table below. Note that a task will in general be given different levels in mathematics and programming.

Level	Mathematics (see, [10])	Programming
4	The task asks students to engage in the disciplinary activities of explanation, justification, and generalization or to use procedures to solve tasks that are somewhat open-ended in nature.	The task has the potential for the students to engage in programming. Solving the task requires an iterative process that is not predictable to the students. Building a solution must be done in a stepwise and cyclic manner with prototyping, and testing.
3	The task requires students to make connections to underlying mathematical ideas but does not	The task has the potential to challenge the thinking of students or to engage the students in making connections

	include explicit requests for generalization or justification.	between programming concepts or procedures. The student must combine several concepts in programming to solve the problem.
2	The task requires students to perform relatively routine procedures without making connections to the underlying mathematical ideas.	The task is limited to engaging students in known procedures, either specifically called for or known from prior knowledge. There is little to no ambiguity about what needs to be done or how to do it.
1	The task requires only memorization or the reproduction of facts.	The task is limited to engaging students in memorizing simple concepts or syntax. There is no need for the students to understand or make connections between the implemented code and facts.
0	There is no mathematics in the task.	The task requires no programming skills. This includes running code without the need to understand the code.

As an illustration of a typical task that is categorized to level 1 or 2 in programming, Chapter 6 in [8] gives an example of solving an equation with Newton's method (all example tasks are translated to English):

```
def f(x):
    return x**2 + 2*x - 1 # Enter function here
def d(x):
    return 2*x + 2 # Enter the derivative here
x = float(input("Choose a starting value for x: "))
while abs(f(x)) > 0.0000001:
    x = x - f(x) / d(x)
print("The answer is x = ", round(x,  5))
```

In this chapter the textbook proceeds to give 6 tasks that ask the student to solve different equations with the Newton method, e.g.,

> Find approximations of the two zeros of the function:
>
> $$f(x) = x^2 - 5x - 5$$
>
> by using Newton's method and Python.

These tasks are therefore classified as level 1 in programming because the student should only replace the expression for the function and its derivative. It is classified to level 2 in mathematics because the student must use known procedures to calculate the derivative of the function. Similar tasks are classified to level 2 in programming if the modification to the provided program is more demanding.

An example of a task that is classified to level 3 in programming is given by task 4.92 in [6]:

Let f be given by $f(x) = \frac{1}{5}x^2 - x - 1$ Write a program that finds the smallest whole number, n, such that $f(n)$ and $f(0)$ have different signs.

Here the student should recognize that the task can be solved by a combination of a while loop and an if-statement. The complexity of a script that solves this task is similar to the Newton problem above, however, in this task no examples of similar worked tasks are provided. The task is categorized to level 2 in mathematics.

2.2 Textbook analysis

First, two of the authors read all tasks given in the textbooks and sorted out the tasks that explicitly asks to be solved by programming. There are other tasks that have the potential to be solved using programming, but we only included tasks explicitly asking the student to use programming. Further, we did not include tasks that are to be solved by other digital tools, such as Computer Algebra System or graphical computer software (e.g., GeoGebra). Both textbook series use Python as a programming language. The 11th grade textbook of Mønster [6] has a dedicated appendix that is an introduction to Python. Tasks in this appendix were not included in the analysis as it mainly focuses on basic programming skills and not mathematics.

The programming tasks were then classified according to the five levels of cognitive demand along the two axes of mathematics and programming. All tasks were classified independently by two authors that have different background and competence; one author has a background from engineering and applied mathematics with considerable knowledge about programming, and the other author has extensive experience from teaching of mathematics in upper-secondary education, with less knowledge about programming. Tasks that were classified to different levels by the authors were discussed until an agreement was reached.

3 RESULTS

Table 1 shows the number of tasks categorized for the two textbook series at 11th and 12th grade (16-17 year old students). In both series the number of programming tasks is more than doubled in the second book (12th grade) compared to the first book (11th grade). Furthermore, programming related tasks cover a wide range of mathematical topics and are given in almost all book chapters of both series. Fig. 1 shows how the programming tasks are classified for the 11th and 12th grade textbooks. The average programming level is 1.9 and 1.8 in the 11th and 12th grade textbooks, respectively, and the average mathematics level is 1.6 and 1.9 in 11th and 12th grade textbooks, respectively.

Table 1. The number of tasks in the four textbooks that include programming. The parentheses give the ratio of programming tasks to the total number of tasks for each textbook.

Name of textbook series	*11th grade*	*12th grade*
Sinus	20 (1.7 %)	46 (4.5 %)
Mønster	24 (2.2 %)	60 (7.9 %)

Table 2 shows how all tasks in the two textbook series are classified. 105 of the 156 tasks are classified as having a low cognitive demand (level 2 or lower) in both mathematics and programming. There are 35 tasks that are classified to level 3 or 4 in mathematics and 26 tasks that are classified to level 3 or 4 programming.

Even though the majority of tasks are classified as less demanding (level 0-2), many of these tasks do include relatively complex programming and mathematics. The reason they are given a lower level is that examples shown previously in the text are very similar to the tasks given the student. Both textbook series extensively give tasks that require the student to modify provided examples. These tasks are mainly classified to level 1 or 2, depending on the complexity of the modifications.

We will now study two selected tasks in depth. Task 1.32 in Mønster [7] is translated as follows:

> The sum below converges to Euler's number e quickly:
>
> $$1 + \frac{1}{1} + \frac{1}{1 \cdot 2} + \frac{1}{1 \cdot 2 \cdot 3} + \frac{1}{1 \cdot 2 \cdot 3 \cdot 4} + \cdots$$
>
> Write a program that asks the user for the number of terms in the sum and then calculate the sum of these first terms.

This task can be solved by a double loop (or a single loop and using the factorial function in the Python *math* library) and the students are not given any similar examples. The task is classified to level 3 in programming, and in terms of mathematics it is classified as level 2. The other textbook series, Sinus [9], gives an equivalent task (1.306) where the students are asked to study different series

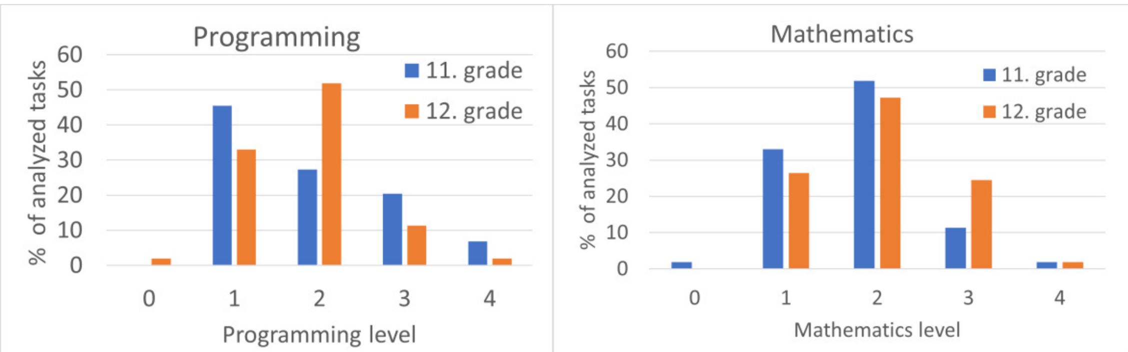

Fig. 1. The fraction of programming tasks at each cognitive level for programming and mathematics.

Table 2. The number of tasks classified to the different levels for programming and mathematics. E.g., there are 36 tasks classified to level 2 in both programming and mathematics and 20 tasks that are classified to level 2 in programming and level 3 in mathematics. The top row and rightmost column give the column sum and row sum, respectively.

Programming level \ Mathematics level	0	1	2	3	4	Sum
Sum	3	44	74	33	2	156
4	1	0	0	3	1	5
3	0	3	12	5	1	21
2	2	15	36	20	0	73
1	0	24	26	5	0	55
0	0	2	0	0	0	2

expansions of the Euler number. However, this textbook takes a different approach; Here the task provides the students with a script for calculating the sum given in the task above. The students are then asked to modify the program by trying different approximations of e, e.g.,

$$e = \frac{1}{2}\left(\frac{1}{0!} + \frac{2}{1!} + \frac{3}{2!} + \frac{4}{3!} + \frac{5}{4!} + \cdots\right),$$

and compare the different approximations and reflect, discuss, and evaluate the different convergence rates of the sums. This task is classified as level 2 in programming and level 3 in mathematics. This illustrates how different formulations of a task may change the classification of the task. In Mønster, the focus is on the implementation of the task in Python, while Sinus uses programming as a tool for studying and understanding different convergent sums.

Both textbook series use programming to motivate concepts in mathematics. In task 2.72 in [9], programming is used to investigate the derivative of the natural logarithm. Both derivatives and numerical approximations (including Python implementation) are presented previously in the chapter, however, the analytical derivative of $\ln x$ is unknown at this point:

> We will now look at the function:
>
> $$f(x) = \ln(x)$$
>
> Make a program in Python that prints out a and a numerical approximation of $f'(a)$ for $a = 1, a = 2, a = 3, \ldots, a = 10$.
>
> Can you generalize a rule that seem to be true?

The purpose of this task is to let the student discover the relation between the natural logarithm and its derivative, and the students must themselves make conjectures. This task is given a programming level of 2 because the students have previously been exposed to numerical derivatives and making tables of function values using a loop. The task is classified to level 3 in mathematics.

4 DISCUSSION AND CONCLUDING REMARKS

One of the main arguments for introducing programming in mathematics education is to improve the computational thinking and problem-solving skills of students. From the analysis of the textbooks in Section 3, however, we show that most of the given tasks do not require a higher cognitive demand of the students. Only occasionally do the tasks ask the student to explore, investigate or evaluate the answer obtained by programming. Of course, not all tasks in a textbook should require a higher cognitive demand, and drill and routine tasks should also be provided in a textbook. The optimal ratio of cognitive demanding tasks and practice tasks is an open area of study. A line of further research is to investigate if tasks that include programming are in general scored at a lower or higher level than the tasks that do not include programming.

In our analysis we use the presented two-dimensional framework on the programming tasks provided in four mathematics textbooks. We find the framework useful when discussing these tasks, and the framework works as a communication bridge between the two authors with substantial different programming and mathematics background. Labelling the tasks also initiated reflections upon how tasks could be improved and extended. While the framework is tested on upper-secondary textbooks in this paper, we believe that it can also be used in both higher and lower educations as well.

When classifying the tasks in textbooks we assume the students to follow the progression of the textbook. In a classroom, the teacher can use the textbooks in different ways, e.g., carefully selecting or adapting textbook tasks. This will, however, require teachers that are confident in their programming skills. The original framework in [10] has been used as a tool for selecting and adapting mathematical tasks. We believe that the extension presented in this paper can be used to select and adapt mathematical tasks that include programming. Further research is planned in the “Programming for understanding mathematics” project to study how these textbooks are used in practice by teachers.

For the engineering educations, the introduction of programming in schools will have an impact on the background of new students. As shown in this paper, Norwegian students will probably learn elementary programming with Python, but they will have limited experiences with cognitive demanding programming tasks, also on the highest level of mathematics courses in school. In most countries, programming is a new topic in the school curriculum. If the aim is to give students problem solving skills, in mathematics, or in programming, this paper shows that the curriculum resources given the teacher may be insufficient to stimulate this. For the engineering educations, it is therefore necessary to investigate both the curriculum changes and the curriculum resources such as textbooks, to understand how programming is implemented, in the respective countries, and how this might affect student outcome. Based on our experience, the proposed framework can be used as a tool to analyse tasks given in upper-secondary education.

ABSTRACT

Autonomous vehicles (AVs) are of great interest for the automotive industry and are expected to revolutionize mobility and public transportation. The university can contribute to the design and development of autonomous vehicles both in the field of teaching and in research and technology transfer. In this paper, it is described how this topic is introduced in an undergraduate engineering course, "Implementation of Automatic Control Systems (IACS)". The IACS course is based on project based learning (PBL) and learning by doing methodologies. Several practical examples that correspond to real automatic systems are discussed throughout the course and one of them, a low-cost AV to which a Raspberry pi has been adapted, forms the basis for a final project of the course. The control algorithms are developed on MATLAB/SIMULINK and are sent to the Raspberry through a wireless communication network. The control objective of the system is the automatic guidance of the vehicle through a single lane indoor closed circuit, the detection and identification of different traffic signals and the automatic response to these signals. Students check the behavior of the vehicle and proceed to make improvements. Based on the assessment of the students and the robustness of the autonomous vehicles, it is time to consolidate this type of project within the course. Students that want to get deeper into the matter have the opportunity to do a final degree project related with the AV.

1 INTRODUCTION

1.1 Autonomous vehicles

Autonomous vehicles (AVs) are expected to revolutionize mobility and public transportation [1]. There are different types of autonomous vehicles for research and academic purposes. A system classification is required. The most system classification is the one proposed by the Society of Automotive Engineers (SAE) [2]. In this classification there are five levels of automation: from low levels related to human drivers assistance to high levels are related to high automation or fully automation (the autonomous vehicle has the functionality of fault tolerant hardware).

The context of this classification is operate an AV in on-road traffic and developing dynamic driving tasks. The driving automated systems is capable of guiding the AV throughout complete trip, interacting with other AV, solving contingencies, minimizing risk, diverse traffic and weather conditions.

In this paper autonomous vehicles are related to low cost autonomous vehicles with the flexibility to incorporate control electronics, communications with the environment and scalable functionality to generate a wide range of experimental tasks. In a first approach the context of use is in laboratory conditions. The dynamic driving tasks of the SAE must be adapted in this scenario. The main objective is the design and development of a robust AV and proof that this AV can perform dynamic driving tasks with high effectiveness.

2 METHODOLOGY

2.1 Academic aspects

In the university industrial bachelor degrees of the Barcelona East School of Engineering (EEBE) on the Diagonal-Besòs Campus of the Universitat Politècnica de Catalunya (UPC), authors develop the course "Implementation of Automatic Control Systems (IACS)". This course is an elective course in the last semester of the industrial degrees with 6 European Credit Transfer and Accumulation System (ECTS).

This course applies the control theory in the development of electronic prototypes and using tools and devices as MATLAB and Raspbebrry pi.

It is an interdisciplinary course since students come from all areas of engineering that are taught in the teaching center (mainly industrial electronics and automatic control, electrical and mechanical engineers). The prerequisites of electronics, programming and linear control theory that are necessary for student success are provided in previous core courses. Good skills in team work are required for the design, development, programming and evaluation of autonomous vehicles prototypes. The course is also available to Erasmus / Exchange students that can have different backgrounds.

The appearance of failures, unexpected vehicle behavior, battery performance, performance of programmed algorithms, require the group to show its ability to resolve contingencies and obtain good vehicle performance.

Authors are driving too final degree projects with the aim to develop first autonomous prototypes with help of the maintenance staff. With the idea of building scalable systems in mind, the student's training is focused on recommending that they first take the course and secondly that they can develop the final degree project.

For the development of fully AV, more capabilities are required. In this sense, the approach presented in this paper should be extended to engineering master's courses and research activities. The authors are developing active work in the development of fault tolerant and safety AV and can provide feedback. The research is developed in a research laboratory and there is a relationship with the academic laboratory commented in this paper.

2.2 Laboratory Practices

The IACS course is based on PBL [3] and learning by doing [4] methodologies. Several practical examples that correspond to real systems are discussed throughout the course and one of them, an AV, forms the basis for a final project. There is a student teaching guide for every practical example with the description of the steps to follow to success in the implementation of an automatic control in a real system (modeling, identification, design, implementation and assessment of the performance) and a description of the results that the student should obtain.

In particular, in the AV example, the implementation of a simple driving automated system in an adapted Van vehicle (shown in Figure 1) is proposed. The vehicle is equipped with a Raspberry Pi 3 B board, a servomotor (steering angle), a DC motor (forward and reverse speed of the vehicle) and a camera. The power supply of the module consist of 5 AA rechargeable batteries and a voltage regulator of 5 Volts. The total cost of the components of the adapted Van vehicle is around 200€.

Fig. 1. Van vehicle adapted with Raspberry Pi 3 B+.

The system is presented as a particular automatic control system composed by the different elements: plant (Van), controller (Raspberry board), actuators (motors) and sensor (Camera). And the control objective is defined as the automatic guidance of the vehicle through the single lane closed indoor circuit depicted in Figure 2.

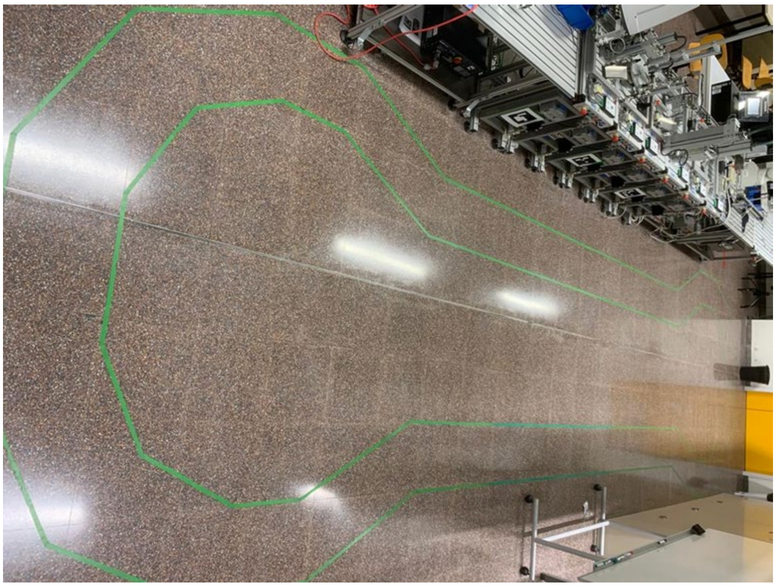

Fig. 2. Single lane closed circuit in the Automation and Indsutrial Robotics Lab. of the EEBE

The AV guided practice consist in three different steps:

a) connecting the vehicle with MATLAB/Simulink through a wireless communication network WIFI conection (router WLAN connected in the Cisco Switch of the laboratory) in such a way it is possible to process the images captured by the camera and control the steering angle and speed of the vehicle.
b) how to extract the bounds of the circuit lane (in green color) from the images of the camera.
c) how to use the information extracted from the circuit lane bounds to try to align the vehicle with the lane of the circuit.

For this last step, the filtered image that contains the bounds of the lanes is binarized and the centroid of the image is computed (Figure 3). When the vehicle is completely aligned with the lane, the centroid will be aligned with the vertical axis of the image. Therefore, the angle of the centroid with the vertical axis is used as the controlled variable in a close loop system where the controlled variable is the direction of the vehicle and the control objective is to maintain as close as possible the controlled variable to zero (vehicle aligned with the lane).

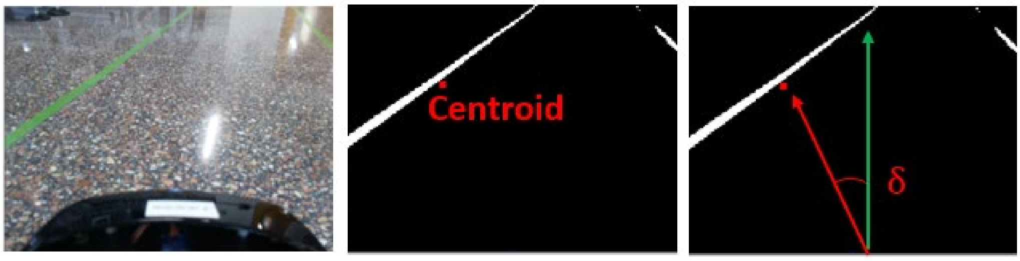

Fig. 3. Raw and binarized images with centroid and angle deviation δ computations.

In this control system there is another variable that has an important role in the performance of the system, the speed of the vehicle. In this first approximation of the automatic guidance it is considered to be constant. Finally, students are encouraged to detect the limitations of this first approximation of the automatic guidance of the vehicle and the final project of the course is proposed as the implementation of a new (and original) solution. This solution should be robust, reliable, stable and should include other capabilities as the detection and identification of different traffic signals and the automatic response to these signals.

2.3 Project development.

When defining the course content, professors discussed about the software to be used in the laboratories. As all students of EEBE school and most of Erasmus students have used MATLAB program in previous courses and some of them even have used Simulink, the election was clear. In addition, the interface of this software makes programming and learning easy and it is relatively easy to implement complex systems as the one depicted in Figure 4 that implements a possible solution to the AV system.

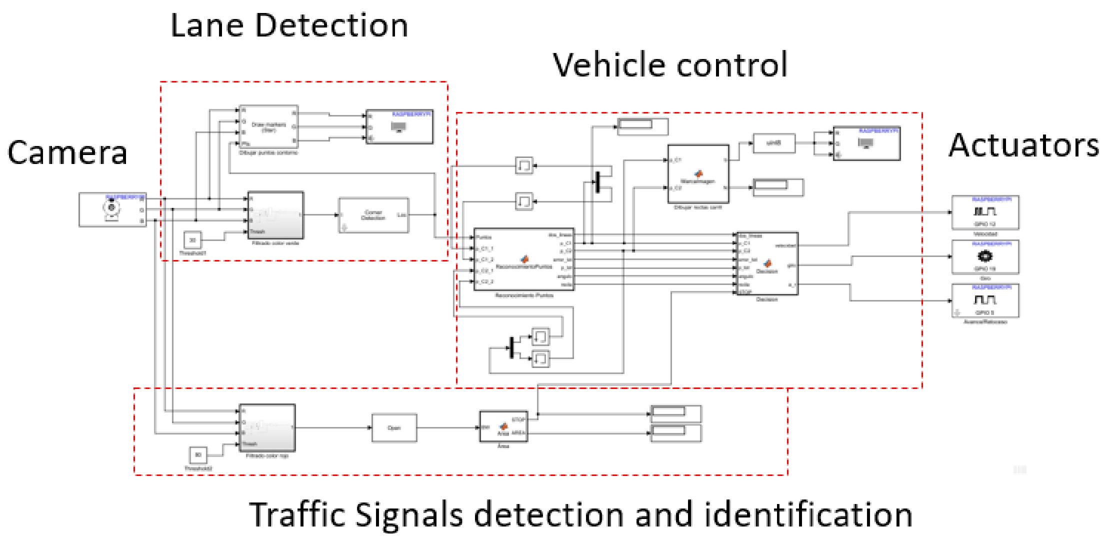

Fig. 4. Blocs of Simulink circuit that implements AV solution

Red boxes in Figure 4 show how is possible to develop scalable functionality using Simulink (lane detection phase, vehicle control phase, etc.).

To develop the project, the students work in groups of two or three and they have 12 hours of experimental sessions to carry out all the work. The professor discuss with the student team and helps to identify the correct solutions but the final solution and the features to be improved are completely proposed and developed by the students. In the last lab session, each student team presents a summary of the project as well as a demonstration of how the AV system works. After this presentation, professors ask some questions in order to clarify possible confusing points and to assess that all the members of the team group know in deep the final design. The evaluation of the final project is done considering the oral exam and the report of the project. This final evaluation of the overall project counts for 40% of the final mark of the course.

2.4 Final degree project.

Students that want to get deeper into the matter have the opportunity to do a final degree project related with the topic improving the vehicle used in the IACS course and using more professional programming enviroments as the Robot Operating System (ROS). ROS requires lower-level concepts and a steeper learning curve than MATLAB/Simulink enviroment but allows the use of powerful vision libraries as OpenCV [5] and the implementation of advanced artificial intelligence algorithms for the control of the AV as in current professional solutions [6][7].

Figure 5 shows the graph diagram that implements a possible solution to the AV system: From the initial nodes *raspicam_node* and *controller* that allow the capture of images and the implementation of manual/automatic mode selection respectively. To the final node *car_control* that implements the auntonomous control considering the environment information obtained from the image processing steps and the controller state. This solution was proposed in a final degree project [8].

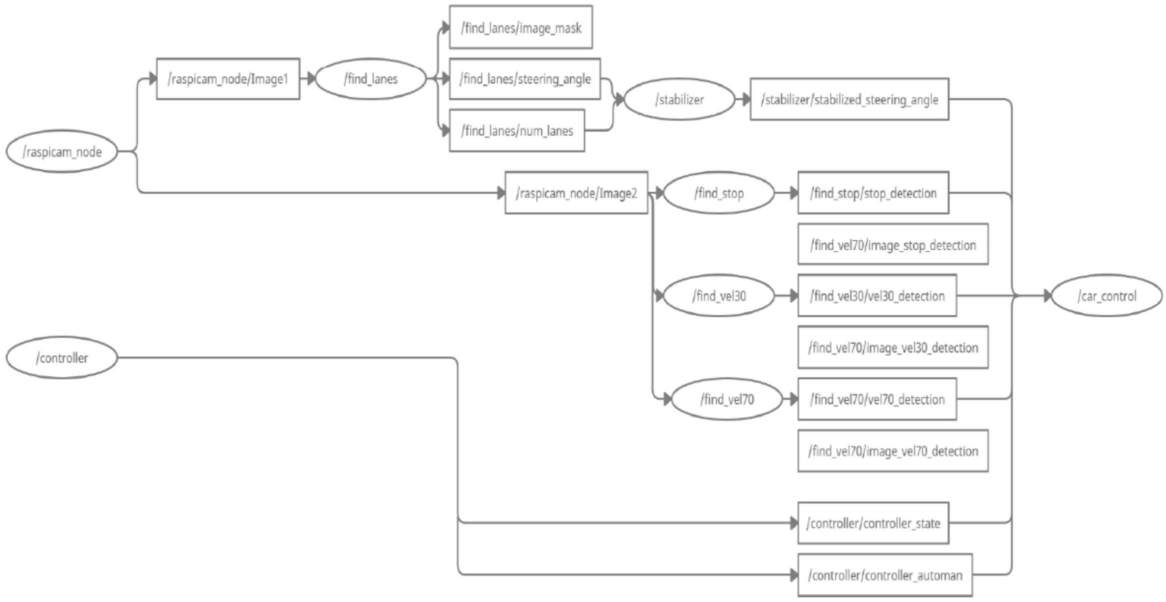

Fig. 5. ROS graph diagram showing nodes and topics to control the AV.

Taking into account the students'experience and feedback, new and more complex solutions usually require modifications not only in the programming but also in the hardware setup as for example the use of more powerful Boards that can require a enhanced power supply. For example, ROS software requires at least Rasberry Pi 4 B board that increases the current consumption. Therefore, the new AV requires a more complex power supply unit. In [8] a lithium polymer battery (LIPO) was selected as a suitable solution intead of the original AA rechargeable batteries solution as it is shown in Figure 6.

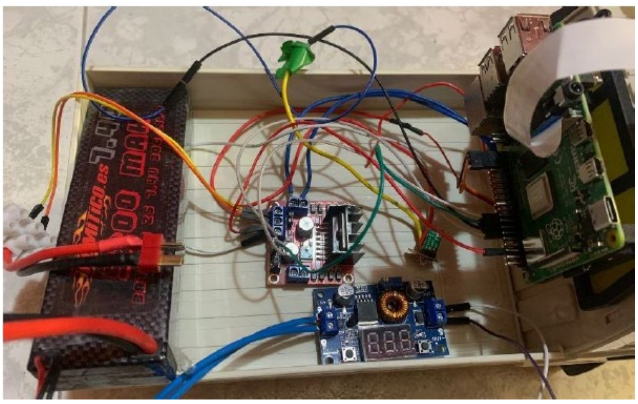

Fig. 6. Van vehicle adapted with Raspberry Pi 4 B.

3 RESULTS

At the end of every quarter, an anonymous survey is conducted by the UPC to obtain feedback from the students of the different courses. In particular, two questions are asked: “1. The contents of the course seemed interesting to me” and “2. Overall, I am satisfied with the course”. Both questions are scored from 1 (strongly disagree) to 5 (strongly agree) and in the case of IACS course the students have graded an average score of 4.14 and 4.43 to the first and second questions respectively. That is a score 0.3 and 0.9 points above the score obtained in average for all the courses offered by the UPC. In addition, more than a halft of the students that take the IACS course are interested in doing the finall degree project related with the topics of the course. Regarding academic results, 13% of the students have satisfactory results [5,7), 40% very good results [7-9) and 40% very good results. Finally, only 7% of students have not satisfactory results [0,5) because they have problems to attend to the experimental sessions.

4 SUMMARY AND ACKNOWLEDGMENTS

This article presents an example of how Autonomous Vehicles have been included in an undergraduated engineering course in a motivating way, in particular, in an elective course of the industrial bachelor degrees of the Barcelona East School of Engineering at UPC. AV have been introduced first in an introductory guided practical lab and after following learning by doing methodology to solve a real-world problem. Learning by doing is used to increase students’ interest and at the same time help them to acquire and apply new knowledge in a problem-solving context. Student surveys and assessment results confirm the student’s great interest and success in the course.

As future lines, the authors want to introduce AV in other courses. In particular, in an advanced control elective course in the last semester of the Bachelor's degree in Industrial Electronics and Automatic Control Engineering. Previous background of students in automatic control, programming and electronics will be deeper than the one of average students in IACS course. This circumstance will allow the use of ROS environment in the implementation of AV algorithms. However, a key point to obtain satisfactory results will be the design of educational modules to simplify learning about this environment. Because ROS is not in the curricula of previous courses of this Bachelor degree.

This work has been partially funded by SaCoAV project (Ref. PID2020-114244RB-I00) from the Spanish Ministry of Science and Innovation.

ABSTRACT

Increasing populations in urban areas create complex problems, such as access to drinking water, sanitation, housing, and traffic. Today's engineers are prototyping solutions for future cities. Engineering education must meet this challenge, with students developing knowledge in their engineering field while addressing Sustainable Development Goals (SDG). Problem-based learning (PbL) is a valuable tool in engineering education, particularly for sustainable development. In PbL, students solve engineering problems by developing projects. For example, students in early courses can confront problems demanding low-tech solutions. The Federal Center for Engineering Education in Rio de Janeiro, Brazil, offers short-term project experience (PbL) focusing on SDG in cities. For 48h, students tackle SDG problems from urban communities and are challenged to create low-cost solutions. In the end, they pitch their solutions to experts from NGOs, governments, and corporations. This article presents a short-term PbL approach for SDG supported by one case developed by the students and concludes with recommendations for a research

program, aiming to understand the process and transform the projects into concrete, sustainable, social innovation actions applied to communities.

1 INTRODUCTION

With the global population increasing and natural resources limited, learning about sustainable living is essential since sustainable development is society's responsibility.

There are several models for sustainable development, the most common being Elkington (1994). In this model, sustainable development is based on a Triple Bottom Line (TBL), where projects must be: (a) financially profitable; (b) environmentally sustainable; (c) and socially fair. TBL amplifies the concept of sustainability to a broader view.

In general, when people are being educated and training to performance in a given professional field, some skills and competencies are required to be developed in early stages of the education, or training program. They constitute the fundamentals of a given knowledge area, disciplinary field, or professional practice. See for example the specific case of engineering design and the development of technical solutions. In this context, engineers must be able to identify community problems and find creative solutions. In this context, and to integrate sustainable development, they should be able to take TBL into account and integrate it when identifying, formulating and solving such problems.

Engineering education plays a significant role through training that creates a design mindset for sustainable development through the integration of UN's Sustainable Development Goals (SDG) and TBL perspectives in the design processes. In addition, it is necessary to encourage behavioral changes through a better understanding of the world, and that problems are complex and interrelated, such as poverty, predatory consumption, public health, and conflicts. This calls for competences such as complex problem solving, interdisciplinarity, systems thinking (Guerra, 2017).

According to UNESCO (UNESCO, 2022), this requires a new view of education, grounded in democratic and emancipatory values, contextual and experiential learning, students' centeredness and active learning, capable to motivate students to, for example change their behavior, take on attitudes, solve challenges, reflect on future scenarios, and contribute to sustainable development across the three axes of TBL.

One methodology that has been used is Problem Based Learning (PbL) to educate engineers for sustainable development. This is a student-centered methodology, where team of students learn by solving real authentic problems through projects. Students and teachers seek to analyze, understand and propose solutions to situations designed to ensure the acquisition of certain skills provided for in the school curriculum. These situations are scenarios that involve students with facts from their daily lives (Graaff & Kolmos, 2007; Kokotsaky et al., 2016) There are several approaches on how PBL process is organized around projects. One example is the short-term projects. In this approach, learning is carry out through learning cycles (sprints), with small teams supervised by mentors, so that at the end of the process, students present a prototype of the solution to the proposed problem. The process develops skills that range from identifying and solving real and authentic problems to the implementation and evaluation of the solution. The problems call to be researched and solved enabling, in simultaneous the acquisition of engineering knowledge and development of professional skills resulting in collective knowledge. Additionally, PbL process creates collective knowledge and sharing as result of students' collaborative experiences which are proven essential in the development of their curiosity and inquiry skills for their and for engineering courses (Freire, 1987;).

In this line of thinking, there are hackathons or bootcamps as a strategy for the creation of new ideas, products or processes. In overall, these events start with a challenge which is addressed through a projects and in a short period of time.

In the context of higher education, engineers have a direct relationship with the knowledge and technologies production that directly impact in society and the environment. In this way, it is necessary that the engineer formation, in addition to being based on solid technical knowledge, is also associated with non-technical knowledge, so that they are aware of their social role so that they can deal with social and environmental aspects of technologies.

PBL is a powerful tool for developing skills related to sustainability, by associating the production of technical knowledge with sustainable development.

It would be interesting to apply a PbL approach to be applied quickly, in a hackathon model. This can serve as a strategy to be developed with students several times throughout the course.

1.1 Expin 48: Short-PbL approach to educate for sustainability

An educational event called Short-Term PbL was developed based on the PbL concept at the Federal Center for Technological Education of Rio de Janeiro *(CEFET/RJ)*. It is a PbL activity carried out in 48 hours, outside class time, which can be used to activate essential skills required for engineering projects, such as teamwork, leadership, and creativity (d'Escoffier et al., 2021a).

CEFET/RJ is a Technology Education Center based in the city of Rio de Janeiro/Brazil, with campuses in 7 other cities in the State of Rio de Janeiro. The Short-Term PbL event was titled *Expin48* (Experience in Innovation Projects – 48 hours). In this event, undergraduate and graduate engineering students and vocational course students are brought together for 48 hours to create solutions to real problems based on existing issues in urban communities focused on the SDG.

During the development of a project, the initial ideas are transformed and matured until the generation of a product or process that addresses the identified problem. Thus, it is to be expected that different products are at different levels of maturation at a given time. It is also understandable that the same product has different levels of maturity in different aspects. Hence the importance of measuring the level of maturity of a product, as it locates the stage of reflection in this aspect, indicating the points that need more attention, assisting in decision making in the development of the project. Solutions planned in this event can be continued later for more in-depth knowledge and better-developed skills. Therefore, the whole process has several stages of maturation. The first stage of this maturation is the presentation made after 48 hours to representatives of companies, research institutions, and NGOs.

Therefore, the projects developed during *Expin48* are not considered finished solutions due to their short incubation time. Indeed, the solutions that come from this initial stage are presented to external evaluators at various stages of maturity, even with the short development time.

1.2 The Problem

PbL is a transdisciplinary approach with complex objectives involving analyzing and resolving heterogeneous problems. Therefore, in parallel to activating and developing skills and competencies, PbL must ensure that theoretical curricular content is transmitted through collective work involving cultural and social aspects.

Although the overloaded and rigid education curriculum for sustainable development makes it difficult to integrate with PbL, this methodology seems to be the answer to incorporating sustainability into engineering curricula (Guerra, 2017).

However, since PbL is a curricular activity, the student must be evaluated at the end of the process. Therefore, the strengths and weaknesses of evaluating projects based on SDG must be addressed.

Sustainability is difficult to measure because it is an extensive topic and mainly depends on the reality of a context. Moreover, this context is usually dynamic and multifaceted, making it difficult to identify common characteristics and ways to measure them.

There is little in the literature regarding metrics for objectively evaluating PbL projects. Assessments are often subjective, where students are assessed by self-assessment or peer reviews. Although these methodologies should not be overlooked, serving as a basis for the teacher's judgment, it is essential to make what is implicit, explicit.

Therefore, this calls for the development of an instrument to evaluate Short-term PbL projects, focusing not only in the engineering learning acquired but also the three axes of sustainability. In the following section, we present the design of PbL intervention, entitled *Expin48*, the evaluation instrument and its preliminary results.

The objective of this study is to reflect on an evaluation proposal for short-term PbL projects based on the three SDG axes of sustainability

2 RESEARCH PROPOSAL

The working hypothesis is that different projects will have reached different maturity levels across various dimensions by the end of the process. For example, in the case of SDG, these dimensions would be the 3 axes of sustainability: financial, environmental, and social. By establishing the project's maturity level along each axis, the degree to which students could assimilate sustainability concepts and concretize them in products can be measured. Furthermore, projects can be given continuity by projecting future goals, potentially reaching a level where the project can be implemented in the reality.

3 METHODOLOGY

3.1 The idea

The process of how the students built the knowledge and the product presented at the end must be understood to determine a project's maturity level across the SDG dimensions. Therefore, indicators of the production of conceptual knowledge need to be created, and scales where values that represent the desired effects need to be defined. This data can facilitate a global assessment of the project's maturity from both the process and product points of view.

3.2 How?

The construction of the assessment instrument comprises two phases: a qualitative phase, conducted using an ethnographic approach; and a quantitative approach, using a maturity map. The first is an ethnographic methodology, where a researcher in the field will accompany the team throughout the project's development. This entire process will take place through observation and description of the process of how students deal with the difficulties imposed by the project, how they interact with mentors, and how they seek solutions. This research will reveal previous knowledge about the SDG dimensions, new knowledge learned, and how teams built their knowledge networks (Braga et al., 2021b; Braga & Guttmann, 2019).

The second will have a more quantitative character. A maturity map will be constructed for this data collection based on the SDG axes (environmental, financial, and social). Previous work on developing the short-term PbL will be leveraged to build this map. These tools will allow the team to document each project's final level of maturity.

The evaluation instruments where pilot in the specific case of a short-term PbL developed in 2020.

4 PRELIMINARY RESULTS

4.1 The problem

In 2020, the winning team of *Expin48* chose the theme "Renewable Energies." The students visualized energy generation as a problem for communities on the banks of the Amazon River system in the northern region of Brazil.

A researcher followed all the group's work as a silent observer, and the students accepted their presence in one of the rooms of the Microsoft Teams platform. From these observations, some questions were raised that can be used to build a project maturity assessment model.

4.2 The context

The group defined 5 basic requirements that the solutions should meet: low cost, clean energy, practical transport, easy to install, and durable. Then, they proposed three alternative solutions: an electric generator that uses the current of the rivers, a system of solar panels with surplus energy credits returned to residents, and a generator that uses reusable oil as fuel.

The group chose to use the river current to generate electricity. Some communities partially use solar energy, but the communities are so isolated that there is no use for the surplus power they generate. Oil was also rejected due to transportation issues and environmental risks. It should be noted that many communities are supplied with energy via a diesel generator.

Brazil is a continental country, with 80% of its population concentrated in coastal cities, interconnected by various means of transport. The Amazon is a region with forests and rivers spread across 9 countries in South America, 60% of which are in Brazil. Almost all communities are located along rivers with different volumes of water. These rivers are the region's roads since the jungle terrain is soaked by daily rains, making maintaining roads in the area impossible. Using rivers to generate electricity acknowledges that all technology has to adapt to the characteristics of each region. There is no standard solution. Therefore, by choosing to invest in this vast river system, a territory offered freely for engineering, the students showed maturity in adapting the project to the problem. In evaluating sustainable engineering projects, they demonstrated the suitability of the Triple Bottom Line in focusing the main project on environmental, financial, and social sustainability.

4.3 The design

After an in-depth theoretical study verifying the technical and budgetary feasibility of the options, the students designed a generator connected to a rotor in the style of old mills. In this generator, the blades are rotated using the river current. These blades are coupled to a generator and an alternator. In addition, there is also a photovoltaic kit consisting of a battery, a 60Wp module, an inverter, and a charge controller capable of capturing the solar energy that falls on the water sluice. Finally, the entire system is coupled to a support structure for stability and buoyancy, as shown in Figure 1. The students calculated that the system generates less energy than a diesel-powered generator, but the installed capacity can generate the same power for a much lower cost since a higher average river speed can generate a higher amount of electricity.

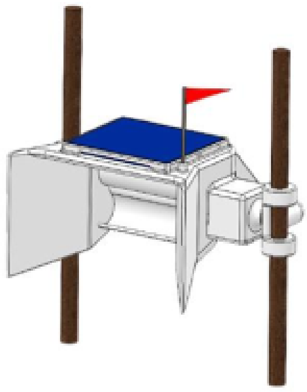

Fig. 1: Prototype modeled in CAD

4.4 Secondary problems

After having the general topics of the project approved by the mentors, they began to face secondary problems that were not part of the reality of the region where they lived.

- Water level variation throughout the year

In the southeastern region of the country, where the students come from, the water level does not vary significantly throughout the year. The original project envisioned the generator floating on the water with axes that allowed it to go up and down. At the same time, this water level variation is critical in the Amazon. The difference in the height of the waterline between the high and low seasons reaches 15m. As a result, the riverbank can recede around 100m from where it was in high water, creating a dry region where the river once flowed. Therefore, any artifact created must float and be installed far enough away from the riverbank to follow the level of the river. This problem was not resolved within 48 hours of the event, but it became clear that it would be an obstacle to the project's economic viability.

- Risk to native species

There was a perception among the students that the rivers in the region do not have clean water. Debris from trees and leaves can prevent water from passing through the rotor. The rotor can also kill fish. This risk analysis was considered during the event. They arrived at a mechanism composed of blades with an angle that promotes self-cleaning and would tend to throw the fish back into the water if the rotor captured them. There was a high level of project maturity regarding the analysis of risks to regional fauna and flora.

5 DISCUSSION

Although there is still no defined scales, some conclusions can be drawn regarding the work presented by the group considering the SDG since some of the authors participated as mentors at the event and followed the process of building the product.

In terms of the environmental axis, the project was reasonably mature. The choice of a renewable and abundant energy source in the region (river currents) and the concern for flora and fauna present in that ecosystem favors a good score in this regard. On the other hand, field observations suggest that the mentors may have driven progress on this issue during the event.

The group did not achieve a good score concerning the financial axis. Although they considered the cost of the generator and the seasonal variation of river levels (even if they did not solve the problem due to the short time), they did not consider, for example, the issue of maintenance. Maintenance can make the project unfeasible since defective equipment can leave the resident without electricity for days or even weeks.

In the same way, the social pillar was not mature either, although local demands for a better quality of life for riverside residents could potentially be met. For example, the students could have included involving the local community in energy issues or creating a network of local workers trained to maintain equipment, generating work and income.

6 CONCLUSION

This article presents a starting point for discussing a methodology for evaluating PbL and PbL short-term events focused on SDG consciousness. The case described offers a new point of view on evaluating PbL projects, making the qualitative and quantitative evaluations. The goal is to build a maturity map about the learning complexity of sustainability, joining of the environment, economy, and social approaches during the project's development. Here, engineering students developed short-term PbL focused on the SDG. However, this methodology could be applied in any PbL, correcting deviations and implementing improvements that can promote projects transforming into concrete, sustainable social innovation actions in communities and positively impact the evaluation of PbL projects.

Abstract

In many universities around the world several events of short term PbL are taking place. These are challenges proposed to the engineering students from concrete problems given by NGOs, governmental institutions, or enterprises. In general, they are named hackathons or bootcamps. The goal is to spark interest and develop skills linked to the design and the engineering project development in short-time sprints. However, most of these solutions are never implemented in practice by the teams that created them. The universities consider these practices as part of the education in engineering. Two Brazilian institutions (CEFET/RJ-Federal Center for Engineering Education-Rio de Janeiro and UFRJ-Federal University of Rio de Janeiro - Brazil) participated and won the

international event named "Invent for the Planet" organized by Texas A&M University in 2019. The students developed an interface for blind people to walk on the streets avoiding obstacles. Back in Brazil, these students patented the product and created a startup to produce and introduce that solution in the market. Today they have an accessibility startup with several other solutions in addition to the one created at the event. This research has the goal to understand the ways that made these students transform an educational project into a feasible/successful entrepreneurial action. What was the motivation of these students? Where did they get additional entrepreneurship training? What lessons does this case can provide to engineering education? A set of interviews has been carried out to understand the process that can contribute to engineering entrepreneurship education in the universities.

Introduction

In many universities around the world, short-term events are taking place to challenge students to solve problems in the field of engineering. Many call such events educational hackathons. This type of event aims to spark interest and develop different skills and competences in the field of innovation and entrepreneurship.

The College of Engineering at Texas A&M University had already been developing short-term events aimed at training in innovation and entrepreneurship for some time (Boehm, 2020). These events are called "Aggies" and aim to create student immersion in a structured, intensive, and innovative design experience. Within 48 hours, after creating and prototyping a solution, students must "sell" their projects to a panel of judges from different companies and different types of institutions.

In 2018, TAMU decided to expand this event model, which was already working with its students, to the whole world. It was then that the "Invent for the Planet" (IFTP) was created based on the Aggies model. This event aims to challenge students from around the world to find solutions to problems provided by international institutions problems ranging from providing access to safe drinking water in vulnerable communities (USAID) to protection against damage to aircraft structures subjected to bad weather at airports (Airbus-USA).

The IFTP started in 2018 with 14 universities and in 2020 it already had approximately 40 universities from other countries around the world. The event takes place over a weekend in February. Each country holds its own event, but at the same time as all the others. It is possible to observe through cameras what is happening live in each country ~~live~~. While the sun sets in one region of the globe, in another it is already rising. You could say that during that weekend "The Sun Never sets on Innovation".

The event has a dynamic based on sprints with deliveries demarcated over time (status review). Mentors can interact with teams discussing the direction of the project without providing ready-made answers or solutions. At the end of the 48 hours, the teams must present the project results to a panel of judges in 3 different ways: a 90s video elevator pitch, a 10min presentation followed by questions from the judges, and a White Paper with the technical characteristics of the project.

Brazil started its participation in the IFTP 2019, when there were 6 teams involved with the proposed themes. The team called Tupan won the Brazilian section of the event with an accessibility project formed by 2 artifacts to guide the blind during walks. The first was a cap with sensors that allows the identification of obstacles ahead. The other was a sensor that, when pointed in certain directions, allows for the detection of holes (electronic walking stick). Both were inexpensively constructed artifacts. In 48 hours, the Tupan team was able to propose the idea, build a prototype and test the product with blindfolded and visually impaired people. The fact of developing a project with rapid maturity gave the team victory.

The elevator pitch and project description were sent to Texas A&M University. In 2 weeks, the team was informed that it had been selected for the final stage in Texas, along with 5 other teams from other universities. At that moment, the team was faced with a new problem that needed a quick solution: how to pay for the trip? After discussions, the team decided to create a crowdfunding on social media to raise contributions for the trip. The goal was reached in another 2 weeks. Arriving in Texas, the Tupan team presented and discussed the project with local mentors. In the end, it was crowned champion of Invent for the Planet 2019. Upon returning to Brazil, they decided to create a startup called Tupan to market that product (https://www.youtube.com/watch?v=g8trcNd7ogU)

In 2020, they expanded their concept to an accessibility solutions company.

As a result, some questions arose:

(a) What motivated the jump from the condition of a winning team in an engineering challenge to the creation of a startup?

Did the students have any training for entrepreneurship at the university? YES. How was it? NOT. How could such training be incorporated into curricula?

(b) Did smart money participate in this process?

We know that thousands of other teams go through the same process at many similar events around the world. However, it takes several steps with the acquisition of skills and new knowledge to make this leap. The big question is whether these skills were acquired at university or elsewhere before the IFTP. If not, it would be interesting to see if, in their view, there is any possible action to be taken in this regard in terms of building a new curriculum for engineering courses. Finally, it is important to know if the team sought this expertise elsewhere in the startup creation process. There are now several courses being offered for this purpose, mainly from SEBRAE, an institution in Brazil that brings together business and government associations to support entrepreneurship. In addition, there could also be the possibility of mentoring with an angel investor (smart money).

The purpose of this concept paper is to gather elements for the creation of a support program for projects that win short-term challenges of the IFTP type. These programs would aim to increase the "Technology Readiness Level" of projects (Mankins,1995), by bridging the gap between the events and the business incubators, both technological and social.

Methodology

During the event, the Tupan team was formed by 6 students, 5 from CEFET/RJ (Federal Center of Engineering Education – Rio de Janeiro) and 1 from UFRJ (Federal University of Rio de Janeiro). Of the 6 students, 4 were undergraduate students and 2 were graduate students. Only one of the undergraduate students was from Electrical Engineering, the others were from Mechanical Engineering.

After the victory of the Tupan team in Texas, the UFRJ student left the group. The rest remained in their courses, dedicating their free time to the construction project (planning?) of the startup Tupan.

The victory of the Tupan team in the IFTP took place in April 2019. The collection of information carried out for this work occurred in two stages between September and October 2021.

a) The first step of data collection was an interview with one of the team members who had a leadership role in the process. ~~In~~ During the interview, we sought to know the experience from the point of view of this student. Based on the information provided by him, a focus-group was scheduled with all 5 participants of the startup Tupan.

b) The second step consisted of a focus group including all the participants. The meeting was held virtually in October 2021. The questions were organized from the information given in the interview using a semi-structured model of questions. The use of the focus group aimed to obtain a collective mental reconstruction of the process through which the students went. During this process, each student could talk about their experience in the process and compare it with those of their colleagues. This information gathering technique allows a more reliable reconstruction of the facts, as it is shared by all those who have lived the experience.

c) The report was divided into 3 moments: (1) Before (2) During (3) After.

Experience Reconstruction

(1) Before

Participants reported that they had no background in entrepreneurship. During their university education, they were always more directed and focused on the technical aspects of the courses to which they related to. Participation in the IFTP was encouraged through the suggestion of professors. Despite this effort, there was no immediate interest. At first, they believed that they were going to participate in some type of training activity where their hard skills would be required. The entrepreneurial perspective or becoming a startup never crossed their minds, although the subject of entrepreneurship arouses some curiosity. In essence, they attended the event out of respect for their professors.

(2) During

The idea of the emergence of the product came from the ability of the components in (the team members' familiarity with ???) the use of sensors. From the definition of the problem and of the requirements for the solution, the development of the product occurred quickly. The construction of the prototype did not come across many difficulties.

The effectiveness of the proposal (The proposal was effective ??) and the built prototype was tested with a blind person, who used the product with relative ease. This immediately beckoned to (signaled) the usefulness and practicality of what they were developing. It is possible to consider that the moment of approval of the product by a blind person was fundamental for them to perceive the meaning (relevance ??) of the event. Winning the Brazilian stage was considered the apex of the process. The team did not expect to be in the finals.

People's adherence to crowdfunding on social networks was another incentive. In the United States, they participated collaboratively in preparatory activities for the final pitches. Despite being a competition, the Tupan team quickly realized the spirit of collaboration, one of the pillars of the event. All teams are encouraged to collaborate with each other.

When the winners were chosen by the judging committee, the Tupan team was taken to visit and present their prototype to companies and potential investors to make the product commercial on a larger scale. One of the companies visited, a company offering products for the visually impaired, commented that they regularly received product ideas and that few were relevant. She put to the group the challenge of delivering 10 prototypes to be tested with a greater number of blind people daily. At that moment, the team was faced with a new challenge: the ability to scale production in a short period of time. The prototypes were built and delivered on time. It was understood that there was an interest in the prototype and that the product was economically viable.

As a result of meeting and the demands of the interested company, the team received an offer to purchase the product patent for US$ 10,000.00. Dazzled by the offer and realizing the arising interest sparked by the prototype, they refused to sell the patent and decided to apply for a patent and develop the product upon their return to Brazil. At no time where they guided by the educational institution about business possibilities with the registration, sale, or percentage in the patent registration. It was their experience in the IFTP that led them to the decision of undertaking such initiative.

(3) After

After the decision to become entrepreneurs and start the activities that would characterize a business proposal, the members of Tupan team found at least two specific facts:

1. They had not received, in university education, knowledge that would prepare them for the business environment in the role of entrepreneurs. They were knowledgeable about engineering tools and techniques, but not about business management skills and, above all, how to build a business model.

2. They did not have access to financial, physical, and material resources that would enable the initial steps of the business: Although there is a technology-based business

incubator at CEFET/RJ, neither they knew about this fact, nor was the incubator informed of their desire to create the startup.

Regarding training for the new reality that they began to experience, the new entrepreneurs began to deal with issues that they were not used to, such as: finding suppliers, determining sale prices, establishing profit margins, determining delivery times, and choosing distribution channels. In terms of resources, they began to deal with a constant difficulty for any entrepreneur; for instance, getting smart money and angel investors. They chose to keep and run the business~~,~~ with their own resources. ~~In~~ At that initial moment, the startup became a side project in their personal lives. They sought personal financial support ~~in~~ from other projects and jobs while structuring the company with the proceeds from the sales of the first units that were being commercialized. To increase revenue, they created another product–the accessible personal card– to have one more way to generate resources. The company started to have a concept based on accessibility.

Highlight points from the focus group

Today the startup Tupan already has two products in its portfolio. The first is EVA, winner of the IFTP 2019. The second is a card with data on persons with disabilities that can be accessed by those who wish to obtain information about the person, without having to fill in forms or speak orally. But the startup has encountered difficulties in communicating with customers and distributing products. Everything is done through the company's website (https://www.tupan.net.br/). Revenues during 2021, up to the time of the interview, did not exceed U$ 2,000/year. The prize of US$ 3,000 received in Texas was the only external contribution of financial resources in 2019. The COVID19 pandemic had a strong impact on the business takeoff as well. Confinement has not made urban displacement an immediate necessity. Therefore, no matter how much the products were advertised, users did not feel an immediate need to purchase them. Students continued their courses, making of the startup a secondary activity. They will likely have to become employees of other companies for still some time. Despite knowing that accessibility products are products of a niche market, only after the end of the pandemic it will be possible to assess the real impact of the product on the market.

Asked about what kind of support has made a difference in the development of the startup in the first moments, they highlighted the following items:

1 – Having participated in the University Incubator

For them, being incubated means much more than only receiving a physical space and working in a coworking space. It would be relevant to receive guidance on the market, on setting up a business plan, and to have on access to the use of laboratories with inputs. This incubation includes contact with other startups to receive feedback and learn from the experience of other entrepreneurs in a similar situation (smart money). A great difficulty for them, as they say it, it is having to “pave all the way alone”. They are just good engineers unprepared for the “jungle of the market”.

2 - Venture Capital

Not being connected to investors who provided venture capital and smart money was a limiting factor in the development of the business. Receiving some financial support in the company's first year would have allowed for a smoother take-off. This could have been boosted by opportunities due to the high media exposure they had in Brazil after the victory in the national and international editions of the event. This financial support could have come from: (a) funding grants to participants with the purpose of allowing the transition from an educational project to a startup; (b) resources for inputs necessary for the manufacture and assembly of the product; (c) working capital for day-to-day, sporadic expenses.

3 - Mentorship

In the same way that the IFTP provided mentors for the development of the idea and the prototype, there is a need for systematic and regular mentoring on entrepreneurship in the incubation process. This would have avoided predictable errors by reducing the time spent in the trial-and-error process. Guidance in the Business Plan was also a highlight as, while the tools are easy to understand, reflection on their content is not automatic for university students.

4 – New posture of undergraduate programs for entrepreneurship

It's not about having just one discipline of entrepreneurship. It is about presenting the possibilities to the student from the very first moment of the program. The members of the Tupan team only considered the entrepreneurial possibility after the event. During ~~your~~ training, only technical perspectives are considered. This characteristic makes the search for formal employment the only way to go. Faced with the prospect of running a business, arising from an innovation, the professional in training feels weakened and even discouraged. We can say that developing entrepreneurial thinking is a new and important skill, which goes beyond what are considered soft skills.

5 – Local entrepreneurial ecosystem

One of the most important actions raised by the group is the need to bring the university closer to the local entrepreneurial ecosystem. Innovation ecosystems are knowledge networks (Calon, 1996) where there is exchange of information and learning (Braga & Guttmann, 2019). Collaboration in creative work and in the development of ideas builds a collective intelligence involving different stakeholders from the university and external to it (Braga & Schettini, 2020). The practice of networking facilitates the first steps of startups because it aggregates experiences from other companies at different stages of maturity. The discovery of complementarities can boost the business.

Conclusion

The Tupan case can teach us several learning points in relation to the role played by universities in terms of the entrepreneurial training of engineers. Both CEFET/RJ and Texas A&M University have their own innovation sparking events. CEFET/RJ has

EXPIN[48] and TAMU has Aggies, both of which are very similar in format. The IFTP is an international event spearheaded by Texas A&M that brings together several institutions. The main role of these events is the training of students in innovation and entrepreneurship. Nothing prevents real cases of innovation from emerging from these events and gaining market share through entrepreneurial students. Universities must be prepared for the "bottom-up innovation" because it comes from the student base and not from cutting-edge research carried out in their laboratories. It is essential to build support structures that support these students during their take-off, even before they acquire maturity for flight.

Conference Key Areas: *Student Engagement. Building Communities and Coordination; Attractiveness of Engineering, Gender and Diversity*
Keywords: *Innovative software, Project, Manufacturing, Statistics.*

ABSTRACT

In this work the results about the use of innovative software in the subject Project I is presented. The subject is given in the Degree in Engineering in Industrial Technologies (GETI) in the School of Industrial Engineering of Barcelona (ETSEIB) of Universitat Politècnica de Catalunya (UPC). In Project I, small groups of 12 students or less are defined, with the purpose of developing a collaborative project along one semester. The project discussed in this work was prepared by two different departments: Mechanical Engineering and Statistics and Operative Investigation. It deals with the measurement of shaft diameters with a micrometre, in order to evaluate the measuring system employed. Traditionally, many activities of the subject were recorded in handwritten reports. The present academic year, within the frame of the project EQUIPA'T (equip yourself), innovative software was applied to the subject. As for the methodology, first the teachers attended a training course. Then, the application of innovative software to the subject was planned. Finally, it was implemented. Google forms was used in the first and last classes to gather information to prepare subgroups of students and to evaluate the subject respectively, Edpuzzle was employed to add questions to videos about two lessons of the manufacturing area: metrology and

doi:10.5821/conference-9788412322262.1387

turning, and Trello was used to manage the design of a 3D printed support by different teams of students. In subsequent years, the application of new software is expected.

---

1 INTRODUCTION

1.1 Description of the subject Project I

The subject Project I is given in the second year of the Degree in Engineering in Industrial Technologies (GETI) of the School of Industrial Engineering of Barcelona (ETSEIB) of Universitat Politècnica de Catalunya (UPC). It is a mandatory subject, although the students are divided into small groups with 12 students or less, with a specific theme for the project. The Department of Mechanical Engineering, in collaboration with the Statistics and Operative Investigation Department, offers the following subject:

Are we measuring correctly the parts that we manufacture? In this project, the measuring system for shaft diameters (consisting of using a micrometre and a support) is evaluated. An R&R (Repeatability and Reproducibility) study is used for this purpose.

1.2 Background of the research

In the past, several authors have dealt with innovative software in the engineering area. For example, in the US, in 2011, a new software was developed and presented in order to teach Digital Signal Processing [1]. Other authors have applied existing software to improve teaching in the Engineering area, for example Labviews for data acquisition [2].

On the other hand, some technical universities develop group-environment courses in order to help the students developing employability skills such as team-work, communication skills, problem-solving, organizing, etc. [3,4]. In this sense, the Barcelona School of Industrial Engineering (ETSEIB) implemented the subject Project I with the new GETI degree in 2010. The students are divided into smaller teams of 3 or 4 components, and the subject is evaluated by means of three successive presentations (with a written report and an oral presentation). Some results about the evaluation of the subject were presented in the CIDUI2014 conference [5], and lead to the publication of a journal paper [6].

In year 2017 an important innovation was added to the project about the evaluation of the measuring system. It consists of the design and manufacture of a 3D printed support that helps to fix the micrometer and the shafts when measuring (Figure 1). An example of a support was presented in the CNIM2021 conference [7]. 3D printed supports are commonly employed in industry to fix parts, both in machines and in measuring instruments.

Fig. 1. Example of a 3D printed support used to measure the shaft diameters

As for the development of the subject, along the semester, five sessions are directly related to the Manufacturing area. Session 2 consists of explaining the turning process, to the students. Session 3 corresponds to the measuring systems, both conventional and advanced, as well as the concept of tolerance interval. In session 4, the design methodology for machines is introduced. In session 5, the students design a support that will be used in session 9 to measure the diameter of the parts.

The main pedagogical approach that the teachers use in this subject is the Project Based Learning, with the final objective to perform an R&R study of the measurement system.

1.3 Objective of the research

The main objective of this work is to present the results about the application of innovative software to the subject Project I of the GETI. The purpose of applying the new software is to increase the involvement of students in the subject, and encouraging them to participate in the different activities, but mainly in the of design and manufacture of the 3D printed support.

2 METHODOLOGY

This research is included in a project called EQUIPA'T (equip yourself), in which two different schools of UPC (ESEIAAT-Terrassa School of Industrial, Aeronautics and Audiovisual Engineeing and ETSEIB-Barcelona School of Industrial Engineering) are involved, as well as different departments: Projects, Mechanical Engineering, etc. The main theme of the project is the application of innovative software to the subjects involving collaborative work.

The general methodology of the EQUIPA'T project is summarized in Figure 2.

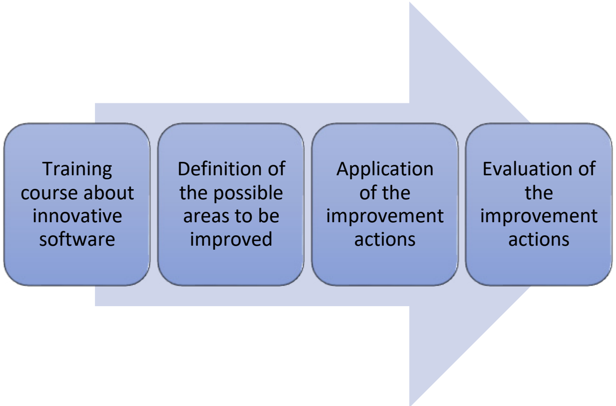

Fig. 2. General methodology of the EQUIPA'T project

The specific methodology that was used to implement the improvements to the subject Project I is explained in sections 2.1, 2.2, 2.3 and 2.4.

2.1 Initial questionnaire

During the first class, a Googleforms questionnaire was used about the different subjects that had previously been taken by the different students. It stated the following question:

Please mark what is your situation about the following subjects: 1- Statistics, 2- Statistical techniques for quality, 3- Manufacturing workshop

And the possible answers for each subject are:

1- I did not attend it, 2- I am attending it now., 3- I attended it in the past

The results of the questionnaire, which are explained in section 3.1, were used to define different subgroups among the students of each class. The idea is that in each subgroup there be, at least, one student with previous knowledge in Statistics, which will help the rest of the students in this area.

2.2 Edited videos

In order to encourage discussion in sessions 2 and 3 (about turning processes and metrology respectively), it was decided to use Edpuzzle to add questions to the videos to be presented in class. In a first step, most appropriate videos were selected among the possible ones. One video about turning operations and another video about tolerance intervals were used, which had been previously edited by other authors. The videos were shortened and more questions were added, according to the objectives and requirements of the subject Project I. The results are presented in section 3.2.

2.3 Management of the design process

The design process of the support is a quite long activity. It starts with the definition of the necessity of the technological object to be manufactured, as well as its main requirements. Then, conceptual design is carried out with the definition of the main moduli of the device. Later, the materialisation design is performed, in which different alternatives for each modulus are stated. Finally, the detail design is carried out, and the final drawings are obtained [8]. In order to keep track of the development of the design process, the Trello software was used. It allows preparing lists of tasks in different columns: - *Pending, - In progress, - Finished*. It also allows adding drawings, pictures and comments to each task during the development of the design activity.

The results of the application of Trello to the design process of the support are presented in section 3.3.

2.4 Final questionnaire

In the final class, a Googleforms questionnaire was used in which the students were asked about 3 positive aspects of the subject and 3 aspects to be improved. The results can be found in section 3.4.

3 RESULTS

3.1 Initial questionnaire

The results about the initial questionnaire that was carried out during the first class are presented in Figure 3.

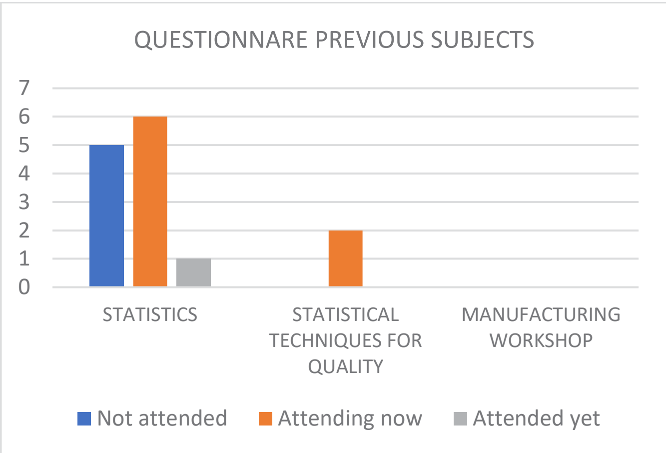

Fig. 3. Results about the subjects that the students previously attended.

Figure 3 shows that 11 students out of 12 had had previously attended Statistics or were attending it, while only 1 student had not attended the subject. In addition, 2 students were attending Statistical Techniques for Quality, and no student had previous knowledge about Manufacturing Workshop. Three different subgroups were defined in which, at least, two components had previous knowledge about Statistics.

It is expected to use the Googleforms questionnaire in the first class again the next academic years, because it helps to balance the subgroups regarding the knowledge of the students on Statistics.

3.2 Edited videos

Edpuzzle software allows the possibility to edit videos in a way that several comments and questions can be added [9,10]. In this work, two different videos were edited, for the machining (Figure 4) and for the metrology class (Figure 5) respectively. In both videos, several subsequent questions appear to be answered by the class group.

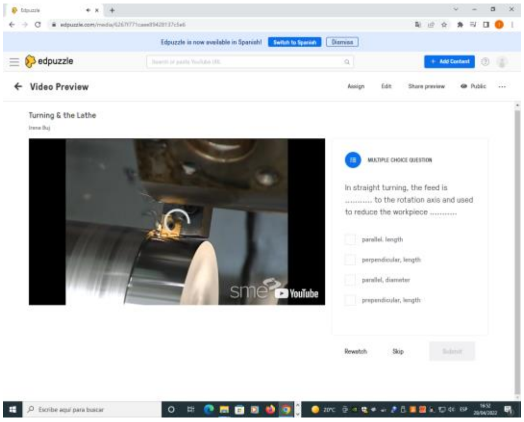

Fig.4. Screenshot of a video about turning

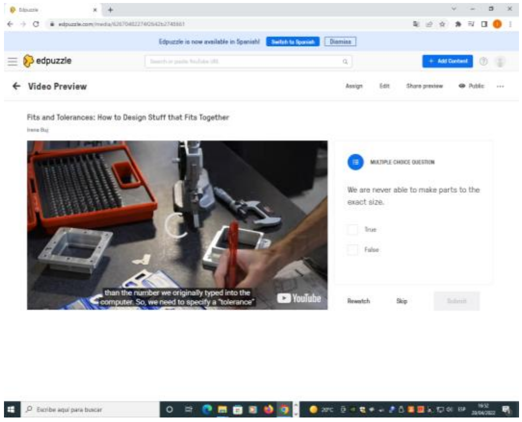

Fig. 5. Screenshot of a video about metrology

The selected video for Session 2 about machining processes is “Turning & the lathe”. In it, different turning processes are described, for example straight turning. In addition, the concept of rough and finish machining is explained.

The selected video for Session 3 about metrology is “Fits and tolerances: how to design stuff that fits together “. The concepts of nominal dimensions and tolerances are explained, as well as the three kinds of fits: clearance, transition and interference.

Both videos led to a discussion in class. For example, regarding the turning operation, the chamfering operation was commented. Its main aim is to avoid sharp edges that could hurt the person that machines or transports the part. In another example, the video about metrology helped to find some real examples for the different kind of fits that are used in mechanical design.

The next year, it is expected to add another video about 3D printing. Another possible improvement is that the students answer the questions individually, in order to analyze the results and to compare them to the final marks.

3.3 Tracking of the design process

The application of Trello led to uneven results: while some groups just used it as a list of tasks (Figure 6), other groups took great advantage of its possibilities, adding schemes, pictures and comments to the list of tasks (Figure 7).

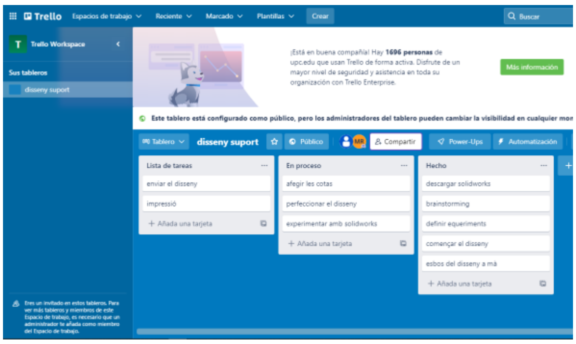

Fig. 6. Screenshot of Trello with three sets of lists

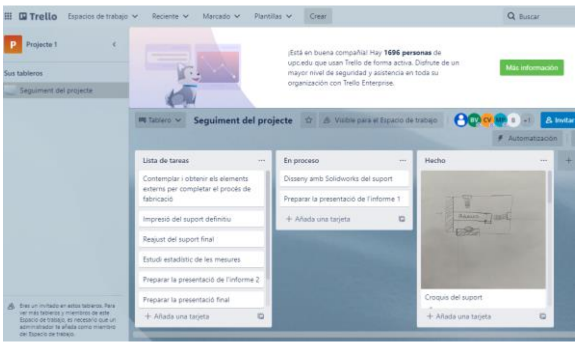

Fig. 7. Screenshot of Trello with lists and schematics

In addition, the use of Trello favoured the use of other software. For example, the Measure app of the mobile phone was used to measure the dimensions of the micrometre from an image (Figure 8).

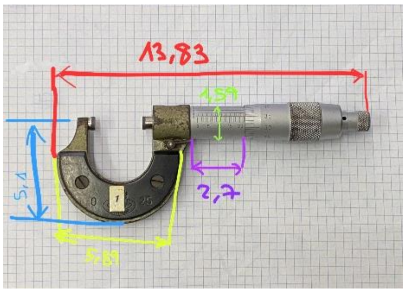

Fig. 8. Measurement of the micrometer from an image

Next year it is expected to replace the conventional written report that was used to evaluate session 5 of the subject with a Trello file, in order to avoid duplication of information.

3.4 Final questionnaire

The results of the final questionnaire are as follows (Figures 9 and 10). The most positive aspects of the subject are team work, followed by oral presentations, to learn 3D Printing and to learn Statistics. The main aspects to be improved are that there are too many presentations, the fact that all the teams deal with the same subject and the fact that there are too few laboratory classes at the workshop.

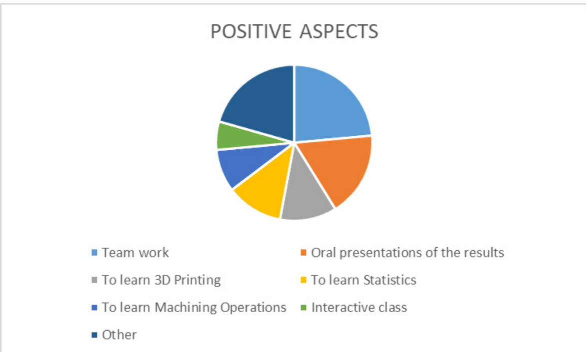

Fig. 9. Positive aspects of the subject

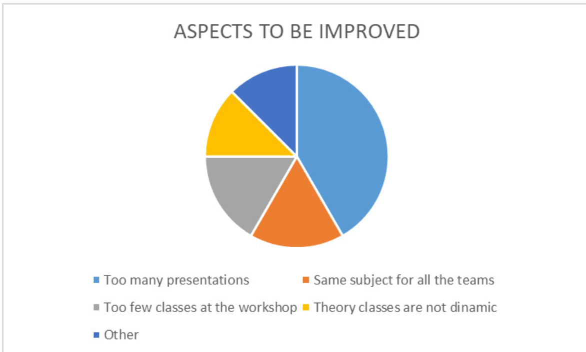

Fig. 10. Aspects to be improved

4 SUMMARY AND ACKNOWLEDGMENTS

In this work the results of the application of innovative software to the subject Project I are presented. In the first session, a Googleforms questionnaire was used to ask the students which subjects they have previously taken. In the second and third sessions, Eddpuzzle was used to add questions to a video, which were answered by the students globally in class. In the fourth and fifth class, the tool Trello was used, which allows to perform a list of tasks that are pending, in process and finished respectively. In the last class, the students were asked about the subject with another questionnaire. From the teacher's standpoint, all the innovative tools allowed to enhance the discussion of the subject with the students in class.

In subsequent academic years, it is expected to use the three tools again, with a special focus on the possibilities of Trello, which could completely substitute the use of conventional reports along the design process of the measuring supports. The students mainly appreciate team work and the possibility to present their achievements.

Thanks are due to EQUIPA'T project, Desenvolupament I avaluació de la competència del treball en equip en entorns virtuals, as well as to Lluís Marco, Lourdes Rodero, Alejandro Domínguez, Ramón Casado, Àlex Lapuerta and Joan Guasch for their help.

IMPLEMENTING A SUITE OF SKILLS MODULES IN A FIRST-YEAR ENGINEERING PROJECT-BASED SUBJECT

G. Buskes[1] **, H. Chan**
The University of Melbourne
Melbourne, Australia

Conference Key Areas: *Curriculum Development, Engineering Skills*
Keywords: *Skills, project-based, first-year*

ABSTRACT

Students commencing engineering at university often have no prior experience of engineering, what the profession entails and the distinctions between disciplines. Consequently, tertiary institutions often offer common first-year engineering subjects that aim to give students an experience of the engineering profession and method, while providing exposure to different disciplines through applied project-based learning. The difficulty with this approach is that there is a wide variance in terms of students' knowledge, skills, past experiences, and expectations. In a team context, these discrepancies could lead to conflict and poor educational outcomes. Furthermore, if the project is of reasonable length, students might be locked into a discipline-focused project that they realise does not suit them as a potential major.

To this end, a suite of self-enrolled skills modules was developed to support student skills development in a first-year, project-based engineering subject under two categories – *technical*, focusing on skills that had direct applicability to the project-work and *general*, focusing on skills related to assessment. The modules aimed to (1) improve individuals' skills in a team context; (2) give students an opportunity to learn skills unrelated to their chosen project in a low-stakes context; and (3) promote interaction and peer-learning outside of their project team and class, building a wider sense of cohort.

This paper discusses the creation of the modules and evaluates their outcomes in achieving their goals based on numerous data gathered throughout the semester and student feedback. Initial results have been positive and suggest future directions for development.

1 INTRODUCTION

In a major review of the knowledge, skills and attributes that will be required of graduate professional engineers in the future, the "development of technical and professional skills supporting collaborative, inter-disciplinary teamwork" has been identified as becoming a more important part of the engineering education of the future [1]. In light of this, many tertiary institutions in Australia have moved to offer large-scale, first-year programmes that teach more general engineering subjects, with the aim to give students an experience of the engineering profession and begin the early development of professional skills such as problem-solving techniques and communication skills, rather than necessarily teach discipline-specific knowledge. Students commencing engineering at university often have no prior experience of engineering, what the profession entails and the distinctions between disciplines and offering general engineering subjects in this fashion can help them more broadly understand what engineering is about before committing to a particular discipline. This approach gives students some flexibility to choose or change a previously nominated engineering discipline after completion of the first year of study, without having to go back and complete discipline-specific first year subjects. This is seen as beneficial to students, especially where a broad range of engineering specialisations are offered and making a choice could become difficult.

The issue with this flexible approach is that there are several inherent concerns with pooling all engineering students into a common first-year subject, particularly one employing project-based learning [2] to help develop professional skills. Firstly, in recent years there has been a marked increase in the number of students entering the university system in Australia [1, 3]. In particular, the increase in intake means that those attending university are now coming from a wider range of backgrounds and, as a consequence, there is a greater variation in their prior knowledge and experiences [4]. The widening variance in terms of students' knowledge, skills and past experiences, even within specific discipline areas, could lead to conflict in a team context and poor project outcomes [5] Secondly, students who are certain about the discipline of engineering that they would like to pursue may become bored or even disillusioned if forced to complete tasks or projects in a first-year, general engineering subject that do not align with their skills and interests. These factors could easily lead to reduced educational outcomes and a negative experience of engineering, which can have dire consequences in terms of student retention.

To address these concerns, a suite of self-enrolled skills modules was developed to support student skills development in a first-year, project-based engineering subject. The modules were broadly classified under one of two categories – *technical*, focusing on skills that have direct applicability to the project-work and *general*, focusing on professional skills more related to assessment. The modules comprised a mix of self-paced online and self-signed up workshops aimed to (1) improve individuals' skills in a team context; (2) give students an opportunity to learn skills unrelated to their chosen project in a low-stakes context; and (3) promote interaction and peer-learning outside of their project team and class, building a wider sense of cohort.

This paper provides a background to the specific university setting and details the development and implementation of the skills modules within the context of a first-year project-based engineering subject. The relationship of the modules to each project and the assessment tasks is outlined, along with a description of the methods of delivery employed. An evaluation of the modules is performed, using numerous data gathered throughout the semester such as number of enrolments, attendance and completion rates, popularity of times when they were taken and student feedback with specific reference to the three aims mentioned above.

2 BACKGROUND

At the University of Melbourne, students must complete a three-year Bachelor of Science degree, majoring in one of the six ‘Engineering Systems’ majors, before choosing to apply for entry into a postgraduate Master of Engineering degree. In their first year of study, they complete the science subjects underpinning the engineering topics that they will encounter in later years of the degree – namely, mathematics, physical sciences such as physics, and possibly computing. In this context, students’ first introduction to engineering is via a general first-year engineering subject – one designed for all students, irrespective of (future) discipline and intended to teach some basic discipline knowledge, introduce and develop both technical and professional skills, and provide an authentic initial experience of engineering.

The general first-year engineering subject, titled Engineering Modelling and Design, was designed from scratch as a new project-based subject, with a backbone of cohort-wide lectures supporting three independent, team projects that are delivered via smaller interactive workshop classes. The lectures were designed to be independent of choice of project and focused on the engineering profession, problem-solving methods and project management. The weekly workshop classes were three-hours in duration and consisted of one-hour of interactive teaching related to a technical part of the project and two hours of team-based project work, completing a series of incremental tasks that would build towards the final project outcome. Students complete only one out of the three possible projects over the 12-week semester in a team of three. At the beginning of the semester, each student nominated the project that they would like to complete over the semester via selecting the corresponding workshop classes in the timetable system.

3 MODULES DEVELOPMENT

The three projects were the core elements of the subject and ranged from programming an autonomous robot to designing, building and testing a speaker, to simulating and mitigating the effects of a coastal flooding event. Once the scopes, goals and content of the projects were determined, the teaching team identified any potential gaps that might exist in terms of students’ prior knowledge or skills with respect to the technical and professional skills requirements for completing each project. This process was completed through a study of the first-year students' backgrounds, observation of the current content of high school curricula and knowledge of what is covered in complementary subjects at the first-year level. These gaps were deemed sufficiently large if it was thought that they might not be able to be overcome by the students over the course of the semester without additional learning activities and support early on.

3.1 Technical skills modules

Six *technical* skills modules were developed that covered a range of discipline skills in engineering, namely Basic MATLAB/Simulink, Arduino, Robot Control in Simulink, CAD & 3D Printing, Circuit Theory and QGIS. Students would find some of these technical skills modules closely aligned with their selected project, however they were not forced to take any one particular module. Indeed, students were encouraged to take the opportunity to develop skills in areas outside of their selected project field through taking additional modules. These modules were delivered in the format of self-sign-up small-group workshop classes. During the 1.5hr facilitated workshop sessions for these modules, students would first progress through a set of guided activities to familiarise themselves with any required hardware or software. They would then be required to complete a set of specific tasks on their own in order to be certified as having completed the module.

3.2 General skills modules

Four *general* skills modules – Teamwork, Report Writing, Video Production and Prototyping – were developed. The Teamwork module was offered as self-enrolled workshops where a demonstrator would facilitate a series of team activities, including team discussion and role play. The other three modules were offered as self-paced online modules developed in H5P, comprising guided activities (that could take up to 4-5 hours) that build towards the submission of a piece of assessment. In all the four general modules, the Padlet App was utilised as a sharing and discussion platform within the activities, promoting student engagement within the cohort.

In total, there were ten skills modules available across the two categories, shown in Figure 1, along with their alignment to either project stream or assessment task. As part of the subject assessment, students were required to complete at least one General Skills module and at least one Technical Skills module to qualify for 10% of the subject mark on a pass/fail basis. The completion of a particular module was based on two components: a preparation activity and either workshop participation or submission of a piece of work. This grading scheme was chosen in order to provide a low-risk environment for students to learn additional skills, either due to the project requirements or out of interest. Under this model, even though students were 'locked' into a project at the start of semester, they would be able to explore some of the skills from the other projects in a low-risk manner.

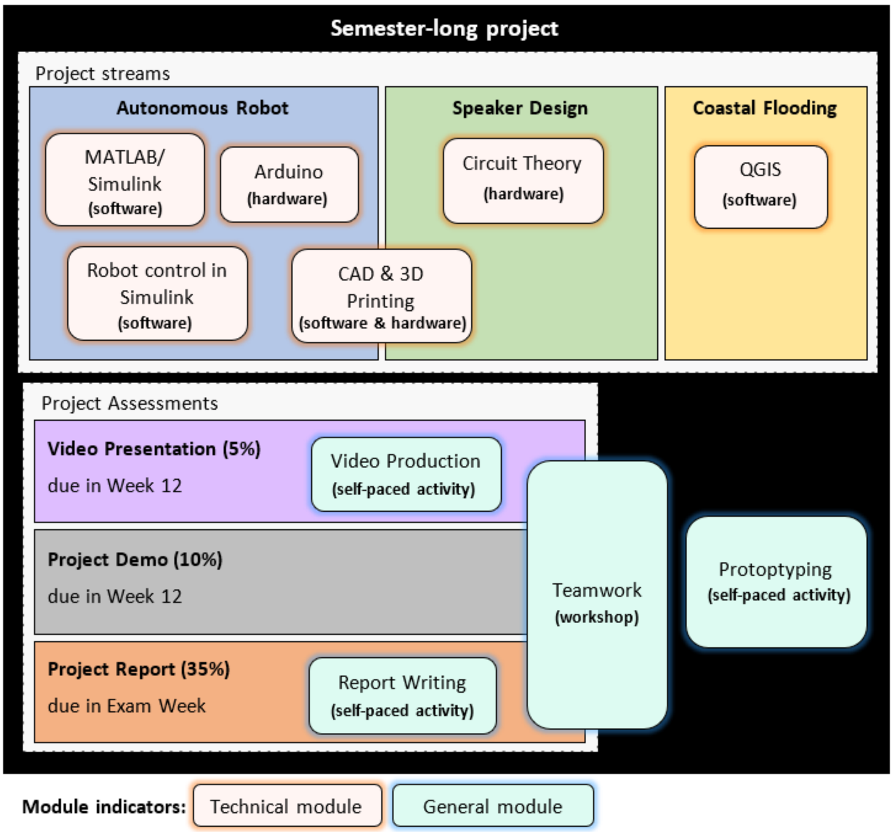

Fig. 1. Alignment of Skills Modules with project streams and assessments

4 IMPLEMENTATION AND EVALUATION

The modules were introduced in Semester 2 2021, with a cohort of 370 students supported by 5 demonstrators. The skills modules that were supported by self-paced online activities could be completed at any time, while the workshop-based ones required students to sign up via the student Learning Management System (LMS). Enrolments were continuously monitored such that workshops could be added or removed according to demand and slots for a particular module were rotated around the week to cater for different availabilities of students.

The distribution of students completing each of the skills modules is shown in Figure 2, split according to project. It was evident that students largely preferred the technical modules most relevant to their project. Based on this data, students' perception of the technical skills modules is perhaps not to use them to explore different skills, as we might anticipate, but instead, to view them in terms of applicability to their chosen project. The Report Writing module was the most favoured general skills module, with a significantly higher completion rate compared to both the Video Production and Prototyping modules, and just ahead of Teamwork. This could be attributed to the high weighting of the report assessment in the subject (35%), and the perception of the importance of teamwork in delivering a successful project outcome. The spread of students across the three project streams for the completion of the general skills modules was relatively balanced, as we would expect since the development of professional skills does not discriminate between the different project streams.

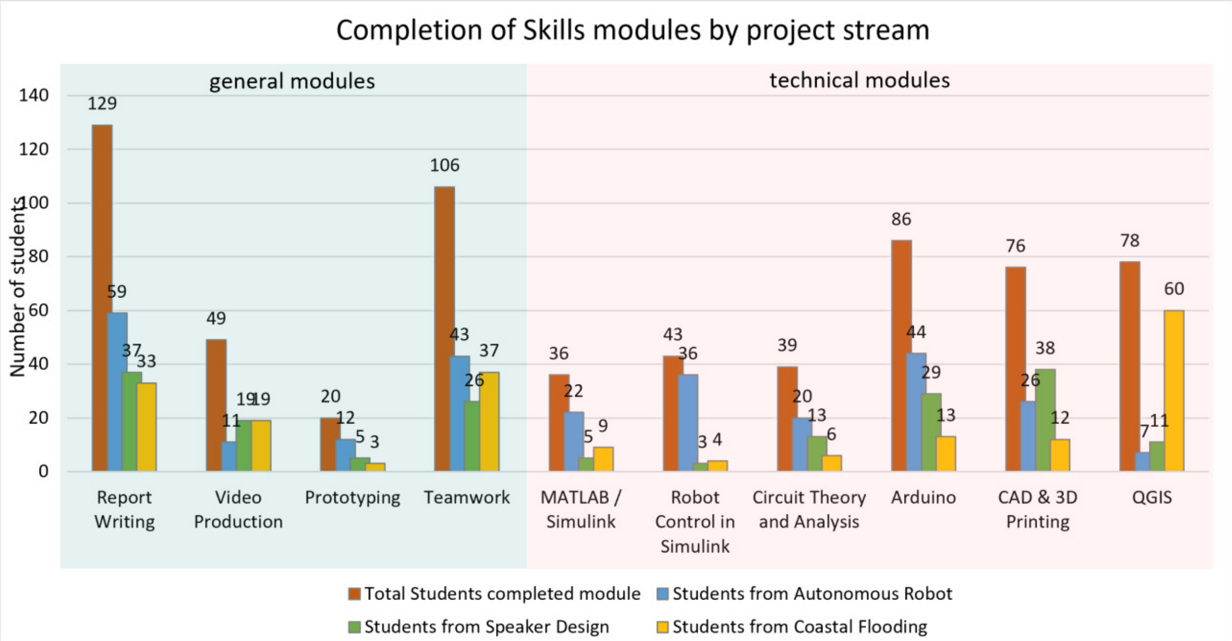

Fig. 2. Completion of all skills modules by project stream

Table 1 provides a summary of the completion of different combinations of the general and technical skills modules across the cohort.

Table 1. Breakdown of the number of skills modules completed

Number of modules completed		Total number of students
General module	**Technical module**	
0	0	36
0	1	28
0	2	5
1	0	13
1	1	265
1	2	17
1	> 2	3
2	1	3
	Total	370

A majority of students (71.4%) completed the minimum requirement of one General Module and one Technical module, suggesting that most are completing only the minimum requirement to achieve the skills module component mark. A total of 22.4% did not manage to meet the minimum requirement: 9.7% did not complete either of the modules, 9.2% completed only one technical module and 3.5% completed only one general module. Only 6.2% of the cohort attempted to take on more modules than the minimum requirement.

Figure 3 shows the uptake of the skills modules that comprised of facilitated workshop sessions. Workshop attendance for the 6 technical modules and the Teamwork module appeared to be lower in Weeks 2 and 3, likely due to students adjusting to the concept of the Skills Modules at the beginning of semester.

Interestingly, there was no strong correlation between the uptake of most of the technical modules in relation to the demands of the respective project(s) at any particular timeframe during the semester, suggesting that students tend to take up the technical modules at their convenience or availability rather than during their times of need in the projects. There was however a clear ramp-up in workshop uptakes towards the end of semester as students rushed to complete the skills modules requirements by Week 11 - the week when the last of the skills modules workshop sessions were offered.

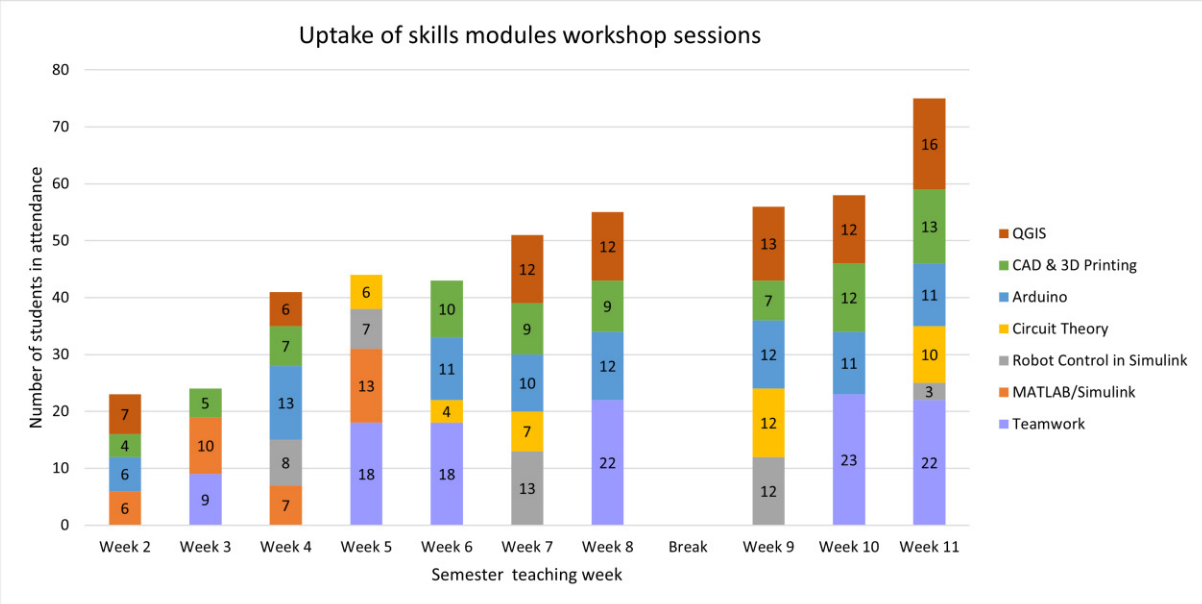

Fig. 3. Uptake of skills modules workshop sessions

A similar ramp-up trend was observed for the submissions of the self-paced online general modules, shown in Figure 4**.**

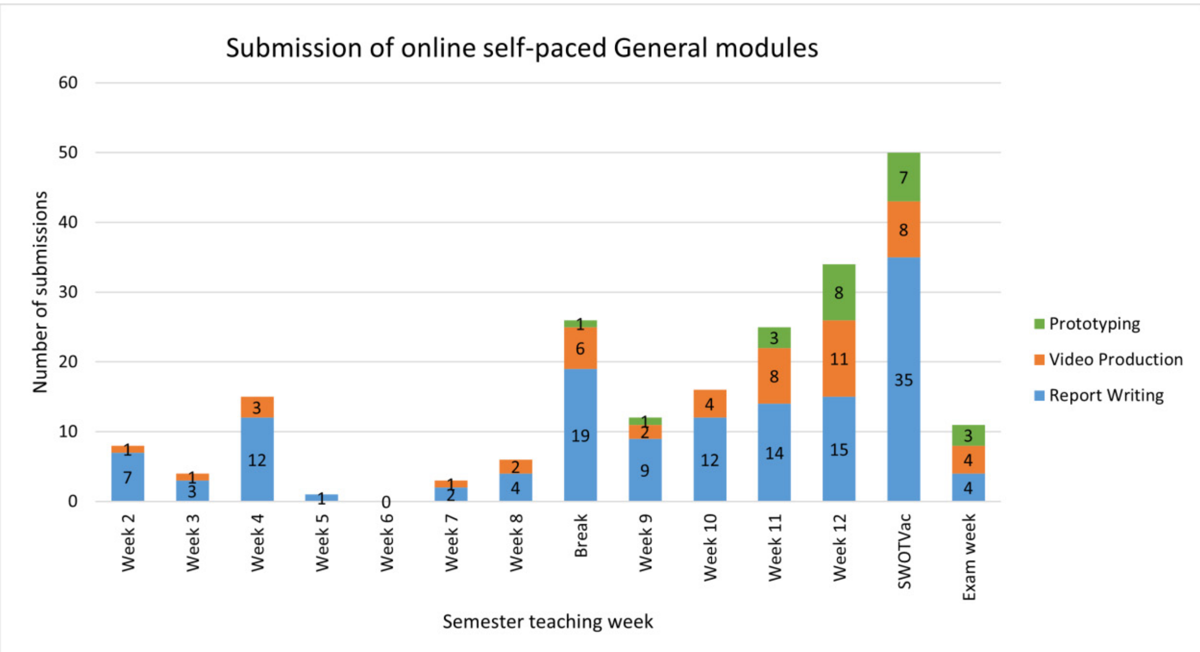

Fig. 4. Submission of online task for the general skills modules

There was a significant increase in submissions during the end-of-semester SWOTvac week, particularly for the Report Writing module, attributed to the project report deadline on the first day of the exam week. The prototyping module, introduced in Week 8, being the only self-paced module that did not offer a skill that was related to the subject assessments, showed interest peaking in Week 12, implying that these students believed their project assessments were under control and had the flexibility to try something different. Approximately 9% of students managed to complete their general modules before Week 5 when the overall subject workload was not yet too demanding and the subtle spike in submissions observed during the mid-semester break week saw about 8.6% of students use this period to complete a module.

Student feedback showed that students found the general modules' materials and skills useful when applied to team assessments within the subject, however they had difficulty justifying the application of the skills to another subject as the nature of assessments were different. It was encouraging that students were particularly positive about Padlet being an effective tool for information sharing that promotes peer-learning outside of their project team and class. This was especially significant as the online self-paced had no direct interactions with peers.

For the technical skills workshop sessions, it was more difficult to achieve a balanced level of satisfaction. Students appreciated the guided activities that introduced a particular technical area facilitated by a demonstrator when a topic was new to them. However, students who have prior knowledge or experience from their project were disappointed that the workshop activities to be too basic and they are not challenged. As this is the first time the skills modules are being offered, there was only one set of activities for each technical area, with limited coverage. Despite the challenges in bridging the gap between student expectations and actual experience, students agreed that the technical modules have provided them the knowledge and application of a relevant engineering skill.

5 CONCLUSION

The skills modules were instrumental components in the subject's project-based framework that offered flexibility in terms of choice and timing in a low-risk setting. With the first-time implementation of these modules, it was found that the majority of students did not complete more than the minimum requirement of modules and, for the technical modules, largely chose them according to the perceived relevance to their project area. This is not necessarily a failure in terms of the stated goals of the skills modules but could represent the fact that most students are largely decided on which discipline of engineering they would like to pursue and accordingly pick a project aligned with that discipline and completed the most closely aligned skills module. The suite of skills modules received overall favourable student feedback and will continue to be developed into the future, including providing students with better guidance around their utility and purpose.

ABSTRACT

In 1984, the film "The Terminator" predicted that a hostile Artificial Intelligence (AI) will threaten to extinguish humankind by 2029. Even though the real present is quite far from this post-apocalyptic scenario where AI rebels against its creator, a growing concern about the lack of ethical considerations in the use of AI is rapidly spreading, leading to the current "ethics crisis". The lack of clear regulations is even more alarming considering that AI is becoming an integral part of new educational platforms. This follows the wave of digital transformation mainly induced by the Fourth Industrial Revolution, with advances in digitalization strategies, and the COVID-19 crisis, which forced education institutions worldwide to switch to e-learning. The appeal of AI is its potential to answer the needs of both educators and learners. For example, it can provide help grading assignments, enable tutoring opportunities, develop smart content, personalize and ultimately boost on-line learning. Although the "AI revolution" has great potential to improve and boost digital education, there are no clear regulations in place to ensure an ethical and fair use of AI. Therefore, this work aims to provide a comprehensive overview of the current concerns regarding fairness, accountability, transparency and ethics in AI applied to education, with specific focus on virtual laboratories. The main aspects that this work aims to discuss, and provide possible suggestions for, are: (i) ethical concerns, fairness, bias, equity, and inclusion; (ii) data transparency and digital rights, including data availability, collection, and protection; and, (iii) collaborative approach between disciplines.

1 INTRODUCTION

1.1 Virtual Laboratories and the introduction of Artificial Intelligence

Recent years have seen an increased focus on sustainable development, which is defined by UNESCO as a *"development that meets the needs of the present without compromising the ability of future generations to meet their own needs"*[2]. One of the 17 core objectives presented in the SDG initiative is to improve the quality of education. Some of the proposed goals are to help countries in implementing innovative and context-appropriate solutions. This aims to provide education remotely, leveraging hi-tech, low-tech, and no-tech approaches, as well as to seek equitable solutions and universal access. In these times of educational disruption[3], where, according to UNESCO, never before have so many students been out of school, drastic changes in education have been accelerated, resulting in significant advances in adopting digitalization strategies [1, 2]. In this scenario, virtual laboratories (VL) offer a solution to provide inclusive learning opportunities [1].

[2] UNESCO Sustainable Development Goals, https://www.un.org/sustainabledevelopment/education/ (accessed April 29, 2022).

[3] The United Nations Educational, S. and C. O. COVID-19 Impact on Education (UNESCO) The United Nations Educational, Scientific and Cultural Organization, https://unesdoc.unesco.org/ark:/48223/pf0000380398 (accessed April 29, 2022).

In the field of Chemical and Biochemical Engineering, for example, educational process computer-aided tools are becoming widespread and are proving their relevance. Simulators, such as ASPEN Hysys[4] or SuperPro[5], were already fundamental tools in the teaching of Process Systems Engineering (PSE), but recent events have contributed to expanding their application.

Differentiated and individualized learning has been a priority for educators across domains for years [3]. Educators are also aware that one of the most effective ways of learning is to receive immediate and continuous feedback [4, 5]. This prevents small errors and misunderstandings from propagating. Educational tools, thanks to the recent advances in AI methods, are trying to replicate the same process. This is done by using algorithms to understand the level and preparation of the students and adapting the learnings and exercises accordingly [6]. It follows that Artificial intelligence (AI) is becoming an integral part of new educational platforms, since AI has the potential to answer the needs of both educators and learners by providing help in grading the assignments, enabling tutoring opportunities, developing smart content, or/and personalizing the learning. For example, Lu et al. (2021) introduced RadarMath [6], an intelligent tutoring system to support intelligent and personalized learning for math education. Another solution is provided by Carnegie Learning, developing 'Mika'[6], a tool that uses cognitive science and AI methods to create personalized lesson plans and tutoring that adjusts based on student's performance, and it also provides real-time feedback [7].

1.2 Ethical concerns

As reported in the EU guidelines on ethics in artificial intelligence document[7], the core principle of the EU guidelines is that the EU must develop a 'human-centric' approach to AI that is respectful of European values and principles.

> *"The human-centric approach to AI strives to ensure that human values are central to the way in which AI systems are developed, deployed, used and monitored, by ensuring respect for fundamental rights, including those set out in the Treaties of the European Union and Charter of Fundamental Rights of the European Union, all of which are united by reference to a common foundation rooted in respect for human dignity, in which the human being enjoys a unique and inalienable moral status."*

Studies [8] researching the awareness of ethical issues in e-learning systems focus on how to prevent students from behaving unethically (e.g., copying assignments from their classmates) or assessing their knowledge of what ethical behavior is. Preventing

[7] EU guidelines on ethics in artificial intelligence: Context and implementation (2019). https://www.europarl.europa.eu/RegData/etudes/BRIE/2019/640163/EPRS_BRI(2019)640163_EN.pdf (accessed April 29, 2022).

this kind of behavior is imperative and should not be overlooked in designing an educational on-line tool, since these platforms might be used for grading assignments; therefore, preventing unethical behavior from the students' perspective is a very crucial issue. However, this work aims to focus on safeguarding students and their digital rights through the investigation of ethical behavior in virtual laboratories.

The focus on ethics and fairness in Artificial Intelligence (AI) has gained traction in recent years, as demonstrated by the establishment of various Conferences focusing on ethics in AI. Among those, the ACM Conference on Fairness, Accountability, and Transparency (ACM FAccT)[8] had its first event dating back to 2018, and the AAAI/ACM Conference on Artificial Intelligence, Ethics and Society[9] will have its fifth edition in 2022.

This recent trend sprang due to the fact that, although AI has proved to be beneficial in many aspects, standing out for the accuracy of predictions and the ability to solve complex problems, it can pose risks to the right of personal data protection and privacy, as well as discrimination, as highlighted by EU guidelines on ethics in artificial intelligence document[10], published in 2019. The EU ethics guidelines provide a good overview of the possible ethical concerns surrounding AI and the principles that should be followed to ensure its ethical applications. On the other hand, these guidelines are non-binding, although concerns over the lack of regulatory oversight to support their implementation have been raised.

On 24 November 2021, the Recommendation on the Ethics of Artificial Intelligence[11] was adopted by UNESCO's General Conference. This work builds on the preliminary study on the ethics of artificial intelligence[12] of UNESCO's World Commission on the Ethics of Scientific Knowledge and Technology (COMEST)[13]. This study emphasizes that currently, no global instrument covers all the fields that guide the development and application of AI in a human-centered approach.

We believe that assessing possible ethical issues regarding how data is collected, stored, and used in modelling when designing a virtual environment is fundamental. Data is currently considered a very valuable resource, which could provide extensive knowledge about a person's habits, preferences, and skills, and could therefore be used, if not regulated, for economic gains outside its primary scope. Therefore, this study aims to build on the current knowledge on ethical applications of AI in

educational platforms and provide cause for reflection on the multiple possible ethical concerns that introducing data-driven solutions to a virtual laboratory might raise. Our objective is that, by highlighting these aspects, more researchers and practitioners working on Engineering Education might contribute with other reflections and resources in the future, to ensure a more ethical and safe virtual experience for learners, where every aspect of the "digital contract" is transparent.

2 BACKGROUND

This work aims to assess the impact that introducing AI can have on Virtual laboratories from an ethical perspective. In order to do that, we focus on the following clusters of aspects to ensure ethical and fair treatment of data: (i) fairness and bias; (ii) equity and inclusion; (iii) data transparency and digital rights; and (iv) collaborative approach between disciplines.

2.1 Fairness and bias

Fairness in AI refers to the attempt to correct algorithm bias in algorithmic decision making models. These models, if trained on biased data, can fail in a multitude of scenarios. This problem is particularly relevant when the outcome can affect people's lives, leading to cases of sexual hiring, racial bias in the justice system, face recognition issues, predicting car robberies, used by the police in Belgium, or profiling unemployed people, as used in Poland[14].

Virtual Laboratories should refrain from using biased data for their predictions and employ effort and resources in investigating this problem.

We provide a possible scenario to clarify this concept. Assume that we created an on-line platform to teach bioprocesses to students. The platform contains a section where the students can practice their knowledge through practical exercises that become increasingly more difficult. The recommendation of exercises is powered by a data-driven model. All students start with a few default exercises, necessary to assess their preparation and confidence. Afterward, the model needs to predict the appropriate exercises to recommend to the students. These exercises have a dual objective: to maximize both their learning curve and engagement, since if the exercises recommended are too easy, the students might get bored and not visit the platform anymore. In order to maximize the likelihood of recommending the most appropriate exercise, we train the model on personal information about the learners, such as gender (which, per se, already entails problematic assumptions), age, education, and country of origin. Furthermore, let's assume that the platform is relatively new and therefore we do not have much data, but from the few examples we gathered, it seems that learners that selected "male" as their gender, perform worse than others. If we

[14] EU guidelines on ethics in artificial intelligence: Context and implementation (2019). https://www.europarl.europa.eu/RegData/etudes/BRIE/2019/640163/EPRS_BRI(2019)640163_EN.pdf (accessed April 29, 2022).

feed this information to train the model, the model will be biased and will learn that new students that selected “male” as their gender, would be less trained on the material, and therefore should be recommended easier exercises.

This example shows that it is very important to assess the fairness of the data available before using it to make predictions, which will be inherently biased otherwise. Multiple metrics have been proposed to assess a model’s fairness, distinguished into procedural fairness, which focuses on the decision process, outcome fairness, a consequential approach focusing on the end result, and dynamic fairness, i.e., integrating formal fairness metrics with ethical principles.

2.2 Equity and inclusion

A well-designed VL should enhance culturally inclusive learning [9]. When designing a virtual laboratory, it is important to reflect on how inclusive the content is. If a VL is accessible worldwide, the cultural diversity of the users should be taken into account. For example, some common sayings or metaphors might be difficult to understand or offend the users’ sensibility.

Moreover, a good e-learning platform should account for individual learners’ differences and cater to their learning abilities. This could become an issue of inclusion since it would be unjust to either make the material more accessible for slower learning students or too challenging to benefit the quickest ones.

2.3 Data transparency and digital rights

Before collecting and storing data in virtual applications, it is essential to establish a clear scope and purpose for data collection and analysis. Virtual laboratories should aim to create a feeling of trust in the user, by being clear and transparent on the nature and extent of the data gathered, and what kind and how much of their data is being stored and used [9]. The data collection needs to follow the Principles of GDPR[15]. Moreover, users should be ensured that their data is secure and there will be no breaches in computer ethics. This is particularly important since it often happens that websites are hacked and data accessed. Therefore, gaining the students’ formal consent on how the data is stored and used is very important.

This “transparency contract” also covers AI applications. The user should be informed about what data is fed into data-driven models to improve their experience on the platform and they should have power over their preferences, such as deciding whether to stop allowing their personal data to be used for training models.

[15] General Data Protection Regulation GDPR. https://gdpr-info.eu/pdf (accessed April 29, 2022).

2.4 Collaborative approach

We believe that engineers working on the design and implementation of virtual laboratories should be acquainted with ethical principles and that ethics should be taught in computer science degrees. However, since these issues with ethics would likely require the cooperation of stakeholders of varying expertise in business, law and other disciplines, regulations must be established and enforced at a higher level [10]. The ethics crisis does not only affect engineers and, therefore, should not be solved only by technical people but as a collaborative effort among different disciplines.

As argued by [10], solutions and guidelines to address the ethics crisis cannot be siloed, i.e., each discipline working on a solution without taking into account the point of view of others. This can be exemplified by analyzing the lack of joint outputs and cross-citations among different fields, for example, between articles in computer science journals and articles in the humanistic social science field. Echoing [10], we argue that the best way to address this issue, which should be perceived as a transversal problem that involves theories and methods across several disciplines, is through a collaborative effort between disciplines.

In summary, this study aims to address ethical concerns due to the introduction of AI in virtual laboratories. We aim to build on established knowledge and inspire researchers to contribute to the discussion. In our analysis, we focus on different aspects, such as the evaluation of fairness and bias, equity and inclusion, the necessity for data transparency and privacy protection, and the need for a collaborative effort across different disciplines to establish clear regulations.

3 RECOMMENDED FRAMEWORK AND FUTURE DIRECTIONS

We recommend following these four checkmarks in order to assess the ethical application of AI to virtual laboratories: (i) clarify scope and purpose; (ii) ensure transparency; (iii) protect users' privacy; (iv) help students – the ultimate goal.

(i) Defining a clear scope and purpose for data collection and analysis allows for setting ethical boundaries. Before starting to collect users' data, it is important to be clear on the scope and purpose of the collected data. It is important to reflect on whether all the data points collected are necessary, and establish a plan for exactly how the data will be used. If the scope changes, a new assessment will be necessary.

(ii) Once the data is collected and safely stored, it is important to assess its quality and fairness, before using it to train data-driven models. Assessment of fairness can be performed through various fairness metrics, defined as formal criteria to score fairness. This will build control into the design of the implemented algorithms. Establish guidelines on how to assess whether the data contains bias and remove the biased content from the data. Also, investigate the transparency and understanding of the algorithm: what the prediction is based on, the features that lead the model to that specific prediction, and consider probing the model to understand what the model knows about the user. Moreover, consider the whole process in a holistic way, rather than analyzing small pieces of the process as a silo.

(iii) Regarding transparency and consent, learners should be aware of how and why their data is being collected and used. This process should be clearly described and shared with the users. Consent must be established before data is collected. Also, consider and clearly communicate whether the students can decide to revise their selected preferences on data sharing at a later stage.

In order to protect the students' personal data, access to the data should be restricted to only the necessary fields, and not all stakeholders working on the VL need access to all data. For example, access to credit card information, passwords, and similar field should be restricted. The available information should also be assessed carefully when selecting the parameters to be used in training a data-driven model.

Finally, we aim to highlight that educational platforms should have the purpose to help students. The ultimate goal of a virtual laboratory is to help people learn, so the solutions implemented should be directed towards this goal. We also argue that platforms should provide the possibility for students to freely share their ethical concerns, ask questions, and in return receive transparent elucidations on their requests.

4 SUMMARY

This study aims to address possible ethical concerns arising from the introduction of Artificial Intelligence in virtual laboratories. Building on established knowledge and regulations, we provide a checklist of aspects to consider when evaluating how to ethically incorporate AI models into an on-line educational platform. Specifically, we focus on fairness and bias, equity and inclusion, the necessity for data transparency, and privacy protection. Moreover, we address the need for a collaborative effort across different disciplines in establishing clear regulations, with the final goal of safeguarding students and their digital rights.

Our objective is to spur researchers and practitioners working on Engineering Education to contribute with reflections and resources to ensure a more ethical and safe virtual experience for learners, where every aspect of the "digital contract" is transparent.

ABSTRACT

HEDY - Life in the AI era is a 2-year Erasmus+ project started in November 2021 targeting higher education audience. Its goal is to offer a comprehensive and shared view of how Artificial Intelligence (AI) is affecting our lives and reshaping our socioeconomic, cultural, and human environments and to define which topics related to AI are of interest to different university studies and how they should be addressed.

Four specific free and accessible sources of information will be produced to reach these goals, the first of which is the Booklet, the subject of this paper. The Booklet is an essay defining the HEDY position on life in the AI era and its aim is to identify the challenges, opportunities and expected impact of AI on four different areas: business, governance, skills & competencies, and people & lifestyle. In this paper, we summarise the content of the Booklet. In particular, we describe our methodology to build our rationales based on collecting information from two sources: i) Literature survey, and ii) Focus groups. These two sources provide a unique contribution on AI panorama by combining state of the art research with first-hand opinions and debated questions, concerns, and ideas of interacting individuals. The main finding is that there is the necessity to train citizens in AI by providing teachings, courses and trainings in schools and higher education institutes to facilitate the use and adoption of AI for young people and future generations.

1 INTRODUCTION

The digital is invading our world, with technology being used in all dimensions of life, from education to work, health or governance. Knowledge and skills development is now a lifelong process, demanding growing digital literacy. Assuming that AI will transform the labour market, it is relevant to imagine the education system in a world where work is not a central factor in life or where jobs, as we knew them, do not exist. What would be the role of education? How could we organize it? What would be its aims and what needs would it address? How do we ensure that every citizen develops the necessary skills to remain included in an increasingly digital society? And how achieving fairness rather than amplifying inequalities?

This is the leitmotiv of HEDY – Life in the AI era [1], which is a 2-year Erasmus+ project started in November 2021. HEDY project stands for being a *free and accessible source of information* regarding the AI. The purpose is to provide teaching and course materials to incorporate the possible positive future applications, the challenges, the opportunities, and the possible impact of AI into university studies. Four specific results will be produced, being the Booklet the first of them.

The scope of the Booklet is to organise the AI features, identify challenges, opportunities, risks associated with certain uses, and expected impacts on different ambits of our society. At the time of writing this paper, we have delivered the first version of the Booklet for internal and external review. We consider therefore appropriate to present a summary of the content of the Booklet in this work.

The rest of the paper is organised as follow. In Section 2, we describe the objectives of the HEDY project as well as more details about the Booklet. In Section 3, we present the methodology we adopted to build our rationales. Section 4 discusses the main findings and highlights the key ideas. Section 5 concludes the paper.

2 THE HEDY PROJECT AND THE BOOKLET

HEDY – Life in the AI era provides tribute, in its own title, to Hedy Lamarr [2], an Austrian actress and inventor (1914-2000), co-creator of wireless communications technology and currently still used in mobile networks, Bluetooth devices and Wi-Fi. HEDY's goal is to offer a comprehensive and shared view of how AI is affecting our lives and reshaping our socioeconomic, cultural, and human environments by promoting critical reflection, self-based learning and debate on these issues. The main (but not exclusive) target group of this project is higher education audience.

Four specific objectives will be produced to reach this goal:

1) A **Booklet** – an essay defining the HEDY position on life in the AI era and the rationales for that position;
2) A **Toolkit** – a collection of influential AI audio-visual related tools, including films and expert talks with the ability to have a more immediate impact to the audience;
3) A **Massive Open Online Course** (MOOC) – a course to spread out the awareness of main developments in AI and promote extensive knowledge, critical reflection and debate on AI and its key impact on society;
4) A **Guideline** – a concise and easy-to-read documentation for the best use of the assets produced and for the creation of a solid foundation to ensure the usability of the HEDY results by a wider community of practice network.

The Booklet is the subject of this project. As stated above, its scope is to identify the challenges and the risks associated with the use of AI and the expected impacts on four different ambits of our society: **business**, **governance**, **skills & competences**, and **people & lifestyle**. Besides describing the current applications and expected impacts of AI for each ambit, we also aim at identifying the 5/6 more concerning issues about AI. Nonetheless, we are not trying to provide general solutions of these concerns; on the contrary the idea is to offer an engaging way to stimulate reflection and debate on knowledge society topics, discuss the ethical effects of these emerging digital technologies and provide paradigmatic examples.

Currently, the first version of the Booklet is under the internal review process. After that, the Booklet will be presented in a so-called Multiplier Event to a group of at least 40 selected participants. During this event, the Booklet will go through the external review process. After implementing the feedbacks received from both processes, the Booklet will be published in the project website [1]. It will be freely accessible and available in 7 different languages: English, Portuguese, Bulgarian, German, Spanish, Catalan and Hungarian. The expected publication date is July 31th, 2022.

3 METHODOLOGY

3.1 Introduction

We collected information from two different sources to build our rationales: 1) Literature survey, and 2) Focus groups. Clearly, the first source consisted of collecting the current state of knowledge about the applications and impacts of AI. The second source consisted of gathering information by interviewing people through focus groups with expert and non-experts in AI in 5 different European countries. Due to the space limit, here we can provide only a summary of our methodology while all details will be added in the extended version of the Booklet soon available in the project website [1].

3.2 Literature survey

Our first source of information came from the available literature on AI in general and on the four ambits described above in particular. The aim was to acquire an in-depth grasp of the subject and to understand current knowledge. This allowed us to: i) identify relevant theories, methods, and opinions in the existing state of the art and report them in the Booklet; and ii) organise and guide the participants through the focus groups with these bases already learned so to obtain the complementary information we needed.

Hence, we searched, read and evaluated more than 250 documents, between research papers, magazine articles, expert blogs, companies' reports, agencies' guidelines, etc. to get the proper knowledge on the challenges and opportunities of AI and the current applications and expected impacts in both short and long terms.

3.3 Focus groups

During February 2022, we prepared and conducted two different focus groups in each of the project partners' countries: one focus group with only experts in AI and one focus group with only non-experts in AI. The project defines the term *expert* as a person with a university degree, working for at least 5 years in the area of AI, digital society, human-robotic interaction or Industry 4.0, and at least 3 published scientific or professional articles. The number of participants for each group was set to a minimum of 5. In one case, the focus group was not possible to be organised due to conflicting schedules/COVID restriction; we substituted the focus group for a questionnaire. The questionnaire was created with similar questions used in the focus group. In summary, nine focus groups and one questionnaire were organised and the results analysed following the directives available in [3]. More details are listed below:

1) Two focus groups in Budapest (Hungary) about AI challenges and opportunities
    - 8 experts (7 males, 1 female) aged 28-61 years old;
    - 5 non-experts (2 males, 3 females), aged 20-28 years old, university students enrolled in a Master's degree
2) Two focus groups in Münster (Germany) about AI in business
    - 7 experts (7 males) aged 26-50 years old;
    - 7 non-experts (3 males, 4 females), aged 22-30 years old, university students enrolled in a Master's degree
3) Two focus groups in Barcelona (Spain) about AI in governance
    - 9 experts (7 males, 2 females) aged 35-70 years;
    - 10 non-experts (7 males, 3 females), aged 22-70 years old, from civil society with no previous knowledge on AI.
4) Mixed approach in Lisbon (Portugal) about AI in skills & competencies
    - 9 experts (6 males, 3 females) aged 26-67 through an online questionnaire;
    - 5 non-experts (3 males, 2 females) aged 23-55 master students or recent graduates through a focus group.
5) Two focus groups in Varna (Bulgaria) about AI in people & lifestyle
    - 6 experts (4 males, 2 females) aged 29-59 years;

- 15 non-experts (4 males, 11 females), aged 20-24 years old, students enrolled in a university degree.

4 DISCUSSION

AI came to stay in our daily lives. This is an obvious conclusion and we need to deal with it. So, how can we do that? In this paper we have reviewed many literature sources and talked directly with experts and non-experts in AI to have a better understanding of the problem, the concerns, and the opportunities AI can bring to the humanity and its impacts to our society. In this section, rather than presenting the literature survey and focus groups results separately, we prefer to discuss them together. In this way, we can reflect and contrast people's (both experts and non-experts) first-hand opinions with state-of-the-art research and vice versa. Thus, we are now able to provide a set of key ideas.

There is a clear indication that AI is conceived in two different ways:

a) **Restrictive view**: AI as one more technology and therefore needs to be treated like any other technology.

An expert said: *"AI is technology and a technology is not for everything, it is for what it is".*

b) **Disruptive view**: AI as a differential technology, which marks a before and after in human society and the relationship with technologies.

An expert said *"It simply came to stay. He has come to change society and, moreover, we will not be able to go back".*

These two ways of conceiving AI appear alternately throughout our two-fold sources. While seemingly restrictive and disruptive views may be understood as contradictory, they are in fact complementary views that make it possible to grasp the complexity of opinions, concerns and proposals around the use of AI systems.

From a restrictive point of view, AI tends to be seen as a chance: it can create new, very qualify and remunerated jobs, open new market and business opportunities, make life easier and heathy, the bureaucracy faster, etc. [4][5]. The common idea is that AI is useful in decision-making processes [6]. The challenges that may be raised by these processes are considered restricted and possibly overcome by drawing a clear border between when AI may be employed and when it cannot. In this sense, AI is thought to be particularly effective for data management and analysis, as well as information assistance for decision making and assessment, but not for automated decision making [7]. In this sense, it is thought that decisions that have a direct impact on people must be decided by people.

An expert said: *"In the end they are algorithms and we should not let them decide for us".*

In contrast, from a disruptive view of AI, the argument is that in contemporary societies any area already integrates or will integrate soon AI. It is thought that, while we do not want AI to participate in many aspects of our daily lives, it is vital to analyse the costs and benefits, based on assessing what would happen if AI systems made incorrect decisions [8]. This may affect several areas of our environment and is in these specific areas that the risks of using AI systems need to be assessed. The justice, the people's privacy (i.e., freedom), the algorithms themselves (aka, the bias of the data), the biomedicine, the finance are only few examples of the areas identified [9].

A shared concern, which is mostly associated with a restrictive view of AI, and which appears both explicitly and implicitly throughout all sources, has to do with the relationship of AI systems with science fiction imaginaries or with the idea that AI can solve all problems of any kind.

> An expert said: *"I think I know the difference between science and fantasy, but it is the interaction between these two fields that has led to the development of both".*

> A non-expert said*: "It is important to see and read how science fiction artists think, and be inspired to develop real-world solutions supported by AI to help humanity evolve".*

Numerous applications have been developed in the field of AI and can be applied in many fields [5], but there is a significant gap between current functionalities and technical capabilities and the narrative of what AI could do in the future [10]. This type of narrative around AI, which does not correspond to current developments, is considered to have two types of negative effects: i) The difficulty of articulating a proven public debate on accountability when using forms of AI in decision-making processes; ii) The emergence of a series of catastrophic imaginaries that generate reluctance towards AI between public opinion and citizens [11].

Regarding the specific ambits analysed, we can summarise that:

- In **business**: AI is seen as a great potential especially when it comes to saving time, facilitating tasks and bringing innovative solutions, especially in field such as medicine, biomedicine and finance. Risk is related to finding a balance between the economic interests of companies and the non-violation of citizens' rights in matters related to privacy and individual freedom [12].
- In **governance**: there is a global agreement on a fundamental set of five AI principles that are functionally algorithm-agnostic, technology-agnostic and sector-agnostic to provide a trade-off between company's strategies and objectives, legal requirements, and ethics: accountability, transparency, fairness, safety, and human control [13].
- In **skills & competences**: the need for physical, basic cognitive and manual skills will be reduced due to the taking over through AI while digital competencies, critical thinking, teamwork, communication, technological as well as social and emotional skills will be more demanded. Education systems' priorities need a shift to reflect this to better develop students' abilities. Major risk is related to "less developed" countries which are in danger of being left behind even more [14].
- In **people & lifestyle**: AI should contribute to make person's life more productive, efficient, secure and easier. We may have personalised monitoring and diagnostic

capabilities, an increased free time, the possibility to develop our natural interests and talents, a better and faster infrastructure, etc. Major risk is related to the fact that AI can be biased and perpetuate or even increase the gender, racial, and ethnic disparity and inequity [15].

It is worth to mentioning also one of the most important topics not addressed in our survey and focus groups. That is the impact of AI to our environment and how it can help with the current crisis due to the climate change. On the one hand, AI is a major energy consumer given the complexity of training and inferencing on big data, above the fact that all ICT ecosystem is already one of the major contributors to greenhouse gas emissions [16]. On the other hand, AI has also been presented as the solution of the climate change due to its multipurpose capabilities, which include tracking and cutting emissions, allowing creative economic models to aid the environment, and enhancing climate resilience. For instance, a study commissioned by Microsoft [17] concluded that using AI for environmental applications has the potential to boost global GDP by 3.1 – 4.4% while also reducing global GHG emissions by around 1.5 – 4.0% by 2030 relative in business, up to 2.2% in energy and up to 1.7% in transport.

Many considers that human social and intellectual capacities like creativity, empathy, innovation, teamwork, etc. are irreplaceable by AI (see for instance [18]). In short term, the vision is that we will face the emerge of more artists as a response to the lack of those works replaced by an AI. Nonetheless, this vision seems too optimistic: AI is already able to compose symphonies, paint pictures, write poems, songs, and stories as well as play games. Some countries like Australia already accepted that an AI machine can be registered as an inventor in a patent. In the future, it is likely that these capabilities will be even more explored.

Finally, a common opinion is also that AI should not replace human capability and human freedom to make decisions should be prevented from being influence by AI-driven tools.

> A non-expert said: *“I only believe in AI when it gives the same result as human intelligence”.*

In particular, ethics is a recurrent problem raised in all our sources. Even the experts we have interviewed consider that they do not have enough knowledge to be able to decide on ethical and social issues, a knowledge that should be integrated in an interdisciplinary way.

> A non-expert said: *“An investigation to recognize a person from the iris was funded through tax haven funds, to identify women with burkas and whether or not they were with their husbands. I was very surprised […]. How to do it? Getting here, yes? Getting here, right? What’s the limit?”.*

In order to avoid this type of narrative and its negative effects, actions related to information and citizen participation are needed:

- **Information**: Ensuring that the media reports ethically and honestly when talking about AI systems, which allows for a clear distinction between speculative futuristic visions and current developments and possibilities. Develop a pedagogical task that allows the public to know how AI works and what applications are being developed.

- **Participation**: Involve the public in the establishment of priorities for the development of AI, in the service of needs. This is considered to be the added value of the European AI development strategy, compared to other strategies that may be more technologically advanced or in terms of implementation, such as China or the United States. It is considered that the European strategy can incorporate as an added value to its AI the integration of citizens in the establishment of priority areas in which to develop or apply it.

5 SUMMARY AND ACKNOWLEDGMENTS

In conclusion, AI is a technology that in its design and development is so far removed from everyday life that experts believe that the population is not trained enough to make decisions about how to use AI. Although, at the same time, it is considered necessary for citizens to make decisions and decide on the course of AI. For this reason, we point out the necessity to train citizens in the operation, potential and possible effects of AI. We need therefore to provide teachings, courses and trainings in schools and higher education institutes to facilitate the use and adoption of AI for young people and future generations. This is indeed the main goal of the HEDY project. Throughout the next two years, in addition to the Booklet, HEDY will provide a MOOC with exactly the aim of reaching higher education audience and show them the capability of AI, the opportunity our society has in this moment to change our environment to a better one but also the risks we are facing from different point of views. This material will be complemented with the Rootkit: a set of supporting multimedia tools with the ability to have a more immediate and visual impact to the audience. The final contribution will be an easy-to read Guideline to ensure the usability and sustainability of the HEDY results, and promote a wide and solid community of practice network.

Finally, it is worth mentioning the limitations of our analysis. On the one hand, it is a qualitative analysis therefore general conclusions are more difficult to elaborate compared to a quantitative one. On the other hand, there is the limitation of the heterogeneity of the focus groups since most of the experts were academics and the non-experts were students. However, our two-fold approach allows us to contrast people's opinions with the available literature and vice versa, so we believe our findings are valuable and other similar work is likely to reach the same conclusions.

We would like to thank all members of the HEDY project and all people who have generously and openly participated in our activities.

This work has been co-funded by the Erasmus+ programme of the European Union (HEDY project KA220-HED 0C8D3623) and by the Spanish Ministry of Science and Innovation (TRAINER project PID2020-118011GB-C21).

Keywords: *Programming, Sustainability, Carbon footprint, SDG, Automatic Evaluation.*

ABSTRACT

Computer programming is an essential skill for today's engineers, and sustainability plays a role of growing interest in any of the design phases of an engineering project. The fundamentals of sustainability, with basic concepts such as "carbon intensity", must be covered in any engineering curriculum.

We propose a basic computer programming course in which the lab sessions incorporate exercises related to the computation of environmental impacts. For instance, an exercise might request the computation of the carbon footprint of the lab

doi:10.5821/conference-9788412322262.1261

sessions during a whole year. Lab sessions use an automatic evaluation server, so called Jutge.org that assesses about the correctness of the programs submitted by the students. New exercises concerning sustainability topics are included in the Jutge.org course.

The course involves the effort of a multidisciplinary team. First, lecturers on basic programming are required. An expert on automatic evaluation of computer programs is essential to prepare the statements and the test sets of the proposed exercises. Finally, the advice of economists and sustainability experts is crucial to guarantee judicious conclusions are drawn from each exercise. Forming a team with this profile is a challenging task.

Our Computer Science (CS) department lectures basic programming courses to more than 1700 students/year. The success of this approach could bring a substantial social impact in our ecosystem.

---

1 TEACHING PROGRAMMING AND SUSTAINABILITY

Sustainability principles are playing an increasingly important role in our society.

Nowadays, the environmental impact of any major business, social or policy initiative is always examined. In the task of promoting sustainable behaviours, universities must play a prominent role and teaching sustainable development must be part of the curricula. For students motivated in the subject, books on sustainability like Bill Gates' [1] or William Nordhaus' [2, 3] can be recommended.

Basic programming courses are common in science and engineering majors. Introducing fundamental concepts of sustainability in programming assignments is a way of disseminating this knowledge to many students. While keeping traditional learning goals, we propose a first computer-programming course that considers, besides standard lab exercises, assignments concerning the computation of environmental costs.

This approach is close to the one described in [4], where the pedagogical results of a programming course that introduces a list of sustainability-themed assignments are reported. The novelty of our course is to integrate this type of assignments in an automatic evaluation server, so called Jutge.org [5], which assesses about the correctness of submitted programs.

The exercise statements in Jutge.org have to be short, clear and self-contained. More importantly, they also need to be easily understandable without prior knowledge on sustainability. New sustainability lab exercises need to be carefully designed, involving the effort of a multidisciplinary team. First, lecturers on basic programming are essential to assess the suitability and understandability of the new proposals. Second, a Jutge.org expert is required to incorporate the new exercises and test cases to the evaluation platform. Third, experts on ecology, sustainability and economics are required. A multidisciplinary team with combined expertise contributes to design meaningful assignments with convincing outcomes. Our CS department lectures basic programming courses to more than 1700 students/year. In the long run, the approach we propose can have a significant impact on the environmental awareness of students.

2 THE JUTGE.ORG APPROACH

For fifteen years, our CS department is using Jutge.org [5], an automatic evaluation platform, in several programming courses. Jutge.org has an extraordinary amount of exercises organized in lists and courses. Each programming exercise consists of a statement and several test cases. Public tests shown in the problem statement improve global readability and help students to find a correct solution. Additional private tests, not visible to the user, are included to evaluate the submitted programs.

From our experience, we think Jutge.org provides an invaluable help to student progress. The immediate feedback about submissions allows student self-learning at any time and place. During lab sessions, instructors can focus on aspects Jutge.org cannot assess, like program readability, coding style, and basic principles of algorithm efficiency. Beyond immediate feedback, the use of the evaluation platform is a way to develop an active learning approach.

3 BASIC PROGRAMMING COURSES

Courses taught by the department consider specific School circumstances, but lab sessions are always an unavoidable course part.

3.1 At Computer Science School

The first programming course is a very basic course. As a typed approach is considered, C++ is used. Sequential decomposition and case analysis are first introduced. After that, item sequences are considered to deal with loops. Emphasis is placed on sequential treatment schemes: treat-all and searching. Later, procedures and functions are shown. Vectors and Tuples (Structs) are also taught. No more data structures are introduced.

The schedule is 2 hours/week of theory lectures on fundamental programming concepts and 3 hours/week guided lab.

3.2 At Engineering School

As the introductory course will be the only general programming course for most students, more programming features are taught but in a less depth way. Python is the programming language and lists and dictionaries are the main data structures. The schedule is 2 hours/week of theory lectures on fundamental programming concepts and 2 hours/week guided lab.

3.3 School influence on jutge.org courses

Specific School requirements translate to specific Jutge.org exercises. This should be considered when we deal with sustainability topics.

4 SUSTAINABILITY CONTENT IN PROGRAMMING EXERCISES

A computer program processes a data set to obtain new results. Two crucial points when proposing a new exercise are to provide right input data and to formalize, unambiguously, the questions the program has to answer. Regarding these points, a number of issues arise when writing new exercises with sustainability content. Some of these difficulties are described below.

The main problem faced by the team is: programming exercises designers are not experts on sustainability. They follow suggestions about possible exercises of the team's experts; they ask questions and get answers. The dialog is fruitful, but it takes time, sometimes a lot of time. Following two aspects of such difficulties.

4.1 About input data

Lack of intuitive meaning of big numbers and data reliability are the main concerns about program input data.

Lack of intuitive meaning of numbers. *What does 51 gigatons of Co2 per year mean?* [1] That is $51 * 10^9$ tonsCo2/year. As Bill Gates points out, *this number means nothing intuitively for most of the people*. In order to get some insight, let us compute the ratio per capita. The world population is $7.93 * 10^9$. Therefore, the number of tons per capita is 51/7.93 = 6.43 tonsCo2/human. It seems that 6.43 tonsCo2/human looks both, more understandable and very impressive!

Data depends on the source. At https://www.worldometers.info/co2-emissions/ we found the ratio per capita 4.79 tonsCo2/human. At least it seems to be of the same order of magnitude. Another example, looking for the Co2 emitted by a query on the Web, we found 0.2 gCo2/query for a Google search (look at https://searchengineland.com/calculating-the-carbon-footprint-of-a-google-search-16105) but we also found 0.09 gCo2/query (look at https://www.altavia-group.com/en/green-web-needs-to-happen/). As 0.2/0.09 = 2.2, there is a degree of uncertainty about data.

Even working with uncertain data and unintuitive numbers, the topic is so important, that makes sense to introduce sustainability concepts in basic programming courses.

4.2 Issues working with rough numbers

Imagine that you would like to prepare a lab exercise on the number of trees needed to absorb the annual CO2 emissions. After asking an expert, you assume that one tree absorbs an annual average of 24 kgCo2. As a first idea, you will work with rough numbers. From Bill Gates book [1] you assume an annual emission of 51 billion tons Co2 = $51 * 10^{12}$ kgCo2/year.

From https://www.gotreequotes.com/how-many-trees-in-world/ we find that the number of trees in the world is $3.04 * 10^{12}$.

As $51 < 24 * 3.04$ you may conclude, that trees will absorb all Co2 emissions and thus, there is no problem. This reasoning is quite incomplete and shows a lack of knowledge about the carbon cycle. Computer scientists without expert's advice can make big mistakes. A way to avoid this type of mistakes consists on working with an interdisciplinary team. Having members with depth knowledge in ecology and sustainability is fundamental.

5 SUSTAINABILITY IS A HUMAN PROBLEM

As we are in an Engineering University, we are familiar with units like kgCo2/kWh.

It could be tempting to think that all sustainability problems can be solved through good engineering improvements. From our point of view this is a big mistake. Of course engineering is fundamental to improve the situation [1] but according to Nordhaus [2, 3], the problem is motivated by human society. Therefore we have to consider human aspects. Most relevant ones are described as global goals in the United Nations collection SDGs.

Sustainable Development Goals (SDG, https://sdg-tracker.org/*)* are a list of seventeen goals designed to be a plan for a better and sustainable future. A straightforward way to encode SDGs as a data structure is by a dictionary, a resource available in Python as basic structure:

dic_SDG = {"Goal 1": "End poverty in all its forms everywhere",

"Goal 2": "End hunger, achieve food security and improved nutrition and promote sustainable agriculture", … ,

"Goal 17": "Strengthen the means of implementation and revitalize the Global Partnership for Sustainable Development"}

Taking *dic_SDG* as data structure, we can design exercises to introduce SDG to our students. In Engineering Schools dictionaries appears in the program and there is no problem. As in CS school dictionaries are not in the basic course but we can develop exercises through the targets of the goals.

Do not forget economic aspects. The economic activity (figure 1 on pag 10 of [2] and figure 5 -1 of [3]) is at the core of the problem. Some exercises, need to face this. According to Brundtland Commission [6] a sustainable development "meets the needs of the present without compromising the ability of future generations to meet their own needs". We need to compare today consumption with tomorrow consumption. This implies to discount the future to valuate into the present. This is an old problem (chapter 11 of Keynes [7]). Having an economist in the team is also fundamental.

Biodiversity. Topics like biodiversity (chapter 11 on [2]) are even more challenging.

6 PROGRAMMING EXERCISES

6.1 On the mechanics of designing an exercise

It all started with a meeting between a CS member and a sustainability expert. This meeting was fundamental in two aspects. First, it provided to CS members team with a list of links to start working. Second, the expert strongly emphasized the need to give a concrete meaning to the big numbers. After that, the team start planning exercises for Jutge.org.

The development of exercises for the Jutge.org takes much more time than expected. Even if some of the CS members has an informal knowledge on sustainability [1, 2, 3]; this knowledge was too general to be transformed into exercises. They go through the links over and over, talk and talk with sustainability experts, reread the books and slowly tentative ideas for exercises appears. As Tony Hoare point out years ago over ambition was the problem for CS members. Following we give an example.

6.2 Example of Jutge.org Exercise: Co2 to Trees

Statement. Co2 is one of the most important greenhouse gases. Trees extract CO2 from the air and convert it into oxygen and plant material through photosynthesis. Browsing the web, we got the following data.

First, the annual average kWh_consumption, denoting the household energy consumption (due to electricity):

- France: 4760 kWh
- Germany: 3149 kWh
- Ireland: 4200 kWh
- Spain: 3487 kWh

Second, considering how electricity is produced we get different conversion_factors:

- France: 0.059 kgCo2/kWh
- Germany: 0.181 kgCo2/kWh
- Ireland: 0.292 kgCo2/kWh
- Spain: 0.209 kgCo2/kWh

Finally, from https://www.encon.be/en/calculation-co2-offsetting-trees let us assume that the average annual CO2 offsetting_rate is 24 kgCO2/tree.

For a given country, we ask to compute the number of trees by household needed to absorb the Co2 generated in a year. Write this number with 2 decimal places.

Input. The input is formed by a non-negative integer *n* followed by a sequence of *n* triples. Each triple consists on a country name (string), a household energy consumption (double) and a Co2 conversion factor (double).

Output. For each country in the input sequence, a line with the number of trees by household to offset its Co2 emissions. Follow the format in the example below.

Public test cases.

Input

```
4
France 4760 0.059
Germany 3149 0.181
Ireland 4200 0.292
Spain 3487 0.209
```

Output

```
France: 11.70
Germany: 23.75
Ireland: 51.10
Spain: 30.37
```

6.3 List of Programming Exercises.

Following the list of currently available exercises in the Jutge.org

a	Co2 emissions by activity
b	Co2 to Trees
c	Carbon intensity of electricity generation
d	Life expectancy
e	Income inequality
f	Carbon emission reduction

Most of the proposed exercises, a, b, c and f are related to the carbon emissions. The exercises d and e are inspired in SDGs. Currently some topics are missing on the list. Exercises based on economy are missing. Should appear exercises based on Carbon Tax or Green Premium. In addition, exercises that relates the present versus the future should appear. We could do that through the idea of present value. Some of the missing exercises are under construction. Others will need much more reflection and time.

7 POSSIBLE COURSE ORGANIZATIONS

Jutge.org offers facilities to create new courses and also to update the list of exercises on existing courses. This offers different possibilities.

7.1 First year programming course.

We plan to update the introductory programming courses of our Department with sustainability exercises. In fact, we start doing that. In the first Control, of CS students, it appears one exercise of the list. Doing that we expect to catch the feeling of the CS students about this kind of exercises.

7.2 Transversal first year sustainability course.

This is a very ambitious project because it is difficult in our University to offer new courses. This course should offer the possibilities to our students to get basic knowledge about sustainability. It should consider, both, engineering aspects but also human aspects. The course could be seen as a guide for self-study and active research. As basic readings along the course, we consider Bill Gates book [1] and or William Nordhaus book [3].

Several topics could be considered in this course with the corresponding links.

- *Co2 and trees:* Encon: from emissions to trees.

  https://www.encon.be/en/calculation-co2-offsetting-trees
- On ways to produce electricity.

  ourworldindata.org: primary energy versus consumed energy.

  https://ourworldindata.org/energy-substitution-method

  electricityMap: conversion of kWh into Co2.

  https://app.electricitymap.org/zone/ES?solar=false&remote=true&wind=false
- SDG

  https://sdg-tracker.org/
- Co2 and streaming videos.

  idea: carbon footprint of streaming videos.

  https://www.iea.org/commentaries/the-carbon-footprint-of-streaming-video-fact-checking-the-headlines

Programming possibilities: To have a guide on programming exercises you can take any one (or both) of the following choices:

- Jutge.org

  https://jutge.org/
- Jeffrey Stone projects: 9 topics each one with a self-contained video.

  https://sites.psu.edu/sustainabilitycis/active-projects-cpp/

8 SUMMARY AND ACKNOWLEDGMENTS

We have introduced our efforts to deal with sustainability in first-year programming courses.

J. Castro, J. Cortadella and J. Gabarró have been financed by: Proyecto PID2020-112581GB-C21 financed by MCIN/AEI/10.13039/501100011033.

E. Vidal has been supported by the Spanish Ministerio de Ciencia, Innovación y Universidades, the Spanish Agencia Estatal de Investigación (AEI), and the Fondo Europeo de Desarrollo Regional (FEDER), from study design to submission, under grant number RTI2018-094982-B-I00.

ABSTRACT

This article describes the outcomes of a completed study of practice in civil engineering education. The study is aimed at infusing Construction 4.0 content to a Bachelor degree on Civil Engineering. A set of STEAM-rich activities are created in the form of an individual learning path. These activities are conceived with a threefold perspective: i) Construction 4.0-related, ii) STEAM vision by-design and iii) hardware-software independent (open-source, accessible, affordable). Cornerstone and capstone projects as well as a set of workshops represent some demonstrators of these activities. All these demonstrators are knitted together in a single path in that is pegged to the traditional curriculum The STEAM perspective provides completeness to the whole development. During the last two years, design, development and implementation of several demonstrators have been completed. Some results related to the application of some activities are already available. In the years to come, it is expected that an improved systematic deployment of such activities will allow assessing the evolution between tools, pedagogies and the needs of the sector. In this paper, the description of the activities together with the discussion on the potential of tinkering on Construction 4.0-based curriculum is addressed.

1 INTRODUCTION

The process of digitization of the Architecture, Engineering and Construction (AEC) sector is relentless. In other sectors, this has represented a major change between players. AEC will certainly experience a significant disruption as well. The built environment sector is reaching maturity for leapfrogging to more efficient production, business models and overall, value chains. Both the natural as well as the built environments provide endless possibilities for digitization when it comes to linking physical assets and virtual models. A balanced path to digitization of a sector implies coordination between stakeholders. Academia where new generations of civil engineers are formed is called to be present and active in such scenario.

Technological advances in AEC are presently disrupting the sector. When applied in a coordinated and systematic way, these advances are much more powerful in efficiency. The coordination between the construction realm and its virtual counterpart is generating a framework in which a tripod of three themes can be identified

- Industrial production (prefabrication, digital fabrication, additive manufacturing, offsite manufacture and robotic assembly).
- Cyber-physical systems (autonomous systems, digital twins, smart infrastructure).
- Digital technologies (BIM, extended realities, interoperability, cloud computing, blockchain, AI, computer vision, etc.).

In AEC, proposals for infusing automation and robotics within the curricula have been discussed for some decades [1]. On the other hand, the adoption of BIM in civil engineering curricula is a matter of survey, debate and systematic scrutiny [2]. When it comes to cyber-physical systems in AEC classrooms, developments are also identified [3-4]. Within «de las MATES al STEAM », an educational project developed between 2019-2021 at the School of Civil Engineering at the Universitat Politècnica de Catalunya in Barcelona, Construction 4.0 and STEAM were put together. The initial conundrums at the onset of this development were : How prepared are existing civil engineering curricula for this disruption?. How is digital and automated fabrication being infused in AEC classrooms? Are AEC students prepared enough for understanding cyber-physical systems conceived for the natural or built environments ? What is the level of maturity of BIM-based curricula in AEC. An extensive academic literature review allowed identifying academic practices worldwide as well as gaps within curricula [5-8].

This paper shows the key takeaways of “de las MATES al STEAM”. The project resulted on the design of set of activities for embedding Construction 4.0 concepts within a civil engineering curriculum. The development of these activities was conceived by-design using a STEAM, tinkering perspective. Findings related to the attractiveness of this perspective in AEC students are also described. The activities are knitted together in the form of an individual learning path that reinforce concepts of traditional curricula in civil engineering with the use of Construction 4.0 open, accessible and affordable technologies.

2 LEARNING PATHS

Standard degrees are necessarily complemented with personal learning paths. This need is embedded into the DNA of intrinsically motivated learners. Civil Engineering Schools may or not have a vast array choice of optional courses. A complementary personal learning path is a learner-centered approach that emphasizes learner-specific goals and objectives, as well as preferences that a learner elects on their own. Students comprehend their personal learning pathways through several ways such as: (i) the identification of optional courses through preference of topics that are the most relevant to student’s current or future professional activity, (ii) use of accountable side-courses, workshops, capstones, hackathons or (iii) development of internships and academic exchanges.

3 LEARNING PATH IN THE PROJECT “DE LAS MATES AL STEAM”

The proposed learning path for the infusion of Construction 4.0 activities within a standard curriculum is illustrated in Fig. 1. By-design, the path is conceived for including the depicted tripod of themes of Construction 4.0 with a STEAM approach. Dissecting this illustration, one identifies several bullet points:

- In the 1st academic year, cornerstone projects related to coding are proposed. These projects are conceived for the sake of introduction to visual and geometrical programming, which are fundamental for subsequent developments. The programming content of the projects is also aligned with the actual syllabus of regular courses of Calculus, Algebra and Geometry. Pilot implementations within formal courses have already been taken place at the School in the last three years. The principal STEAM components of such projects are Maths (M) and Arts (A).
- In 2nd and 3rd year, the activities consist of a set of workshops. Different themes of Construction 4.0 such as Automation and Robotics, Digital Fabrication, BIM or IoT represent fertile topics for the generation of workshops

that can be updated year by year. The principal STEAM components of such projects are Science (S), Technology (T) and Engineering (E). These workshops are self-contained but if students are acquainted with the content of the cornerstone projects, their learning curve as well as their achievements are boosted. These workshops are conceived for 1 ECTS. If this credit needs to be recognized to the students by the system, the minimum number of hours of these activities with proper compeletion is 12.

- In 4th year, a capstone project allows closing the loop by integrating all (S)(T)(E)(A)(M) components in a single activity. Ideally, this represents a fertile ground for more ambitious projects with a multidisciplinary perspective. Its application may range between individual final project for the Bachelor degree to more multidisciplinary projects in which students from electronics, computer sciences and civil engineering may converge. The former option has already been experienced at the School whereas the latter requires more coordination between educational centers at University levels.

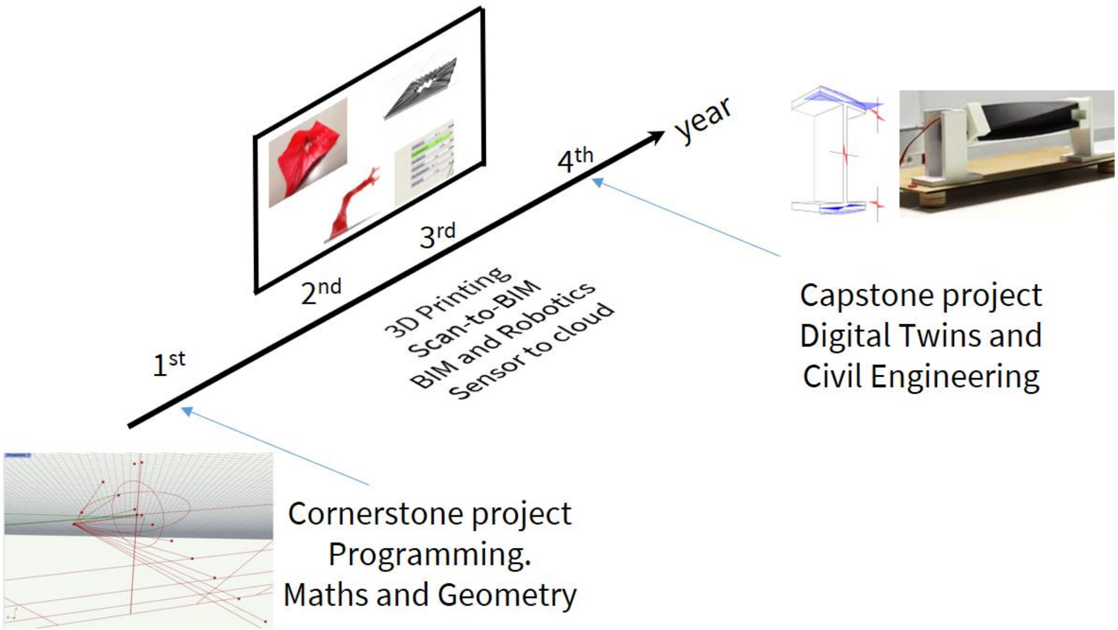

Fig. 1. Schematic view of the proposed set of activitis within the civil engineering timeline

4 LEVEL OF IMPLEMENTATION OF ACTIVITIES IN RECENT YEARS

In the last years, many of those activities have been implemented at both Bachelor and Master levels. In the following, a brief description of these implementations together with results obtained so far.

- Cornerstone projects: The cornerstone projects are established as activities related to Calculus and Computational Geometry for 1st year students. These activities are conceived for the sake of exposing our civil engineering students to the development of computational applications using basic concepts of mathematics and geometry. One of the already implemented projects (2020, 2021, 2022 editions) is related to the development of visual applications using functions and derivatives. An introductory programming challenge is optionally proposed to students. For different editions, students have or not received a reward on the total grade of the courses if the challenges is achieved. The application of the programming activity in the 1st Edition (2020) coincided with the global lock down and the participation peaked 98%. In subsequent years participation has lowered to 50%. Applied introductory programming are always useful and necessary for civil engineering students due to their uneven prior acquaintance with coding skills. The project is aimed at reinforcing concepts of differentiation throughout a hands-on coding activity. The formal Calculus syllabus (M) including derivatives is illustrated by students by designing a beautiful visual application (A).The challenge of the activity is: For a given implicit function, an interactive visual application must be developed. Details on the developments the can be found in [9] and an illustration of the developments is presented in Fig. 2.

- Workshops:

    - ***Sensor-to-cloud***, a workshop already implemented within formal courses at the School, represents a journey from physical-to-virtual. AEC classrooms are filled with countless attempts of understanding both natural and built environment. Practically every single magnitude studied in AEC is prone to be measured with sensors. Acquiring basic skills on measurement is thus, very relevant. This activity has been implemented in varying forms by the educator since 2015, when electronic prototyping platforms such as Arduino were first used in the School. The activity has already reached maturity and present editions are developed in 12 hours (1ECTS). All participants are provided with sensors, microcontrollers (open, accessible and affordable) and an account to a cloud-based IoT platform developed at the School. The development of this activity has evolved rapidly and different cloud technologies have been tested [10] in the classroom.
    - ***3D printing*** (prepared) represents a journey from a virtual space to the materialization of an object. The workshop may provide not only a better understanding of the virtual space but also, it sets some realisms to the boundaries provided by 3D printers. This workshop is prepared yet it has not yet been implemented. The duration of the activity is 12 hours (1 ECTS).
    - ***Scan-to-BIM*** (1st attempt done) represents a journey from physical magnitudes to a BIM-compatible space. The workshop shows one of the most promising technologies for the built environment, which is laser scanning. The workshop provided a real time illustration of how points are measured with sensors (lasers, accelerometers in this case) and virtualized with computational geometry tools. In AEC, the use of

"as-built" entities in BIM software presumes an understanding of these principles. In 2022, the 1st Edition of the workshop was implemented. A short 2 hours experience in which students played with spheres, scanned the spheres and subsequenty, identified the spheres in a parametric-generative modelling tool.

- **BIM-to-Robotics** (under preparation) represents a journey from virtual to physical within a BIM-compatible space. The workshop introduces the potential of automation in construction with accessible and affordable equipment. It illustrates to AEC students what has been more traditionally present in other engineering branches, instrumentation and control of machines.

- Capstone projects: Construction of a digital twins of an asset represents a comprehensive activity that encompasses all previous developments. It represents an information construct in which both the development as well as its systematic usage are didactic. The flow of information goes from physical-to-virtual and vice versa. Sensors are needed, Virtual spaces are needed and a seamless communication between both realms is required. Digital twins also represent a promising conception in the built environment called to help in a better understanding and management of the assets at design, construction and maintenance stages. Five individual final projects at Bachelor levels have been successfully implemented since 2016. Ideas for expanding these projects to diverse teams (electronics, computer sciences, civil engineering) require further coordination between Schools. A sample of applications are found in [11,12]

5 DISCUSSION AND FUTURE IMPLEMENTATIONS

Developments and findings of the recently finished educational project “de las MATES al STEAM” are depicted. The project The following key takeaways are worth pointing out:

- The market-driven driving forces for digitization of the sector are erecting a frame labelled as Construction 4.0. Digital Industrial Production (from virtual to physical), cyber-physical systems (from physical to virtual) and an established framework for digital technologies (BIM) represent the tripod of this definition.

- It is observed that Civil Engineering students are lacking specific knowledge for their proper inclusion in the Construction 4.0-related job market. This aspect is being addressed by educators and schools at a rather slow pace. Civil engineering schools are unevenly integrating Construction 4.0 activities in existing curricula. This lack of content is identified in many aspects such as the use of sensors and measurements, the use of BIM-enabled computational tools and the real time connection between the physical and the virtual realms. In addition, coding and computational geometry tools are required skills for Construction 4.0 related activities.

- Following the identified tripod, a Construction 4.0 learning path for standard degrees on Civil Engineering has been proposed. Cornerstone projects, workshops and Capstone projects were conceived with the intention of filling the Construction 4.0 identified gaps. All activities were knitted together using a (S)(T)(E)(A)(M) educational approach. Cornerstone projects are intended to foster motivation at early stages of the degree. Maths (M) and Arts (A) are blended together in hands-on activities. Subsequently, the set of workshops are intended to provide necessary knowledge on different engineering (E) technologies (T) with a critical scientific approach (S). These workshops are not limited to those proposed herein. Thus, the capstone projects result on integrators of all aspects dealt with along the degree. A (S)(T)(E)(A)(M) development of digital twins for civil engineering represents an accessible, affordable and scalable vehicle for infusing Construction 4.0 in civil engineering classrooms.

ABSTRACT

This paper documents the remote management of a first-year foundations of engineering course with special focus on students' learning by completing a prototype-based project in an online course. The COVID-19 pandemic brought on unprecedented challenges to the teaching and learning communities around the world. Educators made purposeful changes in their teaching approaches, shifting rapidly from in-person to online mode of instruction. This study documents a project-based course that adopted an asynchronous mode of instruction as a part of the general engineering curriculum at a large Southeast university in the United States during the pandemic. This asynchronous course – through implementing necessary changes and adaptations – simulated the experience of a cross-border engineering workplace. The course content focuses on engineering design and problem-solving, physical prototyping, simulated data collection and analysis, contemporary software tools, and professional practices and expectations (e.g., communication, teamwork, and ethics). Learning activities are designed to introduce students to the types of work that engineers do daily and to challenge students' knowledge and abilities as they explore the different elements of engineering by completing an aesthetic wind turbine project.

Our paper reports on the development of the course site as informed by recent national developments in scholarship and practice for online teaching and learning. The principles of course design alignment as well as instructor presence and learner interaction as suggested by these national standards are discussed. Further, the study records strategies adapted to enable students to complete a successful prototype-based project working in geographically distributed and virtual, international teams.

1 INTRODUCTION

The COVID-19 pandemic presented innumerable challenges for multiple fields, including the education sector. As a result of the implementation of social distancing and isolation measures to mitigate the spread of the contagion, educational institutions in the US, including schools and universities [1] [2], faced sudden nationwide closure for months from March 2020. Classes were abruptly shifted from being conducted in person to being conducted online via video-conferencing applications [3]. Active methodologies for optimal student learning [4], which conventionally focus on direct teacher-student interaction in a classroom, were no longer sufficient [1]. Lecture-based instruction was able to continue, however, coursework requirements became an issue – in particular for engineering courses that typically required hands-on, practical components such as labs and the completion of prototype-based course projects.

It is important to note that most engineering students were not used to online education, thus capturing their attention and encouraging their participation could represent a significant challenge. Some factors that contributed to this were the lack of motivation for online learning and academic stress related to it, for example speaking up in class became more stressful [5]. Although teachers adapted well to the sudden transition from teaching in person to teaching through online video conferencing software [6], students struggled with finding uninterrupted time or a quiet place to attend classes at home [7]. Another hurdle was the prevalence of digital inequalities among students [8], such as limited internet or technological resources as theorised by Beaunoyer et al. from a few factors that determine the efficiency of using technology. The primary factors were the quality of available hardware and software to access the tech resources, help provided by peers, and personal experience [8]. Interestingly, student satisfaction with the new learning methodologies differed from the suppositions initially made. In a study [9] it was established that not only did student satisfaction remain high when adapting to remote learning, but this was also reflected in the higher grades, indicating an overall improvement in the learning outcomes [9].

This paper records the ways in which a course instructor at a large, Southeastern university tackled the unprecedented changes brought about by the COVID-19 pandemic. It contains a detailed description of the modifications to the course format and deliverables, and the methods of student communication and collaboration from different geographical locations. It concludes with an account of how student participation in remote teams resulted in successful achievement of the course goals, including the prototype project, while inculcating ethical awareness. The asynchronous course simulated a global engineering workplace by replicating the typical experience of engineering projects whose success relies heavily on both individual and team-based efforts within the context in which team members are separated by both time and space – through implementing various adaptations. The theoretical framework used in this study mainly integrates active learning [4] and project-based learning (PBL) approaches. Simulating an engineering workplace in an asynchronous setting is challenging for a multitude of reasons. For instance, one of the abilities the students are expected to demonstrate is innovation, which tends to be inadvertently suppressed by students reluctant to venture beyond their earned expertise or skill set [10]. The PBL approach overcomes this by assigning projects that often revolve around solving a real-world problem through consistent and focused teamwork [10], so that students experience a learning curve addressing areas inside as well as outside of their major. Active learning has been established as a highly effective mode of instruction in both modern classroom and online synchronous/asynchronous settings [10]. This paper discusses a course in an asynchronous setting that allowed students to access the course materials at a relatively relaxed pace but still used active learning principles. Through group projects, the course ensured active student-student and student-content interactions.

2 METHODOLOGY

2.1 Overview of Course Designs

Foundations of Engineering is the second course in a two-course sequence taught to first-year general engineering students at a large Southeast university. This project-based course serves as an introduction to engineering for students through various skill development tasks. According to the curriculum, this is accomplished by engaging students in coursework that focuses on engineering design, problem-solving, physical prototyping, simulated data collection and analysis, contemporary software, as well as project management skills and standard professional practices in communication, teamwork, and ethics. Students are to design and build a 'backyard' wind turbine that operates as a kinetic sculpture kit that can be sold to homeowners, as an aesthetically-pleasing lawn ornament that generates some electricity. They are expected to be able to demonstrate competencies in using various engineering skills and tools to solve design problems. Students are reminded to implement engineering design processes while evaluating the potential ethical implications of their proposed solutions.

Using SolidWorks as a tool for computer-aided design (CAD), students learn to create physical analogs of virtual geometric solids in preparation for their project drawings. They first individually learn to design simple solids with step-by-step instructions and video tutorials provided. Their learning is then tested through SolidWorks assignments asking students to design the flange, tool block, and shaft.

Students are also introduced to the concept of stakeholders with different objectives. One of the course goals is to train students to not only develop engineering expertise but also interpersonal skills that will enable them to communicate engineering decisions to technical managers in an effective manner. To facilitate the acculturation of learning and working in a project-based environment, students are introduced to various aspects of day-to-day engineering tasks as they familiarise themselves with the different elements of the engineering design process.

2.2 Project Management and Professional Skill Development

Even though the course had to switch to remote instruction for this particular cohort, expectations on course outcomes were upheld. Students were expected to be able to define the project specifications as communicated to them through the Client's Project Description Letter. They were also to know the project timeline, to become familiar with project management tools, and to understand the uses of Comprehensive Assessment of Team Member Effectiveness (CATME). When discussing project management, the importance of early planning in relation to cost and influence was emphasised, highlighting the need to complete the project and deliverables in an efficient manner. Teamwork and issues with roles, responsibilities, and communication were thoroughly explored along with task management and the use of project scheduling tools such as Gantt Chart. Students were also briefed on details on project deliverables with milestones and important due dates throughout the semester.

Students were first given a Project and Team Start-up Package assignment to complete that contained: (a) the context and background of the design problem, (b) statement of given specifications, (c) major stakeholders, (d) questions that they may have about the project, (e) an initial project schedule, (f) identification of the major roles of team members, and (g) a team contract (agreement among team members). This assignment provided them with crucial guidance on resource management and planning throughout all major phases of the conception and design of a modified solution. Students were instructed to develop the scope for what needed to be done, identify all necessary tasks, and define the milestones and deadlines that would allow them to track their progress towards completion.

An essential first step was for students to demonstrate their comprehension of the design problem and their awareness of its technical implications to the project client. After identifying specifications, describing major and minor tasks, and providing the background in their project plan, students were asked to specify: (1) the stakeholders, (2) project management logistics (team roles and team contract documents, software tools being used for remote communication, file repository, and task management), and (3) individual questions for the client from each team member. Within team contracts, students were prompted to identify team goals and strategy, schedule and location of team meetings, team reporting and communication details.

With the help of first-quarter project and team status update reports (similar process was in place for the third quarter), the importance of periodic reports was emphasised - ensuring adequate project progress on time, within scope, and under budget. All teams were expected to have completed the design and construction of a first set of prototypes before the report was due. Hence, the main purpose of this report was for the teams to discuss the progress they had made and to present summaries of their early designs. In addition, the students were also required to reflect on what they had accomplished to date, examine their plans going forward, and make the necessary corrections to keep the project on track.

2.3 Decision Matrix and Prototyping

Students were encouraged to engage in individual design ideation and freely generate ideas and sketches (Figure 1) for the wind turbine's design. Then, they had to use the qualitative approach for the evaluation of alternative designs of fellow team members (Figure 2). This approach involved the use of decision matrices in the identification of the relative importance of the features/criteria through a set of systematic comparisons by using a pairwise comparison chart, followed by the assigning of weightage to features based upon the rank order of importance, scoring their alternative designs, and eventually narrowing down one final design to prototype (Figure 3). Using the specifications list as their guide, students were first instructed to submit five decision criteria for testing their team's wind turbine designs. Once a final design was selected, teams were instructed to build the model wind turbine with accessible materials and test it with a fan or hair dryer to observe whether a pattern was created when it spun (Figure 4). MATLAB was used to calculate the power and the torque generated by the specific wind turbine. As a team, students then virtually tested their prototype using Computational Fluid Dynamics (CFD), which analyses fluid flows using numerical solution methods. A video of their working turbine model was required to be submitted for grading.

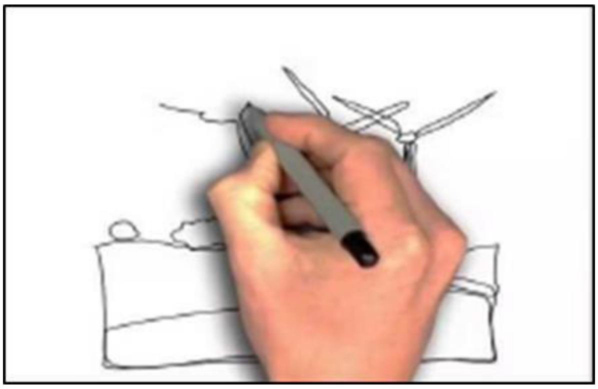

Figure 1. Freehand sketching of a student's online design ideation

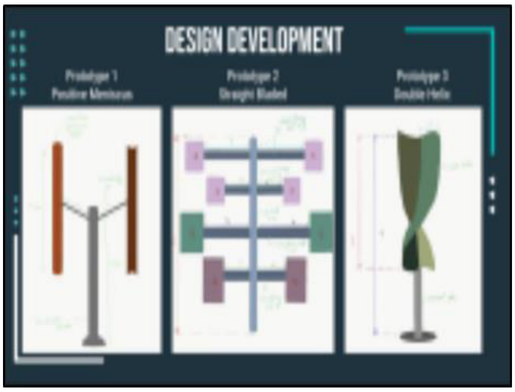

Figure 2. Design development with competing alternatives

Figure 3. An example showing the use of Decision Matrix

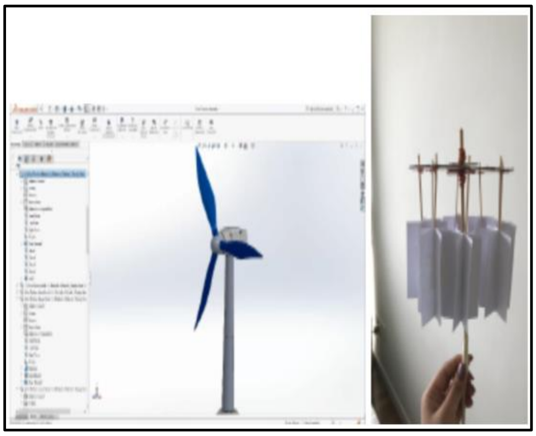

Figure 4. Virtual and physical prototyping examples

3 IMPLEMENTATION AND ADAPTATION

A cohort of 61 students was divided into 11 virtual teams of 5 students and 1 team of 6. Considering the asynchronous mode of instruction, the Canvas (a learning platform available for use by the university) site setup of the course was informed by recent developments in scholarship and practice for online teaching and learning (https://www.qualitymatters.org/rubric) with a particular emphasis on the purposeful planning of the online space alongside its structure and delivery. Table 1 summarises the primary changes and adaptations that occurred in the online format.

3.1 Highlights of Course Organization

First, an introductory video was included on Canvas to depict the instructor's passion for teaching. Adhering to the guidelines of quality assurance and management of online courses, the course homepage was strategically formatted for easy accessibility. The Modules page was also set up to contain one module per week, making it easy for students to find resources and lectures. The weekly class activity, learning materials, and weekly objectives were all linked thematically. In addition, the grading criteria were made clear for the graded discussion board.

Table 1. Summary of the primary differences between the two formats of the course.

Regular In-person	Post-COVID-19 Asynchronous Online
Mandatory **attendance** of class sessions and active in-class participation are expected.	Geographically dispersed students worked through course/project materials on Canvas in different time zones at their own convenience.
Team members are given class time to engage in **team-building activities** at the start.	Team-building exercises could not be executed due to the asynchronous nature of the course.
Team members regularly **meet in person** during scheduled class times to check in and to schedule group meetings outside of class.	Heavy reliance on online applications (e.g. Zoom and WhatsApp) for communication, and for completing project-related group tasks in general.
Materials typically required for team project prototyping are readily available throughout the course duration.	Students were expected to use their creativity in sourcing and securing suitable materials from their immediate surroundings.
Access to the well-equipped Frith **engineering design lab** on campus.	Students did not have access to special tools and lab equipment or lab assistants.
Live **CAD instruction sessions** are given to provide individualised help during class.	Students were given access to a set of pre-recorded CAD demo videos on CANVAS.
The use of **Computational Fluid Dynamics (CFD)** for testing prototypes is optional.	All teams used CFD as a means to virtually test their prototypes.
In-class **final project presentations** that showcase the teams' final physical prototypes.	Recorded online presentations were the only feasible option.

3.2 Feedback on Outcomes: Support, Accessibility, and Usability

All in all, feedback collected from students as part of the course surveys per IRB guidelines was overwhelmingly positive, such as "*the Sunday night email containing links with helpful resources helped a lot and the instructor was always welcoming and approachable*," giving much needed confirmations that students were able to benefit amply from this course delivery format.

The requirements for learner interaction were clearly stated on the discussion board. The instructor sent weekly emails that introduced the topics for that week, which allowed a more personalised approach generally uncommon with asynchronous teaching. This helped establish rapport with students, who lauded the instructor for being "*really friendly and understanding…helps the students in both course materials and mental health*." There were other comments and positive feedback from this cohort of students directed at how the instructor was handling the course, such as the instructor was "*always available for students, and … responds to emails very quickly*", "*helped me learn how to clearly use SolidWorks…was very helpful whenever I had any questions*", "*very helpful during her office hours and also a great person to talk to… understands the situations us students go through, and helps us accordingly*", and "*always provided instructions clearly and used recordings to explain content*.". Another student shared in the end-of-semester teaching evaluations that "*(instructor) is one of the best instructors I've had so far in my university. She always delivers the course material very clearly and effectively. The course is always engaging and I've never felt bored at all. The assignment feedback makes me improve always, and the weekly announcements help me stay on track and not fall behind.*"

An evaluation of the course from a faculty who provided a teaching evaluation review states: "*The instructor provides thoughtful learning experiences and resources that support her students at every step. For example, the instructor introduces conflicts of interest in an effective way and provides scaffolding through examples and an* *exercise to help students practise what they learned. The instructor managed to effectively teach, not only virtually, but also in a fully asynchronous mode*."

Navigating the entire course through the modules on Canvas was easy. Each week's resources could be located both on the overview page and the specific resources page. The PowerPoint files with audio were made easily accessible (yellow matter on Canvas). A testimonial from a student supports the above criteria of the course quality management guidelines: "*I really liked the course. It was engaging and interesting. … we had to collaborate on the interesting topic of the wind turbine. I really liked the part when we had to come up with our individual designs. Each team assignment, we had the time to socialise and talk which was really fun too. Overall, this class helped me awaken my creative sign with a mix of my academic side.*"

Not being able to meet in person encouraged students to switch to alternative methods of communication for completing group tasks. Zoom, Discord, and WhatsApp turned out to be popular and effective applications for direct student communications. Tools like Canvas, Google Docs, and Google Drive were used for shared storage and editing assignments. A student testimonial (edited for brevity) reads: "*While the course may not be as fun in an asynchronous setting, the course was most definitely productive … functionalities like screen share, and posting links in the chat were very convenient and reliable ... This made us more efficient and made our work even more valuable as everyone did their best work in their own style*."

Positive feedback apropos to the connection of the taught course with an actual engineering workplace was recorded by a student whose testimonial (edited for conciseness) reads: *"Taking the class online has made learning harder .... However, real-world engineering problems often deal with incomplete information and uncertainty. I believe that the uncertainty pushed the students to work by themselves and not count on anyone. In this way, we learnt basic engineering skills. In fact, engineers usually do experimentations with software, models, or prototypes in order to deal with uncertainty. Experimentations are one the first steps in engineering design. In fact, each engineer has his own plan to solve problems..."*

4 DISCUSSION AND LIMITATIONS

This study covers the various aspects of an engineering course forced to abruptly transition online due to the Covid-19 pandemic. The paper also reports the technical details of the course as well as the course outcomes that were achieved through the inculcation of communication, teamwork, and understanding of ethics in students. The course format was asynchronous, i.e., the minimum attendance course policy was suspended, to accommodate international students who resided in different time zones. Further, to reduce workload for students, the weekly assignments had been reduced to biweekly. Prompt steps, as highlighted above, were taken by the course instructor to fulfil the remote pedagogy requirement after the pandemic began.

The essence of the course was delivered through simulating the experience of remotely-connected global engineering teams. While working asynchronously, completion of the course project – a final design analysis and critique of a physical prototype made from a CAD model – remained a primary course requirement. Ethics in the engineering workplace was also a required consideration in the final assessment; how well students complied with stakeholders' interests was evaluated. Special consideration was given to ensure that students were provided with an immersive experience of how engineers work, remotely, on a regular basis: following industrial standards, collaborating in teams, complying with the customer design requirements, and completing projects with ethical considerations. The widely distributed geographical locations of international students, collaborating in an organised way and coming up with creative ways to procure the required materials, was a significant challenge. Working remotely, each group needed to spend time planning the project, organising the work, identifying action items for each person, and following up to ensure the work was completed on time as well as accurately.

The unavailability of hardware lab equipment and wind turbine kits for international students led towards devising creative solutions driven by conceptual clarity. Students used whatever resources that were available to build the project from scratch, such as cardboard pieces, tapes, straws, canes, etc. For the final prototype submission, the constraints of the previous version were solved to build a better working model. Data for the torque generated by the wind turbine as proportional to the wind speed and other factors was recorded and analysed for proficiency calculations and error estimations. Where this project showed positive results for the instructor's implemented methodologies of online pedagogy, it also exemplified the students' (a) keenness to learn, (b) remarkable adaptability to remote learning, (c) versatility to handle responsibilities in remote teams, and (d) resourcefulness and ability to reproduce results comparable to an actual engineering workshop.

However, some of our findings may not be entirely generalizable; for example, the scope of this study does not necessarily extend to non-STEM project-based courses taught online during the pandemic that may require different skill sets. In addition, the personal quality and previous online teaching experience of the instructor, as well as the availability of additional support could potentially have significant impacts on students' experiences. Further, the course introduced here was at the undergraduate level; findings of current study may not be replicable at other levels of education such as high school and lower, or in different educational settings. Lastly, future research is needed to help us more fully understand the challenges and opportunities in this specifically under-explored modality of online prototype-based learning, while possibly looking to integrate the best practices of using information and communications technology (ICT) in e-learning of courses specifically involving PBL.

5 CONCLUSION

This study presents findings from a first-year engineering PBL course that was taught online asynchronously during university closures due to the COVID-19 pandemic. Through various adaptations, the course simulated the global engineering workplace by imitating the experience of engineering projects within the context in which team members are being separated by both time and space. The essence of this paper is to provide fruitful insights into the prompt steps taken by the instructor for effective implementation of online learning methodologies for the course. It also shed light on how students living in different parts of the world communicated with the instructor, learned through asynchronous instructions, collaborated in teams, made ethically informed decisions, and timely completed the course project according to the stakeholders' requirements. The outcomes from this course add to the various methodologies being used in online learning. Highly favourable student feedback represents additional affirmation that the sudden pivoting to online learning had been a much welcome success in this setting. This experience of conducting a PBL course remotely, with further adaptations, can serve as a useful template to help guide colleges of engineering in similar courses if such need arises in the future.

ABSTRACT

In today's world, globally interconnected, volatile, and characterized by a sky-rocketing complexity, significant and unprecedented interdisciplinary is required among various stakeholders to create resilient and innovative value chains. Within this compelling context, we focus on the new role that university-industry collaboration plays on a large scale in bridging the gap between idea generation and value creation to economy and society. A new way to promote attitude towards entrepreneurial leadership at an early stage among students and teachers is experienced by linking curricular and extra-curricular teaching and contents, as well as by supporting voluntary learning "on demand" among students. Intertwined links are indeed possible within a nursery environment, so-called *Entreprenursery*, where students are encouraged to express their creativity, both by raising startup ideas and by solving companies' technical and scientific issues. Entrepreneurial students are thus supported in their innovative ideas

doi:10.5821/conference-9788412322262.1192

through collaboration with teachers, experts, entrepreneurs. They are also stimulated to engage other students to be part of an interdisciplinary team. Cooperation in supporting cross-fertilization of creative ideas will be fed by competencies, an open-minded environment, and where diversity integration plays an important role. Only through different thinking is it possible to develop outstanding achievements. Coordination is guaranteed by a collaborative IT platform, which is also open to SMEs to facilitate them in involving entrepreneurial students. Within this new collaborative framework, all stakeholders will profit from reciprocal learning and creativity, increasing the entrepreneurial attitudes of students and teachers and thus accelerating the transfer of academic startup ideas into industrial applications and business opportunities.

1 INTRODUCTION

Since 2017 an experimental way to encourage creativity among students in engineering has been developed. Finally, a method has been put into place to implement entrepreneurship consciousness and attitude. Thanks to continuously ingoing feedback, a set of services has been developed to help entrepreneurial creativity to evolve and to enable innovation.

The main goal is to transfer knowledge gained by students at school and to apply it by working on their own entrepreneurial ideas. It is expected that the chances to set up and develop science-based companies will increase and science-based innovation will be encouraged. In promoting science-based entrepreneurial initiatives, connections between higher education institutions, the private sector, and society will be strengthened and accelerated also through the use of digital tools [1].

Within an innovative work structure, an ideal place was built, the so-called " Startup Garage " (the Garage), for which an associated metaphor of a sailing ship has been chosen. Students are Skippers driven by passion and leadership and are ready to explore new lands ─ ideas and new innovative approach on problems' solving. They will be able to involve the crew ─ mentors, experts, researchers, entrepreneurs ─ and be ready to get back on course by defying winds and bad weather, i.e. mistakes and difficulties. So the Garage is a safe haven to meet, interact, exchange ideas and create effective teams and it has fertile ground, where entrepreneurial creativity and productivity are fostered.

While the need for tangible resources, such as physical meeting spaces, laboratories and materials, is obvious, the essential role potentially played by intangible resources should not be ignored. This approach, aiming to put into practice the quadruple helix model [2], includes an entrepreneurial university culture, an informed and constantly updated sustainability-focused innovation program, access to innovative research projects and ideas produced by the university's academics, as well as involvement of internal and external faculty members and industry practitioners as program mentors [3]. In such a nourishing environment, the mentors are one of the key innovative aspects. There are no teacher-and-students or expert-and-novices binomials, but simply peers working together shoulder to shoulder towards the final entrepreneurial goal. In The Garage, the mentors are called Standby Mentors, since they are requested on demand when the students need to confront with a specialist to overcome an obstacle. However, they do not offer a solution, but share their knowledge openly. They show to the students how to find the way to the solution, leaving them even to make mistakes if that could be a useful path to the increased knowledge. Within this creative working framework, the 17 ONU Goals are pursued, thus representing a sort of compass for all Skippers. In this way the entrepreneurial creativity is harnessed for value generation.

Intangible resources are also made of a non-formal learning process providing three evolving steps to develop further startup ideas in their scientific and technological feasibility [2], as well as in searching for business opportunities. Once students have received a bachelor's or master's degree, they can stay in the Garage for a further six months, thus having more time to choose whatever they want to do with their startup ideas already developed along three previous steps. Actually, step validation makes startup ideas much closer to real feasibility.

Thereafter, the step out of the Garage is compulsory, but nonetheless favours either entrance into academic startup incubators or a professional career as entrepreneurial employee.

2 CREATIVITY

2.1 Students' creativity on the road

By collecting data during the five years of the testing approach to creativity, some interesting consolidated results develop. They will be used to drive creativity to the next implementations.

First of all, we can say that engineering students are ready to put entrepreneurial ideas into a processing and developing system, especially when they are enrolled in the Department of Innovative Technologies (DTI) as first-year students.

Table 1 shows the retained ideas ─ the startup ideas to be worked in the Garage after selection ─ and the number of members forming up teams of skippers around the ideas development. In the last 5 years, more than 10% of all students of the Garage's project have shown an entrepreneurial attitude (Tab. 2).

In order to scout creativity, students are informed and encouraged to submit ideas at the beginning of the academic year through a digital platform, called Pingel@p [4]. This application helps to facilitate both competence and need/issue sharing at all levels of the 4 quadruple helix model [2].

The collection of ideas takes place in this online platform and facilitates the homogeneous description of ideas according to a predefined structure, which is also captured and frozen out in smart contracts based on Blockchain technologies in order to guarantee intellectual property (IP) protection [2].

Every student enrolled in Bachelor and Master programs can submit her/his innovative idea which is then collected through a „Call for Ideas" event managed by an ICT system. The internally developed system enables the student's ideas to be matched with the best fitting Standby Mentor by automatically picking teachers, researchers, experts, company managers based on their expertise.

Table 1 — Garage's Data

Table 2 — Garage's Major Trend

	First-year students	Number of Applicants	Teammates	% of Entrepreneurial students
2017/18	130	17	13	10
2018/19	141	15	26	18.4
2019/20	202	11	23	11.4
2020/21	228	7	26	11.4
2021/22	269	21	30	11.1

After the submission of an idea, applicants are recognized as Idea Owners. Then, after a digital assessment process involving Standby Mentors, some of the brightest ideas are retained to be developed later according to the Startup Garage methodology.

In addition, a new tool for accelerating a potentially more valuable idea, has been integrated into the Pingel@p platform: the call-for-needs resolution. This tool aims to have a more open innovation cross-fertilization approach, where companies can describe some specific actual needs and share them in a nurtured way with other platform actors. In order to support the call-for-needs resolution process, regular “creActivity” events are organized by the Garage on a monthly base. These meetings with companies which concretely describe their needs or current impelling issues, take place in the Garage space and enable a first person contact and a live discussion between the different actors.

So cross-fertilization of fresh-minded Skippers with entrepreneurial spirit/attitude can accelerate the investigation of new solutions towards faster prototype development and market adoption, supported by a digital platform and nurtured in the Garage environment.

2.2 Creativity Spotlight

Pingel@p fulfils some essential requirements such as collection and evaluation of idea proposals, matching of students with suitable mentors, call-for-needs resolution from industry partners, as well as call–for-expertise to promote team-building among entrepreneurial students. In particular, the last two are in line with the theoretical model proposed in [3], where the Garage should comprise a number of fundamental components, including one to create positive collaboration and creative synergies, and another to generate productive interaction between entrepreneurial students and industry.

While today Pingel@p is a one-to-one match between a student’s idea and a mentor, we aim to build this connection multilaterally, enabling companies to promote young talents and creativity.

A virtual environment has also been thought to combine social and professional features in existing networking applications, such as Facebook, Instagram, LinkedIn. The goal is to create a virtual space for the Skippers to exchange opinions and resources, to encourage team building through cross-fertilization and gender inclusion. Moreover, we will create events in main city squares with activities managed by Skippers. They will promote interaction with the local community, stimulate general public thinking, and promote the university brand.

Actually, the lonely situation of the creative student, such as the need for help, can be overcome by exploiting the Pingel@p Webapp call-for-expertise [2] to look for students willing to help a single Skipper. This is a main goal, which will be pursued systematically very soon, because innovation for a sustainable future is a complex endeavour that cannot be accomplished by the solo-sailing of even the most talented and eager home garage-based entrepreneur [3].

2.3 Ongoing generation of creativity

An academic community of students interested in entrepreneurship has to build and connect to enable the visibility of startup ideas being processed in the Garage. Most active actors of this community will be referred to as Skippers hereafter, a new terminology for entrepreneurial students engaged in building up tight-knit teams working on startup ideas. All teammates should regard themselves as chief officers operating jointly in tune with their interests and competences to put sail to startup ideas by forming a cohesive and qualified crew. Actually, all people with good ideas can be Skippers, who are at one time at the helm or another time go onto the ideas' deck: a symbolically furnished corner built within the Garage.

Hereafter, an interconnected system ─ recalling quadruple helix model [2] ─ has been realized to support creativity aiming to transfer its value to the industry, as shown in Fig. 1 below.

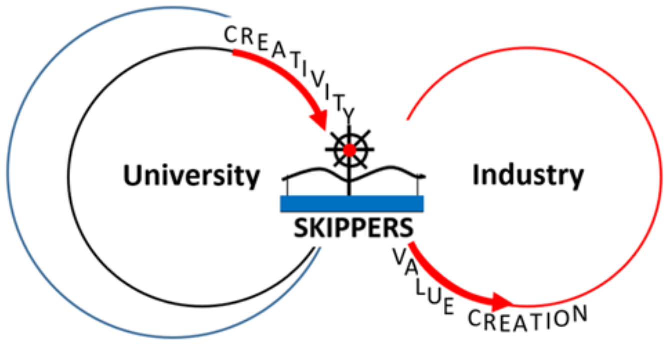

Fig. 1 ─ Creativity Interconnections

3 VALUE CREATION

3.1 Entreprenursery

Recently, an entreprenursery has been born focusing on entrepreneurial students and implementing the Garage's Concept&Method within a framework of a sharing creativity involving different stakeholders. Actually, the Garage should be seen as a nursery taking care of students' creativity and development in an entrepreneurial value dimension without being pressured by monetary constraints.

Relative to the general population, university students have an overall higher risk tolerance, as they are frequently unconstrained by overwhelming financial or family obligations that dampen risk-seeking behaviour [4]. It is essential to positively harness the risk-taking inclination through a structured process of "learning-to-fail" while limiting the scale and fallout of such failure.

As Charles Camarda, a NASA astronaut and Senior Advisor for Engineering Development stated, "You have to fail in order to be successful and there are smart ways to fail. So, I try to teach students how to fail smart, fast, small, cheap, early, and often" [5]. A cleverly designed entreprenursery would be the ideal environment for aspiring entrepreneurs to learn to fail with limited fallout.

Within a challenging, safely upgrading dimension, the entreprenursery project aims to expose entrepreneurial students to actual issues proposed by local companies: similar processes have to be formalized to support students in tackling such challenges and to create feasible and marketable solutions. Local companies have the opportunity to provide a call-for-needs-resolution (a business idea in need of development), through a predefined institutional gateway designed to give industry participants access to the Pingel@p platform. Skippers can adopt and investigate this idea, potentially proposing a solution and developing a prototype. Alternatively, firms can ‘tap’ the pool of existing ideas at various stages of development available on the Pingel@p platform, potentially offering funding or bringing them in-house (creative ideas transfer) for further business development. Likewise, companies can source entrepreneurial talent from among the students working on their startup idea in the Garage and offer them internships or employment opportunities alongside or upon completion of the university degrees. In this manner connections between company-student do not remain only in the classroom but they can go further in establishing entrepreneurial relationship. Indeed, companies will propagate opportunities for summer internships, creating strong cooperation between the academic world and local businesses [3]. Such early-stage interaction and team building contribute to the formation of extensive and heterogeneous professional networks, which, according to successful entrepreneurs themselves, are a fundamental prerequisite for entrepreneurial success [6].

A high priority is to ensure that no one is left behind. In building inter-multidisiplinary team, Startup Garage Management is highly aware of untapped potential of the gender diversity for entrepreneurship, but gender inequality, or the underrepresentation of women in top positions of business and industry as well as universities, remains an unresolved issue across Europe. Giving priority to diversity, equity, and inclusion in universities is often a strategic choice. This environment helps to build synergies, develop new ideas and investigate new fields. Often equality, equity, diversity and inclusion are used interchangeably, despite the fact that they may mean different things.

3.2 Entrepreneurial education

The continuous and fast evolution of new technologies and their adoption to innovate industrial processes, products, services and business models, requires an increasingly comprehensive vision of society‘s expectations and people‘s roles in managing market-reactive and human-oriented companies. As a consequence, education is a key factor to deal with the ongoing challenges for manufacturing companies from both the consumer-oriented and the worker-oriented perspectives. To deal with such a challenge new education and competence development methods [7] and instruments have gradually been introduced in the last decade within university education paths.

Nowadays, as a consequence of the disruptive, ongoing digitalization and industrial transformation processes, moving from the industry 4.0 to the industry 5.0 paradigms [8], a further relevant innovation in the overall education framework is of even increasing importance with specific reference to the complex “creativity to value” process chain management. According to the discussed novel open education framework, enterprises must share their practical and professional experience with students, so as to enable them to put their startup ideas and entrepreneurial skills into practice. In particular, companies should also involve students in facing production and product innovation problems, and ask them to suggest implementation proposals. Similarly, professionals and representatives from the society should inspire students to identify future needs and to propose potential solutions, based on their knowledge, skills, creativity and interdisciplinary teamwork. Such a virtuous and heterogeneously integrated approach sets the basis for a co-operative process and innovative transdisciplinary co-creation approach [9].

The proposed education paths and experiences will de facto enhance the student's entrepreneurial attitudes in facing real world challenges and increase their risk of failure acceptance and management capacities that constitute skills highly demanded today by industries, that have to compete within a more and more challenging and innovation-driven economy and society [10]. The aim is indeed to offer the academic system a synergistic framework that stimulates and transforms talented students into entrepreneurial employees, or to support them in turning business ideas into entrepreneurial projects. A system of intertwined connections is going to be put in place, in which the Startup Garage Management is much more extensiverly involved and engaged as is shown in Fig. 2 below.

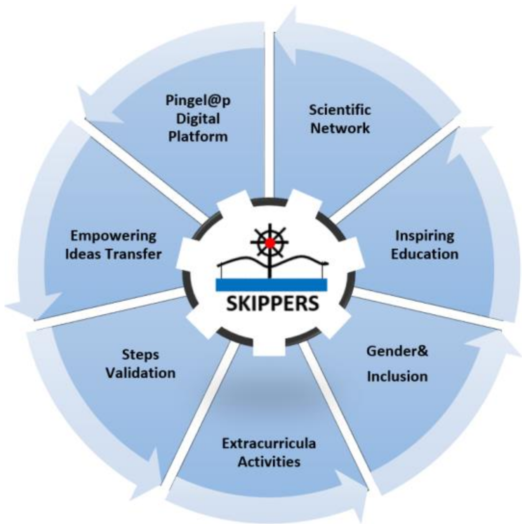

Fig. 2 – Garage's System

4. CONCLUSIONS AND FUTURE WORKS

The growing new centrality of humans within sustainable society, economy, and industry requires more and more to valorize soft and distinguishing skills like creativity, problem-solving and teamwork in strict correlation with entrepreneurial attitudes like business orientation, leadership, gender and cultural inclusivity, learning-to-fail, and resilience. The priority objective of the Garage is to let students express easily entrepreneurial ideas trying to optimize their skills without interfering or inhibiting their creativity. In this respect, it is however paramount to leverage the osmosis among industries, universities, and entrepreneurial students by means of the ICT applications, such as the Pingel@p, which acts as the driver to scale up the Entreprenursery concept. In this context, universities must embrace and face plainly the challenge and play their crucial role in sustain creativity as core value of the entrepreneurship. An impactful communication has to be put in place, making real such an important educational turnaround. The implementation of a new tool for accelerating potentially more valuable ideas, i.e. the call-for-needs-resolution, is underway to helps fresh minded skippers with entrepreneurial attitude to nurse their creativity towards new value creation.

ABSTRACT

The connection between the activities carried out by universities and cooperation projects for development is of great interest in achieving the Sustainable Development Goals and the 2030 Agenda.

This work shows the activities developed by the Universitat Politècnica de València (UPV) in terms of human development and international cooperation in the agri-food field. It starts from a description of the experiences and internships by the research staff, students, and technical staff of the UPV in a rural community of Uganda (Kitega), where it has been possible to connect two projects. The first one is related to improving agricultural systems, and the second one is on food conservation and processing techniques. Both intend to develop sustainable agri-food and are always based on actions that affect the needs of the most vulnerable groups.

Agricultural production in rural areas allows food to be obtained for self-consumption, while surplus production is offered for sale without any conservation or transformation system during its useful life. Poverty and lack of technical knowledge are essentially causing food unsafety and malnutrition. In addition, the narrow variety and low quality of the products sometimes do not allow to cover the nutritional needs of the families.

The conclusions obtained point to the importance of students, researchers, and staff from universities' participation in development cooperation projects to achieve a transition towards fairer societies in a sustainable and lasting environment.

1. INTRODUCTION

1.1. Cooperation for development and Research

Main world challenges (e.g., environmental protection, energy security, natural disaster mitigation, preventing and curing infectious diseases, ensuring food security) are increasingly the subject of policy-level deliberations, both nationally and internationally. It is recognized that international cooperation in science and technology is needed to deal with these issues. Cooperation between developed countries and developing countries is of special importance, because the first ones are often the ones most severely affected by global threats, and because they possess much of the expertise, data, and resources that are needed for finding effective solutions. [1].

In this context, universities play an important role as a source of knowledge and resources.

1.2. Cooperation Department at UPV

The Cooperation Department of UPV aims to support and encourage the participation of the university community in university cooperation activities for development.

Some of the programs offered and related to this paper are:

The Adsideo-Cooperation research program aims to promote the development of R&D projects in Development Studies, International Cooperation, and the application of Technology for Human Development.

The Meridies cooperation scholarships are intended for UPV students to carry out internships or Final Degree Projects in development cooperation programs and projects through universities, non-governmental development organizations, social entities, and any other international development cooperation system organization.

The staff Meridies cooperation program allows non-professors staff to stay in a short internship in an organization.

The development of one project or the participation of individuals from the university already positively impacts the community. Undoubtedly, when it is possible to connect more than one project and have more people involved, the results have even more impact. The university facilitates this connection through forums, expositions, meetings, and seminars in collaboration with NGOs.

In this paper, we will show an example of the participation of different people and the connection between two projects in the agri-food field.

1.3. Context

Uganda is a landlocked country in Eastern Africa located at the Equator. It has an area of over 240.00 km^2, and according to the latest Human Development Index Ranking from the United Nations Development dated 2019 [2], Uganda's data were:

- Position 159 (from a total of 189)
- HDI (value): 0.544
- Life expectancy at birth (years) 63.4
- Expected years of schooling (years) 11.4
- Gross national income (GNI) per capita: 2.123 $

1.4. Agriculture in Uganda

Agriculture accounts for 70% of employment, overwhelmingly on small farms; it occupies half of all land area and provides half of all exports and one-quarter of GDP in Uganda. It is considered a leading sector for future economic growth and economic inclusion in the current National Development Plan. Yet despite having excellent natural resources and climate conditions for the production of a wide variety of crops and livestock, the difference between aggregate output growth and the growth of all inputs and factors of production that produced it--in Ugandan agriculture has been negative for the last two decades [3].

The effects of climate change have not gone unnoticed, and the influence of foreign crops without knowledgeable technicians has resulted in an impoverishment of the soil. Dependence on seeds and uncontrolled use of plant protection products to combat pests and diseases have not helped its development.

1.5. Kitega Community Center (KCC)

Kitega Community Centre is located in Kitega, a rural village where the local economy is mainly agriculture-based. However, most of the population is unemployed, and the standard of living is low.

Kitega Community Centre Uganda is an NGO in Uganda founded in March 1999, to support children with disabilities, as a result of the stereotypes surrounding disability, the children were rejected and marginalised in the community.

In a bid to foster an inclusive community in which everyone is respected as valuable and contributing to the development of the community, the organisation launched a community development model to build capacity of local communities to address their own development challenges in Partnership with the Organisation. The community development model includes; Women empowerment, Legal Aid, Mobilising local farmers and training them, support to marginalised schools among others. Today, the centre is partnering with over 15 communities in Central Uganda.

Kitega has received international volunteers since 2009, and some have developed specific projects. Some of them have been under the frame of the Universitat Politècnica de València.

Kitega has an NGO partner in Spain who facilitates the connection with people and institutions.

1.6. Agri-business cooperation projects

The two Adsideo projects that successfully connected are: "Diagnosis of local production system in rural areas of Uganda. Proposals for a sustainable agriculture", which started in 2020, and "Evaluation of techniques for the conservation, transformation, and reuse of food in the community of Kitega (Uganda)" started in 2022.

The first project was proposed with an agroecological approach, characterized by minimal alteration of the ecosystem, by the nutrition of plants from organic sources and inorganic, the use of natural biodiversity, and oriented to the production of food, raw materials, and other ecosystem services, following the recommendations of the FAO in the Guide for those responsible for policies of sustainable intensification of production (FAO, 2014).

The approach for the second project has to do with the situation of farmers in Africa incurring the enormous loss of fresh horticultural agro-produces attributed to limitations in accessing modern food conservation technologies such as the use of electric dryers, freezing, canning, refrigeration, and cold-chain facilities [4]. Faced with this problem, several investigations highlight that the design of equipment for solar food drying is a practical and economical method that allows for the conservation of fresh horticultural products for extended periods [5, 6].

The local NGO, Kitega CC, has a relevant role in gathering farmers and local leaders, facilitating the network of contacts and the translation necessary to make communication possible.

2. METHODOLOGY

2.1. Diagnosis of local production system in rural areas of Uganda. Proposals for a sustainable agriculture

This project included the diagnosis of family farms to improve crop production from an agroecological point of view.

A group of farmers is involved with the help of Kitega staff, sharing their native knowledge, being part of the improvement process and decision making, and connected through the staff from KCC with the researchers from the university to discuss farming techniques.

The methodology used has been the field survey of farmers and interviews to study agronomic models, know the techniques they use, and the main difficulties they face.

The people who have contributed to the project through the Cooperation Department's support are:

- A staff person (Agronomy Engineer) specialized in training, who carried out an initial diagnosis on the knowledge of agriculture in farmers.

- A group of research professors (Agronomy Engineers and Biologists) to monitor crops and provide advice on crop pests and diseases.

- A group of students enrolled in the Master of Plant Health collaborated with the diagnosis from the university.

Fig. 1. Interview to the farmers for the initial diagnosis

Fig. 2. Farmers involved in the project and staff from KCC.

2.2. Evaluation of techniques for conservation, transformation, and reuse of food in the community of Kitega

As one of its objectives, this project has the design, construction, and commissioning of a solar drying system for the use of the community. The prototype is based on the design of a drying system successfully implemented in other countries such as Burkina Faso [8]. The choice of construction materials is adapted to the environment's limitations, and available materials have been sought with good resistance to climatic conditions.

Drying tests have been carried out by direct exposure to the sun and inside the dryer chamber to get drying curves and study dehydration kinetics for different local fruits and vegetables.

The fruits and vegetables are selected from surplus for consumption, extending the shelf life of these foods and avoiding the generation of waste. The process includes recommendations for good practices in food hygiene to obtain a safe food processing diagram.

The roles participating in this project are:

- A group of research professors (Agronomy Engineers and Ph.D. in Food Science and Technology).

- A student (Master in Food Processing) with a Meridies internship who has been in charge of the solar drying construction and first food measurement for three months.

Furthermore, it is planned for the following months:

- A student with a Meridies internship who will be in charge of exploring other ways of conservation.

- A person with a Meridies staff specialized in cooperative and entrepreneurship to encourage and motivate the community to commercialize the products.

3.3. RESULTS

3.1. Diagnosis of local production system in rural areas of Uganda. Proposals for a sustainable agriculture

A total of 20 farmers were interviewed to study their production systems, know the typology, understand their relationship with the environment, and find an approach that allowed improving agriculture from an agroecological perspective.

The answers showed that none of the farmers had specialized in agriculture training; they had learned only through practice. Extension services in the country are scarce, reaching a maximum of one visit a year when it happens. Some of them have heard of organic farming, which they associate with not using chemicals, but cannot explain more about it.

There is a low level of knowledge about the products they are using. None of them can identify labels or understand the scope of concentrations or solutions they are applying. That situation leaves the application of products entirely at the mercy of companies and sellers.

All farmers depend interviewed on rainwater for irrigation. In the context of climate change uncertainty, it is complicating traditional harvests as they have been doing until now when they were able to manage the seasonality. Their traditional agriculture labours, such as soil preparation, fallow, and sowing, have no dates anymore.

However, the way these family farms cultivate is more respectful and less invasive to nature than intensive agriculture. Nevertheless, that is mainly due to the lack of resources as a goal for sustainability.

During the project, several crops were monitored in an exhibition garden available at the KCC compound and in the family gardens; tomato, onion, pumpkin, pepper, eggplant, beet, and broccoli were cultivated with different results. A corn trial has also been carried out, with the varieties available in the area to determine its efficiency.

It can be pointed out that the most relevant result obtained in this project has been the built team of farmers, previously cultivating in isolation and now sharing knowledge and experiences. They have also shown great interest in food preservation techniques, aware of new business opportunities.

3.2. Evaluation of techniques for conservation, transformation, and reuse of food in the community of Kitega

The construction of the drying equipment was carried out in collaboration with local carpenters. The wooden structure was bought and built locally while the plastics were purchased in Spain.

Compared to the drying by direct sun exposure, the drying tests in the chamber of the built equipment offered dehydrated products with better characteristics and in more acceptable hygienic conditions than traditional drying.

The drying inside the equipment chamber was carried out at a temperature between 40 and 55 ºC without direct sun exposure, while in air-drying and by direct exposure the temperatures suffer a greater oscillation. Direct exposure to the sun also produced a greater deterioration in the products to be dried, in addition to the greater risk of suffering contamination and attack by insects.

Workshops were held mainly for women and young people, who showed great interest in this type of processing. It was insisted on establishing a clean working procedure, which includes the pre-treatment of the fruits and vegetables to be dehydrated, all of which allows for more stable and safe products.

Fig 3. Drying carrot testing

Fig 4. Drying banana testing

Fig 5. Drying banana testing

These results showed the importance of solar drying to promote food availability and security. Since the project seeks human development in the region, the actions impact the most vulnerable people and groups, especially young people and women who usually carry out daily agriculture and food preparation tasks.

The channels already established in terms of communication by KCC facilitated the development of face-to-face training talks, promoting the exchange of knowledge between local farmers and researchers.

Fig 6. Solar drying on construction

Fig 7. Workshop

4. SUMMARY AND ACKNOWLEGMENTS

In Uganda, as in many African countries, food insecurity amongst poor households remains a severe problem, contributing to poor health, problems with learning in school, and lack of socio-economic development. Family agriculture is in better conditions to optimize the better use of land. Besides, it has the most significant potential for increasing the overall base growth and creating sustainable wealth. Thus, all effort to improve them is not enough for the considerable benefit they offer. Encouraging these families to move to agroecological models would improve their lives.

The processing of agricultural surplus offers new business opportunities, which can be approached at family or community levels.

The support of the Universitat Politècnica de València in the two projects, grants, and internships given to the people who are participating, have made it possible to pass through the different phases of diagnosis, creation of teamwork, crop monitoring, surplus drying monitoring, workshops, meetings, and business opportunities analysis.

The researchers provide the knowledge and work methodology; the students contribute with time, data collection, knowledge, reports, and enthusiasm. The staff contributes with a professional approach. The excellent relationship and significant involvement of the KCC staff, together all around above, contribute to the project's success.

Can Decolonising the Curriculum Provide an Enhanced Engineering Education?

G. J. Collins

London, United Kingdom

https://orcid.org/0000-0003-4767-3870

Conference Key Areas: *Ethics in Engineering Education, Curriculum Development*
Keywords: *Decolonising the curriculum, AI ethics, curriculum development, engineering education, cognitive load*

ABSTRACT

Decolonisation is defined and discussed. University College London has several initiatives to decolonise the curriculum and enhance diversity and inclusion. In 2022, a series of online flipped lectures were developed for the postgraduate software engineering module. The aim was to provide a range of perspectives on artificial intelligence (AI) ethics. Teaching was through the decolonisation lens, highlighting historical viewpoints and imbalances in power. Students could reflect on the ethics of AI systems and how these systems perpetuate colonial biases.

Students had previously indicated their interests in AI, environmental and social issues, including climate change. Before lectures, students completed questionnaires, providing an understanding of their prior knowledge of topics.

A qualitative analysis of the reading material using coding within ATLAS.ti provided insight to select schemas to scaffold students' knowledge. The suggested reading was then adapted to ensure a greater diversity of viewpoints. The analysis also indicates that adding these additional perspectives may not increase cognitive load.

Lectures include real-world perspectives from guest speakers from diverse backgrounds, reinforcing the importance of different opinions. Students greatly valued the different perspectives and opportunities to discuss ethical dilemmas. Students' answers, following ethics discussions, indicated an improved understanding of engineering concepts. This study suggests that incorporating a range of views can enhance the topics students want to learn. Providing different perspectives can also

doi:10.5821/conference-9788412322262.1359

deliver a more balanced engineering pedagogy. Adopting a decolonisation approach that recognises the past but provides alternative narratives may strengthen opportunities for engagement with other universities: creating new scenarios in engineering education.

1 INTRODUCTION

> *Decolonization involves identifying colonial systems, structures and relationships, and working to challenge those systems. It is not "integration" or simply the token inclusion of the intellectual achievements of non-white cultures. Rather, it involves a paradigm shift from a culture of exclusion and denial to the making of space for other political philosophies and knowledge systems. It's a cultural shift to think more widely about why common knowledge is what it is, and in so doing adjusting cultural perceptions and power relations in real and significant ways.*
>
> Keele Manifesto for decolonising the curriculum [1].

Decolonising the curriculum is about overcoming the structural disadvantages and barriers in education and the lack of representation of black and minority ethnic groups. At its core, it is ensuring that what we teach and how we teach is 'more responsive to the problems of colonial racialised privilege and discrimination' [2].

Over the past few decades, there have been movements to decolonise universities to allow equal access and better educational outcomes for marginalised groups. There are efforts across UK universities by students and staff to dismantle the legacies of colonialism. Shortly following the Rhodes Must Fall campaign led by students and communities within South Africa to remove the Cecil Rhodes statue, several campaigns at University College London (UCL) have renamed buildings linked to racism. Not only to dismantle colonial statues but also to address the domination of structural inequalities and the idea that somehow the Global North is superior intellectually. In response to strong student interest, the SOAS was one of the first UK universities to commit to delivering a decolonising agenda. Their resulting toolkit [3] was one effort to provide suggestions to transform the legacies of colonisation. The toolkit suggestions were the starting point for developing the series of online lectures outlined within this paper.

The decolonisation projects at UCL are just one aspect of broader developments to enhance equality, diversity, and inclusion (EDI) to ensure that the university provides a welcoming environment for students from around the globe. The UCL Department of Computer Science has been recognised for its EDI initiatives. The department was awarded the Athena SWAN Silver award in 2015 and 2019 in recognition of advancing gender equality. When invited to deliver a series of lectures for the MSc software engineering professional practice module, the author was keen that this should support EDI initiatives and enhance the efforts to decolonise the curriculum.

The author had initially co-developed this module to include a range of guest speakers to provide a leading-edge and alternative perspective to the academic lectures. The speakers represent a diverse range of ethnicities and genders. Developing the new lectures was also an opportunity to tailor these lectures to students' interests in AI ethics. Students in the software engineering programme attend machine learning and software engineering modules and the professional practice module. The last module is focused on project management and ethics to provide students with the necessary knowledge to deliver their industry research projects. Machine learning is covered by theory and practical lab sessions, focusing on technical areas. Developing a series of new lectures provided an opportunity to align with the university's decolonisation initiatives.

This paper covers the development and open-ended approach (allowing for multiple answers) for the three AI lectures for the spring semester of 2022. These were designed as online flipped lectures with pre-lecture reading covering: research papers, reports, and textbook chapters. The emphasis was on discussions of the material before and during the lectures.

2 METHODOLOGY

2.1 Decolonising the reading lists

Reading lists have a role in decolonising our universities [3, 4]. The SOAS toolkit suggests providing a more comprehensive range of source materials, particularly from the Global South. A range of research papers and texts were considered, from geographic regions, particularly where they critiqued the subject matter or provided a different perspective. Where research papers had authors with more than one affiliation, the institution and country origin of their correspondence email was selected. The analysis included all authors for each research paper. The author's identification of gender and geographic/institution affiliation was confirmed by referencing publicly available web pages, the publication, and the journal itself or other research papers the author had published.

A more comprehensive representation of authors and countries [4] is one approach to decolonising the curriculum. The reading material was updated to include authors representing a more comprehensive range of countries, Fig.1.

Data collected 2020/21 via a departmental questionnaire indicated the highest number of students logged on from the UK and the second-highest number of students from China.

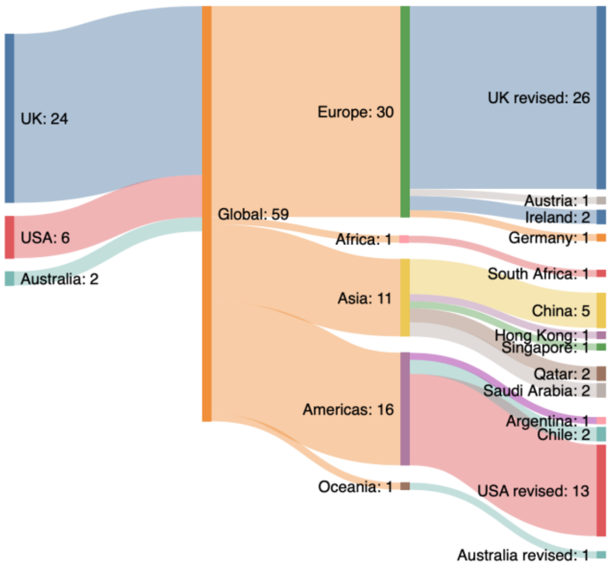

Figure 1. Geographic distribution of author locations for reading list and research papers cited. The left-hand side represents the initial documents selected for the lectures. The right-hand side indicates documents after analysis and review. The recommended reading now better reflects the many countries UCL computer science students are from during 2021/22.

UCL Postgraduate computer science students during the academic year 2021/22 registered from many countries, including Austria, Ireland, Germany, South Africa, China, Hong Kong, Singapore, Saudi Arabia, and the UK. An analysis of the reading list now shows a broader range of perspectives, including the Global South, Fig.1.

2.2 Use of questionnaires to understand student's prior knowledge

Questioning is a powerful tool to unlock learning and new ideas. Asking students what they already know does not create a defensive response. Students frame their replies as part of their perspective and view of the world. Understanding what students know can be used to tailor the lecture content, which avoids the repetition of well-understood concepts. Once each student had answered each question, more detailed information and resources were provided automatically according to their answers, ensuring that time during the flipped lecture was devoted to developing a deeper understanding of the topic.

Students had previously shown an interest in health and sustainability, including climate change, when answering questionnaires. Analysing questionnaires and incorporating data from online posts, Table 1., helped determine the three main AI topics delivered during 2022: AI and bias, AI emotion recognition software, and AI and sustainability.

Lecture topic	Year and Student Registrations	
	2019/20 N=39	***2020/21 N=42***
Sustainability	10	18
Inclusion and Diversity	18	20

Table 1. The two topics with the highest level of interest as indicated by online posts for lectures during the last two years. For 2021/22, 36 students registered for the module.

An analysis of student's answers to the questionnaires indicated the level of understanding of each topic. Students demonstrated a high level of understanding of most machine learning concepts. However, one question regarding receiver operator characteristic (ROC) curves was less understood. 66% of students (N=24) provided option (c) as the correct answer for this question.

What does the area under the curve (AUC) for a receiver operator characteristic (ROC) curve tell us?

(a) How well the model works at its optimum decision threshold
(b) Indicates which is the optimum decision threshold
(c) Provides a summary of how well the model works across a variety of thresholds

The information from the questionnaires provided an opportunity to adapt the lecture material accordingly, with a threshold example within cancer diagnosis. It was optional for students to retake the questionnaire. After class explanations, every student who retook the questionnaire selected the correct answer. The teaching highlights a research paper that indicates medical professionals often have difficulty interpreting threshold data [5]. This research suggests an alternative approach to independently examine the ROC curve's axes of sensitivity and specificity by encapsulating the data as one metric: net benefit to the patient.

2.3 Using computer-aided software to develop the schema

ATLAS.ti version 22 [6] was used for quantitative analysis of the reading list. Segments of the text of the intended reading list had codes attached (or tags) representing social phenomena, such as colonisation, bias, and perpetuation of bias. Analysis of the data within the software tool provided a way to integrate the data in numerous ways. The data querying also provided a visual impression of the interrelated concepts, helping formulate ideas to refine the schema. Visualising the codes, for example, as a heat map, also provided information to ensure there was adequate coverage of concepts.

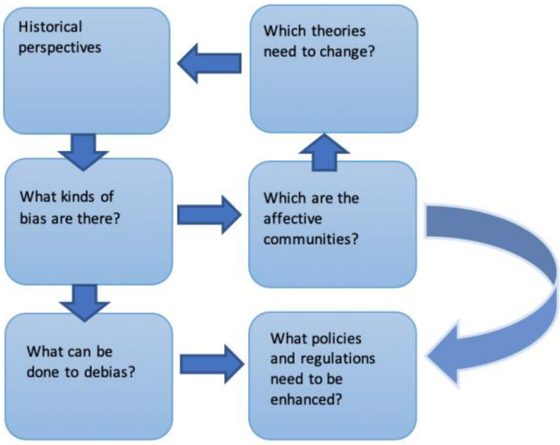

Figure 2. The schema developed for the lectures focuses on historical perspectives, the categories of bias, and which communities are affected. Discussions also encompassed techniques to debias and if underlying theories need to change.

Analysis of the selected documents helped refine the schema to emphasise adversely affected communities Fig.2. Discussions focused on what developers need to do and how regulations must adapt. It also helped students consider how communities can be empowered to have a voice in the deployment of AI systems.

Research indicates that providing appropriate schemas of related information can reduce cognitive load and improve learning [7]. Building on what one already knows with schemas helps retain information. Adopting appropriate schemas aids the rapid assimilation of new concepts and information. Although the reading list now has a broader range of references, the specific pages for suggested reading are limited to ensure an overall reduced cognitive load.

2.4 Flipped lecture examples

The focus during the first lecture was on machine learning: selecting data, bias, and how to debias. The pre-reading [8] includes Amazon's failed attempt to use AI to recruit staff, resulting in the AI system training on the predominantly male workforce data, perpetuating gender bias. Students readily identified solutions such as removing gender or words used by a specific gender. As students had mentioned an interest in health-related topics, lectures covered medical examples, including how medical data is often biased. The material also covered how a proxy of healthcare spending per person determines future healthcare spending for communities within the United States. Research shows that monetary spending per patient is less for black and ethnic minorities; this perpetuates inequality of healthcare provision for these communities. The students recognised that if the data is biased, this will exacerbate the problem. Historically clinical data has been collected predominantly from white non-Hispanic populations. Using AI algorithms with these records provides poorer identification of illness for other ethnicities. Discussions covered approaches to mitigating these situations, such as oversampling. An outline of how synthetic data could compensate for the lack of data for ethnic minorities and help reduce the bias in clinical data was also introduced [9].

Several students had previously outlined their interest in advanced AI techniques. Therefore, the background reading and slides included the use of adversarial techniques [10], illustrating how using AI, new data sets for under-surface ice profiles can be created to determine ice melt and better understand climate change. The students recognised the importance of these measurements and the threat to global communities at risk of sea level rises, often in the Global South.

The class pre-reading also includes using AI systems to identify cancers during surgery [8]. These critical decisions with a high risk have a human-in-the-loop approach. In this case, the surgeon makes an informed decision based on the AI system prediction combined with their expert knowledge. Students appreciated that the EU recommends this approach as oversight for many AI systems that affect individuals and society.

3 DISCUSSION

Although there are numerous papers covering AI ethics, there is a paucity of research papers on how AI ethics should be taught [11]. Also, the canon of AI ethics does not necessarily prioritise students' interests; students' environmental and climate change concerns are often a sub-category of AI ethics [12]. Students have recognised the importance of alternative perspectives and have suggested alternative sources during their discussions. Accepting the value of students' suggestions is one step toward co-creating the curriculum.

Tailoring content can have a positive impact on cognitive load. Linking knowledge to well-understood schemas can decrease the cognitive load. These schemas then act as a scaffold to learning new information. The questionnaires also provide a chance to learn from smaller units of information. Students can steadily build their knowledge via the automated feedback within the questionnaires. Ensuring well-understood concepts are not repeated during class allows for more challenging problems to be discussed. Evidence from answers to questionnaires suggests that considering ethical and moral dilemmas can improve technical understanding.

Providing questionnaires in quiz form with an assessment also provides students with an indication of their progress. Detailed explanations after each choice also help students prepare for the lecture, provide time to assimilate this knowledge into a schema, and embed information into long-term memory.

The discussions helped students appreciate the relevance of ethics; how we can balance choices. The discussion regarding interpreting the ROC curve highlighted the need to lower the threshold to improve cancer diagnosis. However, it raised potential resource problems associated with the increased number and ratio of false positives. The discussion also raised further questions, such as the availability of medical testing and whether tests should be free of charge, a particularly relevant societal issue in the UK. The discussions also reinforced that persons affected by AI should be empowered to participate in its regulation, a key recommendation of the Ada Lovelace Institute's Policy Briefing 2022 [13] to strengthen the EU AI Act.

4 CONCLUSIONS

The interests and knowledge of students should be considered when designing modules. Incorporating the perspectives of countries where students come from acknowledges the importance of their communities. Ensuring all students see themselves and their cultural backgrounds reflected in the curriculum helps ensure all students feel welcomed and engaged.

These preliminary studies have indicated that decolonising the curriculum can support the development of engineering skills. However, these studies have focused on AI ethics and bias, and future research is required to confirm the validity and efficacy of this approach for other teaching contexts and other engineering fields.

Diversification of the reading list has an essential contribution to the decolonisation process. Encouraging students to suggest additional research which critiques the reading or has a different perspective is one way to co-develop and decolonise the curricula. Decolonisation provides an opportunity for staff and students to collaborate. This approach may be one starting point for comparative studies across universities.

Viewing the curriculum through the decolonisation lens helps us consider that not all students have equal chances in education. Considering perspectives from around the world, examining the histories that have led to injustices, and sharing our decolonisation practices, we can hopefully break down some of the barriers in engineering education.

ABSTRACT

Engineers must engender trust in order to collaborate successfully to produce solutions that the world needs. As part of building this confidence, students with an accredited degree must meet learning outcomes i.e. demonstrate skills to an acceptable standard. Cheating during such assessments reduces professional integrity and future work quality. Through careful assessment practice and encouraging a professional culture with ethics, we may minimise student's opportunity and motivation to take short-cuts. With this in mind, it is useful to understand which technical and professional skills are most affected. Cheating is evolving, with more collaborative online opportunities. Previous research suggests a majority of student's admit to dishonesty at least once, and that there are several motivations, including individual, demographic, institutional, and societal. We describe today's engineering education environment in terms of how it affords cheating behaviours and their methods, including the popularity of online services such as Chegg. By analysing potential cheating methods against a current agreed inventory of contemporary engineering skills, we highlight where educators might focus efforts to reduce bad learning practices. We also consider how the covid pandemic with more online and remote studying amplifies the situation.

1 INTRODUCTION

Prior to employment, a young engineer's development relies heavily on meeting learning outcomes through university programmes. Accreditation bodies set these objectives at national or multinational levels, and higher education institutions (HEIs) provide the environment to teach the skills. Universities and the accreditation bodies foster mutual trust in the teaching and evidencing student achievement through rigorous assessment.

HEIs use a variety of assessment methods, either to assess individual teaching blocks, or synoptic assessment for a series of modules. While accreditors don't determine the testing and evidencing regime, they observe, probe and draw on their experience of visiting other places to satisfy themselves that the quality of education is comparable. They will look at programme structure, teaching materials, and various assessments including examination scripts, coursework, and laboratory reports.

Graduate employers trust HEIs to award degrees which are fit for purpose. University ranking, reputation, and the accreditor's seal of approval increases industry's confidence. This is particularly so for a vocational degree like engineering, where the question becomes whether the graduate, with the correct blend of emerging technical and professional skills, will fit into the company and contribute to its commercial success.

In this paper we reflect on the challenge for HEIs to maintain confidence in student achievement, which in turn, preserves the confidence of accreditors and potential employers that engineering graduates are not only well taught and that the assessments accurately demonstrate competency level, but that no cheating has taken place which might inflate grades. The sudden move to online assessment during the COVID19 pandemic has undoubtedly increased the potential for academic dishonesty, and the question we face is how to detect and deal with it rigorously, fairly, and with compassion.

We reflect on issues related to students cheating - which existed prior to the pandemic - but have been accentuated due to the increasing reliance upon online teaching resources and assessment. We base our commentary on experiences over the past three years both at our home institution and through discussions with other institutions that have observed similarities in the approach of some students to dishonestly enhance their performance, thus potentially deceiving future employers that their learning outcomes are truly reflective of their achievements.

2 BACKGROUND

2.1 Academic dishonesty

Academic dishonesty is endemic, as evidenced by the longitudinal studies on American and Canadian college students by Bowers then McCabe [1] [2] spanning over half a century; e.g. in one study between 2002-2010, 59,907 of 90,145 students anonymously self-reported one or more of nine identified cheating behaviours which we'll refer to by their numbers in later sections: 1) Copying sentences from material without quoting / citing sources. 2) Adding unused citations to the bibliography. 3) Plaigiarizing published works. 4) Getting questions and answers before taking exams. 5) Copying another student's work. 6) Unpermitted collaboration with other students. 7) Submitting another students work as their own. 8) Giving answers to other students in exams. 9) Using unpermitted notes.

The motivation to take short-cuts includes wider societal norms and behaviours, and more localised peer, family and classroom expectations. A framework proposed by Murdoch [3] on motivational factors for cheating identifies 3 questions that students may ask themselves. Table 1 lists these questions, together with examples of influences we've identified from the literature and our own practice (column 2).

Table 1. Motivations for cheating (adapted from [3])

Motivational question	**Examples of influences which encourage cheating**
What's my purpose ?	Low grade expectations, unfavourable peer comparison, inconsistent faculty approach to cheating, extrinsic goals overriding subject mastery.
Can I do this?	Underconfidence, limited available effort, inadequate learning level reached, unclear assessment standards.
What are the costs?	Low personal morals, unfollowed or ignored codes of academic practice, poor faculty monitoring and detection of cheating, perceived classroom injustices.

The multitude of influences suggest that efforts that we make to contain academic dishonesty must utilise a several strategies. Typically, most faculty rightly claim to adopt a consistent approach to cheating through clear assessment standards and requiring students to agree to codes of academic practice. These approaches however, may not inhibit all influences.

2.2 New engineering skills

The challenge to teach new skills in engineering degrees can motivate academic dishonesty because our understanding of what is required is still evolving. The SEFI engineering skills special interest group surveyed 25 2021 conference delegates about 8 typical barriers faced by educators when teaching emerging technical and professional skills (Figure 1). Responses revealed that an overloaded curriculum (row 4 and 8) and lack of time and resource were common hinderances, despite industry demand being strong (row 5).

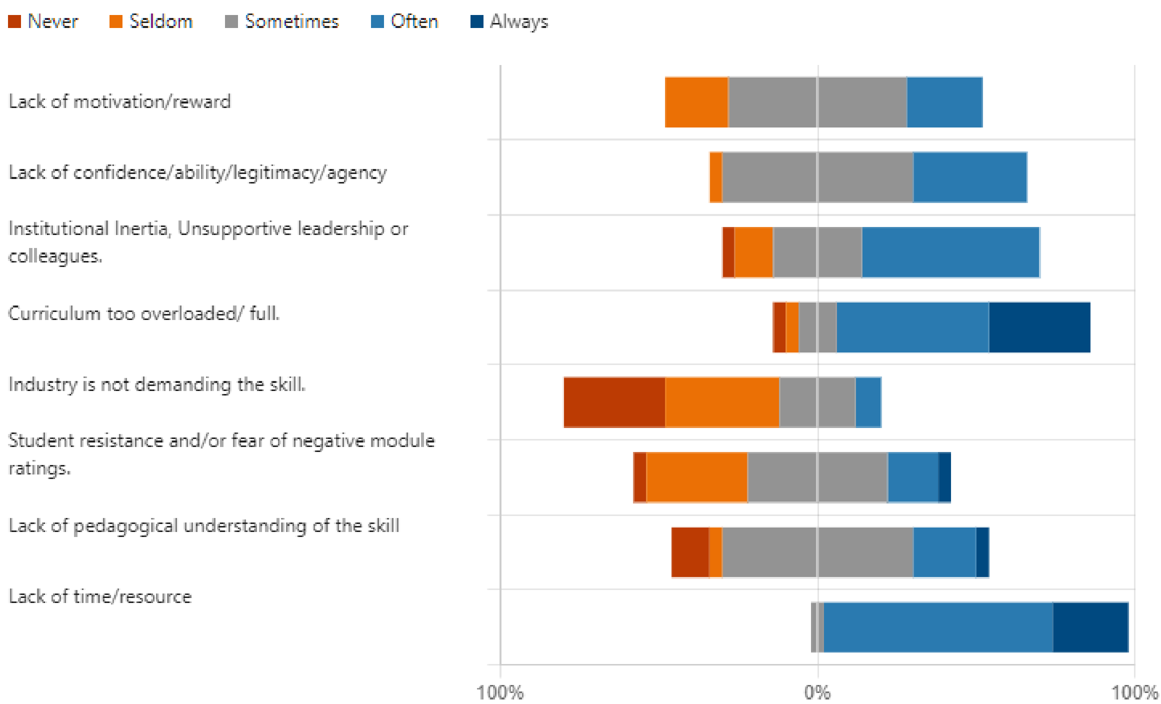

Fig. 1. Responses of the SEFI 2021 Engineering skills SIG survey to the question “I have come across the following hindrances in teaching new design, technical or professional skills:” (n=25)

Although the sample size from this survey is too small to draw meaningful conclusions, many of the hinderances identified can be related to the influences which motivate cheating in table 1. e.g. An educator's lack of pedagogical understanding in teaching the skill results in an inadequate learning level reached and unclear assessment standards, which influences students to answer affirmatively to “Can I do this?”. Thus, educators must be aware that, as we evolve the curriculum, our barriers to teaching skills effectively may inadvertently motivate cheating.

3 THE CURRENT ENVIRONMENT

3.1 Academic integrity process (honour code)

The methodology relies on our experience of operating a ‘academic integrity process’ at our home institution in which engineering is but one discipline and therefore being able to compare the concerns faced with other scientific but also non-scientific disciplines. We consider how each of the nine cheating behaviours in section 2.1 manifests in modern practice in sections 3.2, 3.3 and 3.4, and outline our process for detection and resolution in 3.5.

The issue of academic integrity is introduced to students by a presentation and they’re pointed towards online resources which set out its importance and the consequences of falling short. The materials explain what is acceptable assessment practice. This is part of an “honour code” [2] which is a learning agreement between student and university.

3.2 Plagiarism detection in coursework (behaviours 1,3 and 7)

Universities have moved to online submission of most coursework to allow checking for copying through similarity checking software such as Turnitin [4]. Students upload their submissions and Turnitin checks its extensive database to identify matches that contain either a fully copied piece of work from another author at one end, heavily copied and unattributed or badly attributed material in the middle of the scale, to badly referenced material which can be improved through better referencing practice. Turnitin is helpful in investigations into plagiarism when students would have to explain why the similarities have occurred. However, what it cannot reliably identify is work translated from other languages, or copying of text or table via their inclusion as images that are not textually searcheable.

3.3 Online resources that facilitate cheating (behaviours 2,4,6 and 7)

The internet affords the academic community many helpful resources such as substantive reports and research studies, but information can be weak and not peer-reviewed. Students in particular will use public search engines such as google to help them in their learning. The challenge HEIs face is in how to point students to good external assets on a particular topic. For engineering, some online materials use different methods to solve problems and explain concepts, which may enhance overall understanding or clarify misunderstandings from the in-house teaching.

However, a recent issue that became a challenge with wider use of online assessment is using sites that invite students to upload questions that others can answer that the student then uses substantially as ‘their’ answer. A platform rapidly gaining popularity reported by many institutions is ‘Chegg’ [5] . This file-sharing platform offers services to students which range from access to notes to providing expert advice on ‘homework’. Subscribers can upload questions and receive answers with the term ‘homework’ used rather than examination. Chegg allows HEIs to request the email and the IP address used by subscribers. At this stage the laws of countries where students are using this and similar services do not judge the sites to be illegal.

3.4 COVID19 pandemic and closed-book examinations (cheating behaviours 5, 8 and 9)

The procedures for dealing with closed-book examinations and those for online examinations are different and present different challenges. The pandemic resulted in a sudden move to only online examinations or only continuos assessment through coursework which in many cases universities and academics judge as appropriate to replace closed book examinations. Most universities also introduced emergency regulations to help arrive at fair outcomes in terms of actual module marks and overall GPA or degree classifications. They have produced challenges in themselves, however this is not the subject of this paper.

3.5 Code of Practice on Academic Integrity – detection of cheating.

Our home university operates what is referred to as a Code of practice on academic integrity (including plagiarism and conduct in examinations and class tests), which like other codes of practice is reviewed on an annual basis. It sets out the responsibilities of the principle academic units, the responsibilities of the students and the processes for investigations into different aspects on academic integrity. It describes categories of plagiarism, how investigations are to be conducted when a student is suspected of breaching academic integrity and the sanctions available to the principle academic unit to impose. Very serious cases are referred up to college misconduct committees and the students have a right of appeal which can reach senate and the external body for student affairs if a student pursues an appeal all the way through the university processes but is still dissatisfied with the outcome.

The sanctions available range from a revise and resubmit to the recording of a mark of zero and no further opportunity to resubmit, which depending on the weighting of the component under investigation, could result in failure of the whole programme. An example of this is a taught master's level project, which counts for one third of the credits for the 12-month degree programme. Should a student be awarded a mark of zero after an investigation and not be allowed to resubmit, the student could not achieve enough credits to be awarded the master's degree and would therefore leave the university either with no degree or a diploma or certificate depending on the number of credits achieved.

There are three levels of plagiarism or cheating which the code asks Academic Integrity Officers (AIOs) to judge in any investigation. They are: poor academic practice,. moderate plagiarism (or cheating), and serious plagiarism (or cheating). The level at which the student is studying is a factor as it is expected that a first year student's understanding of plagiarism and cheating is less thasn that of a more senior student.

Following a referral to the AIO from an assessor raising concern related a student's piece of work, the AIO decides whether the concerns merit an investigation and if so, calls the student to a meeting where they have an opportunity to respond. The AIO in consultation with a memebr of the module team determines the plagiarism level and then decides upon a sanction based on the options provided by the code of practice. Most cases under poor academic practice relate to inadequate referencing or to a misunderstanding of how to write a report following extensive reading in which it is not clear which parts relate to the literature read, and which parts are the student's own writing.

4 REFLECTION

4.1 Plagiarism detection in coursework (behaviours 1,3 and 7)

Plagiarism continues to be challenging in relation to student research and report writing skills. Making the judgement about what is synthesising and reporting other authors' findings rather than the student's own writing does not come easy to students. It is a skill that requires time for development. It is particularly difficult for students whose first language and culture are different to the university. What has become clear over several years is that the concept of plagiarism is considered differently in different countries. Students often argue that in their home countries they are encouraged to identify ‘the best resources’ and to include text from them without following appropriate referencing practice to distinguish between their words and those of an original author.

Attempts to encourage correct referencing at the start of programmes and then to reinforce the importance of avoiding plagiarism continue as students progress through their degree programmes. However, the issue of English language competence adds a further challenge to students attempting to read widely, to synthesise correctly and to then refence accurately. Experience by many academics who use Turnitin indicates that a substantial proportion of students use it at the draft stage of report to paraphrase sentences and paragraphs to reduce the similarity with the source they’ve copied. The skill being developed by students becomes beating the similarity algorithm, rather than developing the skills to write and reference correctly.

4.2 Online resources that facilitate cheating (behaviours 2,4,6 and 7)

This does seem to be an increasing threat to the integrity of the assessment system, which the COVID19 pandemic extenuated but will also apply to online assessment going forward. It’s important to start with an acknowledgement that if it were not for online examinations, the progression and completion of university degree programmes during the pandemic would have been extremely difficult, especially with many students studying remotely.

By their nature online examinations were typically open-book, which for many engineering academics was not the norm and therefore may have risked pedagogical frialty. Extra time to complete the exams was given to allow for uploading the answers and to help students overcome internet difficulties. Students taking the examinations in different time zones meaning some would start and finish before others within a designated window. Even with this flexibility some students failed to upload their answers as specified, and emailed them afterwards claiming they uploaded the wrong version, raising suspicions as to whether they had obtained external help with the final versions. The decision on whether to accept a later emailed answer version was left with individual lecturers resulting in potential arguments and disputes.

There was also the potential that students used social media apps such as WhatsApp and telephones to obtain the examination paper from another student who logged on and stared the examination early in the time window available and therefore to gain unauthorised extra time to complete the examination.

For both coursework and online examinations the potential to use platforms such as Chegg to upload questions and purchase answers was encountered. It is in theory possible to post questions at the start of an online examination, to start answering the questions but then amend answers if external answers were offered in time. Sometimes these answers were shared with others. Furthermore, students could simply Google a question to see if similar questions have been solved.

While in the early days of these potential incidents occurring, students may have used an email address and IP address that could be identified with them as it was used by them in other communications with the university. But there's evidence that they are now much more careful with this once learning that Chegg responds to queries from universities for information on individuals uploading their questions.

4.3 COVID Pandemic and Closed-book examinations (cheating behaviours 5, 8 and 9)

The challenge in closed book examinations generally revolves around potential cheating through bringing unauthorised resources into the examination rooms, hiding them, and using them when possible. In previous years, this has included the dishonest use of programmable calculators but has in recent years moved towards the use of mobile telephones to store additional materials, such as lecture notes and tutorial questions and answers. Investigation procedures are now long established and if a cheating offence is identified and evidence is collected, the procedures available can deal with the dishonesty in a now established way. The pandemic is gradually easing and the issues with closed-book examinations being compromised by remote exams is seen as less worrysome. However, universities that beleive in developing new online assessments are striving to find a way to keep the integrity of the assessment even when online.

4.4 Further reflections on staff resource

The impact on staff resources of this growing development of academic dishonesty shouldn no be underestimated. More time is required for staff to identify and evidence suspicions of cheating and for the processes employed to continue to be fair and robust. This is particularly the case with 'homework' platforms such as Chegg where the identification of cheating and evidencing it is not always straight forward. The system relies on the module team to identify plagiarism and cheating and to spend time evidencing and challenging the students identified as not displaying the honesty required. A possible reaction to the challenges presented could be to move back to assessment by closed book examinations only, particularly in the latter years of programmes when the recent trend has been to use more diverse ways of assessing the development of skills and attributes.

5 SUMMARY AND ACKNOWLEDGMENTS

We've reflected on the current challenges of academic dishonesty in an engineering faculty through reference to nine cheating behaviours and their modern guises. By considering student motivation for taking short-cuts and the underlying factors, we consider that the barriers educators face when teaching emerging skills may be encouraging students to take the wrong path.

We require multiple strategies to reduce academic dishonesty because there are many influences. While faculty work hard to dampen the third motivating question "What are the costs?", to make progress we need to develop strategies that counter the preceding questions: "What's my purpose?" and "Can I do this?". This means going far beyond a consistent approach to cheating, clear assessment standards and agreeing a code of academic practice, towards upskilling educators to teach and assess emerging skills without hinderance while compassionately addressing students' beliefs and goals.

Conference Key Areas: Attractiveness of Engineering, Gender

Keywords: *Bachelor in engineering, gender, broadening participation*

ABSTRACT

There are nine study programmes awarding the degree bachelor in engineering (högskoleingenjör) at the University of Gävle. Some of these have only a few applicants, even though the graduates are appreciated by a relatively large regional primary and secondary sector industry.

A major revision of the programmes is planned. One objective is to increase the attractiveness of the programmes. In the revised programmes, students are proposed to study most courses together during the first year of study, even if they belong to different engineering specializations. This is intended to improve the study environment. Students in programmes with low numbers of applicants will become part of a richer and livelier student collective. However, the attractiveness could further be problematized by asking to whom higher education is attractive. A special focus will be on increasing the admission of students from groups in society that have been underrepresented in higher education. More specifically this may be linked to individual factors such as the educational level of parents, family income,

immigrational background and geography. There may also be societal explanations in traditions of gendered professions. Engineering programmes, and especially some of the specializations at the university, are dominated by male students.

This study focuses on how universities can take action to further increase the attractiveness of the engineering programmes, with a special regard to groups that are known to be underrepresented among the students.

1 INTRODUCTION

1.1 The growth of technological education in Sweden

In Sweden, the question of who or which groups in society are given the opportunity to take part in higher education, has a long tradition. For example, a governmental report 1965:11 stated that the number of students in tertiary level education at the three existing institutes of technology should increase from the 2001 admitted students in 1964 [1]. According to Statistics Sweden (SCB), there were 12051 admitted students in 2018, of which 4195 were students for a bachelor degree in engineering. The development of the proportion of the population has increased steadily. In 2020, 44.6% of the population between 18 and 64 had a degree in higher education [2]. It is above the OECD average (38.6%) but lower than countries such as Canada, Japan, and South Korea which are above 50% [2]. At the same time, there is also an objective to broaden participation in higher education. This has also a long history but the development has intensified in recent decades. Not least, the amendment to the Higher Education Act 2005 has clearly stated this change [3]. It stipulates that higher education institutions "actively promote and broaden recruitment to higher education". This is also connected with more general formulations in, for example, the global goals for sustainable development. This type of issue is also raised in the Bologna reform for a consolidated education platform within the EU. The London Communication 2007, for example, states that “the student body entering, participating in and completing higher education at all levels should reflect the diversity of our populations” [4]. In the bill text (Prop. 2001/02: 15), several measures are proposed that the higher education institutions should take to affect the new law. There are ideas about establishing local action plans, increasing the number of preparatory educations (so called “basical years”, complimentary courses to secondary education programmes), increasing the number of distance education, enabling lifelong learning, and more. The purpose is stated as "to increase diversity and reduce social bias in recruitment" (Prop. 2001/02: 15). However, similar objectives already existed in the major higher education reform in 1977. In the new Higher Education Act of 1977, the objective was “to promote social equalization and increase access to higher education” [5]. An important part of the reform was to transfer several different post-secondary educations to the higher education sector. Among them are teacher and nursing educations that came to be those that included the large educational cohorts. However, the technical education took on a different design. The technical education remained in the upper secondary school, having a duration of four years and leading to a high school engineering degree. As a complement, a two-year technical post-secondary education was developed that would lead to a university degree in engineering. These educations were placed in several newly established smaller colleges outside the traditional university cities (Prop. 2001/02: 15).

In summary, there are two parallel objectives for universities regarding admission to engineering programs. One is an increased number of students in total and the other is that these students should have a more heterogeneous background.

1.2 Previous studies of attractiveness in a national context

Programmes in engineering are known to attract mainly male students. The Rose project investigated attitudes to learning science and technology in several countries [6]. The results show that there is a big difference between boys and girls. In Sweden, almost 60% of boys express that they want to work with technology, but less than 20 % of girls. The situation is similar in other wealthy countries. This corresponds well with national statistics presented by Royal Swedish Academy of Engineering Sciences [7]. In 2016, only 25% of the admitted students at bachelor of engineering programmes on a national level were women. In certain specializations, e.g chemical engineering, there are more than 50% women, but others have far fewer, e.g. specializations in electrical, mechanical, and computer science engineering, which all had less than 10% female students on a national level. In 2022 a thorough examination of broadening participation was published by the Swedish Higher Education Authority [4]. This study continues to pin-point at the lack of equality in recruiting students. The report also broadens the scope of attractiveness by addressing oblique recruitment of more social issues such as immigrant background, parental education level and geography.

1.3 Engineering education at University of Gävle

University of Gävle offers programmes on the level of bachelor in engineering. There are presently nine such programmes. The programs are often developed in close relation with industry and are given in Swedish. The level of internationalization in the programs are therefore low. The main rationale for the supply of programmes is to provide regional business and industry with qualified competence. However, many of the programmes have only few applicants, implying difficulties for the education as well as recruiting problems for the companies that employ the graduates.

In Swedish, the name of the degree is *högskoleingenjör*. This is a first cycle degree (undergraduate) awarded to students after three years of dedicated engineering studies. The programs normally extend over three academic years, i.e. 180 credit points (cr) according to the ECTS (European Credit Transfer System).

Our engineering programs aiming at the degree of högskoleingenjör correspond to what in Anglo-American countries sometimes is called bachelor of engineering in <major> (B.E. in <major M>) and sometimes bachelor of science in engineering (B.Sc.E. in <major M>).

The framework is regulated by the Swedish Higher Education Ordinance (1993:100), Annex 2 – System of Qualifications [8]. However, the scope or specialization of the studies is to be decided locally at each university. At the University of Gävle, the major field of studies of these programmes comprises a minimum of 90 cr, including a 15 cr degree project. Depending on the field of studies, the curricula include 15-37.5 cr of mathematics. The remaining third of the study programme includes relevant courses required to give the student the knowledge and skills required to work autonomously as a graduate engineer in their respective fields.

1.4 Rationale for the work

At the University of Gävle, there is an ongoing strategic revision of education. Regarding all existing study programmes, the following perspectives are focused: (1) attractiveness of the programmes in terms of number of applicants, (2) the capacity for the University to offer a complete study environment in the subject, from undergraduate to Ph.D. level, and (3) utility of the study programmes in terms of demands from society and employability. In the revision, all bachelor in engineering programmes at the university have been suggested for a major reform, with the objective to strengthen connection to research and improve student recruitment. A desire that the number of engineering programmes should be reduced has been expressed.

The authors of this paper are all involved in reforming the engineering programmes. In this paper, we focus on attractiveness. We wish to elaborate on what can be done to improve student recruitment. Our purpose of presenting this at SEFI is to share experiences with others who are interested or involved in similar situations or processes.

Attractiveness could be problematized by asking to whom higher education is attractive. Initially, the authors took a broader approach when studying admission data of students from groups in society that traditionally have been underrepresented in higher education. More specifically this is linked to individual factors such as age, the educational level of parents, family income, immigrational background and geography. However, the pre-study concluded that in these cases the University of Gävle did not stand out in comparision to other universities in Sweden. Although showing skewed distribution, it was not different from sociaty as a whole. However, one criteria stood out as slightly diffrent and intersting to further elaborate on. This was gender and the attractiveness for female students to choose technical disciplines. Gender issues may be interesting, as several of the programmes have a very low proportion of female applicants.

2 METHODOLOGY

2.1 Measuring attractiveness

Attractiveness depends on many factors and can be measured in different ways. A review is presented by Widiputera et al. [9]. In our context, in order to effectively monitor the present situation and the future development, we have chosen to focus on three measures: Limits regarding admission, number of applicants, and presence of underrepresented groups, in our case women.

In Sweden, a commonly used measure of attractiveness of study programmes is the limits regarding admission. These limits concern the grades for students coming from upper secondary school as well as results from the Swedish Scholastic Aptitude Test (SweSAT), in Swedish *Högskoleprovet* [10]. The limits are defined as the lowest score among the admitted applicants. The values of previous years are of high interest to prospective students and they have an impact on what programmes students choose. The values are often seen by students as an indicator of the status or quality of a study programme. Students tend to apply for programmes where they get “use” for the grades or results that they have received.

The number of applicants is another significant measure of attractiveness. In cases where all applying students are accepted, the number of admitted students equals the number of applicants. As the number of admitted students may be restricted by other factors unrelated to attractivness, we argue that the number of applicants is a more valid measure of attractivness than the number of admitted or enrolled students. This measure is more important for the study environment and the economy of the education than the above described limits regarding admission.

Attractiveness can also be measured by what groups of students that are attracted by a programme. A way of increasing attractiveness, in this sense, would be to attract groups of students that are underrepresented on the programme. If only the gender balance is considered, this measure may be represented by a value, e. g. the percentage of women.

2.2 Data collection

To monitor attractiveness of the bachelor in engineering programmes at University of Gävle, we have examined data from the Swedish Council for Higher Education (UHR), Statistics Sweden (SCB), and the local university administration. These data are publicly available and can provide a picture of the present state and a point of reference for future comparisons when we wish to evaluate implemented efforts to increase attractiveness. In some cases we have used data only for 2021, but to get a more solid background description regarding women, we have used data for 2008-2021.

3 RESULTS

3.1 The present state

Regarding the bachelor in engineering programmes at University of Gävle in 2021, all applying students that fulfill the requirements were admitted. This implies that the study programmes presently don’t have limits regarding admission, and thus are likely to be perceived as low status. In order to increase attractiveness, a first goal could be to obtain values for the admission limits. This would require that some, or at least one, applicant is rejected. If the University chooses to take actions in this direction, we hope to be able to elaborate these ideas and study the effects on attractiveness in a future paper.

The engineering programmes at University of Gävle have few students. The numbers of admitted students are presented in Table 1. Several of these students are admitted through the preparatory educations ("basical year"), which implies that they don't contribute to providing the programmes with limits regarding admission, as described above.

The third column of Table 1 presents the percentage of women on average during the period 2008 - 2021. A star (*) after the percentage of women indicates that two different programmes have been offered during the period. In these cases, the value represents the average for students from both programmes.

In the fourth column, the number of years that the programmes have admitted two or less female students is presented. In parentheses, the number of years that the programme(s) have been offered is presented. That is, for the programme in Automation engineering "9 (of 10)" means that the programme has been offered for ten years during the period, and during nine of these there has been at most two female students among the admitted.

Table 1. Number of admitted students, percentage of women, and number of years when two or fewer female students were admitted to the bachelor in engineering programmes at University of Gävle.

Study programme	Students admitted in September 2021	Percentage of women, average during 2008 - 2021	Number of years with two or less women admitted
Industrial Engineering and Management	26	35%	0 (of 2)
Automation Engineering	9	10%	9 (of 10)
Building Engineering	49	33% *	0 (of 14)
Computer Engineering	43	11%	7 (of 14)
Electrical Engineering	12	14% *	9 (of 12)
Energy Systems Engineering	26	23% *	1 (of 12)
Environmental engineering	20	57% *	0 (of 5)
Land Management and Engineering	11	21%	3 (of 4)
Mechanical Engineering	25	15%	7 (of 14)

3.2 Findings in existing data and proposed actions

In the revision of education at the University, we have so far investigated the situation, identified problems, and started suggesting possible solutions. The reformation process will probably go on for some years. We will here share some of our findings.

Table 1 shows that the number of admitted students in 2021 varies between 9 and 49. Seven of the nine programmes admitted less than 30 students. Here, the value 30 is chosen arbitrarily as it represents a typical class size in some contexts. During the education, several students quit their studies prematurely. Most that quit do so during the first year of study. This implies that classes in the programmes will be small, unless students from several programmes can participate in the same courses. In the present programmes, many courses are associated to a unique programme. In the reform of the engineering programmes, we propose that the revised programmes would share courses to a large extent especially during the first year of study. This would provide a richer and livelier study environment.

A low number of students in connection with an uneven gender balance may worsen the difficulties for the minority. In table 1, the third and fourth columns indicate that 25% women seems to be a suitable limit in this context for when there is a risk of having two or less women admitted to a programme in a year. In our context, six of the nine programmes have an average of less than 25% women. As seen in the fourth column, there are two or less women among the admitted students in half of the years or more frequently when there are 15% women or less. In these situations, a woman has at most one fellow female student, which is a vulnerable position as the risk of being left alone is obvious, temporarily due to e.g. illness, or permanently if the fellow female student quits. In many of these cases, the woman is the only admitted student from the start of the studies, or there is actually no admitted female student. Larger classes would help to build a more sustainable study environment for women, where the risk of being alone is smaller. Therefore, class sizes matter. If women would feel less vulnerable, the gender balance may improve, which could further reduce the risk for women to be the only female student in class and improve the study culture regarding gender equality in the programmes. This could further increase the attractiveness of the programmes, for both men and women.

3.3 Conclusions and a proposed rule of thumb

Higher education in Sweden today has a clear goal to increase broader participation. This is about increasing the attractiveness of education for groups that have traditionally been outside of higher education. The rationale of this may be linked to both societal and industrial needs of competence development but also from a more democratic stand point that participation in higher education should reflect the constitution of the general population as a whole. Focus in this study has been to examine the gender distribution between different engineering programs at the University of Gävle. In order to increase attractiveness in the sense of broader participation, all programmes should strive to attract men as well as women.

One proposed action is to share courses between different engineering specializations. We have been working with an idea that a majority of courses in the first year of all engineering programmes are shared. It may contribute to a livelier study environment and improve economy, but it may also contribute to more gender balanced study courses. It reduces the risk of being the only female student in class.

We can observe two significant limit values in the average percentage of women. The first limit is 25% women, below which we can see a risk for having two or less admitted women on a study programme in a year. The second limit is 15% women, where having two or less admitted women on a study programme seems to be the normal situation, occurring at least every second year.

We must point out that these limit values depend on the number of admitted students. However, it may still be useful to keep these values in mind as a rule of thumb. The values are easy to obtain which is an advantage if they are to be used as indicators. They may guide e.g. programme directors and directors of study for when care must be taken regarding admission and gender equality.

We propose the following formulation as the rule of thumb for when actions regarding course sizes may need to be considered:

- When there are 25% women on average on a programme, the risk arises that women may be left without fellow female students.
- When there are 15% women, they are often left without fellow female students.

This model, or rule of thumb, will also provide a scheme for evaluating the need for more changes within the study programmes.

4 ACKNOWLEDGMENTS

We wish to express our warm gratitude to Krister Ågren, who has patiently helped us to extract relevant data.

ABSTRACT

This article shows the experience of working on project-based learning using scientific posters, on the study of the mass geometry of matter, with students of various Physics subjects of Degrees in Engineering of the School of Design Engineering of the Polytechnic University of Valencia. The development of this work has been carried out with a dual purpose: on the one hand, to improve the teaching-learning process of mass geometry; and, on the other hand, to improve the acquisition of skills by students. This matter, which is studied in the Physics subjects of the first year of the degree, forms part of the basis of the studies of resistance of materials and theory of mechanisms of subsequent courses. The inclusion of two sessions of laboratory practices, as an extension of the work carried out in the theory and classroom practice sessions, has allowed us to study more deeply the theoretical concepts of mass geometry and their application to a real project, improving the learning by the students. In addition, the presentation of the project through the scientific poster has facilitated the acquisition of cross-curricular competencies such as application and practical thinking, teamwork, effective communication, and critical thinking.

1 INTRODUCTION

1.1 Context

This project was born in the subject of Physics-10270 of the bachelor's degree in Industrial Design Engineering and Product Development of the School of Design Engineering of the Polytechnic University of Valencia, taking into account that one of the professional opportunities of this bachelor's degree is the industry of the furniture. Later it is extended to the bachelor's degrees in Electrical Engineering and Mechanical Engineering, of the same School, being implemented in the subjects of Basic Physics and Physics Complements, respectively.

In the laboratory practices of these subjects is where the theoretical knowledge is applied to the experimental practice, carrying out tasks like those of laboratory research on physical phenomena studied in the classroom.

The initial decision to carry out this project was due more to a spirit of innovation and improvement than to a problem or difficulty in teaching Physics-10270. Although, despite the good academic results of the students, the experience in recent years courses showed us a slight decrease in the grades obtained in the laboratory practices with respect to the global grades of the Physics subject.

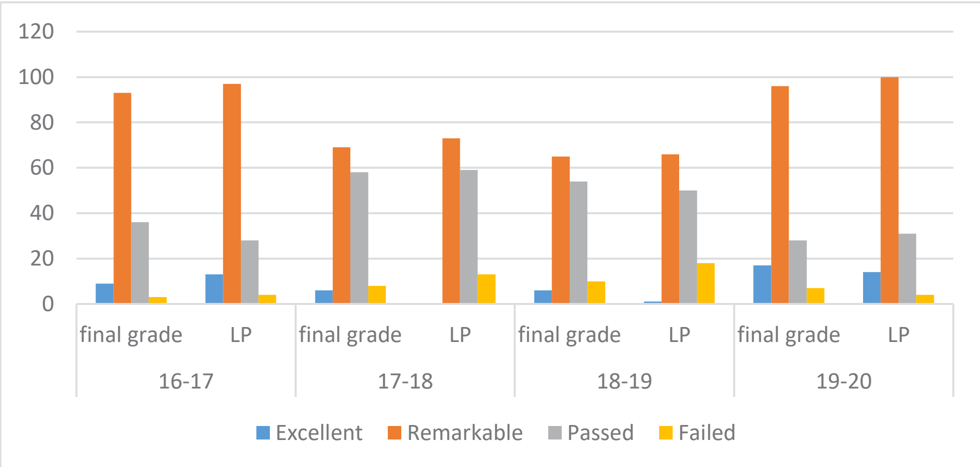

Fig. 1. Number of students and grades obtained in the final grade of the subject Physics 10270 and the average grade of the laboratory practices LP.

Even so, it is inevitable to think that, sometimes, the teaching of Physics, and the rest of the basic sciences, can be tedious; therefore, the inclusion of some methodological strategy can motivate students, and even "entertain" them [1].

1.2 Project-Based Learning (PBL) and Scientific Poster

The commitment to the PBL methodology is based on the conviction that the development of a project in engineering studies, even at a basic level, can be a great incentive for first-year students, as it facilitates the connection between training they receive and their future performance in the profession, in addition to the development of self-learning and creative thinking [2]. In fact, among the benefits of this method, it stands out that: it increases autonomous learning, prepares students for jobs, increases motivation, strengthens self-confidence, establishes connection between learning at school and reality, offers collaboration opportunities to build knowledge, increases social and communication skills, increases problem-solving skills... If we add to this the benefits of collaborative work in terms of increased interaction and critical thinking skills in the negotiated solutions, PBL seems to be a good strategy for improving the quality of learning [3].

For the transmission of the results of the project, the scientific poster format is chosen because it is expected that the students, who work as a team in the laboratory practices, will be able to build knowledge through the projects worked on, and to present them orally. Therefore, it is established as a teaching and evaluation tool within the course.

According to the Dictionary of the Spanish Language, a poster is a "banner that is fixed on the wall, without advertising purpose, or having lost that character". But we also understand the poster as a multimodal communicative genre, with text, graphics, color, speech, and even gestures, used to convey ideas. It is an alternative to the oral presentation, but with the same purpose [4].

Normally, the presentations of the tasks carried out in the laboratory practices are presented through written reports as a scientific article. In these works, we have verified that, very often, more than a true collaborative work, what is produced is rather the sum of pages created individually, despite the mechanisms and strategies that we carry out to try to avoid it. With the creation of a poster, we want to minimize this problem in some way, as well as the frustration or demotivation it generates.

In addition, we think that the presentation in poster format can be more stimulating, since the way of presenting the posters puts the communicator and the audience on the same level, facilitates the exchange of ideas and the comparison of results, and offers a panoramic vision of the different topics and contents presented. The poster is intended to see the other mode of presentation that takes place in academic and scientific conferences, with a more relaxed atmosphere, which promotes interaction between students in the meeting place.

2 METHODOLOGY

2.1 Objectives and Learning Outcomes

The main objective of this action is to initiate first-year students in the development of projects and their presentation through posters, so that they see the relationship between learning a basic training topic, such as mass geometry, and the future performance of the profession. The specific objectives of the action, related to the teaching methodology, are:

- Increase student motivation, through the development of a project, at a basic level, that gives meaning to the acquisition of knowledge.
- Improve the ability to apply the contents to practice, broadening the vision of the students' professional future.

- Promote the acquisition of cross-curricular competencies such as effective communication and critical thinking, through the delivery of the project in poster format and its exhibition.
- Quantify the degree of acquisition of knowledge by students.
- Quantify the degree of satisfaction of students and teachers regarding the effectiveness of the PBL methodology in the learning process.

Regarding the learning outcomes, it is expected that the students, upon completion of the project, will be able to:

- Detail the starting conditions for the design of a piece of furniture: materials, densities, shapes, etc.
- Analyse furniture elements by modelling the whole by decomposition into simple geometric figures.
- Calculate the basic parameters of mass geometry of furniture elements.
- Check the coherence of the results with respect to the selected reference system and axis.
- Prepare a report on the behaviour of a piece of furniture using the poster format for its presentation, paying attention to the correct use of scientific-technical language.

2.2 Work development

The work teams are made up of 5-6 students. The project is developed in two phases: first, a partial delivery is made, whose evaluation is used as feedback for the optimization of the work; and in the second phase, the final delivery is made, in which the complete development of the project is formalized, in poster format.

The development of the project is indicated in the following steps, briefly explained, considering that some of them are worked on at the same time, despite the exposed order:

<u>Sketch</u> (1.1): Each team will select an element of furniture to design, from those listed in the project script (chair, table, bench, shelf, staff, canopy, etc.), and will make a sketch of the design of the selected element.

<u>Modelling and decomposition of the element</u> (1.2): The team will model the furniture element in such a way that the simplicity requirement is met, to apply the calculation hypotheses. They will decompose it, into all the parts that are considered necessary, to analyse the element as a system of simple geometric figures.

<u>Table of materials</u> (1.3): The team will select the manufacturing materials of the different parts of the element, considering that it must consist of at least two different materials in its manufacture.

<u>Delivery of the first phase</u> (1.4): Each team will include the information from the previous sections in the script prepared by the teaching staff for delivery. Teachers will correct this delivery before starting the next phase of the project, so that students have the necessary feedback.

Choice of the reference system for calculating the centre of mass (2.1): Each team must analyse its element to select the reference system with respect to which its centre of mass will be calculated.

Choice of the axis with respect to which the moment of inertia will be calculated (2.2): Each team must analyse its element to select the axis with respect to which it will calculate its moment of inertia. This choice will be supervised by the teaching staff and their approval will be required to continue with the subsequent calculation.

Calculation of the centre of mass of the element (2.3): The team must apply the calculation equation for the centre of mass of material point systems.

Calculation of the moment of inertia of the element (2.4): The team must apply the calculation equation of moments of inertia of material point systems.

Preparation of the poster (2.5): All the elements described above in both phases of the project must integrate the poster that the work teams will present. The basic instructions for making a poster will be followed [4], leaving the structure arranged in title, authors, degree, introduction with hypothesis and objective, methodology and development, results, and conclusions.

Presentation of the poster (2.6): The day of presentation will be defined, in the course programming, as a congress. Teachers will oversee printing the posters and leaving them presented on the panels. The teams will explain their projects in the corresponding session.

Fig. 2. Exhibitions of the posters of the Mass Geometry Projects.
Course 20-21 on the left and course 21-22 on the right.

For the evaluation of the achievement of the objectives, the following were designed:

- Teaching materials for the acquisition of knowledge and development of the project.
- Two rubrics for the evaluation of the two phases of the project (first delivery and poster), in which the cross-curricular competence CT02 – Application and practical thinking was also assessed.
- The self-assessment questionnaires for the evaluation of the cross-curricular competence CT06 – Teamwork.

- The evaluation rubric of the cross-curricular competence CT08 – Effective oral communication, used by students and teachers in the exhibition of the posters.
- Questionnaires for student satisfaction surveys.

3 RESULTS

The two aspects that teachers most value at the end of each course are academic results and student satisfaction. Regarding the first aspect, a comparison of the average of the results obtained in laboratory practices 5 and 6 is shown, before including the mass geometry project, and the results obtained in these practices, after the change by the project, compared to the final lab grade (except the current course, which has not yet been completed). As can be seen, the change of the old practices 5 and 6 by the project has led to an improvement in the grades obtained.

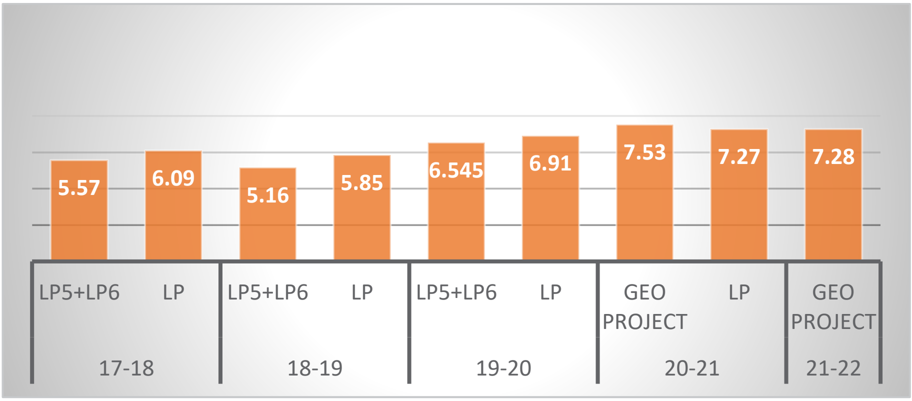

Fig. 3. Grades obtained in 5 and 6 laboratory practices, average grade of the GEO Project, and average grade of the laboratory practices LP of the subject Physics 10270.

Regarding the second aspect, it has been possible to observe a significant percentage of students satisfied with the work carried out, and a slight increase in the motivation of the students with respect to the work developed in the conventional laboratory practices, clouded by the sanitary restrictions that have not allowed much interaction in the development of work.

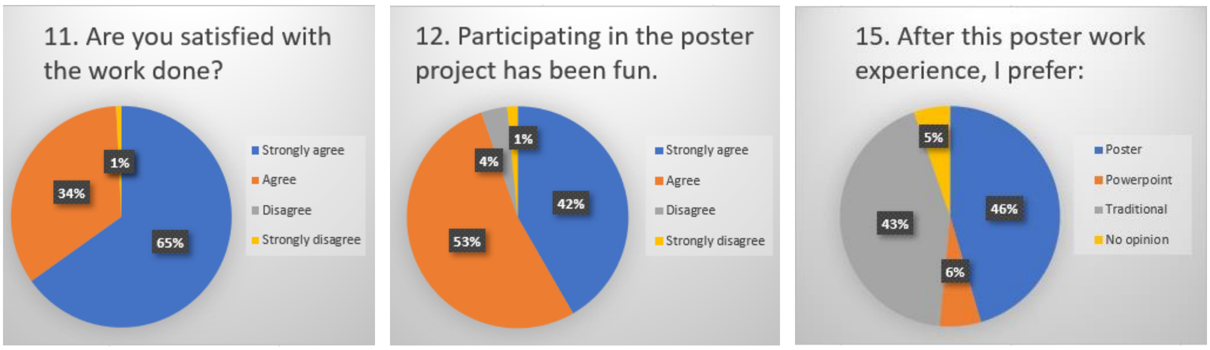

Fig. 4. Answers to some of the questions asked in the satisfaction questionnaire.

In view of the results of the questionnaire, it can be concluded that the application of the PBL methodology using Scientific Poster for improving the teaching-learning process of students of various Physics subjects of bachelor's degrees in Engineering of the School of Design Engineering has been successful. As a closure of this work, some representative posters of the students of Physics-10270 subject are shown.

ABSTRACT

Covid-19 has been a game-changer in engineering education at the higher education level. Even beyond the pandemic, blended learning is there to stay. The design, execution, and delivery of blended learning can be supported by a plethora of fast-developing educational technology.
In this paper we share the experience of the evolution of one engineering course "Uncertainty in Artificial Intelligence" from a rather traditional design strongly relying on face-to-face interaction to a fully blended technology-supported course.

In particular, we share the experience of how an interactive courseware platform called "Nextbook", which allows students and teacher to directly interact on the course material, supported the design, implementation, and delivery. Student experiences measured using a questionnaire are supplemented with teacher experiences to present the following "lessons learnt": A well-chosen platform can help students find clear structure in a mix of types of material, and social annotation features make it possible to connect discussion and questions and answers directly to the course material. Further efforts are needed for engaging students to actively use the features of interactive courseware platforms.

1 INTRODUCTION

Covid-19 has forced all teachers to rethink their education and most often forced them to move their education fully online. As we are now moving beyond the pandemic phase, it becomes clear that returning to the more traditional formats with a lot of face-to-face teaching is unlikely. Students have discovered the virtues of streaming, lecture videos, and other aspects of online learning. While reasons can be of pragmatic nature (less commuting, more sleeping, etc.) students also indicate pedagogic reasons (rewatching explanations of difficult content, more efficient handling of available time, etc.). The challenge for the future is how to create high quality blended teaching, that foster rather than destroy the social aspect of learning. Learning is a social event. Social constructivism, a sociological theory in educational sciences, clearly states that knowledge is constructed through interaction with others [1]. Discussing course material with others is shown to be related to better understanding and higher academic achievement [2]. Nevertheless, it is found to be challenging to ensure students participate in online discussions [2]. The creation of online learning communities could foster students' participation, by for instance allowing for social annotations [3].
In this paper we explore one example of how an interactive courseware platform with possibilities for social annotation can be used to shape blended learning, and how it supports social interactions in this process. This paper builds on the experience of the case studies of using social annotation platforms to connect discussion to course materials reported in [4].

2 PLATFORM, CONTEXT, AND IMPLEMENTATION

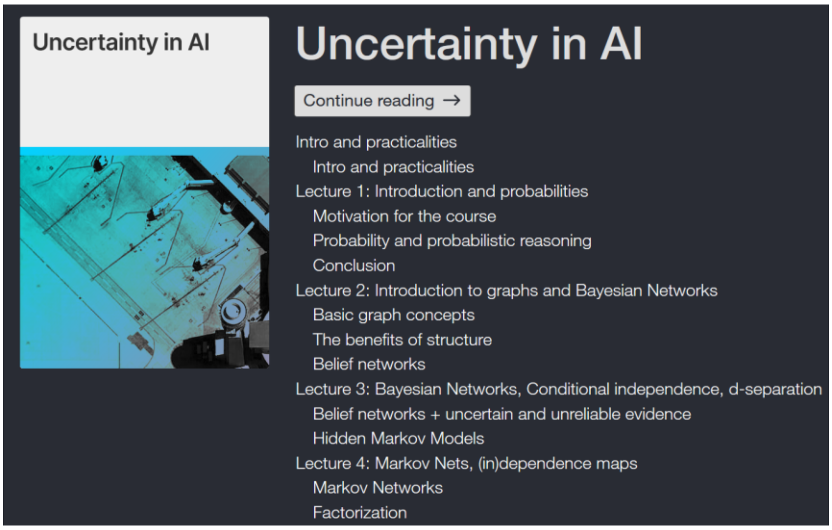

Fig. 1. Part of the outline of the online course material of Uncertainty in AI as available on the Nextbook platform

2.1 Nextbook

In the context of the Erasmus+ project Co-created Interactive Courseware (CiC), we explore the new interactive courseware platform Nextbook (www.Nextbook.be) and develop pedagogical use cases, teachers guides, and learning analytics to support the use of interactive courseware on Nextbook and in general. Nextbook (http://nextbook.be) is a free, online platform for "social reading" of textbooks, which envisions social construction (co-creation) in the future. Teachers can upload their textbook, augmented with video, 3D models, quizzes, etc. This augmented textbook immediately serves as a basis for social learning. Nextbook offers flexible reading on any platform as the book is transformed using web technology offering automatic scaling, free choice of font and text size, dark mode, etc. It also has functionality for reading out loud, a nice supplement on top of a dyslexia-friendly font for students with reading disabilities or challenges. Students can use highlights to mark important parts and even generate automatic summaries from these highlights. They can also add personal notes for later reference. From the social interaction point of view, they can select part of the text, image, formulate, … and start a discussion from this or ask a question. Questions or comments can be responded to in a chat-like manner and liked (up-voted).

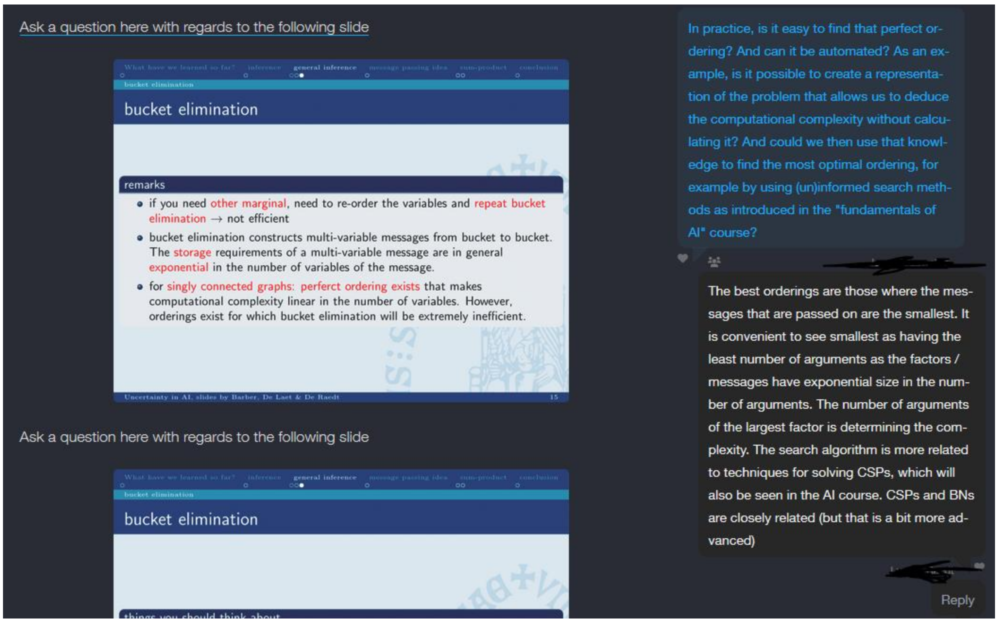

Fig. 2: Slides as used in the video, with the opportunity to discuss/ask questions.

2.2 Context

This paper focuses on the application of Nextbook in the context of blended learning in the 4 ECTS course Uncertainty in Artificial Intelligence, offered in the Advanced Master program of Artificial Intelligence at KU Leuven, Belgium. KU Leuven is a highly ranked research-intensive university both regarding research and education. The master of Artificial Intelligence is a multi-disciplinary one-year master that recruits many international students. Typically, the course of Uncertainty in Artificial Intelligence has around 250 students, and a high success rate of around 85%. Students entering the course have diverse background, with different levels of experience and skills in mathematics, probability calculus, and programming. Although some digitization was taken place before covid-19 (lecture recordings and video solutions of exercises), covid-19 forced the course to go fully online. To ensure a good online and flexible experiences, the two teachers of the course decided to replace the live lectures with a set of videos, where each video focuses on a particular topic. The lecture time slot itself was used for an online weekly Q&A session and elaboration of some additional examples.
After the initial fully online higher education, we have now moved to a new era of blended education. Teachers are expected to still offer online alternatives, but also provide on-campus activity of students. Rather than moving back to the traditional lectures with recordings, the teaching team decided to move to a fully blended format. The video material allowing the student to learn all the content of the course,

were kept but now supplemented with weekly on-campus Q&A sessions (that was livestreamed to accommodate for sick students or students not able to travel). During the weekly on-campus Q&A session, a quiz with exercises support interactive practicing of the course content, was done with the students.

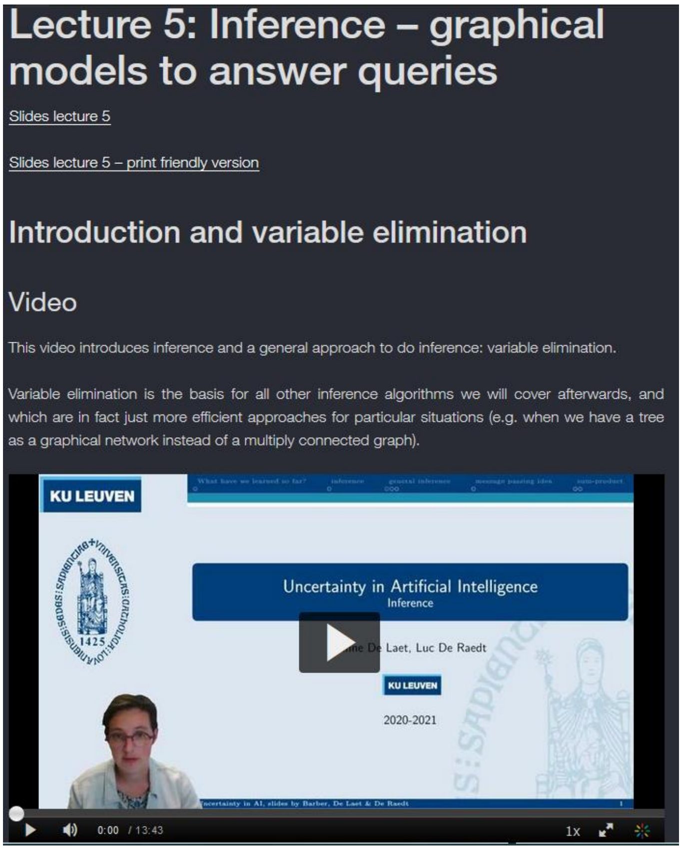

Fig. 3. A video as made available in Nextbook

2.3 Implementation

On the Nextbook platform an outline of the course was created allowing students to get a structured overview of the course content (Fig. 1). Each chapter represents one lecture that corresponds to the content a student must cover in one week. Within each lecture, sections were created for the different topics. For each topic, one video was created (Fig. 3). To allow students to discuss about or ask questions on the material covered, the slides used in the video were added below the video. A student could then add a remark or question next to the slide (Fig. 2).

Students were instructed to digest the material connected to a lecture before the Q&A session and to ask their questions at latest half a day beforehand, in order to allow the teachers to prepare the Q&A session. Answers to the questions were not only provided during the on-campus and livestreamed Q&A session but also in the Nextbook platform itself (Fig. 2).

3 METHODOLOGY FOR EVALUATION

Experiences were collected from the students in two ways: using the universities official Course/Teacher evaluation, and using an online dedicated survey, both were administered in the semester after students took the course.

The **official Course/Teacher evaluation** consisted of a fixed set of 12 questions that students rate on a scale from 1-6, of which 4 were related to the approach of delivering the course material in Nextbook: (Q1) There was sufficient consistency in

the course structure; (Q2) The study materials helped me process the subject matter; (Q3) I could ask someone of the teaching staff for additional explanation; (Q4) I was satisfied with the way the circumstances due to the corona crisis were dealt with in this course. Additionally, students could also leave open remarks in two categories (what did you like and what could be improved).
To get additional feedback on the use of the Nextbook platform in the course an **additional online survey** was sent out to all students in the course with questions targeting the use of Nextbook in the course and potential future use and improvements of Nextbook.

4 RESULTS OF SURVEYS

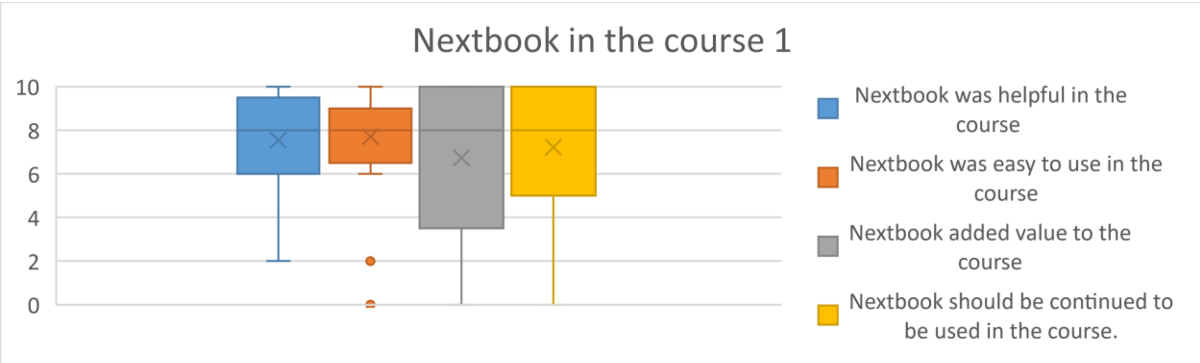

Fig. 4: Results of custom online student survey (N=33) – part 1.

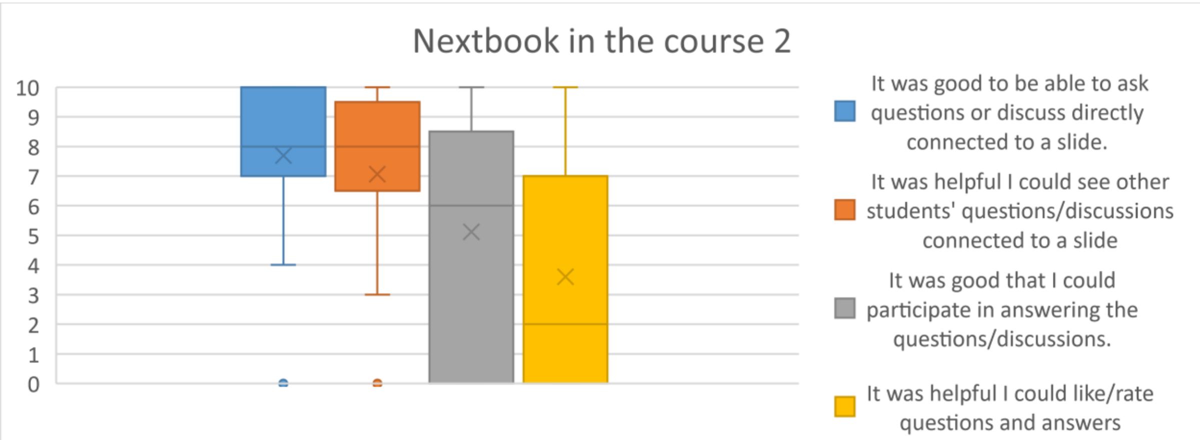

Fig. 5: Results of custom online student survey (N=33) – part 2.

4.1 Official Course/Teacher evaluation

43 students (26%) responded to the official course/teacher evaluation. The course was found to be highly consistent in structure (Q1: 5.28/6), and the material to be very supportive (Q2: 5.53/6). The opportunity for asking questions was rated very highly (Q3: 5.38/6), and it was indicated that the course dealt well with the corona circumstances (Q4: 5.47/5). Hereby the evaluation is in the top quartile of other courses evaluated with a similar student population at the university. In the open comments Nextbook was mentioned on some occasions, all in a positive manner “Nextbook was a very good online learning platform where we could directly ask question about a specific slide!”, “coherent online lecture material”, “Also, the recorded lectures as they were structured in Nextbook platform provided a great way

to find quickly any part of the study material.", and "Online book with direct questions".

4.2 Student survey

Fig. 4- Fig. 6 present the results of the custom online student survey (N=33). The open comments of the students are used in the discussion and recommendations below.

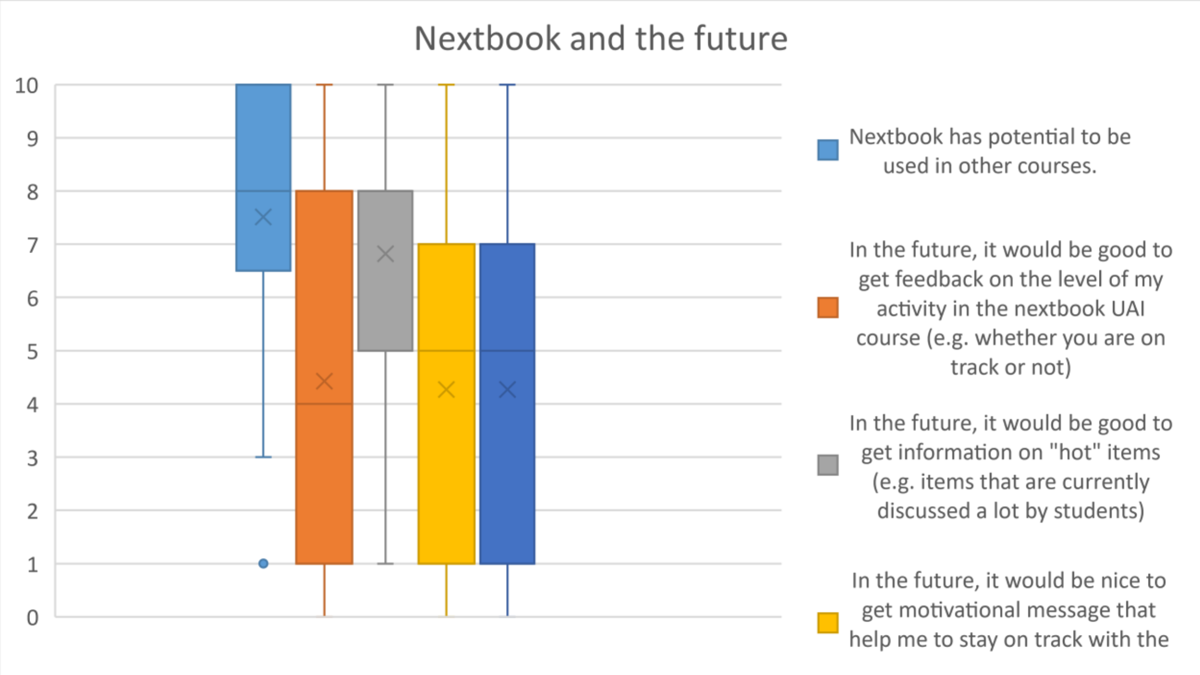

Fig. 6: Results of custom online student survey (N=33) – part 3.

5 DISCUSSION AND RECOMMENDATIONS

Overall, the way Nextbook was used in the course was appreciated by the students (Fig. 4) and was found te be easy to use (Fig. 4). As some students indicate doubts about the added value of Nextbook (Fig. 4), the discussion below digs deeper on some specific themes.

5.1 Structured integration of material

The points that was most appreciated about the use of Nextbook in the course is the **structure** that was provided. 13 out of 31 students explicitly mentioned the structured as positive aspect. Some examples: "It was very structured, which was handy for understanding and learning the material."; "Very structured."; Also, it's very structured, which can give me a better understanding of the whole structure and timeline of the course. "Everything is structured by topic which makes it much easier to digest and process. Also, easier to later find the relevant video in case of any questions".
Furthermore, **the integration of the different types of material** (video and slides) was acknowledged: "Having the whole course videos and slides blended together in the same place and quickly accessible"; "I wish more courses would use this type of combination of video lectures and slides on such a platform."; "[…] Also the mix of video and slides was particularly helpful."
Nextbook is not the only platform that could provide structure and integration of different types of material, and one could argue that the use of a platform as

Nextbook is “overkill” if it is only there for structure and integration. Therefore, the next sections dig deeper on the more social parts of the learning that Nextbook aims to strengthen.
Our recommendation Integration of different types of material in one overviewable structure is worth investing in, as students clearly value these aspects.

5.2 Connecting discussion to the course material

Students indicate that it is good to be able to ask questions or discuss directly connected to the course material (Fig. 5): “Ability to ask questions specific to parts of the course.”; “Students can post questions on a particular slide”; “Also nice to see questions of other students at the relevant slide instead of mixed together on a discussion forum.” One student indicates this is in fact the only added value of the platform “As a mechanism of asking questions, it worked, but that was about the only value of the platform for me.” The teachers however observed that only about 20 different students regularly used the discussion or questions/answer throughout the course. We hypothesize that most students look at the discussions and questions and answers without actively participating, as students indicate it is helpful to see other students’ questions/discussions connected to a slide (Fig. 6), and that they are less positive about the possibility to participate in answering questions and joining a discussion (Fig. 6) and liking or rating questions and answers (Fig. 6). The social aspect of the platform is therefore underused. A student states it nicely as follows: “I think this [asking questions connected to the course slide] exactly is one of the more powerful features. Reading the questions in the "flat list" of Toledo [the VLE of the university] makes it sometimes difficult to "link" the question with the text in the book. Having them both tied-up together would indeed be more interesting.”
The fact that students asked questions directly on the material was very helpful for the teachers in preparing their lectures and Q&A sessions. Rather than looking to a, often unstructured discussion board, the teachers could browse through the course material and immediately see which points were unclear to students. In fact, the teachers just projected the Nextbook slides with the connected questions during the live Q&A session in order to start an additional explanation.
Our recommendation Connecting the discussion to the course material is valuable and handy for the teacher, but additional efforts are required before it can be considered as real online social learning.

5.3 Future of Nextbook

Students agree that Nextbook should be used in the course (Fig. 4) as it provides added value (Fig. 4), and that it has potential to be used in other courses (Fig. 5). When asked about which Learning Analytics aspects would be helpful to be added (Fig. 6), students are more conservative. While they believe that seeing the “hot items” could be of value, they disagree that getting feedback on their activity level, or motivational messages Fig. 6). Like one student expresses, potential reasons are the level of experience and self-regulation of master students and the fear to induce additional stress: “Personally, I liked its simplicity. I think that adding the suggested extra information would just add stress when you happen to have a busy week. Closer following other people’s discussions might also add to that stress. In my experience most master’s students know how important it is to keep up with the material and can find discussions in case they have a question.” While individual

students do see value in such approaches to get additional feedback “Indeed give feedback on how you are performing at the moment and what to do better”.
Our recommendation Learning Analytics should be used with care and should primarily focus on showing students what are students are working on.

5.4 Other aspects

Different students express the concern that the course material on Nextbook is only available online, which causes more screen time, and makes them fear that the material will not be available anymore after they graduate.
The more interactive nature also triggers with some the fear to have to spend more time on the course “What I suppose, is that doing it in a classical style would require less time, while the notebook style is quite more dynamic but needs more time to spend to enjoy it fully.”, while other even ask for more interactive features “Maybe in the middle of some chapters some practical questions could be asked. I’m either multiple choice questions form or blank filling form.”
While Nextbook was in general found easy to be used (Fig. 4), some students still experience difficulties “I had difficulties with adding a question to the slides. I followed the instructions but for some reason it did not work.”. “About 40% of the chapters didn't function properly for me. For instance, I couldn't put the video to full screen or change the volume of sound through the browser.”. Or “I did not really use the ask questions function. It was my fault, but I forgot my password each time, which is required to enter comments or questions”. This is surprising as technical assistance was available throughout the entire course and every single technical issue that was reported was solved within a very short time frame.
Our recommendation Provide ample opportunity for students to ask for technical assistance, and to look for ways students could also use the course material offline and download after the course for future reference after they finished the course.

6 CONCLUSION

Interactive courseware has a potential to support blended learning. A well-chosen platform can help students find clear structure in a mix of types of material (e.g., videos, text, and slides). Furthermore, social annotation features of such platforms make it possible to connect discussion and questions and answers directly to the course material. While this feature is valued a lot by teachers and students, only a minority of the students actively uses it, and therefore we cannot say that there is already a real online learning community supporting online learning. To realize the full potential of social learning, additional efforts are required to trigger discussions and exchanges among students.

7 ACKNOWLEDGMENTS

We gratefully acknowledge the support of the European Erasmus+ programme for the project “Co-created Interactive Courseware”, with project-number 2019-1-UK01-KA203-061669. ABSTRACT

The National Engineering School of Tarbes (ENIT) is a French engineering school with a curriculum from undergraduate to graduate studies for general engineers. Curriculum ends by an equivalent Master degree in sciences. ENIT students are

[1] *Corresponding Author*

B. Trajin

baptiste.trajin@enit.fr

doi:10.5821/conference-9788412322262.1393

particularly involved into mechanical, civil, industrial engineering, material science and design of integrated systems.

From the first year of study, students tackle theoretical tools for engineers. Moreover, in a curriculum composed of several different disciplines, connections between scientific subjects may be difficult to weave. As a consequence, student activities for solving engineering problems were developed. The basic concept is to clearly illustrate how theoretical tools can be used in an activity linked to engineering and more generally to student life.

In addition, future engineers must be acquainted and trained to ethic values, especially those used in team work. During team working, honesty and benevolence are important core values to be encouraged as a basis of trust that has been identified as one of the cornerstones for performing teams. Consequently, the principle of team working for students was adopted and humanities are associated into the project to manage ethical and professional standards.

Thus, the chosen teaching activity is a project-based learning team work that addresses on the one hand application of integration and derivation to expression of needs of consumable supplies and notions around professional ethics on the other hands.

1 INTRODUCTION

1.1 General context

The National Engineering School of Tarbes (ENIT) is a French engineering school with a curriculum of 10 semesters training general engineers. Curriculum ends by an equivalent Master degree in sciences.

The ENIT's mission is to develop a publicly responsible, creative, competitive individual who is receptive to science, latest technologies and cultural values; to promote scientific progress, social and economic well-being. The school is attractive and is able to respond to the environmental challenges and has a great social importance to the national progress.

In this context, ENIT is asked about its competencies, specifically its ability to anticipate developments and drive its actions towards progress. Aware of the stakes, the logic of the development of ENIT has consisted not only of preparing its future engineers in line with the needs of companies, but also of taking into account permanently and supporting the reality of its economic environment. Therefore, ENIT has the ability to put in place new training corresponding to new professions and to social evolutions.

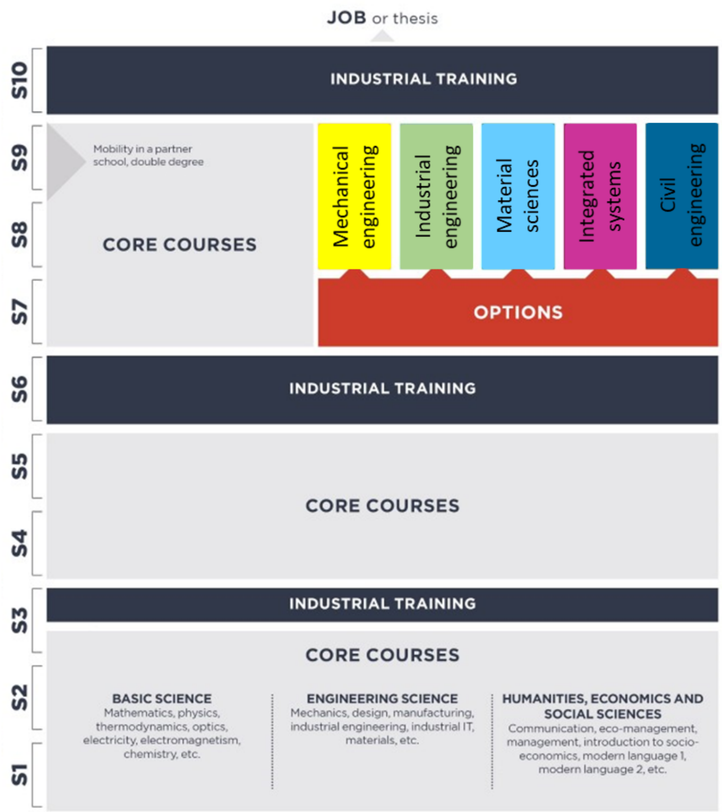

Fig. 1. ENIT's curriculum

ENIT mainly recruits students after high school of A-level. During the bachelor curriculum, the students follow scientific classes such as mathematics and physics but also classes of humanities, economics and social sciences. The part of engineering classes regarding classes of basic sciences increases each semester. During the master curriculum, the students follow core courses of engineering and also an option oriented to mechanical engineering, industrial engineering, civil engineering, material science or design of integrated systems. Moreover, as depicted in figure 1 where *Sx* means *Semester x*, industrial training lasts 2 semester and a half where autonomy of students is developed facing real industrial engineering projects.

1.2 Science and ethics as fundamentals for engineers

The engineers from ENIT can have technical and scientific jobs as well as management activities. The common point between all these jobs is the ability to model the world. Obviously, the model can be a mathematical one based on equations or logical links. But the model can also be an expression of links between people or communities using for example the ARDI (Actors, Resources, Dynamics and Interactions) co-construction method [1]. Based on this duality of models, the students are trained to mathematical modelling as well as humanities and social sciences from the beginning of their curriculum.

On the one hand, it is obvious that mathematics is a fundamental for modelling but is also a basic tool for physics as a common language to describe, solve and predict numerous phenomena. Moreover, in order to clearly apprehend the whole spectrum of applications, many bases are mandatory. That's why mathematics is deeply taught at the beginning of the curriculum.

On the other hand, humanities are also a fundamental of engineering. Indeed, engineers are working in teams, they must communicate and argue all day long. Consequently, the students must be trained to team work, to imagine their roles in team [2] but also to take advantage of collective intelligence.

The paper describes how these fundamentals are introduced to the ENIT's students. Section 2 deals with the activities proposed to incoming students in order to better understand the world and the job of engineers in its complexity. From these first steps, a project-based learning sequence is designed and described in section 3. Finally, conclusion and development opportunities that can be proposed are given in section 4.

2 ACTIVITIES FOR INCOMING STUDENTS IN UNDERGRADUATE STUDIES

2.1 Workshop: Engineering world in its complexity

The first activity proposed to incoming students lasts about 6 hours. It deals with an overview of the environment of engineers and its complexity. Two texts present a realistic situation that can occur in civil engineering companies. The first text exposes the case through the point of view of a client that has to deal with suppliers but also with the *make or buy* dilemma. The client expresses its supplying difficulties and the consequences to respect the delays facing unpredictable events such as the sanitary crisis or international war in countries providing raw materials. The second text outlines the same situation from the point of view of a team member of the supplier. Ethics is introduced with the moral dilemma between the duty regarding the client and the occupational health of co-workers as well as family considerations.

Even if the students are totally unaware of civil engineering, they are asked to work together to firstly model the case from the client's point of view and then to modify the model using the supplier's point of view. Here, the ARDI method is introduced through its application on the proposed example.

Moreover, at the beginning of the curriculum, incoming students don't know well each other. As a consequence, it becomes necessary to assume their own personality. The students naturally refer themselves as introvert or extroverted natures. In groups of 5 to 6 students, it is suggested to students to develop their active listening. Then, each student of the group can express its ideas directly or with the help of its colleagues.

At this stage, the advantages of collective intelligence are clearly underlined in order to introduce a new way of working together based on cooperation instead of competition. A reflective practice is initiated in this workshop with the aim of using and developing it all along the curriculum. The activity shows some students that are focussed on facts or key figures and some students more focussed on moral sensitivity and empathy [3].

Finally, the attention of students is oriented on the analysis of implicit and explicit parts of the texts that implies understanding and interpretation [4] leading to discussion and argue in the group.

2.2 Climate fresk

This activity is also proposed to incoming students and lasts about 4 hours. It is fully complementary with the one described in section 2.1. This workshop [5] is composed of different times where previous notions on team work are applied: ice breaker, puzzle time and collage, creative time, pitch, debate, talking about solutions.

The main goal is here to convince the students of taking into consideration emotions in their behaviour. Indeed, the managers and engineers often tossed out emotions from making decisions. However, the emotions should not be hidden in terms of quality of working lifetime. As a consequence, it seems necessary to better grasp the emotions especially linked to anxiety. The Plutchik's wheel of emotions [6] in figure 2 is here introduced.

Moreover, a particular focused is done to the time evolution of emotions regarding DABDA model [7]: Denial, Anger, Bargaining, Depression and Acceptance. It is required to move as fast as possible from denial or anger to acceptance. A 2D graph showing efficiency of action for climate regarding their personal or societal cost is established by students to demonstrate that a great change that seems difficult can be composed of individual changes that seem easier to realise.

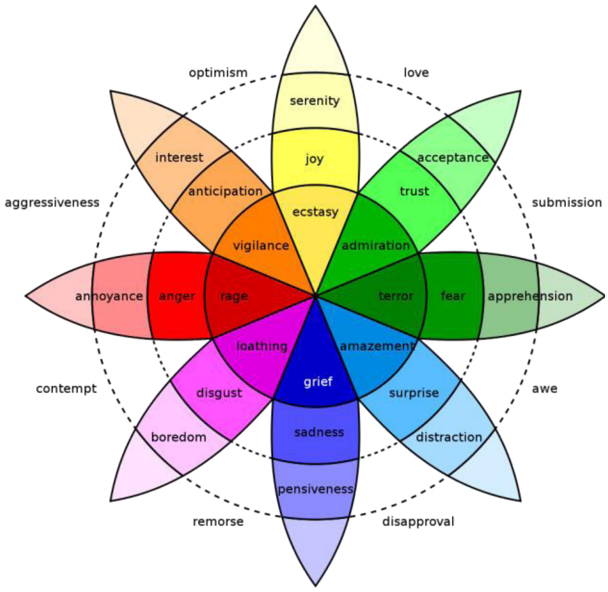

Fig. 2. Plutchik's wheel of emotions

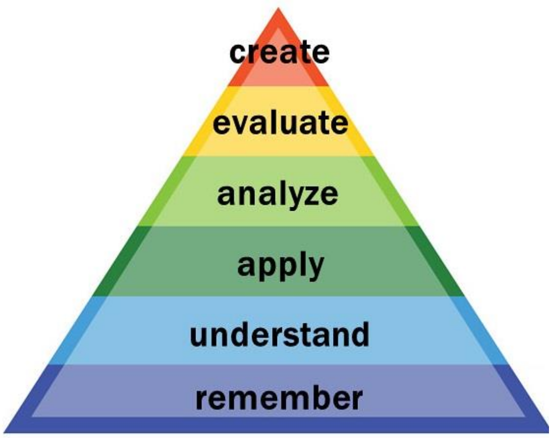

Fig. 3. Revised Bloom's taxonomy

2.3 Deconstruction of gender stereotype

Once the two previous workshops where working in teams is achieved, the behaviour of students is observed from the perspective of gender stereotypes [8]. First of all, the explicit gender stereotypes are underlined in courses where psychological aspects are addressed. The aim is to improve social and professional skills of students.

Moreover, through a reflective practice, implicit stereotypes are also decrypted. In order to uncouple behaviours from students, these ones are invited to participate to a forum theatre session where implied bad behaviours are caricatured in the external appearance of actors. It is proposed to the students to interact with the actors in order to try and check other behaviours.

These two activities last about 4 hours.

2.4 Project-based learning in mathematics

The last activity proposed to incoming students deals with the application of previous notions into a scientific context [9]. It lasts about 6 hours and can be split in two shorter activities. The students work in groups of 5 to 6 individuals.

In this activity, the main scientific goal is not to learn new knowledges but to improve some skills previously trained during high school courses. As incoming students come from different high school curriculums, it becomes necessary to define an activity about basic sciences. Regarding French curriculum, mathematics is a clear choice.

Moreover, regarding the previous activities, it is obvious that a project-based learning activity must be proposed to the students. Indeed, it allows them to apply previous skills such as active listening, cooperation, reflective practices, debating, talking about solutions and all of that with considering the analysis of any stereotypes and emotions during argue.

2.5 Individualized methodological support

All along the first year of study, the academic evolution of the students is closely followed by a team of teachers. This is achieved through the Individualized Methodological Support (IMS) program where the reflective practice is emphasised and guided depending on the students. A special focused is generally done on the working method of students and especially team work performed during revision process before exams.

A combination of previous activities and IMS program leads to a clear decrease of the number of students submitted to academic failure during the first year of studies.

3 DESIGN OF A PROJECT-BASED LEARNING SEQUENCE IN MATHEMATICS

3.1 Competency-based approach

Mathematics as basic science for engineers is often considered as a complex science by the students. They are mainly studied in the ENIT during bachelor curriculum during the two first years. Regarding the revised Bloom’s taxonomy (see figure 3) [10], the students mainly *remember*, *understand* and *apply* their knowledges and skills during courses of mathematics.

However, during the master curriculum, the mathematics are applied in engineering as a tool that must be mastered by the students. It is then asked to the students to develop abilities in mathematics together with acquiring new knowledges and skills in engineering. This induces a clear frustration for the students.

As a consequence, it has been proposed to rethink the teaching of mathematics in the bachelor curriculum by defining new intended learning outcomes. Considering the activities for the incoming students, they become able to reach *analyse* and *evaluate* steps of the Bloom’s taxonomy since the beginning of their curriculum in the application of mathematics. Obviously, this concept is firstly applied on knowledges and skills acquired during high school. In addition, work in teams is encouraged.

3.2 Scientific prerequisites

Considering the teaching of mathematics in high school, a problem-based learning sequence has to be defined where common knowledges and skills that can be turned to abilities during the proposed activity. Following a review of the curriculum in high school, knowledges and skills about mathematical analysis have been defined as the basis of the project especially derivative and integral calculus.

Moreover, during the high school, mathematical analysis is mainly developed through two main lines: *seek* and *model*. On the one hand, *seek* lies in analysing a situation, organising information and validating an approach. On the other hand, *model* is about converting a problem into mathematical language and validating a model.

From this overview, a pedagogical activity leading to work in team on a real problem has been built. It allows to analyse a situation - regarding the revised Bloom's taxonomy - i.e. to draw connections among ideas from different people, to listen, understand, examine and question their own perceptions and ideas comparing to each other's ones. It also allows to evaluate their work i.e. to argue and defend their point of view in a group and to present common conclusions. A feedback ends the activity with a constructive criticism phase between the different groups.

3.3 Ethics in project management

The proposed project-based learning sequence is also an opportunity to introduce the first steps of project management. As described in section 2.1, the students generally spilt in two categories: introvert and extroverted natures. At his stage, some roles in team work may be introduced. The nine Belbin team roles can be considered: three social roles (Resource investigator, Teamworker, Co-ordinator), three thinking roles (Plant, Monitor evaluator, Specialist) and three action roles (Shaper, Implementer, Complete finisher). However, the project is not sufficiently long to clearly define the nine previous roles in groups of 5 to 6 student through a given test. As a consequence, this part of the project is achieved in a reflective practice way. Indeed, the students are invited to note their own feeling about their role in the group and to think about it before ethics classes where the roles will be theoretically identified and where skills about their definition in a given group will be taught.

As a reflective practice, the main point lies in considering and analysing the advantage of cooperation and collective intelligence all along the project from the understanding of the problem, its modelling, its solving to the presentation and defence of a solution.

Some classical project management aspects are also introduced especially through the management of time. Therefore, it has been decided to propose two different projects of three hours each where time is firstly managed by teachers. They use a workflow where each phase is defined with a clear duration: presentation of the project (10 minutes), creation of groups (10 minutes), finding a solution (2 hours), writing a report (20 minutes), feedback (10 minutes).

In the phase of finding a solution, the students are invited to define their own workflow by evaluating the duration of main activities and tasks (analysing, modelling, arguing) and by monitoring their own planning and workload all along the project. Generally, the students begin the analysis of the problem using collective intelligence. Then, the finding of a solution starts with an autonomous thought. After several minutes, a confrontation of ideas is naturally initiate in the group. Finally, the writing of a report is done by a sum of individuals where the Belbin team roles begin to emerge.

3.4 Scientific details of the sequence

The subject of the project is defined as following: “A team of the ENIT's student office wants to paint the external surface of an old half-pipe. They request a subvention from the ENIT who grants them an amount of 300 euros. Their painting has an efficiency of 12m^2/L and a litre costs 21.17 euros (VAT included) for 0.5L or 77.17 euros (VAT included) for 2.5L." The question to answered is then: "Will they have enough money?".

The 3D model of the half pipe and a cross section are given in figures 4 and 5.

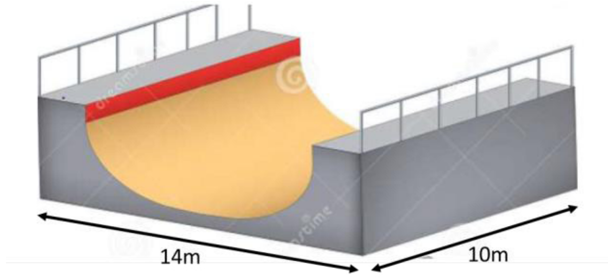

Fig. 4. 3D model

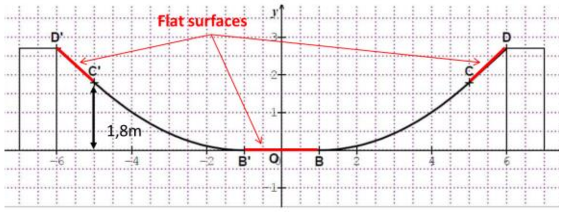

Fig. 5. Cross section

It has to be said that the half-pipe is symmetrical about y-axis. Moreover, the surface presents smooth connections at points C', B', B and C. Furthermore, surfaces from B' to C' and from B to C are defined by a parabola.

Using equations of parabola, linear equations and their derivatives, the students obtain a system of equations that must be solved to find the different parameters of the equations. Then a piecewise function can be defined to model the surface of the half-pipe. Finally, an integration must be performed to find the surface to be painted.

3.5 Evaluation of competencies

As it is the first project-based learning pedagogical activity proposed to incoming students, the evaluation of competencies does not lead to a grade.

First of all, a guided self-evaluation is performed by the students. There are asked to give a mark on a grading scale to 0 to 5 (0 means that competencies are totally unknown and 5 means that competencies are mastered) to several competencies in the fields of mathematics and humanities. Here are few examples of skills and abilities leading the definition of competencies: model a problem, calculate an area, calculate the derivative of a polynomial function, express an opinion in a group, exercise active listening, define my role in the group. This self-evaluation is compared before and after the project.

A collective evaluation of the competencies is then done by each group using a radar chart with six spokes: quality of the produced work, quality of the relationship with the teacher, quality of the analysis of the situation, involvement of each team member, organisation of the team and quality of the atmosphere in the group.

4 CONCLUSION AND DEVELOPMENT

4.1 Conclusion

In this paper, a set of activities proposed to incoming students in ENIT has been detailed. Working in teams and being a part of society have been used as a common link between activities. Moreover, collective intelligence and communication without tossing out emotions and empathy have been presented as ways of working efficiently in teams.

A focus has been made on a project-based learning sequence in mathematics involving humanities in the teaching. The project deals with presumed already acquired knowledges of the students during high school or previous activities. Mathematics is here considered as a heart activity in the wild field of engineering covered by the ENIT's students.

4.2 Evaluation and improvement

Some key performance indicators (KPI) can be defined for these activities. Obviously, KPI resulting from the evolution of the self-evaluation of competencies by the students must be studied. An increase in the acquisition or mastery of skills or abilities is a positive result.

Moreover, a global evaluation of teaching by students is performed at the end of each semester using an open dialogue with the head teacher but also with an anonymous survey with questions such as: “Do you feel that you are making progress in learning about your future profession as an engineer?” or “Do you have sufficient material conditions to work at school during courses?”.

Depending on the evolution of KPIs, activities can be rethought, better organised, developed…

4.3 Development

It is planned to develop project-based learning all along the curriculum. Once the bases about humanities, project management and team work are acquired, it becomes possible to have more and more project-based learning sequences from understanding to evaluation levels in the revised Bloom's taxonomy. Moreover, year after year, the students become more and more autonomous and learning can be realised with a lower rate of coaching. Coaching is then reserved for launching the project and periodically monitor the progression of the students.

ABSTRACT

The need for Digital Education (DE) in higher education has been growing for the past years, as the landscape of education became more diverse and global. It has become apparent with the COVID-19 pandemic that, in terms of width, DE had been mostly neglected so far. In the past year, the master program Global Production Engineering (GPE) at Technische Universität Berlin has been enhanced by a complete digital track, called GPE-Digital. In order to design this online study program a student survey was conducted and lecturers have been interviewed. The results were analysed and requirements for both lecturers and students were identified. Chances and challenges have been identified and a "tool box" for teaching and learning was developed. It contains a multimedia studio, a learning platform, a cloud platform et cetera. Lecturers are supported to develop and adapt their lecture-concepts and to choose the tools needed, which led to a variance of teaching-concepts. In this paper, after presenting the findings of both the interviews and the survey, the "tool box" is presented and its various possibilities for implementation are shown by the example of four different courses offered at GPE-Digital. These examples contain both synchronous and asynchronous teaching and different approaches of preparing joint sessions and lectures. Finally, based on the courses the benefits and challenges are discussed and rough approaches for exploiting the benefits and tackling the challenges are given.

1 TEACHING GOES DIGITAL

For more than 20 years distance learning or distance education is well-known [1] and until the beginning of 2020 it had rather a niche existence. However, during the pandemic distance learning experienced a boom like never before [2]. From one day to another many universities had to cope with the challenge of distance learning which was until then – even though the concepts were generally well-known – still rather a subject of research (having some implementations in e.g. evening study programs) than broadly implemented. Within a couple of weeks tools like Zoom, Microsoft Teams and WebEx were in daily use. To put this into numbers: While on December 31st, 2019, 10 million participants joined a Zoom meeting, on March 31st it was 200 million and on April 21 even 300 million people [3]. Suddenly, servers for educational clouds were working on their limits and were needed everywhere [4].

After two years of higher education in a pandemic experiences have been gained by various lecturers, e.g. [5] and [6]. Benefits which have already been identified before the pandemic could be widely confirmed [7]. A key benefit which is enabled by distance learning is an increased flexibility for students and lecturers, when it comes to their location but also in terms of when learning takes place. For synchronous classes only the time zones became an issue. Nevertheless, in terms of class-time distance learning offers further flexibility by offering recorded lectures and exercises.

Considering these and further benefits of distance learning which were experienced during the beginning of the pandemic the decision at the Technische Universität Berlin was made to enhance an existing face-to-face study program by a fully virtual branch. Global Production Engineering (GPE) is a full-time four-semester master program [8]. The curriculum is designed for international graduate students offering modules in the fields of production, management, engineering, new energy technologies and inter-cultural communication. Within this paper, the experiences of implementing a completely digital study program shall be presented and discussed.

2 SURVEY WITH STUDENTS AND INTERVIEWS WITH LECTURERS

As a basis for designing the digital study program a survey with the students of the face-to-face study program whose class took place virtually due to the pandemic was conducted in order to learn about their challenges in virtual classes, but also to learn from their suggestions for the design of digital classes. Furthermore, interviews with lecturers were made in order to figure out their main challenges digitalizing their classes and by that to get an idea of how a completely digital study program should look like in order to enable a smooth learning and teaching environment.

For the student survey 41 students were contacted. The goal of the student survey was to receive a feedback of the first steps of digital teaching and learning but also to have a basis for designing a fully digital study program. The main comments include the students’ expectations on the presentation of teaching material, which they expect to go beyond simple voice-over Power-Point presentations, the fact that students find seeing facial expressions and gestures profitable to learning and thus prefer live interactions with lectures and fellow students in presence, as they are hardly replaceable. However, they find the degree of freedom of asynchronous teaching in terms of learning times to be advantageous, perceive online tools such as quizzes, exams, external videos, Moodle platforms or course forums as an enriching offer that they would like to retain for face-to-face teaching.

A total of eight interviews with lecturers, who are planned to be included in the digital program, were conducted. Each interview took between 60 to 90 minutes. The main subjects during the interviews were the challenges during the digitalization of classes, the software and hardware which was used and its evaluation, experiences with the current learning platform, changes to the teaching concept and the learning goals due to the digitalization, changes in the communication with the students and its evaluation, acceptance of the digital classes based on the feedback that the lecturers received in their classes, overall positive and negative experiences during the digital classes and the transformation process from an lecturers' and students' perspective, changes in the teaching concept if the digitalization would be permanent, support which could be provided by the study program staff to support the lecturers, and hard- and software which could be used within a (teaching) studio.

According to the lecturers, the main challenge during the early phase was the lack of time to actually plan the transition, but to not directly transfer all face-to-face teaching material one-to-one to a virtual environment. Non-professional equipment often led to pragmatic solutions, but not necessarily to satisfying ones. Lectures were either pre-recorded and uploaded on an educational platform or were given online. This led to a massive decrease in interaction, but was realizable in the short period of time. However, exercises in laboratories had either to be postponed, cancelled and another task had to be given or exercises had to be completely changed so that physical attendance was not required. Software-wise mainly PowerPoint, Zoom, Kahoot and Mural were used next to the Moodle platform. The equipment used was rather "classical" hardware: laptop, camera, headset etc. The previously reserved usage of the Moodle-based learning platform changed rapidly. While many lecturers never had used the platform before, it immediately became a backbone of each class. The teaching concept of the lecturers did not really change - mostly because there was not a lot of time for any changes. Also, the learning goals of each class did only change if the exercise was affected. One major drawback which could be experienced by all lecturers was the decrease in communication with the students. At the time of the interviews no exams had been taken so far. Therefore, no statement could be given on how the digital teaching influenced the exam results. Generally, the students did not complain about the digital classes. Due to the pandemic it was accepted. However, the lecturers were told that the students are missing the interaction in class. Generally, the lecturers saw the benefits in terms of flexibility for themselves but also for the students. For a permanent change to digital teaching, the lecturers saw a need for a stronger involvement of the students during class. Further they identified a need for a better hard- and software. The results of this interview led to the design of the studio, which will be presented in the following.

3 IMPLEMENTATION

3.1 Requirements for the digital program

On the basis of the surveys conducted, the educational, didactic and technical needs were worked out and measures were derived to increase the facilitation of learning. After having discovered the drawbacks and problems with the digital education during the pandemic, particular focus was set on three categories: digital technologies, community building and educational concepts.

The technological requirements are to use adequate, modern technologies with high-end quality media, as students are used to a high standard of image- and sound quality. To build a sense of community, both for lecturers and students, a platform for regular and informal exchange is required, while the educational and didactic aspect has to be, while still regular, more formally presented. These requirements are met by developing a didactic and educational toolbox. To ensure a consistent high quality education, guidelines have been established. The toolbox and the quality guidelines are presented in the following section.

3.2 Conception of toolbox and the learning environment

Toolbox: Digitally driven learning and teaching is particularly dependent on the provision of technical equipment. This not only has to meet the requirements of didactics, support the transfer of face-to-face-based teaching concepts to digital representation and be user-friendly and intuitive for the users. The technologies also open up new possibilities for teaching, group work or interaction by new tools that were not available in face-to-face teaching and whose reasonable integration into the teaching concept must be checked individually for each lecture or module.

In order to support the lecturers in the digital implementation, a so-called toolbox was developed, which contains a wide range of technical aids and tools. Especially in the initial phase, each lecturer is advised and supported on the conceptual integration, trained on the application and supported in overcoming technical challenges by a team of 5 experts in digital teaching and film production.

The centre is the Green-Screen Studio (fig. 1 & 2), which enables the removal of the green background both in real time and in post-processing and replacing it with any background such as lecture slides, images, videos or websites (fig. 3 & 4). In this way, depending on the respective thematic focus of the lecture and educational goal, a suitable learning environment can be created in which the lecturer is placed and that gives students the feeling of still being in a classroom. Even the implementation of a virtual 3D environment has also been successfully tested, in which the lecturer walks through a factory, for example, while the background changes according to the perspective. This makes it possible to zoom into machines, view components in detail, hide parts or make them transparent, while the lecturer is in front.

To achieve a high degree of video quality, professional film lights (amaran 100d & swit) are used since insufficient lighting of both foreground and background can create disturbing digital artefacts. Two high-resolution 6K cameras (Black Magic) are used to record the teaching sessions, while 4K cameras (Brio Logitech) are used for live events. Especially when using green screen technology, cameras with low resolution should be avoided, as they can also produce unwanted artefacts. By means of a streaming software, in this case the Open Source software Open Broadcaster Software (OBS), any image composition can be generated on the computer and inserted as an emulated webcam on all conference tools (Zoom, WebEx, Microsoft Teams, etc.). Sound is provided via a clip-on microphone (RodeLink) whose signal is transmitted to the camera via radio.

To enable the lecturer to share notes in the same way as on a white board or chalkboard, the room has a 55-inch touch screen on which handwriting can be done with a special pen. Written texts can be shared handwritten or converted digitally into machine text. Another 55-inch monitor has been integrated to display the students' video images and a smaller monitor to display the lecture slides for the lecturer. In addition, the lecturers also have a touch screen stand PC and a Wacom board at their disposal, on which manual markings can be created in the slides directly.

An additional input device, an Elgato Stream Deck, was installed to make the operation of the extensive technology more intuitive for the lecturer. On this keyboard, the buttons can be assigned individually with shortcuts and personalized icons. As a result, when changing an application during a live event on the computer, the user does not have to create a complex sequence of clicks on the computer, but can start or stop an application at the push of a button.

The lecturers and students are provided with server-based applications for exchange, provision and communication, such as Zoom, WebEx, Next-Cloud, OnlyOffice and a Moodle learning platform, which are all operated entirely on the university's own servers for reasons of data security and sovereignty. Zoom and WebEx are used as communication software. Every lecturer and student get their own unlimited access and can generate meetings independently. Zoom in particular, with its large range of functions, compatibility, stability and user-friendliness, established itself as the main platform for communication during the COVID-19 pandemic. Functions such as breakout rooms support group work or can enable consultation with the lecturer in digital exams without disturbing other users in their work, also, the platform enables real-time translation of spoken content. At the same time, hiding the own video background or creating a virtual background allows students the greatest possible degree of privacy.

An adaptation of the open Moodle learning environment developed within the university is used as the central learning platform. This learning environment was developed with collaborative learning and teaching methods in mind and allows for the customization of classrooms that can be broken down into weekly or thematic segments. The platform provides a rich portfolio of functions, such as the provision of texts, videos, forums, calendars, glossaries, wikis, surveys, brainstorming tools, learning quizzes or tasks. Learning packages can be created and linked to individual learning progress. Other functions support peer teaching and learning and allow mutual assessment. The individual learning success of each student can be tracked by the lecturer over the semester and additional support can be provided if required. The platform has proven to be particularly useful for digital exams, as new forms of interactive questioning are possible and tasks can be automatically evaluated according to previous definition or digital exam reviews can be carried out. It must be mentioned that for the creation of content and the use of the range of functions, a basic experience in handling software tools is helpful, if not necessary. Practice has shown that inexperienced users, especially in the initial phase, needed special support from the team. In addition to the Moodle platform, external game-based learning platforms such as Kahoot are used, with which students can carry out location-independent learning quizzes in real time. Similar to a television show, the lecturer moderates the quiz, the students enter their answers via their smartphones, the correct solution is then provided and the individual results are evaluated.

The use of a lot of open source software as well as software provided by the university keep the costs for the technical equipment at a well justifiable level of roughly 12.000 Euro. The biggest cost drivers are the cameras (circa 2500€) and the touch monitor (circa 2000€). Another driver for costs is the large amount of data that needs to be stored and processed. For that, several hard drives (HDD for storage, SSD for production) as well as a computer (Mac Mini M1) for production have been acquired at around 1800€. Some of the equipment, like the touch computer were already available from former projects is be valued just under 2000€.

Fig. 1 & 2. Multi Media Studio and typical recording scenario

Community Building: To nurture a positively experienced learning environment, special attention was paid to the aspect of Digital Community Building. In a first step the students have been given an Introduction Event to the whole program. Furthermore, there are regular meetings for the students to give feedback to the program management and administration. Although high level, the meetings are informal. Besides administrative discussions and organizational difficulties, topics of these meetings are also personal or cultural exchange. Additional Community Building is encouraged through partly synchronous teaching with and without the presence of lecturers, e.g. in form of group assignments. Between the third semester and the students' internship, as well as their Master's Thesis, students are welcomed in Berlin to the optional Spring School. Students can meet in person and also get in touch with both staff and students from similar GPE-programs. Future Community Building measures are digital factory tours and fair visits as well as digital or hybrid attendance at conferences.

Quality Guidelines: To ensure consistent quality at high level, quality guidelines have been established. These are mostly mandatory. Lecturers are given templates for their teaching material. Videos are produced by professionals of the team and are conceptualized to shape the learning environment. The background is designed in the way, so there are not too many distractions, texts are readable easily, the room lecturers are presented in is large enough and many more details are considered. Additionally, lecturers are required to use the learning platforms, calendars and communication channels that are provided to ensure a standardized and consistent learning environment.

3.3 Exemplary Lecture Program

In engineering education, subjects are often divided into a lecture and an exercise or a project. The lecture conveys the theoretical knowledge, which is to be applied in the exercises and projects. [9] Most of the modules used as examples here are split into lecture and exercise. They are courses that are currently offered at GPE-D or planned to be offered in the following semesters.

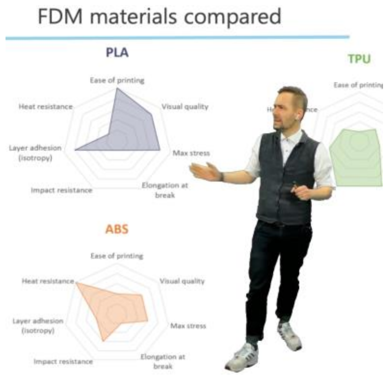

Fig. 3. Live Lecture on Additive Manufacturing

Fig. 4. Pre-recorded Lecture on Digitalization and Industry 4.0

Additive Manufacturing (AM): The module AM is split into lecture and exercise and is very application-oriented. The lecturer has decided, that it is better for his lecture to be able to communicate with the students during the sessions. For this, the green room is used in combination with OBS Studio to place the lecturer into the lecture's slides (fig. 3). This way it is possible to actively show and emphasize arguments and principles of AM. This is transmitted via Zoom, so the students get the impression, that the lecturer is actually standing in front of them. They can ask questions at all times, which enhances this immersion. The lecturer has multiple monitors to observe both his slides and the students in Zoom. The exercise for AM is planned in the Summer School, to teach the students printing strategies, troubleshooting, etc. For students who are not able to join the Summer School, printing via internet is provided. Students have to prepare their print-jobs and can observe via broadcast.

Digitalization and Industry 4.0 (DI4.0) and ***Manufacturing and Factory Planning (MFP):*** The teaching concept of the modules is also split into lecture and exercise. For the lecture professional videos are produced to according to the quality requirements of the program, an example is given in figure 4. Every third lecture is a live session and includes a Q&A for the pre-recorded topics for DI4.0 and a weekly Q&A including discussions of given homework for MFP; in this manner, facts are already established and discussions can be held at a higher level. The Videos for the lectures are usually not longer than 45 minutes to maintain concentration. The exercises are focused on the students' (former) jobs and held in a seminar-style course. The students are presented an assignment in a live lecture and have to present their work after regular Q&A-Sessions. In the DI4.0 exercise an action plan for the transition of companies to a next level of digitalization is asked, for the MFP exercise the students are assigned the planning of a bike factory. The difficulty as opposed to the presence courses lies in the coordination of time zones and finding common communication platforms.

Lean Management (LM): The module lean management integrates lecture and exercise. The lecture is partly pre-recorded and partly held live to answer possible questions. The lecturer also assigns groups of two or three students to summarize the topic of the last lecture. They are completely free in terms of realization. For instance, some students create small quizzes on "Kahoot". The lectures are complemented by short videos, which are tailored to specific subject areas. In these videos principles of Lean are illustrated by the lecturer standing in a virtual factory. The lecturer is able to move and explain all aspects in detail. The immersion of the lecturer standing in a factory can also be used in a live situation to go into questions.

4 SUMMARY

In this paper insights to the planning and implementation of completely digital track of a study course are given. During the planning phase a survey with students was conducted and interviews with lecturers were made. Both students and lecturers had first experiences in the digitalization of a study course due to the pandemic. The survey conducted with the student has shown, that students would have higher expectations on an online study course compared to the situation experienced during to the pandemic when classes suddenly had to switch from classroom to online teaching. Similar feedback was received by the interviews with the lecturers, who generally where able to switch to online teaching, however practical solutions for exercises and especially hands-on work like in laboratories or student workshops must still had to be found. Furthermore, the possibility of social interaction is still quite limited which should be tackled but cannot be completely solved. In the section of implementation, the (digital) technologies in use as well as aspects of community building, and educational concepts were highlighted. A toolbox, which contains a wide range of technical aids and tools, consisting of was presented. Finally, four digitalized modules using different concepts were presented as an example.

5 ACKNOWLEDGEMENTS

The authors thank the German Academic Exchange Service DAAD for funding the Project GPE-Digital within the context of the Program IP-Digital.

ABSTRACT

In a finite world whose limits now seem obvious, future engineers are wondering what their profession will become tomorrow. To respond to this strong expectation, the PISTE[2] curriculum was opened in September 2021: a full semester in the final year of engineering studies at Grenoble INP-UGA (France). The program was co-designed with the students and the different partners. The objectives are to enable the students to experiment a new posture and to offer them the tools needed to meet the challenges they will face in a world in transition. A systemic, interdisciplinary approach, considering planetary limits and environmental and societal impacts, structures the whole semester.

This paper presents and argues the pedagogical design choices. With a view to continuous improvement, the strengths and areas for improvement are described.

1 INTRODUCTION

1.1 Context

In a finite world whose limits now seem obvious (as highlighted by the Sixth Assessment Report of the Intergovernmental Panel on Climate Change), future engineers are asking themselves what their role and their job will be tomorrow. And for example, how can they contribute to achieving the UN Sustainable Development Goals? The global challenges are raising questions among young people who would like to give more meaning to their university education [4].

To respond to this strong expectation, this year we opened the PISTE program to a first class of 28 students: a full semester in the final year of engineering studies at Grenoble INP-UGA (France)[3]. The program was entirely co-constructed with the students and the teachers. The objective is to allow students to experiment with a new posture and to offer them the tools they need to meet the challenges they will face in a world in transition. A systemic, interdisciplinary vision, considering planetary limits and environmental and societal impacts, structures the whole semester.

This paper presents and argues the pedagogical design choices, based on empirical findings and elements from the literature: the overall structure of the program, the contents, the pedagogical methods, the assessment of learning outcomes and the specific support for students and teachers in this program.

With a view to continuous improvement and dissemination, the strengths and areas for improvement are described based on feedback from teachers and students, as well as from the program's co-leaders and the educational developer.

1.2 Approach

To train future engineers in the skills needed to resolve the challenges linked to the ecological transition, we have made the following hypothesis

- A systemic (the whole system in which the problem exists), interdisciplinary (without thematic barriers) and global (from needs and uses to the impacts of the proposed solution according to constantly changing contexts) vision is essential for understanding the transition issues [3].
- The pedagogical approach must be adapted to developing a new conception of the engineering profession, i.e. to be able to approach complex problems in a systemic, interdisciplinary and global manner [5].
- The assessment of learning must be aligned with these intentions and methods [1].
- Co-construction of content between teachers and students, and a collective approach to sharing resources (open science), in a climate of collaborative governance, are necessary because the training is intended to be transformative and emancipating [5] for these future engineers: at the levels of their professional

[3] This work was funded thanks to the french national program « programme d'invertissements d'avenir, IRT Nanoelec » ANR-10-AIRT-05.

identity, their behaviour, their conception of the world, their imaginations and their power to act.

2 METHODOLOGY

2.1 Program Design

We have proposed to build on the elements that we believe are essential for a successful transition in the world of tomorrow and to apply them in designing a 6-month program, during the penultimate semester of the engineering curriculum.

Systemic understanding and approach throughout the whole program

- Interdisciplinary, systemic and global learning, both in terms of knowledge and key skills and engineering posture, which enable the projects to meet their challenges.
- Taking advantage of the diversity of the actors, a variety of points of view, reflected in the diversity of speakers and students (open to all Grenoble INP-UGA components).
- The teachers come from different disciplines at Grenoble INP-UGA and Grenoble Alpes University, and local partners working in research centres, companies, and associations. All of them are involved in sustainable development in one way or another and attach particular importance to it [3]. An important part of the contributions is dedicated to human and social issues, which is a departure from the usual engineering curriculum.
- The courses contents cover a variety of subjects: assessment of the environmental state, analysis of planetary limits, sustainable solutions and adaptation solutions, levers for action, integrated resource management, history of industrialisation, sociology (techniques, uses, innovation), digital sobriety, public policy, green taxation, open science, project management, multi-criteria methods to help decision-making, methods centred on the user experience, carbon assessment, life cycle analysis, risk management analysis, energy performance, low-tech and right-tech.

Adapted pedagogy to develop a new conception of the engineering profession

- A framework that stimulates “transformative” [3] and “emancipatory” [5] learning, mutual understanding, empathy, and trust, as well as collaborative governance (sharing of information and ideas, cooperation, benevolence, mutual respect).
- Interactive teaching to include and engage all students [3, 5], and to reinforce learning and reflective assessment.
- The core of the semester is a group project (10 ECTS out of the 30 ECTS of the semester). The projects are concrete, real-world projects [3], starting from the user's needs and breaking away from the 'business as usual' growth model. The objective is to rethink the design and uses of a product, a component, a system, or an organisation.
- The project work is fed throughout the semester by theoretical and methodological contributions, which are scientific, technical, sociological, political, and economic.

The teaching offered is therefore designed around the projects: they provide useful insights for the students throughout the semester.
- The whole program is designed in accordance with the competence strategy of Grenoble INP-UGA [6].

Learning assessment method based on individual reflection

- Project assessment criteria include: reformulation of the specifications, state of the art in relation to the needs, complete free documentation accessible to the greatest number, life cycle analysis and impact assessment, choice of a solution that meets the needs of users and socio-ecological issues, quality of the report and the proposed solution. Particular attention is paid to the prototype (technical or methodological).
- The assessment of learning outcomes is designed with a view to constructive alignment [1]. It is based, for each of the three teaching units, on an individual reflective writing in which each student shows the links between the learning acquired and its reuse in the concrete framework of the project. This written work is then discussed during an oral presentation.
- The students are accompanied in their reflective work throughout the semester: individual feedbacks are provided on demand on draft versions of their written work; at the end of each oral presentation, teachers and students are invited to write together advise for the next session; workshops are offered during the semester about the assessment method and about the emotions lived during the semester.

Co-construction with the students, the teachers and the partners

- Projects are anchored in the territories. Subjects are proposed by three types of partners, reflecting the diversity of society:
  - public partners such as the municipality or a research laboratory
  - private partners such as companies engaged in transition processes or wishing to hire future engineers capable of addressing transition issues
  - partners representing civil society, such as associations directly linked to transition issues or associations wishing to address these issues without having the expertise
- The groups work closely with partners and potential users to co-construct technical or methodological strategies and solutions. Teachers mentor the groups to support them in carrying out the projects (project management and engineering methods).
- The projects address the challenges of transition: they aim to rethink the design and uses of a product, a component, a system, or an organisation, by developing low-impact, sustainable, documented and widely accessible solutions or strategies. These solutions or strategies should be answering a question directly useful for the user, promoting an open science approach, and fitting into a circular economy model, leading to a more convivial society.
- Regular adjustments occur throughout the semester, according to feedback, observations and questions from students, teachers, co-leaders and the educational developer.

2.2 Overall Framework

The teaching activities proposed throughout the semester encourage interaction between students and between students and teachers. Form and content are co-constructed: students and teachers alike can contribute to the construction of learning.

A climate favourable to learning is based on a set of values, mainly stemming from the currents of popular education, collaborative governance, and collective intelligence. This framework was built with and by the students at the beginning of the semester. Tools were proposed to them, and they appropriated them. The different dimensions of this framework are:

- Benevolence, towards oneself and towards others: we do the best we can, with what we have and what we are.
- Respect: each person has a point of view and diversity is a richness; being punctual, doing one's share of the work, being rigorous and demanding about quality, etc. are all part of respecting oneself, others, one's environment, and the work accomplished.
- Sovereignty: I speak as "I"; I am responsible for my words, my actions, my feelings, my choices...
- Co-responsibility: each person is responsible for respecting the framework and for ensuring that it is respected.
- Humility: nobody knows everything about everything (even the experts), everybody can still learn a lot.
- Legitimacy: everyone can contribute. If an idea has not yet been stated, it deserves to be put in the common pot to be discussed and exchange together on its relevance or not. Mistakes allow us to learn, every obstacle overcome is an experience that can help us move forward, every dead end explored deserves to be identified and shared with the community.
- Criticism and self-criticism: reality is complex and needs to consider a range of points of view (vigilance on a miracle solution or an absolute truth); an idea is distinct from the person who states it (vigilance on arguments of authority and debate of ideas rather than debate of people).

3 RESULTS

3.1 Observations and findings

During the semester, we regularly collected informal and formal feedback from students and teachers and this by different means. Informal feedback was collected during pedagogical workshops, through email exchanges and during two meetings organised with the students, the co-leaders of the semester and the educational developer.

An online questionnaire with 130 questions was proposed to students, at the end of the semester: 75 closed questions on a 4-level likert scale plus a "not applicable" option, 46 non-mandatory open questions, 7 yes-no questions, 1 number question and 1 grade question. The questionnaire was built with pre-tested questions mostly used to assess quality learning and teaching in French speaking Higher Education. It meant to measure the perceived alignment between the aims of the semester and to verify our initial hypothesis (see sections 1.2 and 2.1). 25 out of the 28 students took the time to answer.

In addition, the students spontaneously organised collective feedback, taking the form of a written document worked on in several group sessions.

Systemic Approach

Many comments show the interest of addressing societal issues, planetary limits, putting these questions into perspective, for example through a course on the history of industrialisation, and considering all the stakeholders, in particular with methods from sociology. In their collective spontaneous feedback, the students note in the general feedback paragraph: "The diversity of the courses offers a step back, while developing very technical and practical aspects.”

In the questionnaire, all the answers show that the semester has enabled the development of skills related to solving the challenges associated with the ecological transition. Among the skills developed, students cite

- *Having a systemic vision of the issues*
- *Understanding the mechanisms of climate change and the socio-economic mechanisms of the transition*
- *Having a greater capacity for critical analysis of the technical solutions proposed*
- *Be able to assess the social impact of a technique or technology and to measure the environmental impact with rigour (Life Cycle Assessment, carbon footprint, etc.)*
- *Imagine alternative solutions that break with the growth model*
- *Be an actor in the sustainable transition*

Pedagogy Framework

“The interacting pedagogy framework for sustainability education" [5] is built on two axes: one axe “describes a movement from individuality, structure, and predetermined outcomes to collaboration, agency, and self-actualization respectively” and the other axe “describes a movement from content-focused, objective learning resulting in knowledge and skills acquisition to process-focused, subjective learning resulting in novel ways of being and meaning-making” (p.8). These two axes determine four quadrants.

The core projects were perceived as being at the heart of the course (the courses feed into them) by 75% of the students. 84% felt that the project stimulated interest in the course. All of them felt that they could

- use their knowledge and personal skills (responsibility, initiative, autonomy, reflection) well for the project
- learn and develop their skills by doing the core project
- put the technical knowledge in relation to current societal issues in the project.

56% of the students felt that the teachers ensured their involvement in the proposed educational activities (courses, projects, etc.). 92% felt that a significant proportion of the courses offered activities other than listening to lectures. Among the most cited examples are: debates, open discussions, writing and manual workshops, practical work (applications), mini-projects, serious games, creation of common resources. 64% of students believe that teachers leave room for the co-construction of learning: students as well as teachers can contribute to this learning.

According to Papenfuss *et al.* framework [5], we consider that the major part of the teaching is in quadrant 2 (projects and problem solving, application and critical thinking) and quadrant 3 (experiential learning, transformation of the posture and conception of one's role as an engineer). A smaller proportion, consisting of lectures and readings, is more likely to be found in quadrant 1. Another more significant proportion is found in quadrant 4 (reflection, co-responsibility, legitimacy, future professional orientation): the climate that was established at the beginning of the semester and which, according to 84% of the students, lasted throughout the semester.

This climate aimed to change the usual roles in higher education, towards more horizontality between teachers and students. As the authors suggest, this climate remains difficult to maintain because neither teachers nor students are used to quasi-horizontal relationships. Teachers sometimes need to remind (themselves) of the asymmetry that persists (they are the guarantors of the learning framework and responsible for assessment); some students need to be reminded of the overall framework of higher education (they are responsible for their learning and are bound to respect the didactic contract established at the beginning of the semester).

Learning Assessment Methods

76% of the students consider that the assessment method is consistent with the pedagogical intentions of the semester. However, it deserves to be better structured and more harmonised between teachers. The instructions would benefit from being clearer and explained more regularly throughout the semester. Workshops for students and discussions during oral examinations with teachers were insufficient to prepare them to this unusual assessment method. Indeed, students and teachers expressed difficulties in appropriating the method.

Co-construction

The involvement of the students and the effects of this semester far exceeded our expectations: the students' profiles seem slightly different from the standard profile of students at the school, their expectations were undoubtedly high. The possibility of exchanging views with other people who share their values, in an open climate where everyone is legitimate to co-construct knowledge, has visibly shifted their perception of the engineering profession.

The surveys allowed us to better understand the profile of this first class of students. In fact:

- 68% had participated in the "climate mural" before starting the semester and 44% were a facilitator of this mural; 16% participated in the digital mural"
- 60% were coming out of a gap year that was valued in the curriculum
- 96% had made choices in their personal lives, before the start of the semester, related to the issues of transition and climate change (mainly on meat consumption and transport).

These particular profiles show a prior adherence to a set of values, goals and beliefs related to the transition. This adherence can be understood as a strong commitment in the sense of Marcia [2].

The students shared their questions throughout the semester about their future as engineers: a large majority expressed difficulties in finding an end-of-study internship that corresponded to their aspirations, and several questioned the validity of their future profession. In the end, everyone was able to find an internship that suited them (in a company, a research laboratory, or an association), and 76% of the students can now imagine a future that corresponds to them as a future engineer. Some comments in this end-of-semester questionnaire also show that some students have been able to resolve these issues. This resolution can be understood as a state of exploration in the sense of Marcia [2].

Extracts from student’s answers to the question "What has changed in me during this semester?” show a turning point in the perception of their career:

- *Today I think I could do a job related to my 5 years of study, which was not the case before.*
- *You can come out of an engineering school and not necessarily do a useless job.*
- *I will be able to make a very informed choice about my future job and the social impact it will have.*
- *I think I'll be a better engineer than I expected and I feel more in tune with the idea of being an engineer.*
- *I have deconstructed my ideal of the engineer and I am readier to have a disruptive job (...) I have more hope about the possibilities for an engineer to be an actor of transitions, to have a job that fits with his values.*
- *A much more serene approach to the professional world.*
- *PISTE has given me back some confidence in the future of the engineering profession.*
- *Above all, it gave me hope: the possibility of changing things.*
- *I had a trigger by telling myself that I would choose why I work and not be subjected to a "classic" engineering job in a company that does not correspond to me totally.*
- *My vision of engineering, my vision of the issues.*
- *My vision of the world, of socio-environmental issues and the role of the engineer.*
- *My vision of the engineering profession: you can break the conventions and still be an engineer.*
- *My vision of the engineer, of the society in which I live and my own desires (...) a change in thinking that I believe will never turn back.*

- *PISTE will be a turning point in my life. I probably would never have had the courage to propose my final internship to the school without this semester.*

Global Consistency

These results also allowed us to draw some key conclusions shared by more than 70% of the respondents:

- a very high overall satisfaction of students, teachers and local partners
- a change in the students' mindset
- confirmation, by students and teachers, that the core project is indeed at the heart of the training and that the courses are engaging and interactive
- effective co-construction in most of the learning activities
- the perception of a systemic and interdisciplinary vision, both in the projects and in the teaching.

Overall satisfaction was evident in all the discussions, the questionnaire and the collective spontaneous feedback written by the students.

3.2 Perspectives

As a result of this feedback, and with a view to continuous improvement, we are considering several developments:

- Clarification of shared documents (assessment grids, semester charter, etc.)
- More in-depth pedagogical support on the methods of assessment of learning, both for students and for teachers.
- Further development of sessions dedicated to welcoming students' feelings and supporting eco-anxiety (present at the beginning for some or developed during the semester for others).
- Opportunities for the teaching team to appropriate the framework and the common tools - e.g. collaborative governance, open science - are planned.
- A greater awareness of the teaching team to the interest of calling upon the educational developer to design the learning activities.
- More explicit sharing of prerequisites within the teaching team, to avoid some redundancies and gaps, mainly within the first teaching unit.
- Some changes in course subjects and contents.
- Opening to a wider public.
- Setting up an alumni network and a network of companies able to host end-of-study projects related to the semester.
- Longer periods of time to work on projects.
- Sharing of the different projects with the whole teaching team via short presentations (video, online document, or another format).

4 CONCLUSIONS

We can consider that this program constitutes a niche [3]. It is a place of experimentation, open to its environment, and the actors are particularly willing to co-construct and widely disseminate the impacts, strengths and weaknesses observed, as well as the avenues of evolution of this program.

The co-construction of the semester with all the actors concerned seems to us to be a factor of success of this type of program. In a quest for congruence between the intentions pursued and the means implemented, it seems obvious to consider the contributions of each person as essential and legitimate, regardless of their status. This approach also applies to courses, projects, etc. Transition issues concern the whole society. Each person can contribute. The diversity of points of view considerably enriches the solutions considered, both at the level of disciplines to provide a systemic vision and at the level of personalities to provide diverse perspectives.

Together, we constructed a framework inspired by popular education, collaborative governance and collective intelligence. This framework changes the place and role of learners and supervisors. It opens up co-construction and requires sharing values such as benevolence, sovereignty, mutual respect, criticism and self-criticism, humility. This framework allowed for collective and individual work on professional posture. This work is essential to reinvest the role of the engineer in a world in transition.

We did not conduct more specific individual interviews to explore the question of identity. In the light of the observations and data collected, we presume that some students are on the threshold of an identity realisation while others may be in phases of foreclosure or moratorium in the sense of Marcia [2]. We do not exclude that the development of professional identity, especially at such a young age, may still show forward and backward steps: it is possible that they may experience times of questioning about engagement and/or exploration.

We also proposed pedagogical activities consistent with the objectives [1], to develop the skills needed to solve the challenges linked to transition and, in particular 'transformative' pedagogy [3,5]. The pedagogical approach - built around real projects and supported by local structures – is designed to develop complex learning. It encouraged teachers and students to weave links between each course and their projects, and to experience innovative pedagogical activities. Pedagogical support for teachers and students in these unusual teaching methods (activities and assessment of learning) has proved necessary but still insufficient.

FROM STUDENT TO EXPERT IN A WEEK

Christian Forbrig, Edward Rullmann, Juri Rappsilber[1]
Technische Universität Berlin
Berlin, Germany

Conference Key Areas: Teaching methods
Keywords: student empowerment, theoretical engineering course, iterative process, course framework, self-driven learning

ABSTRACT

It can be challenging to effectively impart higher education content to students. We experienced such difficulty in a lecture series with invited senior scientists presenting their area of Biotech research. Instead of a vivid exchange with the expert, we observed limited and restrained student contributions. In qualitative interviews with these students we learned that they perceive their knowledge disparity as too big and the fear of being embarrassed by asking "stupid" questions obstructed their participation. This let us to radically rethink the course design resulting in our own interpretation of flipped classroom, peer learning and student empowerment. We designed an engineering course that focuses on providing master students with the best possible environment to gain theoretical knowledge in a new field within a limited time period (currently: six weeks - six topics) aiming to empower them in these topics by acquiring new knowledge on their own. Based on seed questions and tag words, students conduct background research and create a team presentation for an invited field expert, thereby getting prepared for a subsequent in-depth discussion with the expert. The current layout is the product of an iterative process over the course of five years, and several rounds of fine-tuning within each year, based on extensive student and instructor feedback. Students particularly appreciate the positive in-course atmosphere with a focus on growth-mindset, the strong experience in teamwork, being taken seriously, and making contact with field experts and frontiers of current knowledge.

1 INTRODUCTION

We designed a lecture series intended to bring students of the Biotechnology Master's programme rapidly to an advanced level of understanding of bioanalytical methods. Our plan was to capitalise on the rich expertise found in the Berlin area as one of the leading cities for German science, so we invited experts to present their area of research to the students. Our assumption was that students would benefit

[1] ORCIDs: C.F. 0000-0003-3624-5440, E.R. 0000-0003-0908-5832, J.R. 0000-0001-5999-1310
Corresponding Author: Juri Rappsilber, juri.rappsilber@tu-berlin.de

doi:10.5821/conference-9788412322262.1240

from top-level teaching by the experts and, as a side effect, make contact with excellent research groups for potential master thesis projects.
The original course format was a classical lecture series with two 90 minutes slots per week. We taught our core expertise and allocated the remaining slots to field experts. After running this course twice, we concluded that engaging scientific experts to teach their respective topics with passion and profound domain-specific knowledge provided an excellent framework for professional teaching. However, the oral exams with the students also revealed a substantial shortcoming. The topic-specific experts had condensed the content that they normally teach to PhD students and postdocs in field-specific scientific courses over a week or two into three to six hours, which was the time allocated to them. While none of the students had any questions - a possible signal of complete understanding - we interpret this now as a sign of information overload. None of the students had conquered the knowledge that they had been provided with, as evidenced by the oral exams and further interviews with the students.
To address these shortcomings, we fundamentally reconceptualized the course by implementing a mixed method format built on flipped classroom [1] and project-based learning concepts [2]. Here we report on the process, the design and the experience of running the course in its reworked form for five years.

2 METHODOLOGY

2.1 Research questions

The low learning outcome despite the substantial framework of expertise strongly indicated the need for a new course concept. So, we went into ideation defining the following main needs:

- How can the students gain confident command of the current state of development of selected bioanalytical methods in the life sciences within the restricted time boundaries of the course?
- How can we maximise the value of leading experts in their respective technologies that volunteer teaching this course, while keeping their time commitment minimal?

We reframed the first question into the core idea of the course in a more accessible way: How would a couple of friends ideally learn the theory of a new technology within one week, or even less? How can they achieve that repeatedly for every topic without feeling lost or overworked?

2.2 Methodology of course development

With the problem explained in the introduction and the needs summarised within the research question(s) we created a course prototype based on a mix of concepts like flipped classroom and project-based learning in expert groups with a focus on activating learning methods.
For the first version of the course (prototype, Fig. 1) we reserved three subsequent days per topic with the experts being invited on day 3. This initial format was used to further learn about the participants' needs by critical observation and regular feedback sessions after each topic round, directly linking to the implementation of minor adaptations (fine tuning) for the following topic.
Based on these experiences and a vast feedback collection we iterated the course for the next year that again was the basis of the following iteration loop. With that strategy we were able to adapt the course structure to its current format (year 2021) that is further described in the results section.

2.3 Evaluation of learning success

In order to display the learning success for each course topic, we designed a questionnaire (see Fig. S3) and asked students to evaluate their confidence levels within each subject on a scale of 0 (lowest) to 10 (highest).
We started data collection on a voluntary basis in 2018 with a printed 2-page questionnaire that was expected to be filled out before the start of the course and then regularly after each course day. Sheets were collected at the end of the course and data points displayed as box-and-whisker plots, individually for each topic (fig. S1), and as a mean of all topics (Fig. 2).Students were also asked to evaluate their team-, research- and presentations skills before and after the course based on a similar scale (Fig. S2).
The same type of paper questionnaire was used in 2019 and, since 2020, has been replaced by a digital survey with identical topic and skill related questions, now only being accessible at the time of data collection.
To also get the impressions of the invited experts, we asked them to rate the students' performance in an informal feedback session after the course. Finally, we graded students with a portfolio exam (compare section 3.2).

3 RESULTS

3.1 Prototype development and theoretical background

From the initial shortcomings we learned that students need preparation time to learn basic concepts and translate these into further questions to feel comfortable to interact with and hence effectively benefit from the experts. One way of doing that would have been to give students selected materials prior to the expert lecture to be worked through at home. That way of flipping the learning from the classroom to out-of-class might have already resulted in prepared students and more time in class for further discussion of the content [1]. However, in other courses we have observed that only a certain number of students follow these recommendations, and even fewer master the content in depth. Also others have observed insufficiently prepared students, even if the pre-work was mandatory [1, 3]. To help students focus and assist whenever needed, we decided to integrate the preparation phase into the classroom.
In their review about problem- and project-based learning, the authors describe that a problem to solve might act as an incentive for students to learn and can be used as a central principle to enhance students' motivation [2]. So instead of just letting students prepare with topic related material, we expected them to create a team presentation about the method within two days that finally should be presented to the expert. Proven to enhance deeper understanding [4, 5] we implemented peer learning by splitting the course into expert teams of four to six students. Each team was then randomly assigned one predefined subtopic of the collective final presentation, meaning that each team was responsible to prepare the content not only for the expert but also for their peers. Regular progress updates should ensure that the group does not lose sight of the bigger picture and has assigned times to help each other across teams.
At the end of each topic a feedback round with students and instructors should provide insights for a potential fine-tuning of the next topic round.
We further assisted the participants by providing a clear daily structure with two progress presentations as intermediate goals, accessible team support and a coworking-friendly environment by dividing a seminar room into movable team

spaces with coffee and tea being available over the whole course time.

3.2 Description of the prototype

We came up with a course prototype held in summer 2017 with 19 participants (compare Fig. 1 to see the basic course structure), that were briefed about the concept and our expectations in a pre-meeting.
In randomly assigned teams, students were supposed to work through five topics successively, with three eight-hour days devoted to each topic. They brought their own laptops and had internet access through the university Wi-Fi. For students without a mobile device we provided a laptop for the duration of the course.
The first day was designed to get an initial understanding and perform further research about the assigned subtopic. In a plenary session, the outcome was shared with the whole group and the structure of the joint presentation drafted collectively.
On day 2 the collected information was intended to be condensed and accumulated into presentation slides and the final presentation rehearsed in the afternoon.
The resulting lecture composed of the four group presentations was presented to the expert in the morning of day 3 followed by a discussion. The rest of the day was used to conserve the acquired knowledge into a collective document (wiki). A voluntary seminar was offered at the end of day 3 after a feedback round.
To foster perseverance, each day students could earn a small proportion of portfolio points for collaboration and punctuality. Presentations and the prepared slides were graded as well and summed up with the points achieved in a final test at the very end of the course.

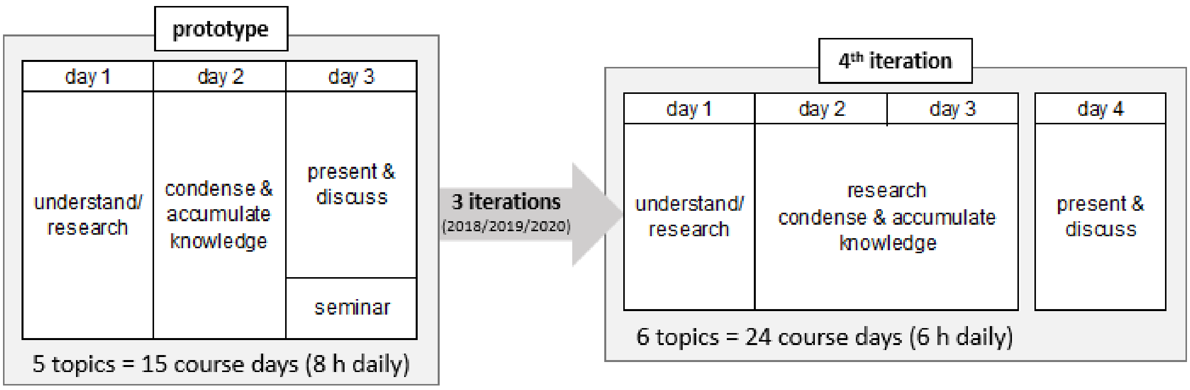

Fig. 1 Course structure development from prototype in 2017 to the last version in 2021. The prototype started with 3 days per topic (8 h daily) including an optional seminar and was iterated to the current format of 4 days per topic with a daily workload reduced to 6 h, including a course-free day before meeting the expert, if in accordance with calendar dates.

3.3 Lessons learned from the prototype

After having run the prototype of the course we learned that the concept itself worked out very well - vivid discussions with the experts have been observed as well as clearly positive feedback from the students stating that they have learned a lot about the topics and themselves and gained confidence in important soft skills, such as teamwork towards a hard and heavy deadline, as well as presentation and research skills. That matched the results of the self-assessments summarised in Fig. 2 (and more detailed in Fig. S1) and Fig. S2. Besides that, the motivating and clear course environment was praised repeatedly.

Nevertheless, eight hours a day for three weeks with only the weekend in-between was very demanding for most of the participants. It was not possible to do anything else than this course. It was also reported that the time per topic was not enough and students would rather have more time to digest the accumulated knowledge and learn more about the other subtopics. It was also requested to have more narrow-framed subtopics and topic specific guidance to not get lost during literature research. The optional day 3 seminar was attended by only a small subset of the group; non-participating students reported that they were just too exhausted to join. From the lessons learned during the prototype course we developed the basic setup of the course, which is still valid to date and described in section 3.4.

3.4 Basic setup of the course and its overall development over time

With the basic course structure, we created a “space to learn” where we assist student teams in preparing a presentation for invited field experts and fellow students by providing seed questions and topic related keywords. Within the now three days long research and content creation phase (6 h/day) we provide guidance whenever needed and a micro-timed schedule with organised time slots for information exchange between the teams (compare Table 1). On day 4 the lecture is presented to the invited field expert who detects and fills potential knowledge gaps and answers further questions. The expert also gets the opportunity to present their own research - now to a prepared audience that is confident to discuss the content. The learned content of all teams is then assembled into a document (wiki) and from 2020 onwards, read and enriched by all students via perusall, a social e-reader that should “turn the online reading assignment into a social experience to encourage students to engage with the material and with fellow classmates outside of class” [6].

When conducted in person (2018 and 2019), each team had an assigned team space within a seminar room. For regular meetings of the entire team, the room was transformed multiple times a day. During the research and content creation phase (day 1-3) instructors were present at preassigned times, and could be called in via digital communication. We started off with the course organisers being the only instructors, and then expanded successively by calling onto the help of other members of our research lab with more advanced topic-specific knowledge. Since 2020 we also provide an introduction lecture on day 1 to clearly define the level of expectation and learning goals.
When conducted online (2020 and 2021), we used a video-chatting service with breakout rooms for the sub-team meetings. As a noted benefit of the online format, we could expand our set of field experts internationally. We set up a channel in a messaging app to allow students to communicate with each other and instructors throughout the course. This kept in-course chatting away from other digital channels and allowed a clean differentiation of learning and leisure time. The collective student notes and presentation slides were created in a freely accessible online editor, allowing students to simultaneously work on the respective documents.
As due to the local pandemic situation the initially planned final exam could not be offered in 2020, we demanded homework instead. That consisted of finalising an assigned part of the knowledge collection (wiki) after it has been proof-read collectively. The handed-in documents were then marked individually. Having had the positive side-effect of further deepening the understanding of the topics, we decided to keep that substitute for further iterations.

Each tool contributed an essential component to the course communication. Note that students very much focused on this block course for its duration, and these tools essentially formed major elements of their work environment. As students are working in small teams, they can also help each other if aspects of these tools should be less familiar to some of them. A course page in our university Moodle system served as the central information platform with all details needed.

Table 1: tentative weekly course schedule at the beginning of the course with (intermediate) presentations framed in blue.

Day 1	Day 2	Day 3	Day 4
10:00 morning round	10:00 morning round	10:00 morning round	10:00 day/expert intro
10:10 overview lecture	10:05 prepare rough presentation	10:05 present improved presentation	10:05 presentation & discussion 10:05 student presentations 11:05 break 11:15 expert questions 11:35 expert research presentation 11:50 discussion / open questions
11:10 subtopic assignment	10:35 speakers present rough presentation	12:00 lunch break	13:00 lunch break
11:20 subtopic-team-research (I) solo research, lunch break, share with team and define tasks/sub-subtopics	11:50 prepare presentation (I)	13:00 finalize presentation, start team-wiki	13:40 complete team-wiki
14:00 subtopic-team-research (II) work on tasks/sub-subtopics, discuss presentation plan with mentor, combine tasks/sub-subtopics into presentation draft	13:00 lunch break	15:00 internal rehearsal and proceed on team wiki	15:20 answer survey
15:50 check out	13:40 prepare presentation (II)	15:50 check out	15:30 feedback
16:00 end of day 1	15:50 check out	16:00 end of day 3	16:00 end of day 4
	16:00 end of day 2		

3.5 Learning outcome

The experts commented extremely positively regarding the students' performance, both, about the presentation and the subsequent topic discussion and repeatedly renewed their commitment for the next years' course.
When looking at the self-assessed confidence levels summarised in Fig. 2 (and more detailed in Fig. S1), it is visible that participants greatly improved over the four course days in both the in-person and digital formats.

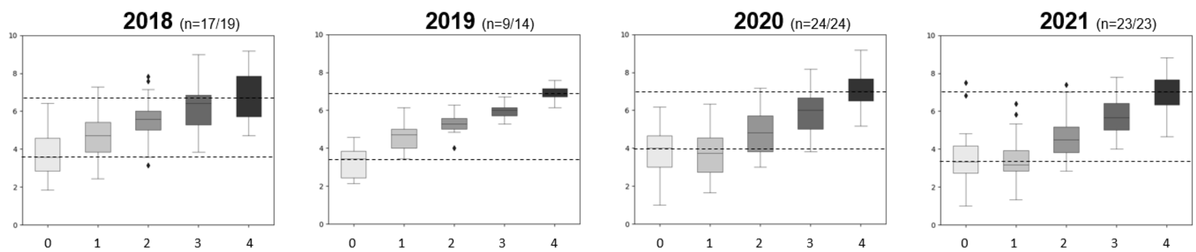

Fig. 2: Self-assessment of topic confidence levels before the course (0) and after each day (1 - 4) plotted as a mean over all topics. Each plot shows a year (2018 – 2021). Scale used on y-axis: "0 = absolutely no idea" to "10 = feel like an expert". The dotted lines highlight the median before and after the course.

Notably, when offering the course in-person the learning curve rose constantly while in the digital format in 2020 and 2021 confidence levels often dropped after the first day but rose even steeper within the following days. This features similarity to the Dunning-Kruger effect pointing out that people being unfamiliar with a topic tend to overestimate their initial knowledge [7]. Beside the influence of shifting the course into a digital format, we also provided a clear pre-lecture on day 1 confronting participants with the expected depth of knowledge. Figuratively spoken, this might have pushed them from “Mount stupid” into the “valley of despair”, that however helped them to enter the phase of “enlightment” more easily within the next days. The non-observed drop after day 1 during the in-person version of the course might be due to the missing pre-lecture but also could be led back to the way data has been collected - students were indeed reminded to fill out the paper questionnaire regularly, but we observed some students filling it out not until the very end of the course, possibly resulting in distorted self-estimation.

CONCLUSION AND OUTLOOK

The increased topic confidence of the students and the positive feedback obtained by all stakeholders (students, instructors and experts) let us to conclude that we managed to create an environment to assist students in gaining theoretical knowledge in a new field within a limited period of time. Empowering students to benefit from invited field experts by providing a prior team mission (the final presentation) should be transferable to a multitude of disciplines and we highly recommend trying it out.

Based on our observations we plan the post-pandemic version to be hybrid by allowing students to work from the comfort of their homes during the research and content creation days and, on the presentation day, coming together in person to allow practising in-person presentation skills, strengthen the positive course atmosphere and intensify contact with the field experts through in-person experience. We intend to keep our digital work space as described above, and hope to maintain participation of international field experts digitally. We expect the resulting mixed in-person and digital presence of attendees during the presentation and discussion to require careful planning and set-up of technical infrastructure. Importantly, we will continue our weekly feedback rounds, which will plausibly lead to changes of these plans. We will remain open to adjust the opportunity space provided by this course to maximise the learning experience of the students.

ABSTRACT

The paper explains the design and the first part of the implementation of a project within the subject of Statistics with first year students in a Bachelor's degree in ICT Systems Engineering in Manresa School of Engineering, part of the Universitat Politècnica de Catalunya. We use the methodology of *study and research paths* within the Anthropological Theory of the Didactic and under the paradigm of "Questioning the world".

The project topic is the "water". The experience is linked to a broader UPC-driven project, called AquaeSTEAM, based on questions to spark new ideas and science

[1] *M.J. Freixanet*

maria.josep.freixanet@upc.edu

doi:10.5821/conference-9788412322262.1126

and technology solutions to solve water-related problems. After narrowing down the issue to concrete problematic questions, the students analyse data published in IDESCAT, the Statistical Institute of Catalonia, related to water consumption, both domestic and industrial, factors related to climate change, such as temperature and pluviometry, among others, and will also carry out a survey to link all these studies with the water footprint.

The implementation sheds light on the conditions needed to integrate project-based proposals in the traditional organisation of the subject. It also provides information about the changes that may take place to facilitate the integration, in both the subject's content and instructional structure (lectures and tutorials). The conditions required are then compared with other experiences of study and research paths in engineering education carried out these past years in the Anthropological Theory of the Didactic.

1 INTRODUCTION

This paper presents an inquiry-based instructional proposal called *study and research path* (SRP) we implemented this academic year 2021-22 in the subject of Statistics of the bachelor's degree in ICT Systems Engineering in Manresa School of Engineering, one of the schools of the Universitat Politècnica de Catalunya (UPC). Like other European universities, UPC has been going through a methodological transformation in education for some years, especially from the adoption of a competence-based curriculum within the European Higher Education Area, but it is the first time an SRP is implemented at this school although some other project-based activities had been carried out before in the same subject, by one of the authors [1]. The analysis of an experience at secondary school was presented and discussed at CERME Conference this 2022 [2].

Study and research paths belong to the theoretical framework of the Anthropological Theory of the Didactic and respond to the pedagogical paradigm of *questioning the world* introduced by Chevallard [3]. In contrast with the prevailing paradigm of *visiting works* that gives priority to the works of knowledge students must learn, in this new paradigm, questions go first, and knowledge works are only used and studied to elaborate answers to the questions. An SRP begins with a generating question that is given to the students who address it under the guidance of the teacher(s). In the process of answering the generating question, new derived questions arise that the study community (made of teachers and students) need to answer to develop the inquiry. Addressing the derived questions requires searching already available information (knowledge works, empirical data, etc.) and studying it. It also requires testing it and developing the available resources to elaborate the final answer.

Barquero et al. [4], present different modalities of SRPs implemented in university education during the past 15 years and illustrate different strategies for integrating them into traditional course organisations. They also analyse the effects produced by a change in the generating question within a given course and modality. In terms of the share of responsibilities between the teacher and the students – the *didactic contract* –, these authors show the importance of introducing an external instance (like a fictitious client or consultant) that raises the generating question and to whom the final answer is addressed. This strategy supports the new didactic contract that needs to be established and the means used to validate the final answer. It is the "client" and not the teacher who determines what a good final answer is according to the initial demands. Therefore, the validation criteria can be separated from the pure instructional ones.

This contribution presents an SRP that introduces a new modality in what concerns the choice of the generating question. Instead of being proposed by the teacher or by an external instance, it is the students who are asked to choose it according to their interests in a fixed theme: the water. This new option has given rise to special features in the development and management of this SRP and also in the students' learning, which will be listed in the last section. It will be interesting to analyse them from the ATD point of view in upcoming works. To get there, section 2 summarizes the design and the first steps of the SRP and section 3 discusses the development of the main question of the SRP.

2 DESIGN AND FIRST STAGE OF THE SRP

2.1 Setting the context

This SRP design and implementation were subject to some conditions found in the school. The subject of Statistics is taught in the first year and second semester of the bachelor's degree in ICT Systems Engineering at Manresa School of Engineering, at UPC. The group consists of 40 students and the subject is developed in two weekly sessions of two hours each, one session for the full group and the other session for half of the group, at the computers lab, where the SRP has been developed for several weeks. The syllabus, exercises list, and lab questions, and assessment criteria are shared with other degrees where Statistics is taught at the same time. Because of that, the SRP could not play a primary role in the subject, and it had to share space with traditional lectures and tutorials. However, the assessment was slightly modified to give the SRP a weigh of 20% divided into a final report (10%) and a poster with an oral exposition (10%). Nevertheless, it is expected that the benefits provided by the SRP will indirectly influence positively the percentage coming from other evaluation activities. In addition, the subject has been assigned the evaluation of the competence of autonomous work.

From the previous experiences and the competences assigned to this subject, two aspects were taken into account: empowering students' autonomy and promoting learning around quality and data management.

Unlike other SRPs previously implemented at the university level, this one does not start with a main question proposed by the teacher. Here students were asked to propose their own questions in the framework of a general topic: the "water". In this way, the experience is linked to the project AquaeSTEAM and focuses on the role of water in our daily lives and its relation to science and technology. AquaeSTEAM is a project co-funded by FECYT to promote scientific culture and to build up resources to be used at all educational levels with an interdisciplinary approach in relation to the Sustainable Development Goals (SDG) of the 2030 Agenda for Sustainable Development, approved by the United Nations on 2015. The project promotes the habit of questioning the world, proposing several questions and suggesting different approaches to each one.

2.2 Brief description of the first part of the SRP

The first activity carried out in class gave the students an insight into what they were going to study in the subject. It also illustrated the process followed from the consideration of an initial question until finding a final answer. It is an activity in which each student receives a dice and they have to decide whether it is tricked or not. In this one-hour activity, the students start gathering data, they see how to organise it, the main points of descriptive statistical analysis, a bit of probability and the beginnings of statistic inference [5].

After this activity, the SRP was presented to the students. Instead of the teacher presenting a generating question, which is a key element to starting an SRP [6], this responsibility was passed on to the students who had to think about a question they would be interested in answering around the given topic. Students organised themselves in small groups.

The first step for each group was to start doing some research and gathering information to formulate a question. The second step was to link questions with data and define the aim of the study and which variables are going to be analysed. Some derived questions showed up and students were invited to build up a question and answer map, which will be completed throughout the project. Figure 1 includes an example from one of the groups illustrating the structure of some derived questions.

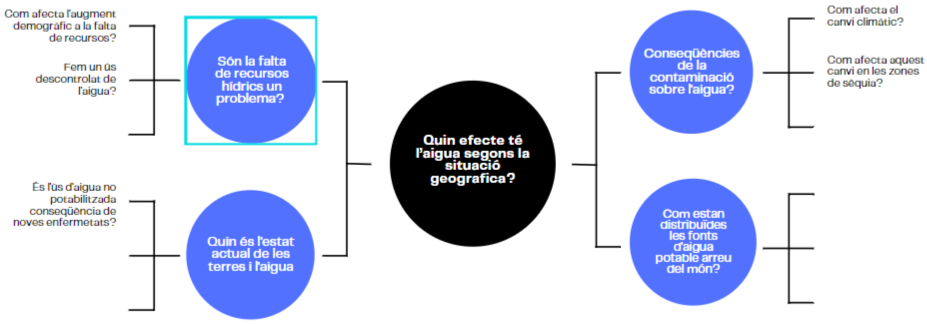

Fig. 1. Questions map of a group of students

Before beginning to look for any answer, a third step was required: the analysis of the study proposal, namely the viability of the study, by analysing the kind and quality of the data provided. This is one aspect that very often remains in the shadow in educational contexts. The study community, composed of the students and the teacher, was in charge of that during several sessions. Examples and exercises on descriptive statistics were discussed, and time was devoted to discussion and peer reviews. More details on this part are described in [7]. Questionnaires were used to make the application of a rubric easier and also to gather information from the point of view of didactic research. Results will be discussed in section 4.

3 DEVELOPMENT OF THE MAIN QUESTION

Since the data provided by the students were not in most cases easily "studiable" and to begin with all the questions in parallel will be too wide, the teacher looked for common ground to focus the work on a common issue: water consumption. Both domestic and industrial consumption was going to be considered, with data provided by official sources. In future stages of the SRP, each group of students could channel these first findings toward their initial question and could help them narrow it down.

Each group chose a region of Catalonia for their study, keeping a relationship with their initial question, and checked what data was available in the IDESCAT (Institute of Statistics of Catalonia) for each municipality, which could be related to water consumption. It was agreed to study the following variables: number of inhabitants, sex, age ranges, domestic water consumption, industrial water consumption, surface, price of water, unemployment, number of inhabitants enrolled in Social Security, sports facilities, touristic accommodations, home building and municipal waste. Eleven regions were studied: Bages, Berguedà (as central regions), Vallès Occidental, Baix Llobregat and Barcelonès (as metropolitan regions), La Cerdanya and Vall d'Aran (as northern mountaineous regions), Ribera d'Ebre and Baix Ebre (as southern regions), La Selva (as north-coastal region) and Pla d'Urgell (as rural region). Each group carried out a descriptive statistical analysis and checked the correlation between variables.

Some of the results of this analysis can be seen in the following graphics and tables. The analysis was not reduced to usual histograms or pie charts, but students experimented with other graphics. For example, Figure 2 shows two charts. On the left, the box plot is associated with the various variables, allowing us to compare what it is telling for each. On the right, it is illustrated how the same group of students experimented with sophisticated graphs to show the comparison of values of the variables for the different municipalities in the region.

Concerning the study of correlation, Table 1 shows the summary of the correlation coefficients between domestic or industrial water consumption and the different variables, carried out by another group of students.

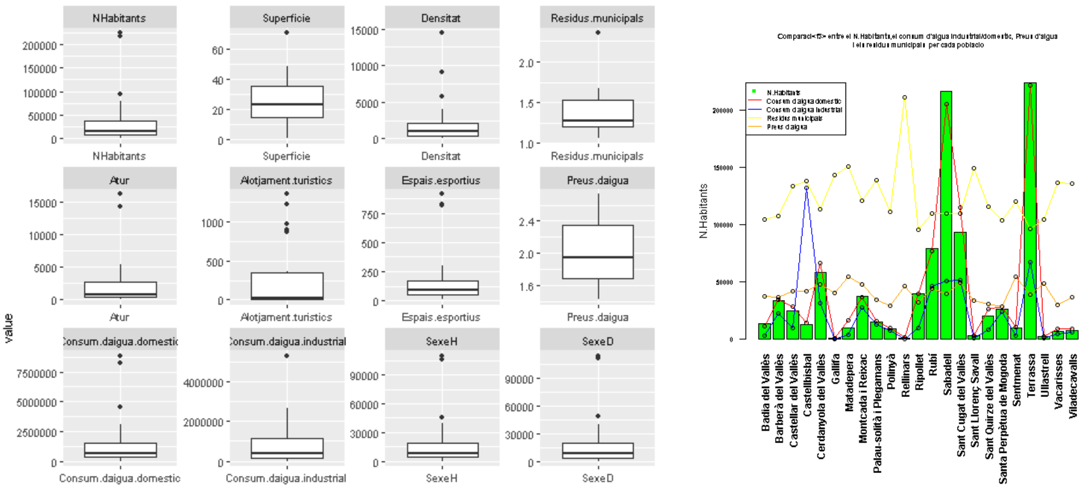

Fig. 2. Plot boxes for several variables and simultaneous comparison of variables by municipality (Vallès Occidental)

Table 1. Coefficients of linear correlation (Berguedà)

	Coefficient of linear correlation (r)	
Variable	**Domestic consumption**	**Industrial consumption**
Inhabitants	0.9944899	0.7686851
Surface (km2)	-0.1910381	-0.04068739
Price of the water (€/m3)	0.3382914	0.3876078
Unemployment (mean of people)	0.9941054	0.74788869
No. of inhabitants enrolled in Social Security	0.9924128	0.77418386
Sports facilities	0.8695737	0.68088891
Touristic accommodation	0.6494041	0.44081208
Home building	0.9724515	0.69912799
Municipal waste (tones)	0.9960272	0.75759798

After sharing this part of the study, the students have the chance to carry on with their first proposal of the SRP, in case it was good enough to do so or have the chance to change the first approach, set a new main question to be answered. In the first case, they have the chance to merge all their findings until that moment (previous research and first proposal, and analysis of the region about water consumption). In the table below, it is shown the first proposed generating question, the region afterwards studied and the definitive generating question of some groups of students. The question in green represents the question that has been maintained, the questions in yellow represent the questions that have been kept but have been narrowed down and the cases in red represent the questions that have been totally changed.

Table 2. Generating question proposed – Region studied – Final question

FIRST QUESTION	WATER CONSUMPTION IN SPECIFIC REGION	FINAL QUESTION
Has the 2020 confinement affected the level of water consumption in Barcelona?	El Barcelonès	Has the 2020 confinement affected the level of water consumption in Barcelona?
How much water do nuclear plants consume?	La Ribera d'Ebre	How much water does Ascó nuclear plant consume?
How does water brought by rivers in Catalonia vary?	El Baix Llobregat	How does water brought by river Llobregat vary?
What effects has society had in water?	El Berguedà	Do the political views of the inhabitants of El Berguedà affect on water consumption?
Is it possible to maintain a swimming-pool efficiently not letting fungus grow?	La Selva	What is the water footprint of the technology of first-year ICT Systems students?

The following stage will be reported and analysed in upcoming works.

4 ANALYSIS AND FINDINGS ON THE FIRST STAGE OF IMPLEMENTED SRP

Questions proposed by students were creative, and the map of derived questions showed their interest in water issues and SDG in general, part of the goals of this project. The main difficulty was to link the questions with suitable data, as their knowledge about how to manage data was limited, and in some sense lower than what was expected. However, it led to going deeper into that part, usually disregarded. Some sessions on data management and analysis were introduced, complemented by a peer reviews activity that increases learning opportunities for the students.

The perception of students about their learning process was collected through a questionnaire, with the aim they could see where the question is driving them. When asked about the limitations of their initial proposals, they confirmed our analysis with answers such as: "Improper and/or unnecessary data were provided" or "The main question was too wide". When asked about what they learnt from review activity (own one, peer and teacher reviews), they also wrote explicit answers such as: "Different approaches and how the others have used the data", "To carry out a good descriptive analysis and to select proper data", "To check if the revision and our data were correct", "Possible mistakes we hadn't taken into account previously", "Possible relations between variables", "Inspiration for our project", "Aspects the others can improve and so can we".

From the analysis of the development of the generating question some interesting features related to autonomous work and critical sense could be listed too.

- Students used more complex graphics, other than the usual histograms or pie charts, and experimented with them for several variables.
- Some new questions appeared due to the use of real data, and students argue: "*When grouping the data in classes (number of inhabitants), some criteria cannot be met. Most of the municipalities in "El Berguedà" have less than 1000 inhabitants, but the capital city has a lot more (16.682) and we do not know how to set the classes: either we make more than 20 classes or the class (0,1000] contains more the 30% of the data.*"
- Students also experimented on software further than the presented option: "*We have decided to calculate the classes using R and not R Commander. It is more efficient since it generates a table with two columns: one with all the classes and the other one with the absolute frequency of each of them.*"

Experience is still in progress and this "in vivo" analysis was very interesting and fruitful because it allowed feedback on the same experience.

An a posteriori analysis will be conducted from the point of view of the ATD. However, since it is the first SRP experience at UPC, it makes sense to sketch some comments related to the first phases. Following Barquero et al. [4], when the generating question "is taken seriously", that is, when the teacher lets the question lead the inquiry, she does not know the paths that will be followed and assumes the role of a guide who helps students progress in their study, organizes the sharing of results, orients the search of new information, etc. Since the question is open, the teacher does not know the answer – and many times there is no unique answer to the question – and the decisions made during the SRP (by the teacher and the students) are not based on pedagogical criteria – to better learn such or such topic – but are subordinated to the sake of finding an answer to the generating question. In the case here considered, students were requested to formulate their own questions related to the topic. A logical consequence is the increase of complexity for the teacher to guide several parallel inquiries at the same time.

In terms of the didactic contract, this choice produces a change in two directions. On the students' side, it increases their responsibility with delimiting the question to address and finding criteria for it, which entails the learning of new competencies and knowledge. However, some groups could experiment with the frustration of having to abandon a path already taken that later appears to be unproductive. New responsibilities also appear on the teacher's side, like managing the students' proposals and finding criteria to guide the delimitation of the questions. SRPs' questions need to be addressed in real-time, and their selection or rejection can be tainted with a certain subjectivity: what makes a question worth studying? What (and who) determines if it can be properly addressed or not? What are the assumed conditions? A new study, at the end of the activity, will shed light on these questions.

Castelldefels School of Telecommunications and Aerospace Engineering,
Universitat Politècnica de Catalunya
Castelldefels, Catalonia

Conference Key Areas: *Student Engagement, Mentorship and Tutorship*
Keywords: Academic performance, Electronics course, University newcomer students, Student engagement.

ABSTRACT

The subject Electronics for Telecommunications (ET) is taught in the first semester of the Telecommunications degrees at the Castelldefels School of Telecommunications and Aerospace Engineering (EETAC). The academic performance is relatively low compared to the same course taught in a double degree of Aerospace and Telecommunications, in part justified by the large difference in the university access marks of the students between both degrees. Several actions have been implemented in courses 2019/20 and 2020/21 to address this issue, especially in theory classes where student attendance is lower than in laboratory sessions. Implementation difficulties have arisen because the presence of the COVID pandemic. Even so, performance has greatly increased, especially at the first semester of each academic year. In addition, a student survey shows a good satisfaction with the introduced actions and others in process of introduction or assessment. Some of the actions, particularly those to be applied in the theory sessions, could be easily extrapolated to other first-semester courses of the degrees.

1 INTRODUCTION

The subject ET (Electronics for Telecommunications) belongs to the first term (1A) of the Telecommunications Bachelor degrees and the double Bachelor degree of Aerospace and Telecommunications at the EETAC (Castelldefels School of Telecommunications and Aerospace Engineering) of the UPC (Universitat Politècnica de Catalunya). Enrolment in Telecommunications degrees is 120 students (100 in September and 20 in February) and 40 students in the double degree. In the first semester of each academic year, there are separated class groups of Telecommunications and double degrees, but on the second semester, they share the same class groups.

Student pass rate of the degrees was analyzed for the three academic years before the implementation of the proposed actions (16/17, 17/18 and 18/19). During the first semester of each year, pass rate in the double degree was relatively high (approximately 70 %). However, in the Telecommunications degrees pass rate was significantly lower and declining from 41.9 % in 2016/17 course to only 19.4 % in 2018/19. In the second semester of each year, with shared class groups, most of the students are repeaters and from Telecommunications degrees, and the pass rate ranged between 46.7% and 34.4%.

These large differences in the student pass rate between both degrees are mainly justified by the respective admission marks (ranging from 5.0 to 14.0 in Catalonia). Telecommunication degrees have admission marks of 5.0 because not all places are filled. Double degree has an admission mark that has increased from 9.29 in 2016/17 to 10.38 in 2018/19. Furthermore, average access marks of double degree students are 2.5 to 3.5 points higher than Telecommunications students. Additionally, students' profile is heterogeneous in the Telecommunication degrees and more homogeneous in the double degree (students with good aptitude and attitude, in general).

The ET subject is organized in theory classes (large group, 50 students maximum) and laboratory classes (small group, 25 students maximum). Theory classes are based on lectures and resolution of exercises. Laboratory sessions consist on experimental developments based on preliminary laboratory assignments. Theory accounts for 60 % and laboratory for 40 % of the final grade.

Double degree students attend regularly to both theory and laboratory classes. On the other hand, as the course advances, student attendance to theory classes for Telecommunications groups decreases while attendance to laboratory sessions keeps more regular due to continuous assessment [1]. Theory classes include midterm and final exams. Laboratory marks are higher because students work in groups of two or three members. In this way, some students benefit working with mates who have better performance, thus improving motivation and marks than working alone. Lecturer continuous feedback in laboratory classes can also make a difference and become another positive factor [2].

Our aim is to increase the student pass rate of the ET subject, in particular for the Telecommunications degrees and by increasing the theory exams marks. We believe that a greater pass rate will be possible increasing students' engagement, motivation and implication. Therefore, several actions are proposed and some of them already implemented to achieve this goal.

2 PROPOSED ACTIONS: DESCRIPTION AND DEVELOPMENT

We propose 7 actions, 3 have already been implemented, mainly focusing on theory classes, and 4 are going to be implemented in the next academic course, mainly focusing on lab classes. We describe these actions and their motivation, methodology and development during 4 semesters corresponding to the courses 2019-20 and 2020-21.

2.1 Action 1: Initial tutoring meeting

Most of first semester students enrolling the ET subject each academic year are university newcomers. Our School organizes welcome sessions for discussing most commons issues and an initial academic tutor is assigned to each student for guiding them through the first year of the Bachelor degree studies [3]. In addition, each lecturer has several tutorial hours (6 h for full-time personnel) at his office for solving the students doubts and questions about the subjects he teaches. This last resource, which can be very useful, is, however, not much used by new ET students, especially those in Telecommunication degrees. Students show prevention for attending tutoring time at the lecturer office, maybe because this resource is not usually present in pre-university studies.

In order to palliate this issue, we propose the ET lecturer meet all their students for a first interview within its tutorial time at his office, generally 5-10 minutes long. Students can attend alone or in groups, for example those used for the laboratory classes. The lecturer fills a form sheet with student personal information (name, age, pre-university studies and access mark) and informs the student on common academic issues: lecturer tutorial time and purpose, weekly study time, class attendance control, proposals of exercises, and bibliography. These indications are also given in the initial theory class and are intended to reinforce the message through personal interaction. Students can also put open questions they consider to the lecturer. The main goal is to first personally interact with the students to promote their use of the lecturer tutorial time from the very first week in order to improve their academic success. In addition, there are some questions addressed specifically to repeater students to find out why they failed the subject and agree with right proposals for succeeding in the new course.

This action was carried out the first two semesters and also the fourth. In the third semester, partly due to COVID pandemic, it was replaced by a midterm tutoring for those who failed the midterm exam.

2.2 Action 2: Attendance control at theory classes

At laboratory classes, attendance is monitored indirectly because students are assessed at each session. However, assessment of theory content is carried out by means of 2 exams, one at midterm (accounting for 25 % of the overall assessment of

ET) and another at the end of the semester (accounting for 35 %). By default, attendance is not monitored at theory classes. Unfortunately, and for many subjects, student attendance decreases while the course advances, especially in Telecommunications degrees. This has a strong impact in their possibilities of passing the course.

Therefore, we propose implementing an attendance control at theory classes. While it may seem like an out-of-place measure at the university level, it is considered to be beneficial for newcomer students. In this way, missing students can be contacted by the lecturers (by e-mail or in laboratory classes, if they attend) to find out the reason for non-attendance and try to redress the situation, if necessary, by mutual agreement.

In the first semester, time for problem discussion (Action 3) was used for attendance control. In the second semester, however, it was stopped after classes became remote due to COVID. In the third semester, even though theory classes became remote some weeks later, attendance was yet monitored thanks to Google Meet (the used remote platform) that sends attendance automated reports. In the fourth semester, again in face-to-face mode, attendance was surveilled and annotated trough an attendance tool available in Atenea, the virtual platform used in the UPC. Students who were repeatedly not attending theory classes were contacted, mostly by e-mail, and some of them returned to classes.

2.3 Weekly exercises proposal

In order to encourage students to attend theory classes, a weekly list of exercises is proposed as homework. At the beginning of each class, students discuss problem solutions with each other and then the lecturer and the students solve the problems on the board. Students who do not do the exercises regularly are contacted to be able to correct this situation.

This action was implemented in all semesters, including those in which classes were remote. In the first semester we annotated who did them while discussing the exercises in groups. In the second semester, however, this control was not performed when switching classes to remote format. In the third semester, despite most classes were remote, the control was activated again creating tasks in Atenea where students scanned their solutions and submit them before the session. In the fourth semester the control was implemented in the same way.

2.4 Action 4: Demonstrator of the final laboratory project

In the last two laboratory sessions, students implement a short project that covers many of the course topics. The project focuses on measuring and controlling the temperature of a small-scale room. Students have to implement it in a breadboard. This action proposes to implement a prototype in printed circuit board (PCB) in order to show it to the students as a demonstrator. Fig. 1 shows the prototype and its schematic implemented with the Proteus software (Labcenter), which also allows its electronic simulation. The demonstrator will be shown at the beginning of the ET course to increase the motivation and interest of the students towards the subject and also before they start the lab project. In addition, PCBs without the components (students buy the components at the beginning of the course) will be freely distributed to students that want to solder and test the project in the PCB. The demonstrator has been just finished and will be used in the following courses.

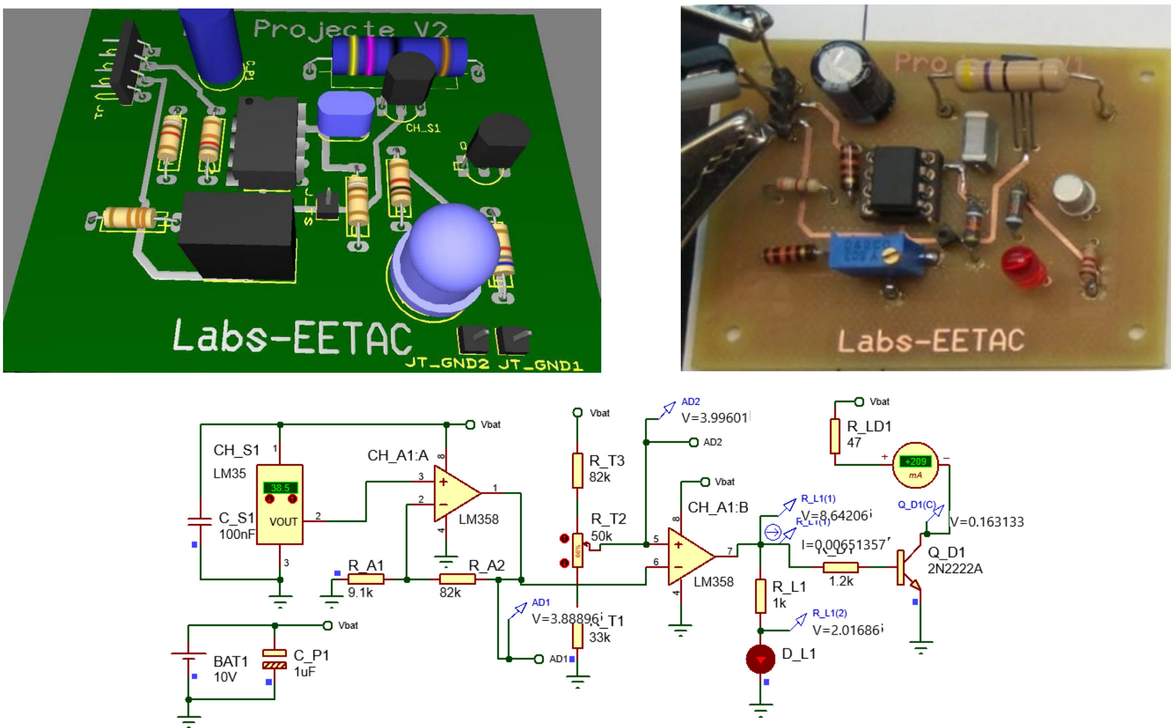

Fig. 1. Laboratory project prototype and its simulation with the software Proteus (Labcenter).

2.5 Action 5: Additional module for the final laboratory project

Fig. 2 shows a digital thermometer based on Arduino that will be used to monitor current and reference temperatures when connected to the prototype of the final project. The module will be used by student lab groups to give more visibility to the work done. This module will also be used as an application example for CSD (Digital Circuits and Systems), a second-year subject, thus promoting interaction between subjects. As the demonstrator of action 5, the module has just been finished and will also be used in the following courses.

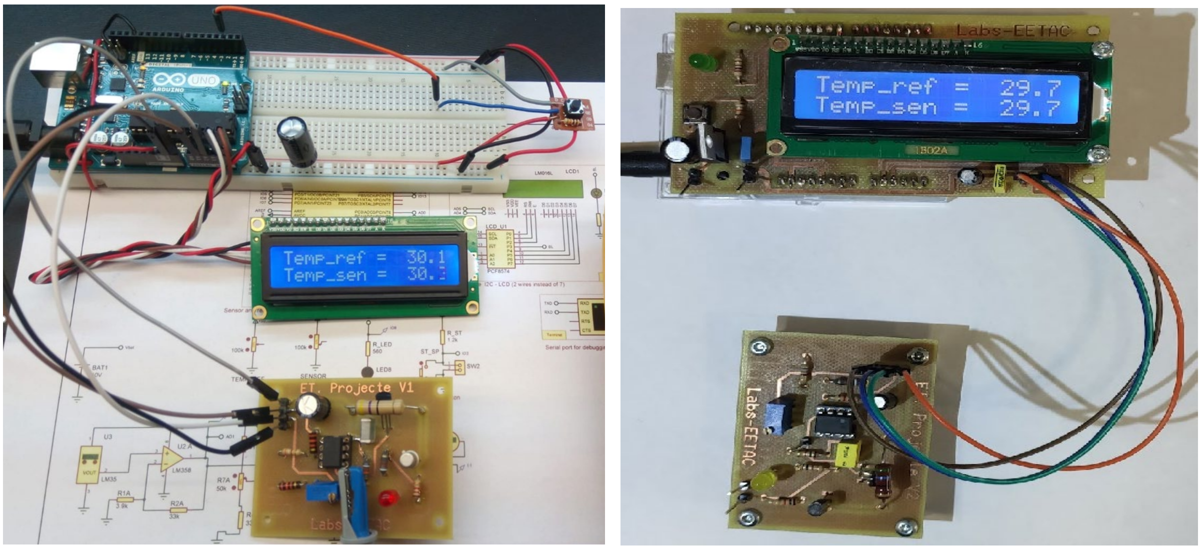

Fig. 2. Displaying current and reference temperatures with the additional module .

2.6 Action 6: Portable multi-instrument device

We have acquired 12 portable multi-instrument devices to be used by the students outside the laboratory (Fig. 3) [4]. The device can be connected to a laptop via USB. Its use can allow students to better prepare the experiments, especially to those student groups who present major difficulties in following the lab classes at a good pace. It would also allow to organize remote labs (at least in part) if laboratories were closed for unforeseen reasons, as was the case during COVID pandemic. In this case, more devices should be purchased to reach all students or establish a loan system. The devices will be distributed to the students in the following courses.

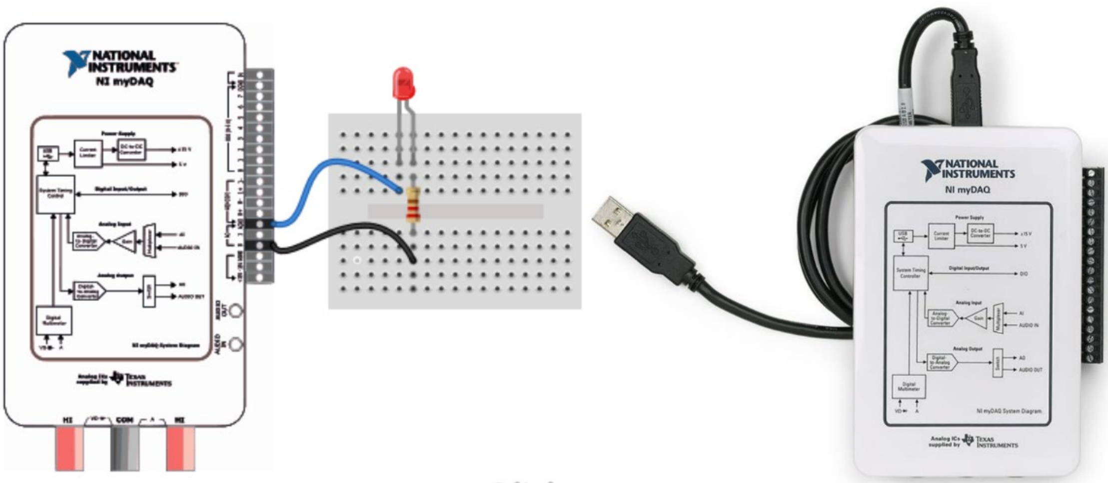

Fig. 3. NI myDAQ, portable multifunctional instrument from National Instruments.

2.7 Action 7: Initial preparatory course

Before starting September classes, the School offers optional preparatory courses of 15 hours in basic subjects (Physics, Mathematics, and Graphic Expression) [5], aimed especially at students from secondary and vocational school who are lacking comprehension on these basic topics and need to review some of these concepts in order to have a better starting of the studies at the EETAC. Even though no electronics previous knowledge is required for ET, we have proposed the same kind of introductory course. Its first edition will be in September 2022.

The intention is to address it especially to students with low university access marks, with no or little prior knowledge of the subject and/or with little or no experience with the basic laboratory instrumentation. The ET preparatory course will consist of some introductory theoretical and laboratory lessons. It is expected registered students have a better initial adaptation to the ET subject and hopefully increase the pass rate.

3 STUDENT SURVEY AND FINAL ASSESSMENT

3.1 Student survey

At the end of the 4th semester, 45 students filled in a survey to assess the proposed actions. Table 1 shows the results, showing for each action the number of students that find it useful or not useful. Some of the students did not know or answer.

Table 1. Results of the survey about the actions to 45 students

Action	*1*	*2*	*3*	*4*	*5*	*6*	*7*
Useful	30	36	43	36	34	36	35
Not useful	7	7	2	4	3	4	4
Don't know/answer	8	2	0	5	8	5	6

Based on the results of the surveys, it is considered positive to continue with actions 1 to 3. Actions 4 to 7 are also considered useful and will be initiated in the following course starting at September 2022.

3.2 Student performance

The project has been developed in a complicated context due to the COVID pandemic. Table 2 shows the student pass rate during the first semester (S1) of each academic year. Included are the 2 semesters where the improvement actions have been implemented as well as the immediately preceding one (*2018/19*, in *italic*). If we compare the latter with the 2019/20 academic year, the overall pass rate rose significantly, from 35,1 % to 53,8 %. In the case of Telecommunication degrees, the pass rate doubled and also rose significantly in the double degree. In the 2020/21 year, there was a slight drop, which we attribute in part to the situation caused by COVID. Anyhow, the pass rate is higher than it was before this project began.

Table 3 shows the pass rate of students during the second semester (S2), where there are not differentiated groups between degrees. As can be seen, the number of students fell in the 2019/20 semester due to the increase in pass rate during the first semester, which is a positive fact. In addition, pass rate also rose significantly with respect to the 2018/19 year. In the 2020/21 year, the pass rate was again relatively low and equal to that of the 2018/19 year.

Table 2. Student pass rate of ET during the first semester. In italic the academic year (18/19) before the improvement actions were applied.

	Total			Telecom Degree			Double Degree		
Course	**Stud**	**Pass**	**%**	**Stud**	**Pass**	**%**	**Stud**	**Pass**	**%**
18/19-S1	*151*	*53*	*35.1*	*103*	*20*	*19.4*	*48*	*33*	*68.8*
19/20-S1	160	86	53.8	117	49	41.9	43	37	86.0
20/21-S1	149	70	47.0	109	37	33.9	40	33	82.5

Table 2. Student pass rate of ET during the second semester. In italic the academic year before the improvement actions were applied.

	Total		
***Course**	**Stud**	**Pass**	**%**
18/19-S2	*79*	*30*	*38.0*
19/20-S2	55	29	52.7
20/21-S2	71	27	38.0

4 CONCLUSIONS

Several actions have been implemented and other are in progress in order to improve the academic performance of university newcomer students in an electronics introductory course. The actions are both addressed to theory and laboratory classes. The actions were well rated by students in a survey and the academic performance of both Telecommunications and double-degree students increased.

5 ACKNOWLEDGMENTS

This work was supported by Universitat Politècnica de Catalunya under the Teaching Improvement Funding Program during the year 2019.

ABSTRACT

In 2013, an ambitious plan was implemented at Universitat Politècnica de València aiming at ensuring that all graduates achieved a set of 13 transversal competences which would make them excellent graduates not only from a technical point of view, but also beyond.

[1] *Corresponding Author*
E. Gimenez-Carbo
esgimen@cst.upv.es

doi:10.5821/conference-9788412322262.1157

One of these competences in which we want to train and assess our students is "ethical, environmental and professional responsibility". This paper presents the study carried out to check whether this objective is achieved or not for graduates from six different degrees taught at UPV.

To this end, we analysed activities developed within each Bachelor degree curriculum, studying the suitability of each activity to the level of knowledge required in each course. We also analysed the perception of students and lecturers in charge of incorporating this transversal content within their subjects.

In view of the results obtained, "good practices" are proposed, indicating the activities carried out which have succeeded in increasing the students' training and knowledge related to this topic. Activities, which, despite being carried out for a certain purpose, do not manage to work on and assess this cross curricular competence, are discussed.

1 INTRODUCTION

The work presented herein summarises the main findings of the work carried out by the educational innovation and improvement team (EICE Remyp_07), by analysing the way in which the cross curricular competence of ethical, environmental and professional responsibility is worked and evaluated in several bachelor degree courses taught in different schools at UPV [1].

In particular, we focus on indicating the different teaching methodologies used to incorporate this cross curricular competence in the classroom and we analyse which of them have been most successful into their application.

To carry out the analysis we analysed materials used in subjects developing the competence within six degrees taught at UPV. This information was provided by the faculty teaching the specific subjects of the bachelor degree curriculum in which these competences are worked on and evaluated.

2 RESULTS

The specific description of the activities to be carried out for the achievement of the cross curricular competence is uneven, with a high number of subjects detected (27.45%) that do not describe them in detail [2].

After analysing the activities described by the faculty, interviews were conducted with lecturers to deepen their knowledge of activities carried out in the classroom. Even after the interviews, some of the proposed activities were not clear.

The way in which the incorporation of cross curricular competences at UPV degree programmes was approached has room for improvement. Once again, the workload was "passed on" to lecturers, who a priori had to work on and evaluate contents they did not necessarily are experts.

Participation in training courses was facilitated, but on a completely voluntary basis and as an additional task to the usual daily teaching and research tasks. On the other hand, there has been a lack of institutional evaluation of the way in which these competences are being incorporated, with control being limited to the marks obtained by students (without considering whether we are evaluating these competences correctly). This fact leads to a loss of interest in correctly carrying out the difficult task of incorporating cross curricular competences into specific subjects.

Among the most common activities, one can mention the case study, used in 19.61% of subjects, followed by project-based learning and reading, both used in 11.76% of subjects (Figure 1). There is a very strong correlation between some methodologies and the particular Bachelor's degree.

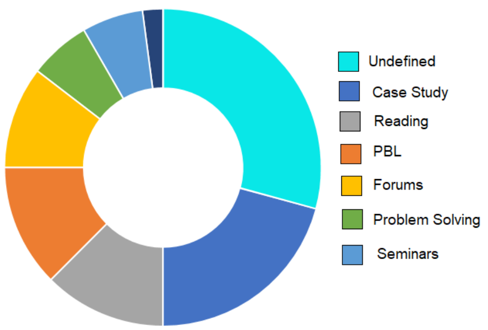

Fig. 1. Methodologies used for developing the UPV cross-curricular outcome [2]

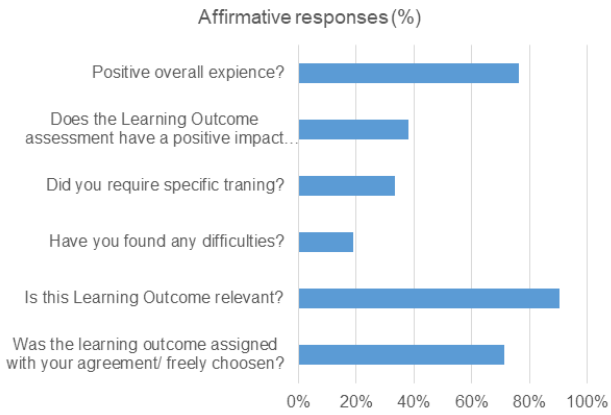

Fig. 2. Lectures´opinions [2]

However, it is remarkable that most lecturers are willing to incorporate this content into their subjects along with other specific content. Most of them are also willing to design activities related to it. However, in a competence such as ethical and professional responsibility, it is essential to have knowledge of ethics in order to be able to do it correctly (although around 80% considered that they had no difficulty in incorporating it, Figure 2)

3 RECOMMENDATIONS FOR GOOD PRACTICE AND CONCLUSIONS

Having analysed all the material provided by lecturers in charge of working with and assessing the cross-curricular competence, we can highlight:

- It is necessary to train students who are to be assessed on the cross-curricular competence. Ethical, environmental and professional responsibility is not something that students have innately, nor is it something "personal" or belonging to the private sphere of individuals. For this reason it is imperative that students are trained prior to carrying out the activities in which they will be assessed.
- It is very difficult to assess both aspects of the competence in a single activity. As it has been shown, in most cases only one of the two parts of the competence is worked on and assessed effectively. For this reason, better results are achieved by developing activities that work on and assess the part related to environmental

responsibility and other activities that work on and assess the ethical responsibility linked to professional performance.

- It is very important to link activities designed for the assessment of the cross curricular competence to the content of the specific subject, and if it is not possible, at least to the bachelor degree scope. Doing so, students become aware of the importance of responsibility in their professional performance.
- Lecturers in charge of working with and assessing the part of the competence related to ethical and professional responsibility need guidance in training and designing activities for assessing students. Approximately 40% of the activities that are currently being carried out in the classroom do not work on or assess this competence despite the desire to do so [2].
- Students have four academic years (the duration of the bachelor degree) to achieve a certain proficiency level of the transversal competence. This means that it is necessary to design the training in an evolutionary way, increasing the level of difficulty and complexity of the activities throughout the curriculum. It is desirable to develop coordination between lecturers who are going to work on this transversal competence throughout the degree, in order to correctly design the activities and increase the degree of complexity without repeating content, and taking into account the progress in the development of the competence.
- Accordingly it is interesting to start in the first years (first proficiency level) with less complex activities (identification of unethical and unprofessional behavior, for instance [3-4]). As the curriculum progresses, more complex activities such as the resolution of ethical dilemmas that require knowledge in order to be able to argue the most appropriate solutions can be proposed.

4 FUNDING AND ACKNOWLEDGMENTS

This work has been developed with the funding by Universitat Politècnica de València, through the project PIME/20-21/219 "Evaluation of the level of acquisition of CT07 Ethical, environmental and professional responsibility in undergraduate studies at the UPV. Proposals for improvement".

Authors want to express their gratitude to lecturers responsible for analysed subjects. We also thank all members of the educational innovation and improvement team (EICE Remyp_07) for their work and engagement.

Keywords: *Challenge-based learning, vertical learning, community of practice, self-directed learning*

ABSTRACT

Collaborative learning communities are becoming popular in engineering education. The department of Industrial Design at Eindhoven University of Technology (TU/e) has almost 20 years of experience in the organization of small-scale and challenge-based education (CBL). In Industrial Design, students work in 'collaborative communities' called *'squads'* that share an interest in specific application domains. Within the squads, vertical learning takes place and students from different bachelor

[1] *Gómez Puente, Sonia M.*

s.m.gomez.puente@tue.nl

doi:10.5821/conference-9788412322262.1285

and master years exchange experiences and learn together in a learning community while solving open-ended societal challenges. The purpose of the research was to map the characteristics of two ID *squads* (for the purpose of this study we will name the squads *Vitality and Crafting Everyday Soft Things (CEST)*, and study the educational elements influencing students' learning. In nature, the two squads share the same educational principles, however, the differ in the organization of education and the level guidance provided, decreasing, to some extent, the open-endedness characteristics of CBL. To conduct the study, we used the constructive alignment as a research framework to map the alignment between vision, teaching and learning activities and assessment of the *squads*. Results show alignment of the Intended Learning Outcomes (ILOs) with teaching and learning activities, and assessment in the two *squads*. The analysis draws attention to the similarities and differences between the two *squads,* specially in the manner of structuring learning. Finally, the suitability of the framework to analyse the CBL curriculum in engineering education contexts is demonstrated. This research opens up opportunities for future studies to investigate learning in small communities.

1 INTRODUCTION

Design is a discipline that fosters creative thinking to design products and systems and solve innovative real-life problems. Design is a complex, multifaceted problem-solving activity involving various cognitive abilities. Creativity and spatial ability are considered critical in design process. The work of a designer is perceived as 'making' the artifact or a description of what that artifact should be like and the communication around that specific design. Communication and socialization are essential elements of design education to prepare students for the workplace, therefore, replicating industry practices are important elements in the learning environment in which students learn and work collaboratively with other students [1]. Furthermore, communicating and socializing through participation in a community of practice [2] is a promising environment for learning representing authentic working places acquiring meaningful learning, developing competencies and skills, and shaping an identity as a designer.

From students' point of view learning communities are suitable environments that provide benefits for learning. According to Dodge & Kendall [3], students benefit from learning communities as they discover together *how concepts learned in one subject can be applied to projects assigned in another; can work together to solve class-related problems; reinforce students' own skills by teaching and mentoring fellow students in various subjects; learn how experts in each field coordinate classroom activities across disciplines; adapt to multiple faculty members' perspectives and classroom environments; make friends with students enrolled in the community; arrange a convenient class schedule of closely integrated courses; and increase their chances for success in personal, academic, and professional arenas'.* Furthermore, the goals and activities of the learning communities organized around workforce skills learning communities can stimulate students to practice skills, gain motivation and develop self-regulation [4]. Challenge-based learning

(CBL) is an educational concept and method by which students work together in open-ended, real- life and multidisciplinary wicked projects [5-6]. Within the context of ID, students work in *squads, i.e. learning communities,* to propose innovative solutions to global challenges.

In this study, we focus on investigating the characteristics of two *squads* as learning communities that foster students' learning. We apply a framework for this study to research two *squads* using the context of the constructive alignment [7]. The purpose of this study was to research the following questions:

1. What are the characteristics of the organization and structure of the *Vitality and CEST squads*?
2. How does the organization of the squads supports students' learning?

2 THEORETICAL CONSIDERATIONS

The notion of communities of practice has been related to the idea of having novice students to work collaboratively with experts in order to learn from each other and transfer knowledge and skills to less experienced students or staff [8]. Other researchers identify communities as 'discourse communities' or 'communities of practice' [2] as a means to socialize. Socialization in this regard is considered a powerful paradigm in which the scenarios to exchange experience from experts to novices provide useful opportunities for learning. Differences among these concepts lies in the formal or informal approach to learning. While Swales' idea of 'dicourse communities' focuses on academics interacting with different disciplines, Lave and Wenger's approach emphasises an informal way of learning where 'communities' and 'apprenticeship' are central to involving people based on common interests participating in a joint project or task.

Modelling expert practices has been characterized in the literature under the educational concept of 'cognitive apprenticeship [9] emphasizes processes employed by experts to handle complex tasks and teaching cognitive and metacognitive (as opposed to physical) skills and processes. Critical to the notion of learning communities and communities of practices is the theory of situated learning [2] in relation to CoP as a self-defined and self-developing approach. Researchers differ about the added value of external support such as facilitators or moderators. Other investigators of this concept [10], however, highlight the importance of the role of 'academic staff developers' who can be considered crucial in the 'harmonization' process when new academic staff join a CoP to streamline learning.

In the last decades, the concept of 'learning communities' and 'communities of practice' have become an instrument to materialize informal learning in organization, and, more specifically, for the purpose of this study, in learning organizations such as universities [6]. Collection of examples in this regard include 'models' for classroom organization of communities [11], or for the stimulate learning through a process of socialization [8] as a mean to promote practices that represent the workplace environments where informally learning occurs through the interaction with more experienced colleagues. The theoretical insight behind this rationale lies in that learning takes place during the process of co-participating and co-creating by socializing with practitioners resembling authentic scenarios or withing the working places [12].

Grounded on these theoretical insights, we investigate the characteristics of the *squads* as learning communities, and more specifically, we pay attention to the impact of the educational organization of the *squads* on students' learning.

3 *SQUADS* AS LEARNING COMMUNITIES

Squads are the learning environments in which students learn and work together. Squads are thematic contact points for structural contacts between research and education as well as between academia and industrial/societal partners. Squads represent the expertise areas or disciplinary domains that give form to the content on the curriculum and cover all diversity in design elements and offer students a rich and diverse learning environment. Squads, as thematic learning communities, consists of academic staff, BSc and MSc students and external stakeholders, who collaborate on shared interests for the duration of a semester. The learning organization of the squads promotes selfdirectness and students can choose among a variety of projects. Furthermore, squads integrate the research interests of three to four academic staff members and PhD candidates, with the societal interest of clients, user groups and experts from practice, often represented by one or two Industry Liaisons, and the educational interest of 2nd and 3rd year Bachelor students and 1st year Master and 2nd year Master research students.

Cultivation and socialization processes allow students to become part of the previously described community. Teachers act as role models and model important values and implicit beliefs that students experience. The organization of learning fosters, therefore, feeling of community that stimulates the sense of belonging and inclusion amongst students, staff and partners. This allows the squad and the squad structure to become rich educational eco-systems that promote educational experimentation, innovation and differentiation.

The creation of smaller communities in a squad is an important mechanism to channel students' learning processes using horizontal peer learning (same year and same project) and vertical peer learning (different year, similar project and same squad). Peer learning is a valuable way for students to learn by receiving feedback from more senior students or equals and providing feedback to less senior students and equals.

4 METHODOLOGY

4.1 Context

Our study was conducted in the department of Industrial Design, in the context of two *squad* teams, which included several projects with a great variety in student characteristics (e.g., bachelor or master level) and project characteristics (team or individual projects, open-ended).

4.2 Data collection

Data were collected using a qualitative method approach to gain in-depth information about the structure of the squads, and the alignment between vision on education implemtation, Intended Learning Outcomes, Teaching and Learning activities, and Assessment. Observations of coaching situations were conducted for 1 semester. Interviews with students, coaches and experts from the industry were conducted at the end of the course. Interviews lasted approximately 45-60 minutes, and the participation was voluntary.

4.3 Participants

We conducted interviews and observations with coaches, industry experts and students from different levels (e.g. bachelor, pre-master, master, etc.). In total 31 interviews were conducted with students and 8 coaches were alongside with weekly observations of *squads* teaching and learning activities. An overview of participants can be found in Table 1.

Table1. Overview participants from Vitality and Crafting Everyday Soft Things (CEST) squads in this research

Participants	***Vitality Squad***	***CEST Squad***
Coaches	3 (1 internal 2 external industry coaches)	4 (2 internal coaches and 2 industry experts)
Teaching Assistant	1	
Bachelor students	3 (1 group)	4
Final Bachelor Project (FBP) students		1
Premaster	4	2
Master	9 (4 individual projects, 2 groups: 1 group with 3 and I group with 2)	2 master students.

4.4 Data analysis

Data were analyzed using thematic content analysis. An iterative process was followed where the two researchers read the transcripts of the interviews several times and followed an open coding approach. After several discussions, they developed a coding framework applied for all interviews**.** The Constructive Alignment model by Biggs and Trang (2011) [7] was used as a framework to map the characteristics *Squad* A and *Squad* B, in order to understand the differences and similarities of the organization of these two squads that may impact the learning of the students.

5. RESULTS

5.1 Mapping characteristics of the *Squads*

Despite the fact that *Squads* are different in expertise and thematic areas, they share similar educational principles and characteristics including the focus on the development of students' self-directed learning skills and the development of their professional vision and identity by working on projects where students can acquire and apply their design knowledge and skills. Another commonality among the squads is that they share the same way of assessing students learning with the use of a rubric that describes all competencies students are expected to develop (Table 2).

Table 2. Overview of general educational characteristics of the squads

Squads common educational chaterisctics	**Collaborative learning community**
Self-directed learning (SDL) is on of the pillars of the educational model.	**Coaching:** students are coached to make own choices on courses that best match their interest, at project level but also on career development. **Personal Development Plan (PDP**): students set learning goals and reflect on progress.
Professional Vision & Identity (PV&I)	Vision and identity as a designer are fully embedded in the reflections and designs students produce.
Application/acquisition knowledge	Knowledge is acquired and applied in design steps students go through in iterations. New knowledge is generated and used again by prototyping, etc. (Mid-term) Demo Day is a feedback and assessment moment to demonstrate designs, prototypes, etc. Students get feedback used to improve the product upo which they are assessed.
Assessment	**Rubrics** are used to provide feedback during the process, and finally, to assess students.

5.2 Linking vision with implementation: Constructive alignment from a curriculum perspective

The results suggest that squads provide an active learning environment of collaboration among students of different levels.

Regarding, constructive alignment both squads identified broad Intended Learning Objectives including knowledge acquisition, knowledge application, self-directed learning and professional development as designers. To achieve these objectives,

both squads have adopted a Challenge-based learning approach as means of their education.
This entails providing students with real-life, open-ended, and hands-on projects. The squads as learning communities provide to students a wide range of teaching and learning activities that aim to foster the ILOs.

The organizational set-up of the *squads* is similar (e.g. learning takes place in the form of a community where students from different bachelor and master levels provide peer feedback, learn from coaches and industry liaisons, and share themes' interests), promotes ***vertical learning*** as a structure.

Common activities targeting ***knowledge acquisition*** in both squads involved: weekly workshops on key topics that would assist students to get some baseline information for their project.

In terms of ***peer learning***, both squads provided an interactive open space for students to interact and learn from each other. ***Cross –coaching*** did take place in specific times of the semester before midterm and final demoday in *Squad Vitality* while in *Squad CEST* all coaches had a discussion with all groups on a weekly basis.

Regarding ***knowledge application***, in both squads students were encouraged to ***work on prototypes*** that were exhibited in the rooms so other students and coaches could provide feedback on their evolving efforts.

Self-directed learning was encouraged by giving to studnets autonomy to focus on interesting projects about them as well as coaching throught the semester to scaffold the process. In both squads, similar activities (e.g. individual feedback on PDP, coaching on self-directness and vision on professional identity, peer feedback, etc.) stimulate SDL.

Differences between the *Vitality and Crafting Everyday Soft Things (CEST) squads* are the structure provided to guide students learning. While in CEST s*quad* students get general information about organization of the activities and deadlines for delivery of products with no further indication of how deliverables must be submitted; Vitality s*quad* provides more strict guidelines on the form of the deliverables framing the students' expectations more closely. Finally, regarding ***final assessment*** as described above both squads employ the same rubric for assessing studnets'developmet of key competencies. For students assessment process was clear but still the criteria for assessment were considered quite subjective.

Table 3. Overview results mapping squads characteristics

Mapping characteristics squads	***Vitality Squad***	***CEST Squad***
CBL	General Intended Learning Outcomes (ILOs) for *Vitality squad* are provided. Open-ended: projects have no predefined end goal. Students need to define their own project objectives after consultation with external clients and their coaches Hands-on: designing interventions for behavioral change at an individual or systems level Real-life: projects focus on designing solutions for healthier lifestyles. Projects are often in collaboration with industry clients	General Intended Learning Outcomes (ILOs) for *CEST squad* are provided. Open-ended: Students formulate own project that meets own learning goals and fits within CEST s*quad* ILOs. No guidelines are given and therefore problem is ill-defined depending on students' own directions. Real-life: Projects framed in a design to contribute to societal and industrial interests. Students contact stakeholders (some time outside the university) to test or validate product. Multidisciplinary: challenges converge several disciplines, e.g. design, business, society, health components, etc., depending on the challenge goal.
T&L	Workshops are provided in the first half of the semester for students to acquire important baseline knowledge that could be useful for their project Weekly inspiration shot activities aim to foster students' creativity and develop skills (e.g., photography) that are useful for their project or deliverables Weekly coaching sessions Cross-coachings sessions in two predefined moments during the semester and ample opportunities for feedback on demand Workshops on PDP and individual coaching sessions on demand (Mid-term)Demo Day is meant to serve as milestones for students' project development and opportunities for practicing important professional skills	Workshops aimed at providing 'just-in-time' content and knowledge on a specific topic, i.e. are organized. Focus on provided knowledge needed to apply in solving the challenge. Friday morning feedback moment organized where coaches and industry experts provide feedback and advice. Peer feedback from students is organized and cross-coaching is from different experts to support students' learning. Individual feedback on PDP. (Mid-term) Demo Day is meant to encourage students to practice some professional skills

Assessment	Rubrics used to assess students' competencies development Assessment is based on various deliverables that assess not only students' final product but also highlight their progress and development throughout the semester (e.g., prototype, final report, final report on PDP, presentation etc)	Rubrics are used mainly for assessment. Rubrics are not fully always used for feedback.

5 CONCLUSIONS

In this study, the organizational structure of two *squads*, *Vitality squad* and *CEST squad* , as learning communities is investigated. Mapping the organization of learning following Biggs and Trangs' model (2011) [7] is applied and shows similar characteristics in the structure and alignment between the learning outcomes, teaching and learning activities and assessment. Among the most helpful teaching and learning activities include the provided workshops to support students' just-in-time knowledge acquisition, the feedback provided on progress as part of the weekly coaching, and cross-coaching sessions that supported students' learning in the design process. Students also appreciated the informal learning moments and collaboration between different groups and teams.

Likewise, vertical learning and self-directed learning are clearly identified in both squads. This shows that the ID educational model with its educational principles on learning is widely applied in the organization of the squads to promote learning. This has been confirmed in the students' interviews.

Interesting to see is that differences are mainly encountered in the level of structured guidance provided to the students when conducting project activities. Although guidances does not hinder learning, it highlights a difference in the application of the CBL educational form and SDL, in which students are expected to take the lead in the learning process.

Finally, this study shows the suitability of the famework [7] used to map and analyse the characteristics of the squads as a learning community, and more specifically, the alignment between the learning outcomes, the teaching and learning activities, and the assessment methods of the two squads researched.

6 ACKNOWLEDGMENTS

We would like to thank you very much the Industrial Design students participating in the *Vitality squad* and *CEST squad* for their availability and valuable information they provided throughout the research. Likewise, we are very grateful to the coaching staff and external industry experts and partners for sharing their experience, values and vision on supervision of students in design-based and challenge-based settings.

ABSTRACT

The emerging adhocracy of sustainability in every field of life, do also claims its legacy in the field of education, particularly in the discipline of engineering. Institutions necessitate to adapt their curriculums to the possible changes so that the engineers of the future are ready to address interdisciplinary and evolving challenges in their careers. As a European University Alliance aiming to define and implement a European engineering model, EELISA project has a dedicated work package to explore and propose various approaches to address this challenge by deploying disciplinary broadening workshops. This paper scrutinizes the initial outputs of the first full-day workshop organized by three partner universities of the alliance under

doi:10.5821/conference-9788412322262.1403

the theme of “Cities and Communities” in October 2021, and opens it to a broader discussion.

This paper is structured in four parts while deploying qualitative research methods to analyze the collected data. Initially, it expresses the role of EELISA University, the state-of-the-art skills of today’s engineers and the challenges for enriching them to materialize the vision of European engineering, including bridging and expanding disciplinary domains. The second part explains the workshop structure that was organized under four interdisciplinary subtopics related to the theme to increase the involvement of various engineering and non-engineering academics and professionals. Then the workshop outputs, the participants’ brainstorms about the skills, competences, proposals to overcome challenges and barriers are conveyed. The final part summarizes the workshop results and introduces valuable inputs to the search for the European engineer profile and the roadmap of the EELISA.

1 INTRODUCTION

1.1 EELISA European University

The **European Engineering Learning Innovation and Science Alliance (EELISA)** is the first alliance of Higher Education Institutions from different countries in Europe meant to define and implement a **common model of *European engineer*** rooted in society. The alliance of nine universities from seven countries has a mission to transform European higher education into the seed for a future in which society masters global challenges with smart and sustainable solutions enabled by engineering. EELISA envisions a higher education system that enables student citizenship participation and employability by:

- *Evolving interdisciplinary engineering learning*
- *Fostering knowledge and technology transfer*
- *Stimulating inclusiveness and diversity*
- *Connecting academic excellence to social impact and commitment*

The EELISA project has nine work packages to realize the mission and vision of the project ranging from curriculum development to education management and accreditation, from establishing communities for societal challenges to the link between Education, Research and Innovation, from effective internships to mobility with inclusive student participation.

1.2 Disciplinary Broadening Work Package

EELISA project has a dedicated work package called “Disciplinary Broadening” (WP8) with an ultimate goal of enriching the skills of the engineers of the future after an exchange with other disciplines and reciprocally incorporating engineering methods in other areas by realizing tasks of

- Identifying interdisciplinary needs of the engineer of the future
- Designing of bridging models for multiskilling in engineering education
- Identifying engineering skills needs of other professional domains
- Designing bridging models between engineering skills and other professional domains
- Implementing multiskilling pilots for other disciplinary domains
- Gathering feedback and adapting pilots

The objective of the work package is to nurture international and interdisciplinary stakeholders of academic and non-academic members of our communities, who address complex problems. EELISA’s vision of European Engineering will help us bridge and expand disciplinary domains, and focus on skills needed by engineers as well as engineering skills needed by other professional fields.

1.3 Disciplinary Broadening Workshops

The main activity of the Disciplinary Broadening Work Package of the EELISA Project is a series of full-day workshops. These workshops are designed to help EELISA meet the specific goals of the work package by starting with the description of skills of the engineer of the future in various disciplines and exploring ways of enriching engineering skills with non-engineering competences and introducing engineering skills to other professional domains. Workshops help collect inputs from the stakeholders with various profiles including academics, higher education administrators, student representatives, representatives of scientific societies, industry/society stakeholders and policymakers, and representatives of placement offices.

Outcomes of the disciplinary broadening workshops will provide direct input into the effort of defining the European Engineer Profile led by WP2 of the EELISA project. This effort is not limited to workshops but also utilizes interviews with top professionals in Europe, surveys with various stakeholders, and the literature. Identification of professional skills is not a brand new point of interest.

European Society of Engineering Education has a dedicated Special Interest Group on “Engineering Skills”, where Murphy et al. emphasize the importance of the regional variations in the definitions while elaborating on common issues within the formation and education of the engineer [1]. A-STEP 2030 project underlines the importance of skills for engineers to address challenges associated with the Sustainable Development Goals (SDG) [2], which are in line with two pilot tracks of the EELISA project, **Smart, Green and Resilient Cities** and **Sustainable and Smart Industry**. Crean et al. obtained similar needs in particular for the concepts of society and sustainability as part of a study on mapping the development of professional skills in a structural engineering program [3]. The interdisciplinary approach is another aspect that came out of the study by Flament and Kövesi especially to address the addressing sustainability issues [4]. Beagon et al. [5] identified sustainability competences from the perspectives of students, industry and academics in four European countries. Their findings are mostly in line with the findings of the European [6] and International [7] framework competences. Disciplinary broadening workshops have the potential to contribute to the literature.

2 METHODOLOGY

2.1 Cities and Communities Workshop

The theme of the first workshop was “Cities and Communities”, which took place online on October 26th, 2021. Including three faculty members from the host institution, the organizing team of the workshop consists of eight professors from three EELISA partner institutions.

The flow of the full-day event contains two keynote speakers in the morning and afternoon sessions, a single panel discussion after the keynote in the morning, parallel interactive workshop sessions managed on a Miro board before the noon and after the second keynote in the afternoon, and a closing discussion session for the organizing team to wrap up the outcomes of the workshop.

2.2 Parallel Workshop Sessions

Four subtopics of the Cities and Communities Workshop include **“Infrastructure and Mobility”, “Energy and Climate Change”, “Culture and Inclusiveness” and “Buildings”**, which are discussed in four breakout rooms, BR1, BR2, BR3, BR4, respectively. In each track of focus, the workshop coordinators accordingly aimed to attain participants’ responses on four interconnected inquiries that constitute the essences of the disciplinary broadening attempts: *mapping the skill gaps, mapping the disciplinary boundaries and learning* in the morning session*; and proposing innovative teaching and learning activities*, and proposing the *bridging models* in the afternoon session (Figure 1).

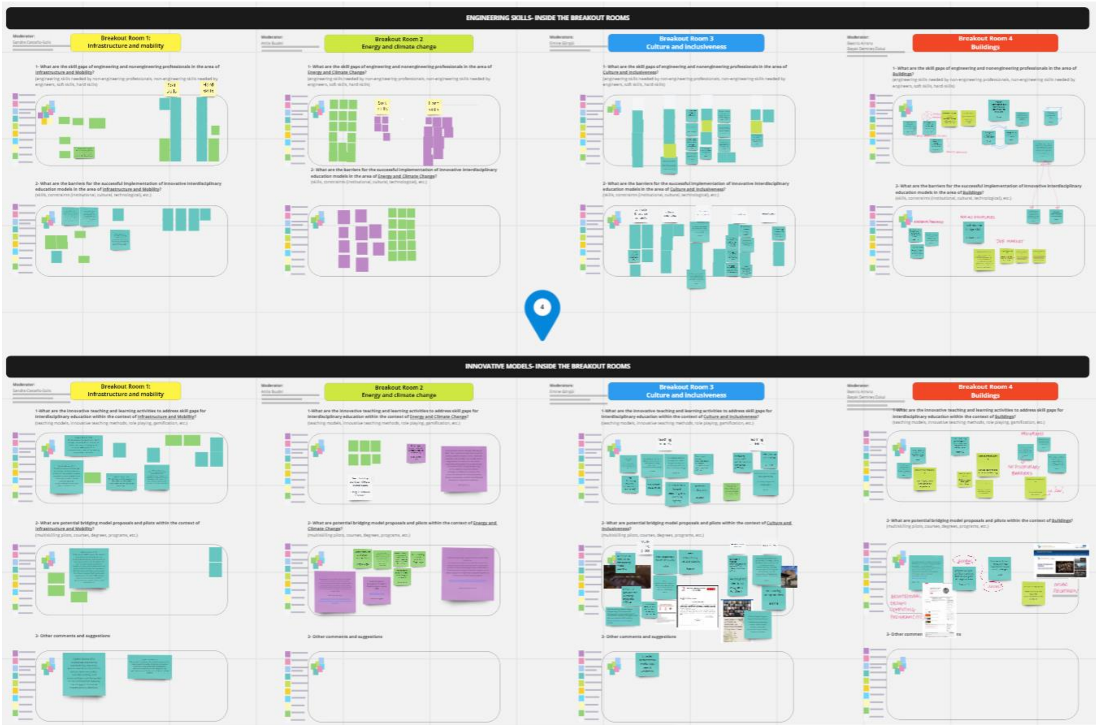

Fig. 1. High-level preview of the miro board designed for the workshop.

3 RESULTS

3.1 Workshop Participant Profile

Among 64 registrants, 44 attended the event, 30 of which were female. The participant profile was predominantly from academia including faculty members, Ph.D. students, and staff. During the discussions in the breakout rooms, some of the participants from academia shared their work experiences or collaborations with partners from public bodies, industry or NGOs. In addition to that, the keynote speakers’ profile and speeches during the event indicate ties and interactions with various stakeholders.

- Roger Hadgraft (Keynote Speaker 1): “Educating Interdisciplinary Engineers for Future Cities and Communities”

    - Overview of a recent review of engineering education in Australia conducted by the Australian Council of Engineering Deans and some examples of curriculum changes to achieve these outcomes.
- Hatice Sözer: “Preparing students to the professional life”
    - Interdisciplinary project-based educational program, InterPROfessional Projects Program at the Illinois Institute of Technology at Chicago, to prepare students for a dynamic and competitive global environment.
- Gülcemal Alhanlıoğlu: “A method proposal for gaining practical practices in higher education”
    - Practice of working together with other disciplines by trainings to introduce business life and laws & regulations, economic knowledge and practice of working together with other disciplines.
- Bettina Szimonetta Jäger: “My journey into the world of complexity”
    - Interdisciplinary work experience at the municipality and collaboration opportunities between the university education and the local government from the perspective of a doctoral student with a non-engineering background.
- Paolo Dario: “The RoboTown vision: bridging research and innovation, education and societal impact”
    - The interaction between local entities and disciplines to integrate robotics into living environments and cities.
- Zeynep Erden Bayazıt: “Spanning Boundaries in Education: Fire-Up Changemaker Community Experience”
    - Overview of relevant interdisciplinary, interinstitutional and intersectoral challenge-based innovation activities supported by a partner entrepreneurship and innovation centre.
- Birgül Tantekin Ersolmaz (Keynote Speaker 2): “Opportunities, Challenges and Good Practices in the Accreditation of Interdisciplinary Programs”
    - Main features of outcome-based accreditation and discuss the opportunities and challenges for accreditation of interdisciplinary programs.

3.2 Workshop Results

About the initial inquiry on mapping the skill gaps, most of the participants in each sub-track reflected their responses based on hard and soft skills. These skills were reflected either as the missing qualities, or the ones that were obliged to be attained from diverse disciplinary backgrounds of engineering and non-engineering groups.

When the outcomes are categorized in similar groups, the urgencies for enhancing the ***trans-disciplinary knowledge skills***, ***system thinking***, ***assessment skills***, ***robotic skills***, and other related skills on ***control and automation***, skills for ***sustainability*** as well as ***business and management*** appeared as the emerging ***hard skills*** for the disciplinary broadening (Table 1).

Table 1. Thematic categorization of hard skills for disciplinary broadening in breakout rooms

Trans-disciplinary knowledge production	Social sciences skills for the engineering (BR3)
	Social science skills for non-engineers (BR4)
	Health science skills for non-engineers (BR4)
	Psychology skills for non-engineers (BR4)
	Analytical skills for non-engineers (BR2) (BR3)
	Indigenous knowledge (BR3)
	Science knowledge (BR1)
	Lack of the knowledge regarding the strategic and legal context (BR2)
	Analytical skills for non-engineers (BR3)
	Thermodynamics (BR1)
	Utilities (thermal, electrical, etc.) (BR1)
System thinking	Systems thinking, relating concepts (BR1)
	Ability to understand indirect and direct impacts (BR2)
	Problem identification and definition and redefinition- for engineers (BR4)
	Synthesis of different type of data (BR2)
Assessment skills	Awareness capabilities (BR1)
	Vulnerability assessment (BR2)
	Adaptation-oriented evaluation (BR2)
	Professionals: research methodologies and perspectives from STS (BR4)
Robotics, control and automation	Robotic skills for non-engineering background (BR3)
	ICT skills for non/engineering professionals (BR3)
	Infrastructure and building informatics, communication systems(BR1)
	Energy storage technologies (batteries, thermal storage, etc.) (BR1)
Green skills	Sustainable energy technologies (BR1)
	Green financial tools (BR2)
	Sustainability management skills (BR2)

	Socio-economic aspects of climate studies (BR2)
	Ecology and sustainability management skills (BR3)
	Misinterpretation of the relationship among sustainability and climate adaptation (BR2)
Business and management skills	Business administration and entrepreneurship skills (BR3)
	Business administration / entrepreneurship skills will be needed for successful implementation of ideas (BR3)
	Audience analysis and management tool (BR3)
	Change and innovation management skills (BR3)

On the other side, related with the ***soft skills*** we observed a broader variability of issues being reflected in each sub-track. When the outcomes were categorized accordingly, the urgencies of ***communication skills***, skills for ***resilience***, ***inclusiveness in multi-levels***, ***collaboration***, ***multi-disciplinary*** and ***system thinking*** as well as ***creative thinking skills*** appeared as the emerging skills for the disciplinary broadening (Table 2).

Table 2. Thematic categorization of soft skills for disciplinary broadening in breakout rooms

Communication (conflict resolution-knowledge skills)	Communication (BR4)
	Social skills (BR1)
	Language skills (BR1)
	Psychological skills (BR2)
	Relationship with friendly and flexibility (BR3)
	Professionals: conflict resolution (BR4)
Resilience	Dealing with uncertainty (BR4)
Multi-level of inclusiveness	Human centered approach (BR3)
	Take care for disadvantages groups (BR3)
	Thinking with ngo and also global and local problems (BR3)
	Awareness capabilities (environmental and social awareness) (BR1)
	Environmental and social awareness (BR4)
	Dealing with real world limitations (designers) (BR4)
	Problem defining and re-defining (BR4)
	Collaboration culture (BR1)

Collaborative skills	Collaboration skills with engineers and design studios (BR3)
	Empathy and problem solving skills (BR3)
	Teamwork (BR1) (BR3)
	Time-management (BR1)
	Sense of responsibility (BR1)
Relating concepts and applying them to multidisciplinary projects, systems thinking	Working in multidisciplinary teams (BR1)
	Introducing multidisciplinary projects at first courses (BR1)
	Industrial exposure (BR1)
	Lacking knowledge in social areas (BR1)
	Re-assigning the notion of complexity in non-engineering background (BR3)
Creativity, curiosity	Thinking outside the box (BR4)

Briefly, in this initial inquiry about required skills for disciplinary broadening, immediate hard skills for enhancing interdisciplinary and trans-disciplinary knowledge such as management and robotic skills and advanced knowledge on sustainability were proposed while blending them with advanced knowledge of humanities and social sciences. Besides, analytical and qualitative assessment skills have been addressed throughout the breakout rooms. In addition, advanced communication skills, problem finding and solving skills, system and complex thinking skills and creative thinking skills further emerged as soft skills that are required for advanced disciplinary broadening.

About the initial inquiry on the ***mapping the disciplinary boundaries and learning,*** most of the participants in each sub-track developed their responses based on hard and soft skills that are required and to be attained from both disciplinary backgrounds of engineering and non-engineering.

So, during the parallel discussions in the breakout rooms, inquiries related with the *tertiary or higher education* ***culture****,* ***curriculum****,* ***teaching strategies*** *and* ***methods****,* ***institutional challenges****,* ***global challenges****,* ***bureaucratic structures, funding opportunities*** *and* ***sectoral linkages*** emerged as the forthcoming issues, that can be further detailed into further permutations with each other.

About the initial inquiry on the ***proposing innovative teaching and learning activities,*** most of the participants in each sub-track developed their responses on the basis of hard and soft skills that are required and to be attained from both disciplinary backgrounds of engineering and non-engineering.

When the inquiries are examined in detail, recommendations about ***curriculum improvements*** are visible on behalf of enhancing the content of courses in terms of interdisciplinary and trans-disciplinary broadening of knowledge while ***updating them in relation to global challenges such as sustainability***. Beyond content, ***educational operations*** such as student numbers capacities, teaching capacities, international collaborations and extracurricular activities, are also highlighted in the discussions.

Based on the synthesis of the workshop content by the rapporteur and organizing team, a number of operational statements have been identified including ***interdisciplinary degrees, graduation design projects and courses, credited interdisciplinary activities, industry-sponsored internships, industry-sponsored courses, industrial design department project courses, eelisa-wide courses, integrated engineering programs, interdepartmental student activities outside the classroom, mobility for innovative teaching/learning activities, experience-based activities, conference participation, competition activities, center of excellence in engineering education*** *and* ***center of excellence in mobility and infrastructure***. Supporting information for these operational statements included the target students, learning outcomes, teaching forms, required infrastructure, and involved academic sectors for guidance.

Workshop results constitute relevant information for various work packages of EELISA. Some of these are direct inputs to various work packages and tasks, while other work packages may found them useful. For instance, the skills explored during the workshop are potential inputs for the task of proposing a shared definition of the profile of the European Engineer by WP2. The innovative learning and teaching activities, and bridging models proposed during the workshop are direct candidates for the design and implementation of WP8 multiskilling pilot applications in engineering education, which will be managed in coordination with the WP2.

Other indirect relevant information from the disciplinary workshop series may help WP3 representatives to reassess and update the curriculum for contemporary teaching inquiries and paradigms, diminishing workload; to inspire many different learning activities such as solar decathlon, by communities developed by WP4; to guide implementing institutional collaborations via diverse teaching methods of small project competitions, vertical studios, joint research studios, international training opportunities, exchange of qualified researchers and graduate students organized by WP5; to guide establishing sectoral collaboration in the research facilities, sectoral needs and knowledge integration to the curriculums, enhancing institutional budgets by WP6; to enhancing students engagement to real-world problems, problem finding activities for students, providing connections with different stakeholders and NGOs, extensive inclusiveness in developing innovative curricular and extra-curricular activities by WP7; to urge organizing relevant events; meetings, workshops, seminars, decathlons, online dissemination such as newsletters, open-source digital archive of events by WP9.

4 SUMMARY AND ACKNOWLEDGMENTS

The first disciplinary broadening workshop of the EELISA project provided a brainstorming opportunity for the partners of the European University Alliance partners to initiate the search for the interdisciplinary skills of the European Engineer of the future under the theme of “Cities and Communities”. The theme presents a perfect match with two pilot tracks of EELISA project and Sustainable Development Goals. Workshop results underline the skill gaps of today’s engineers, the barriers as well as the need for exchange between the engineering and non-engineering professionals. Potential proposals started to pile up for potential multiskilling pilots to be designed and implemented as part of the EELISA project.

EELISA’s second disciplinary broadening workshop in 2021 was on “Sensing Sciences and Technologies”. There are at least five workshops in progress in the year 2022. The themes of them include but are not limited to the following : “Architecture and Archeology”, “Digital Philology”, “Teaching Sustainable Development”, “Data Science for Industries” and “Managing Cities”.

EELISA is an ERASMUS + project funded by the European Commission under Grant Agreement Number 101004081 - EELISA.

ABSTRACT

Challenge-based learning (CBL) is a learning approach that has received increased attention during the last years. In some of the publications about CBL the connections to the CDIO (conceive-design-implement-operate) framework is discussed, and the purpose of this paper is to discuss these connections further. CBL has connections to both Problem-based learning (PBL) and Project-based learning (PjBL), but while these are learning approaches, the CDIO framework has a program perspective, including aspects of learning approaches, and hence a wider scope. The connections and differences between CBL and CDIO are discussed based on the components of the CDIO Standards.

1 INTRODUCTION

Challenge-based learning (CBL) has received increased attention during the last years, and numerous papers have been published. In some of the papers there are references to the CDIO framework, and connections between CBL and the CDIO framework are discussed. The purpose of this paper is to study these connections and discuss the similarities and differences in some more detail. The paper starts with brief overviews over the CDIO framework and CBL in general, and this is followed by some comments about the use of CBL within the ECIU University initiative.

The CDIO framework has existed for more than two decades, and it has been developed within the CDIO Initiative. The CDIO Initiative started as a project involving the three Swedish universities Chalmers University of Technology, Royal Institute of Technology (KTH), and Linköping University, and MIT (Massachusetts Institute of Technology) in the USA. After some years the project evolved and grew into a network of universities all over the world, with an annual conference and several other activities. The key references presenting the CDIO Initiative and the framework are [1] and [2]. For example, via the web site [2] it is possible to reache the Knowledge library, which contains a large collection of papers from previous CDIO conferences.

The framework consists of four key components:

- A characterization of the role of an engineer.
- Goals for the desired knowledge and skills of an engineer formulated using the document CDIO Syllabus.
- Goals for the properties of an engineering education program collected in the document CDIO Standards.
- Methods and tools for systematic development and management of education programs.

It should be stressed that most of the components that form the framework existed and have been known before the CDIO Initiative was formed, and that the key point of the CDIO framework is that the components have been put together in a systematic way. Therefore the CDIO framework can be described as *structured common sense*. Originally the framework was developed for engineering education, but over the years it has been generalized, adapted, and applied in other disciplines outside the engineering field, and examples of this can be found via the Knowledge library [2].

Two of the earlier references discussing the connections between CBL and the CDIO framework are [3] and [4]. The paper [3] presents interesting experiences from Master's theses carried out using CBL in a multidisciplinary setting and with sustainability focus. An important component in [3] is a also the use of the Chalmers Challenge Lab, which is a learning space specially designed for CBL activities. In [3], CBL is presented as an evolution of CDIO, but to a large extent this is based on the view that CDIO is equivalent to project-based learning. In [4] the authors discuss challenge-driven education (CDE) in an international context, and CDE is seen as more or less equivalent to CBL. Also, in [4] CDE is described as an evolution of PBL, where the acronym stands for both project-based and problem-based learning, which means that they are considered to be quivalent. Even though the paper is about CDE the authors use the word project repeatedly when talking about the actual work of the students. However, these comments are not meant to criticize the authors of these paper, but more to illustrate that clear definitions of the different learning approaches are missing.

As mentioned, numerous papers dealing with various aspects of CBL have been published during the last years, and the paper [5] presents an excellent literature overview based on almost one hundred papers. One of the main conclusions of the paper is that the interpretations and applications of CBL vary a lot, and that there is a need for a more unified view of CBL. Some of the common features of the approach include open ended tasks, multidisciplinary and team-based learning activities, interaction with external stakeholders, and often emphasis on challenges related to sustainablitiy. CBL is also seen as a suitable approach to enable for the students to develop various skills. Several of these aspects are discussed in the comparison with CDIO in the sections below.

One context where CBL is an important component is the ECIU University, which is one of the pilot projects within the European Universities initiative from EU. ECIU (European Consortium of European Universities) is a network of thirteen European universities and is running this pilot project together. More information about the ECIU University and the use of CBL within this context can be found via [6]. In [7] the authors discuss the connections between the CDIO framework and the development of the ECIU University in general, which also includes brief discussions about the connections to CBL.

The connections between CBL and the CDIO framework are maybe known to many members of the engineering education community, but since aspects and concepts, despite this, sometimes are mixed up, it is motivated to make an attempt to clarify similarities and differences further.

2 METHODOLOGY

The results and observatons presented below are based on literature studies, various presentations, and participation in both the CDIO Initiative and the ECIU University project. To enable a systematic treatment, the connections between CBL and the CDIO framework are discussed using the CDIO Standards as reference. Thorough descriptions of the CDIO Standards can be found via [1] and [2]. The main purpose of the CDIO Standards is to define twelwe important components for the design, management and execution of an education program. The twelwe items of the CDIO Standards can be split in the following main parts:

- The context, the role of the graduate, and learning outcomes. 1 - 2
- Intregrated curriculum, including an introduction to the intended role. 3 - 4
- Design-implement experiences and related workspaces. 5 - 6
- Integrated learning and active learning approaches. 7 - 8

- Faculty development and student learning assessment. 9 – 11
- Program evaluation. 12

The subsections below are based on most of the elements of the CDIO Standards.

3 RESULTS

3.1 Program perspective – The context

The starting point of the CDIO framework is a characterization of the role of the graduate, connected to Standard 1. Also, the framework has been adapted to other disciplines with corresponding characterizations of the role of the graduate. This relies on a program perspective, where the education program is aiming for a professional role. In the literature CBL is sometimes discussed in a program perspective, but more often as a learning approach as such. The overview in [5] gives that the main part of the applications of CBL can be found within engineering and computer science, but the learning approach itself should be suitable for most types of education contexts. Also, Standard 12 is about Program evaluation, which is a very important aspect of any type of education program. The question if the design and execution of the education program enable for the students to reach the intended program goals is fundamental, but it is based on the program perspective. Hence, Standards 1 and 12 show that the CDIO framework has a wider perspective than CBL.

3.2 Integrated learning experiences and active learning

Standard 7 is about integrated learning experiences, which according to [2] should lead to *acquisition of disciplinary knowledge, as well as personal and interpersonal skills,* which implies that CBL is very much in line with this standard. Here interpersonal skills refer to Section 3 of the CDIO Syllabus, which includes Subsections 3.1 about *Teamwork* and 3.2 about *Communication*. Development of these skills are often referred to as motivating factors for the use of CBL, and in terms of intended learning outcomes the four C:s from the 21st Century skills are often used as reference, where *Communication* and *Collaboration* are tightly connected to 3.1 and 3.2. Standard 8 talks about *active and experiental learning methods*, and since CBL is a highly student centered and active learning approach, it aligns very well with also this standard. The conclusion is hence that CBL is an excellent alternative, among other learning approaches, in line with Standards 7 and 8.

3.3 Design-Implement Experiences

Design-implement experiences, i.e. Standard 5, are key components in engineering education programs. The purpose is to include learning activities that mimic the intended profession, and enable for the students to develop various skills related to this profession. Since more complex design-implement experiences require contributions from several participants, this type of activity is often carried out as team-based activity. The results of such team-based activities are often the most visual and spectactular outomes from a CDIO-based education, ans this has led to that the CDIO framework sometimes is seen as equivalent with PjBL, which is a somewhat limited view. It can be noted that neither the Description nor the Rationale of Standard 5 mention the word project, and that PjBL existed long before the CDIO Initiative was established. The purpose of the design-implement experience is to mimic the real profession, and for that purpose PjBL is a useful learning approach in engineering education. It is natural that PBL or CBL can have similar purposes in education programs aiming for other professions.

A key observation in [5] is that CBL has many different meanings, and similar observations have been reported for PBL and PjBL. For example, there are different version of how PjBL is carried out, depending on the discipline, how the work process is organized, the expected outcome of the project, assessment methods used, composition of the team, etc. Wikipedia's definition of a project reads: *A project consists of a concrete and organized effort motivated by a perceived opportunity when facing a problem, a need, a desire or a source of discomfort. It seeks the realization of a unique and innovative deliverable, such as a product, a service, a process, or in some cases, a scientific research.* In some interpreatations of CBL the process should start even earlier with a very open *Big Idea,* and from that define a challenge that is possible to treat given the available time and other resources. It gradually becomes a question about semantics, but starting from words *need*, *desire*, or *source of discomfort* in the definition of a project it is relatively straightforward to formulate a Big Idea.

Since there are many common aspects between CBL, PjBL and PBL it is desirable to focus on those and make use of the experiences that have been collected. These aspects include:

- Formulation of intended learning outcomes
- Characterization and choice of the Big Idea/challenge/project task/…
- Team formation, roles in the team, and team operation and development
- Structure and methods for the work process
- Methods and tools for continuous feedback and assessment
- The role of the teacher/coach/facilitator/mentor/…
- Interaction with externa stakeholders/challenge providers/…

The importance of these aspects can vary between the different learning approaches and different implementations of them, but it should be possible to extract common factors and enable transfer of experiences. See the illustration in Figure 1.

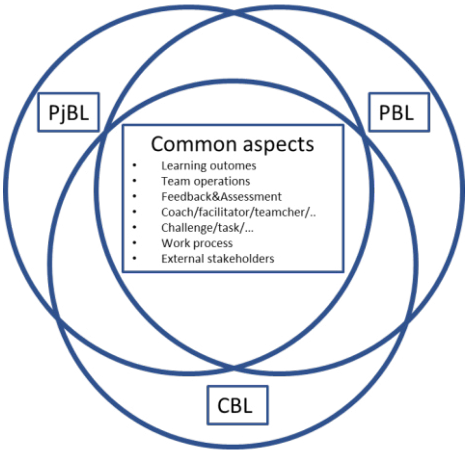

Fig. 1. Common aspects of PjBL, PBL, and CBL.

3.4 Learning outcomes

One of the main arguments behind both the CDIO framework and CBL is the necessity to develop the skills of the students, in addition to the subject knowledge. Within the CDIO framework, Standard 2 is focusing on this question. There are many important aspects of this that need to be discussed, and first it should be noted that there is a big variety concerning the vocabulary which is used when discussing skills. The words and expressions that are used in the literature include, for example, transversal skills, soft skills, transferable skills, generic attributes, and generic competencies. In addition, since there are no strict definitions of what is included in each of these expressions the discussion becomes somewhat vague. The CDIO Syllabus talks about *Personal and professional skills* in Section 2, and *Interpersonal skills* in Section 3, while it is more diversified in the literature about CBL. Second, and partly related to the question about the use of vocabulary, is the reference frame that is used when discussing and formulating learning outcomes. Within CDIO the Syllabus is the natural reference, but also here it is more diversified when it comes to CBL. As mentioned before, the 21st Century skills is one alternative, but there are several possible alternatives.

Via the principle of *constructive alignment* there is a direct link from learning outcomes, via the learning activities to the assessment. Assessment is even more challenging when it comes to assessment of skills. Since CBL, PjBL, and PBL often have related types of learning outcomes concerning skills, the question of assessment of this type of learning outcomes are of common interest. Some papers spend considerable effort on stressing the differences between these learning approaches, but it would be more fruitful to focus on the common aspects, where formulation of learning goals and related assessment for various skills is the most vital component.

3.5 Faculty development

Related to assessment but also teaching and learning in general is the need for faculty development. The literature about CBL stress the somewhat different role of the teacher in CBL, and there often is a need for faculty deveplopment. In the CDIO framework Standards 9 and 10 address the need for faculty development explicitly.

4 SUMMARY

The connections between the CBL and the CDIO framework have been studied, and the main messages of the paper are the following:

- The CDIO framework has a program perspective and hence a wider scope than CBL. The framework includes e.g. curriculum design, learning workspaces, faculty development, and program evaluation, and CDIO is not limited to one specific learning approach.
- CBL is a very good example of an active and integrated learning approach, and hence it fits very well as a compontent in the CDIO framework, where active and integrated learning are key components, as indicated by Standards 7 and 8.

As illustrated in Fig 1, there are many common aspects of CBL, PjBL, and PBL, and the potential for fruitful knowledge exchange concerning these aspects is very good. However, before considering which learning method to use, it is important to first reflect upon the learning goals, in terms of the knowledge and skills that are expected for the intended role of the graduate. Then, in a second step, one can choose a learning approach, including assessment methods, that is suitable in order to enable for the students to reaach the learning goals.

ABSTRACT

Challenge-based learning (CBL) for engineering ethics tasks students with identifying ethical challenges in cooperation with an external partner, e.g., a technology company. As many best-practice parameters of such courses remain unclear, this contribution focuses on a teacher-centric introduction into deploying CBL for engineering ethics. Taking Goodlad's curriculum typology as a point of departure, we discuss practical issues in devising, maintaining and evaluating CBL courses for engineering ethics both in terms of the temporal dimension (before, during and after the course) as well as in terms of the people involved. We will discuss selecting learning objectives, forms of knowledge acquisition, supporting self-organization, and fostering discursive etiquette, as well as cooperative, yet critical attitudes. Additionally, we will delve into strategic

[1] *Corresponding Author: C. Herzog, Christian.Herzog@uni-luebeck.de*

doi:10.5821/conference-9788412322262.1392

matters, e.g., ways to approach potential external partners and maintain fruitful cooperations.

1 INTRODUCTION

Conceptualizing, establishing and maintaining courses that draw upon innovative educational concepts, such as problem- or challenge-based learning (PBL/CBL), requires a host of separate and intertwined decisions geared towards adapting all course parameters to local conditions, such as student clientele and resources available. At least to some degree, deciding upon appropriate learning objectives also often lies at the discretion of the teaching staff responsible. If desired learning outcomes are set, the primary guide behind particular decisions on course parameters usually focuses on how to aid students in reaching these objectives, typically in trade-offs concerning the efficient utilization of resources such as time available to teaching staff, facilities and technical equipment. However, while much is being reported on the educational concepts themselves, details on their implementation to accommodate and account for local conditions is rarely addressed. The present contribution tries to fill this gap based on experience obtained in implementing two challenge-based engineering ethics courses in different universities. Accordingly, we would like to contribute to the field of higher engineering ethics education utilizing CBL approaches by highlighting practical issues that one might face and how to possibly address them. We will offer arguments and experience-based insights from several iterations of and discussions about our courses. The remainder of this contribution is structured as follows. We will first briefly introduce the concept of CBL and its use in engineering ethics courses in higher education. In reference to Goodlad's curriculum topology [1] we will then proceed to tackle relevant aspects before, during and after the course.

2 BACKGROUND

2.1 Challenge-Based Learning

Challenge-based learning lets learners collaboratively define their own challenges based on real-life problems [2]. Students work on challenges under guidance of lecturers and external stakeholders, reflect on them and—if possible—solve them. The starting point is usually an overarching question, from which to derive more specific questions with regard to a self-imposed challenge. Challenge-based course designs typically incorporate public final presentations of student projects. This, e.g., achieves a multiplier effect, i.e., of conveying learnings, heightened awareness and the corresponding solution space also to the general public.

Challenge-based learning has mostly been deployed for teaching engineering development processes marking a shift away from pure knowledge acquisition towards focusing on application, cf. [3]. However, little experience has been gathered in different contexts. Especially its adoption to ethics is relatively new [4, 5]. The working hypothesis for the present contribution rests on the notion that—even though the activity takes place in a specific context, e.g., engineering—it also explicitly requires students to not exclusively identify solutions from a search space confined to the disciplinary context. Instead, students are encouraged to think in inter- and transdisciplinary ways. E.g, technological solutions often might involve accompanying socio-technical solutions concerning work processes, communication strategies as well as a gradual implementation via inclusive participatory processes. Hence, CBL for engineering ethics can be perceived as a way of encouraging transdisciplinary education rather than purporting a disciplinary focus.

2.2 Two Dimensions of Managing Challenge-Based Courses: Time and People

For the purpose of communicating and reflecting upon course design choices, we adapt the curriculum typology of Goodlad, Klein and Tye [1], which distinguishes the ideal, formal, perceived, operational and experienced curriculum. These five aspects can be broadly construed as the dimension of time, which we will more simply structure into phases of before (or intended, as referring to the ideal and the formal planning), during (or implemented as referring to the course as perceived and operated by all involved) and after (as referring to the experience reflected upon as a whole including deducting next steps). The following sections will traverse this temporal dimension and will iterate through relevant considerations of lecturers in their interaction with students and external stakeholders. Goodlad originally considered also the educational institution and external stakeholders, while the latter refered to citizens and policy-makers [1]. However, due to space limitations we will focus on students and external stakeholders more closely in terms of the companies involved in the CBL course scheme to limit the scope, while we do not deny the significance of the institutional and societal perspective. Further, we will add considerations of operationalization to the experiential post-implementation phase.

3 BEFORE THE COURSE

The preparatory and planning phases in CBL courses involve extensive commitments of both lecturers and external stakeholders, while the students' ability to engage themselves in and adapt to CBL needs to be taken into account.

3.1 Lecturers

When designing CBL courses, a crucial question rests on the role the lecturers should (ideally)—but also are willing and able to (formally and practically)—assume: The ideal choice of role should reflect the pedagogic goal pursued. Its matching with the realities of resources available as well as local study conditions and culture, in turn, should instruct the formal planning. In terms of an ideal CBL approach, lecturers should be facilitators by providing an overarching question that students refine, derive a concrete challenge from, and develop a solution for.

However, lecturers must ask themselves whether they will be comfortable guiding through challenge-based coursework ad-hoc, or whether they will want to restrict both the scope and topics to be able to either resort to existing knowledge (bases) or read up on the issues beforehand. Besides skill, this is also a question of the time available both before and during the term, and the extent to which lecturers may indulge in producing preparatory material or be available for frequent counseling. The nature of ethical inquiry in engineering makes these considerations central, as the case studies presented by the external stakeholders might incur vastly different socio-ethical and (socio-)technological aspects. Consequently, the amount and type of canonical knowledge to be presented to students during the term (if any) can—and probably will—largely influence the directions the student projects will take. To alleviate, one may develop an ever-increasing knowledge base and set of modules about specific ethical aspects to point out to student groups at an appropriate time.

A central question to consider is about student expectations and experience with both CBL course concepts and the subject matter of engineering ethics. If students are vastly unfamiliar with self-organized learning and CBL, significant overhead should be granted not only for conveying the general idea, but also for gaining familiarity with all modes of interaction, knowledge acquisition and handing in potential deliverables. If students are also unfamiliar with engineering ethics (which they most probably will, assuming there is only a single undergraduate engineering ethics course in the curriculum), they might be subjected to a doubly steep learning curve. Such general unfamiliarity might require lecturers to make significant concessions, e.g., by enveloping the CBL course concept within a more traditional lecture and exercise structure that might be more familiar to engineering students. For instance, the lecture material might consist of presentations with interactive discussions about a set of issues relevant to the stakeholder projects, traversing from the canonical to increasingly specific ones. Exercises could amount to weekly group meetings to reflect upon the lecture's content in relation to the project and to advance towards identifying a specific challenge. Furthermore, by adjusting the degree of freedom in identifying challenges, students could, e.g., be given initial pointers in varying degrees of specificity, or left with only a general explanation about the external stakeholders' technological case. In addition, by discussing both course organization and expected learning progress during the first few meetings of the course, the lecturers could, e.g., discuss previous case studies as examples from previous instances of the course.

Many more considerations need to be made, e.g., with respect to the number of lecturing staff available, and, hence, the attainable ratio between students and supervisors, lecturers' disciplinary specialties and modes of exchange among these.

3.2 External Stakeholders

The acquisition of external stakeholders willing to participate as real-world case studies in a CBL scheme is a delicate matter that involves a convincing communication strategy, expectation management, sensitivity regarding the stakeholders' corporate viewpoint and available resources as well as negotiations concerning the degree of influence exerted on the student projects. In terms of convincing stakeholders to participate, it may pay off to commit to a longer term partnership with a local business association that can lend its reputation for raising the interest of its members. Despite lacking the perspectives of larger enterprises, a start-up accelerator might make a good partner to regularly interest companies-in-the-making. In fact, the acquisition of start-ups as external stakeholders allows to perceive the interaction in CBL courses as a partnership, avoiding prejudicial tropes of enterprises focused solely on maximizing return-of-investment. Since a start-up will not yet have the resources to perform in-depth ethical analyses, students can step in as agents for constructive and friendly criticism. With product development still in its infancy, students' conceptual contributions could allow for meaningful pivoting.

However, even though acquiring the participation of external stakeholders via partnering with a start-up accelerator may be elegant and convenient, this does not mean that fewer efforts need to be taken to understand and respect each potential stakeholder's corporate identity, viewpoint and needs. For instance, while regular meetings between students and stakeholders may be preferable, flexibility is needed to accommodate a stakeholder's resources. Similarly, stakeholders should be given some room for expressing and realizing their expectations: While ideally deciding upon the students' degree of freedom in choosing a particular challenge is a pedagogical question, stakeholders might want to direct attention towards their most pressing issues. At the same time, lecturers should not give rise to exaggerated expectations with regard to the students' final results. An honest communication about what to expect, including the possibility that weaker students might opt for a particular stakeholder's project resulting in weak outcomes, lays groundwork for a trusting relationship between lecturers and stakeholders.

4 DURING THE COURSE

Key aspects during course implementation concern management, roles and modes of interaction and the coordination of the project work.

4.1 Students

A crucial question for course management is the right combination of knowledge transfer and the CBL-approach: How can the course's schedule ensure that students are exposed to the right material at the right time during their project work? Two basic approaches as well as intermediates are conceivable: One may allow access to all material from the beginning, opening up the possibility of getting an overview over general topics and identifying potentially interesting aspects regarding the "stakeholder project" already in an early stage. Alternatively, topics and access/presentation order are designed to approach ethics from general issues (e.g., basics of moral philosophy, responsible research and innovation) to specifics (e.g., trust, privacy, algorithmic bias), taking into consideration that the material might be very new to students and requires a careful progression. A mixture of both in the sense of allowing quick tabulated overviews (e.g., date, type of lecture/tutorial, building/room, topic, requirements) and making more advanced material available upon request would also be conceivable. It should be considered that not only ethics input is required, but also input for project management (e.g., planning, collaboration, group dynamics) to achieve proper and successful project work.

Ongoing student-student and student-lecturer interaction needs to be carefully fostered. Our experience here shows, e.g., that regular feedback (graded assignments or non-graded feedback sessions) maintains a high ratio of attendance and attention to the material. Interactions within student groups can be promoted by anticipating when lecturers may need to change roles from guiding instructor to accompanying affiliate and vice versa. Additionally, fostering an atmosphere of open exchange as well as cooperative and social learning, cf. [6], facilitates long-term motivation and commitment, e.g., by being upfront about etiquette or being inclusive by specifically encouraging students that tend to be silent[2]. Likewise, additional consulting to mitigate intermediate low motivation will likely be necessary. In addition to proposing creative methods to provide an enjoyable experience of ethical reflection, these may include highlighting the benefits of engineering ethics through real case studies and anecdotes, e.g., by demonstrating thought processes. It is also necessary to consider ways of ensuring a critical, yet friendly attitude of students towards external stakeholders. Continuous effort is needed to respond to attitudes and to encourage students to speak freely and not feel intimidated. Identifying challenges also may imply that stakeholders will (typically) develop defensive argumentation and—at first glance—they may often succeed. Students might need further encouragement to follow up on their early argumentation by highlighting that the stakeholder's initial deflection may only be valid from a business perspective.

During the course, efforts required to support the students' project work in terms of content, coordination and acquiring specific competences (argumentation, reflection, communication, presentation) should not be underestimated. This kind of support scaffolding is an open process, involving many supportive discussions and careful observations to determine what additional activities may help. While tasks such as developing posters to connect lecture contents with stakeholder projects seem to foster creative thinking, argumentative skills may be better developed via written exercises, or enacting debates in role-playing—but all of them require feedback and, ideally, educational material as a reference. It should be taken into account, however, that each student project group needs an individual level of supervision in its project management. Hence, the effort required for supervision can and will vary.

4.2 External Stakeholders

The interaction with external stakeholders requires constant attention for aligning business interests, student interests and capabilities as well as intended learning outcomes. Among other things, this requires to take into account and balance the desire of the external stakeholders to gain new insights within a solution-oriented frame for ethical analysis, at times highly inconsistent student motivation and capabilities as well as the pedagogical premise that ethical challenges need to be identified independently by the students. Additionally, stakeholders are usually short on time, but while students progress, they typically would like to inquire more frequently and more deeply. Primarily though, lecturers need to aid in converging perspectives by both pushing the envelope in terms of what businesses might assess

[2] *In addition, the experiences of CBL during the pandemic, such as diminished interaction, may be addressed. However, an exhaustive consideration goes beyond the scope of this paper.*

as responsibilities they might realistically assume as well as by asking the students to turn critical assessments into actionable plans for improvement.

For this purpose, the interaction of stakeholders and lecturers occurs on two levels: First, a bilateral dialog between lecturers and stakeholders allows the management of expectations and sharing assessments to inform the stakeholders about the actual progress of the project. This as well offers the option to personally intervene if there are any communicative misgivings and challenges, e.g., it may be appropriate to evoke sympathy for struggling students. Second, during the meetings that include all partners (stakeholders, students and lecturers), besides enabling the critical yet friendly attitude of the students, lecturers might need to assume the roles of arbiters, striking compromise between the students' theoretical demands and business realities. In that regard, concepts from ethics might also be novel to the stakeholders, which requires lecturers to support student explanations, but also to continuously argue for why ethics is relevant on a business and societal level.

5 AFTER THE COURSE

After the course, the lecturers' tasks are often strategic and need to focus on sustaining and perhaps even institutionalizing the CBL concept.

5.1 Students

A great strength of CBL is that the students' learning progress can be observed quite transparently. For instance, the quality of regular assignments (such as poster slides on the reflection of engineering ethics topics in the context of a stakeholder project) can be continually assessed in terms of learning outcomes, argumentative skills, etc.. In contrast to conventional teaching approaches such as lectures or seminars with discussion elements, here the steady progress of student work can be tracked.

In engineering ethics, grading is an act of balancing expectations given that this is typically the students' first encounter with ethics. This makes it crucial to clearly communicate requirements by providing grading rubrics, e.g., in terms of clarity and structure, showcasing comprehension and use of literature as well as critical independence and relevance. Detailed and structured feedback will contribute to student learning. Grading group work always carries the risk of allowing free-riding, but transparent grading schemes involving a weighted averaging of individual and group performances can keep the need for discretionary decisions at a minimum.

Student work is subject to privacy regulations, but if students allow, work can be forwarded to the external stakeholders. After completion of the course, further interactions between students and stakeholders may be encouraged, e.g., as a possible opportunity for employment. Students having shown particularly good performance may also continue to be involved as teaching assistants or ambassadors for the same course in the next academic year. To present the results of the students' work to the outside world, public events can be organized. However, it should be noted that the more time passes, the more difficult it can be to motivate students to participate actively. Hence, early on, plans should be communicated and an informal, or even formal, contact to a group of course graduates maintained.

5.2 External Stakeholders

Beyond university-wide platforms and support to engage with external stakeholders, individual lecturers in CBL must consider the steps they can take to ensure a sustained cooperation with stakeholders, or meta-organizations like, e.g., start-up accelerators. Extensive networking and forming a visibility of the group of lecturers committed to CBL appears to be of the essence. This way, stakeholders can pinpoint their partners from university by brand—such as a specific or collective of research groups. In addition, more personal relations should be fostered, with lecturers showing genuine interest into the effects student projects may have had on the external stakeholders' work. Ideally, a successful consideration of student output by a stakeholder is openly and clearly communicated to the students, lecturers and even higher-level university representatives. Such communication could be institutionalized by establishing a CBL course-specific “landing page” that features news and project results, both as a means to advertise, acknowledge and maintain relations. For such an instrument, agreements about the extent to which information on both student progress and case studies may be published need to be made.

A prospect for stakeholders to continue relations is viewing CBL courses as a pool for future talent. Ethics CBL courses may appear less suitable, as students are tasked to showcase their ethics more so than their engineering prowess. As the students' ethical analyses might well include highly critical stances, sustained relations are likely to only be possible with stakeholders that prioritize open discourse over managing reputation. However, economical success often appears to strongly benefit from the later, which makes managing relations a delicate task.

6 CONCLUSION

With this contribution, we have provided an extensive list of considerations for conceptualizing and establishing, maintaining and implementing as well as sustaining and further developing challenge-based courses in engineering ethics. We have been inspired by Goodlad's curriculum typology to structure our exposition according to the two dimensions of time and people under consideration, while we focused on what the lecturers responsible for the course need to take into account, may initiate and should act on. Since the prevailing circumstances at different institutions from higher education will vary significantly, we have formulated our contribution in terms of open-ended questions and considerations, highlighting exemplary choices and their corresponding reasoning where possible, but refrained from overly generalizing into a single or few correct choices. While our list of considerations may be extensive, it is by no means exhaustive and much more needs to be said about the potentialities of course design choices, management issues, an understanding of roles and means of interaction and stakeholder relations. We hope to have contributed to a discussion on these practical issues of conducting CBL engineering ethics courses.

ABSTRACT

Adding ethics courses to engineering curricula seeks to equip students with the critical mindset that enables careers committed to serving humanity. Yet, the knowledge of ethical theories is neither a necessary, let alone sufficient condition for being good [1]. There is no automatism that translates ethical knowledge into action, overriding attitudes that were developed during the enculturation of a student. However, we deem teaching assemblage theory a promising means to achieve a sustained commitment to responsible innovation practice. We base our argument on assemblage theory's (cf. [2, 3]) capacity to conceptualize the interplay of human actors and technological artefacts in terms of dynamic evolutionary systems. The notion of an assemblage as a collection of potentially heterogeneous elements that—despite displaying consistency—remains malleable through reorganization, interconnection and, (re-)attribution forms the ontological basis that guides a conceptual approach to thinking in-between the extremes of technological

doi:10.5821/conference-9788412322262.1390

determinism and social constructivism. Information algorithms, e.g., can be regarded as having the power to facilitate ethical action as part of a larger assemblage [4] and artificial intelligence can arguably only be understood as “trustworthy” within socio-technological systems in which a shared responsibility realizes both epistemic and moral conditions for trust [5].

Ultimately, we intend engineering students to realize the extent of their influence on the world and, therefore, their responsibility for contributing to a prosperous community. Thus, ethics is not only taught by conveying its classical normative theories but rather explored by discovering the entangledness of technology and society.

1 INTRODUCTION—DRAWBACKS OF COURSES IN ETHICAL THEORY

Ethics has always been part of engineering and engineering education at universities and elsewhere—but mostly implicitly, to that extent that everyone who is involved, i.e., educators as well as students, is always endowed with an ethical configuration resulting from their respective socialization process. Our upbringing as well as the experiences we make have a further impact on how we assess moral questions and make judgments. So, if everybody already has an implicit understanding of what is right and wrong that reflects their personal views, why bother using a part of the already limited time for courses at university to add ethics education to an engineering curriculum? What difference can an ethics course make? And what difference would it make if it were based on assemblage theory, cf. [2, 3]?

First, we should look at how a course that teaches ethics by conveying ethical theory works, what assumptions it is based on, and what its (possible) drawbacks are. This will shed light on why we propose a different way which circumvents the pitfalls in ‹classical› ethics courses. Ethical theories, be they deontological (based on duties) or consequentialistic, provide normative frameworks. These start out at a moral problem and help its users to identify a path of action to take, which—according to the respective theory—is identified as either ‹good,› ‹right,› or ‹one's duty.› That is, an action is demonstrated as morally justified by outlining a sound argument.

On the other hand, ethical theory tends to be perceived as eluding the practical side of life. The criticisms voiced regarding the effectiveness of ethics education take place on (at least) two levels: (1) Skeptics of the teachability of ethics in general are claiming that one either is a moral person or not, as this is the result of a socialization process. (2) Skeptics of the knowledge of ethical theories being an asset to a person's ability to better deal with moral problems are claiming this knowledge does not contribute to the formation of moral judgments as it only serves as an *ex post* justification of decisions made without an ethical theory [6, p. 37–38].

Both, Johnson and Fischer, do not deny the teachability of ethics. Johnson thinks that skeptics in (1) have «oversimplistic notions of ethics and of human behavior» and declares «knowledge [of] codes and standards,» «skill,» «reasoning,» and «motivation» the core components of engineering ethics [1, p. 64]. Fischer pursues a different approach and points to evidence from courses in applied ethics for doctors and nurses, which were perceived as being disconnected from the needs of medical practice because the appeal to normative ethics fails by giving the justification of actions precedence over understanding the «morally significant situation». While according to Fischer we recognize such a situation and know what to do without going step by step through a (quasi-)algorithmic judgment process, Johnson regards it a teachable and thus learnable «skill» to «identify ethical issues» [1, p. 64].

Johnson is aware that ethics education will not automatically make people «good» in general but claims that this increased the probability that engineering students will be «better prepared to handle the ethical issues that arise in their professional lives» [1, p. 64]. Based on her assumptions that the knowledge of policies and professional ethics codes equips future engineers with a compass that suffices to handle ethical problems, hand back the verdicts of having «oversimplistic notions of ethics» back to her. Relying on such codes' results and their application is little different from relying on the knowledge of frameworks delivered in theories of ethics. Both are teachable, yet both represent a technical approach to ethics, meaning that a tool is provided to ‹solve› a problem. While theories of ethics are often employed this way, it is better to use them as concepts for analyses and approach real world problems differently. This however exposes a gap between ethical theory and moral practice.

2 AN ALTERNATIVE PROPOSAL—USING ASSEMBLAGE THEORY FOR ENGINEERING ETHICS EDUCATION

To fill this gap, we propose teach engineering in ethics not by ethical theories and their application to moral problems, but in a way that acknowledges the complexity of the world and society as socio-technical conglomerates, or *assemblages*.

2.1 A Brief Characterization of Assemblage Theory

We would like to precede a brief characterization of assemblage theory by disclaiming that our portrait may strike scholars of Deleuze and Guattari as overly simplistic. To the best of our knowledge, assemblage theory eludes a concise summary, perhaps with the exception of [7]. Scholars like Buchanan do, in fact, reject the very idea that something like this should even be pursued. At the core of Buchanan's argument lies a characterization of assemblage theory as an unfinished project whose principles can be extended [3, p. 6], but for which it is impossible to give an exhaustive and model-like description, because this would betray its very project of working against mechanistic ways of perceiving reality [3, p. 5].

If we accept these premises, then whatever we can sketch here will not do assemblage theory as originally conceived of by Deleuze and Guattari in *A Thousand Plateaus* proper justice. However, aware of this, we will try to sketch the general concept, hoping to evoke an idea of why it can be useful and how. In doing so, like Buchanan, we will try to remain true to the original idea that extends beyond—and rejects core tenets of-—the notion of assemblages-as-systems-of-things due to DeLanda [2]. DeLanda takes that properties of a given assemblage are generated by its components, whereas, according to Buchanan, «desire» is primary, i.e., it is giving selected things the properties they have in an assemblage [3, p. 56].

Crucial to understanding assemblages is to realize that assemblages are not defined by their components, but rather that they are defined by their products [3, p. 47]. The virtual (think, e.g., concept) is actualized by the elements' relations and agents. Assemblages are «alive» in the sense that they do not disappear, even if the material things they arrange are removed [3, p. 60]. What matters most are the ideas and notions that remain. In that sense, at the core of assemblage theory as per Buchanan (and hence as per Deleuze and Guattari) is a reversal of the «virtual» and the «actual», which can be exemplified in capitalism: Advertisements based on particular characters from, e.g., movies would only be *virtual*, because they are unaffecting without the stories that *actually* matter to prospective buyers [3, p. 60].

An *assemblage* (an unfortunate translation of *agencement*), then, is an «arrangement or layout of heterogeneous elements» [7, p. 22]. In contrast to portraying unity described by an essence, understanding assemblages as arrangements emphases multiplicity and events. While one cannot extract parts from unities without destroying them (e.g. a heart from a body), assemblages allow for recombinations or removals of parts and are defined by the relations between these. Hence, an assemblage «constructs or lays out a set of relations between self-subsisting fragments» [7, p. 23]. Instead of being about essence, presupposing a static, defining finality, assemblages are dynamic constructs of contingent features.

All assemblages are defined by three kinds of features: their *Abstract Machine* (or conditions, C), their *Concrete Assemblage* (or elements, E), and their *personae* (or agents, A) [7, p. 24–28]: *The Abstract Machine* are the external relations holding the elements together. While the conditions are not tangible objects and thus abstract, the external relations are real. *The Concrete Assemblage* are the actual elements from which the abstract machine is composed. The relation between the concrete assemblage and the abstract machine is reciprocal; they are mutually co-adapting to each other. *The Personae* are the agents that connect the concrete elements according to their abstract relations and are immanent to the assemblage [7, p. 27].

All assemblages are arranged as combinations of basic political types: *Territorial Assemblages (TAs)* are arranged to divide the world into coded segments that define the «natural» norms of life in terms of «this is how things are done, how they have always been done», [7, p. 28–29]. *State Assemblages (SAs)* are arranged to unify all concrete elements in the assemblage [7, p. 30]. *Capitalist Assemblages (CAs)* are arranged such that conditions, elements and agencies form abstract quantities [7, p. 31] that can be treated as globally exchangeable [7, p. 32]. *Nomadic Assemblages (NAs)* are arranged such that conditions, elements and agencies can recombine to allow qualitative transformation and expansion of the assemblage [7, p. 33]

In summary, territorial assemblages are based on essentialist meanings, state assemblages allow centralized command, capitalist assemblages allow exchange in terms of generic quantities and nomadic assemblages allow for participation and self-management. All assemblages constantly change according to different kinds of change (or «deterritorialization» as the way in which assemblages continuously transform and reproduce themselves [7, p. 34]): *Relative negative* processes maintain and reproduce an established assemblage. *Relative positive* processes do not maintain or create a new assemblage. *Absolute negative* processes undermine all assemblages. *Absolute positive* processes create new assemblages.

The above is a concise and ultimately incomplete terminology used in structuring concepts from assemblage theory. Its use will be exemplified next in the context of algorithmic accountability.

2.2 An Example — Algorithmic Accountability

Algorithms are generalizable descriptions of methods designed to accomplish certain well-defined tasks. Ananny frames algorithms as «unstable objects of study» [4, p.

109], which require a framework in which to address ethical implications that can keep track of the dynamic relations. Assemblage theory is a promising candidate.

Algorithms promote quantitative and oftentimes (deliberatively) reductive views that allow for efficacy or increasing the efficiency of various routines. Algorithms can hence be characterized as drivers of *absolute positive processes* that typically create *capitalist assemblages*. However, while not be wrong, this characterization may also be too limited [4, p. 97]. For instance, it fails to capture that algorithms also facilitate new forms of human interaction. Be it through, e.g., match-making, encryption or compression, algorithms have led to qualitative breakthroughs in the conditions under which humans can communicate, organize themselves and act together. Accordingly, they can be conceived of as drivers of *absolute positive processes* creating *nomadic assemblages* as well. Like institutions, algorithms have the power to structure and influence behaviour [4, p. 99] and an ethical analysis of questions of accountability needs to account for all elements, relations and agents involved.

The *concrete assemblages* of algorithms in social media, for instance, consist of actual code of both the social media-based algorithm as well as of systems interacting with it, human practices, i.e., those of the developing individuals, users of social media, policy, and regulatory bodies, etc., as well as norms. A particular *abstract machine* might be identified in the notion of «clout» as the power or influence an institution or individual might exert on social media. *Personae* connecting elements of the concrete assemblage are statistics, aggregations and other abstract means bringing about effects contingent on the abstract machine.

Algorithms working on data, e.g., influence associations by statistical means previously beyond the recognition of humans. More broadly, «[p]eople that fail to leave data that can be categorized are effectively invisible to the … algorithm» [4, p. 101], while those that share data may be viable targets for adverts but may also be offered interactions that induce opportunities. Accordingly, algorithms facilitate processes that maintain, undermine, or create associations and, hence, corresponding assemblages. Much of the effects of social media algorithms strongly depend on how users appropriate a particular platform, similar to, but perhaps far extending beyond the capacity of citizens appropriating urban infrastructure to their needs. In addition, the effects do seldom originate from the utilization of a single social media platform alone, but rather depend on the interaction with further platforms of, e.g., commerce, such as ad-targeting, aggregate news outlets and search engines. Hence, locating the origin of, e.g., the societal effects of a single post going viral, is difficult and can only be possibly understood or traced by examining interactions between the concrete elements of the assemblage. Furthermore, in case of machine learning algorithms, effects may also depend on past and present interactions encoded by various sources of data over time.

Assemblage theory may be a difficult concept to fully grasp. However, we believe that the above sketch outlines that it provokes a way of thinking about relations and events. In Buchanan's words «[t]he assemblage is intended to answer several types of question, ‹how?›, ‹why?›, ‹when?›, and not just a ‹what?› question,» [3, p. 13].

Ananny makes a point that more traditional perspectives from ethical theories, such as deontology, teleology and virtue ethics are at a loss for answering or critiquing algorithms appropriately. For instance, the effect of emerging categories would have to be assessed by outside standards in a deontological sense, by efficaciousness in a teleological sense, or by its alignment with virtue-based expectations in a virtue ethics sense. All of this is useful but overlooks that, e.g., an algorithm could bring about new collectives of ethical concern and that assemblages might incur transitions under which ethical assessments might alter. Ananny's argument for inquiring about the ethics of algorithms via assemblage theory, hence, hinges on a demand to go beyond lists of ethical guidelines requiring «transparency» [4, p. 109] or «justice», but to rather highlight the dynamics of relations and how these could bring about unethical states and conditions.

3 A PROPOSED COURSE DESIGN FOR HIGHER EDUCATION

Above we have elaborated on assemblage theory as a potential candidate for ethical analysis, whose use might mitigate the drawbacks of traditional ethical theory-based engineering ethics education. In the following, we will propose a course design rational and structure, arguing that using assemblage theory, it will be possible to educate engineers to routinely consider the ethical implications of their work «through the back door», i.e., implicitly through sensitizing for ethically relevant relations, conditions and events—in other words, through assemblages.

3.1 Rationale

To avoid any misunderstanding: by ‹employing assemblage theory› to foster a responsible innovation mindset, we do not seek to teach assemblage theory to create a fixed view on ethics. We also do not seek to teach assemblage theory as a kind of blueprint to be mapped onto any given situation, which would go against the intentions of its conceivers Deleuze and Guattari [3, p. 5]. Even though such an approach might be most familiar to engineering students, given the conceptual difficulties in providing for a concise and complete characterization of assemblage theory, it appears hardly possible to design a course that begins with outlining assemblage theory as such and then proceeds to apply it. Hence, to bring insights from assemblage theory to bear in an engineering course, lecturers might be best advised to keep explicit references to assemblage theory terminology to a minimum. In fact, even when scanning the (mostly sociological) literature covering aspects of the ethics of technology by means of assemblage theory, an explicit mentioning of assemblage theory-related terminology in terms of features such as *abstract machines* or political types such as *nomadic assemblages* is rarely found.

Accordingly, an approach to «teaching ethics through the back door» using assemblage theoretical concepts must succeed by conveying the relevance of socio-technical dynamics when addressing innovative technological disruption, the network of influences, responsibilities, and possibilities in flux as well as the interconnectedness of agents and the necessity of a shared sense of collective ethical action to achieve desired outcomes.

At times, conclusions might boil down to rather simple insights. E.g., when making «trustworthiness» the theme of discussion on artificial intelligence-based algorithms, a first realization may be that algorithms cannot be proper recipients of a moral account of trust because vulnerable trustors cannot attribute (well meaning) motivations to an artificial artefact, the trustee [5]. Algorithms may be reliable, but actual trust is to be lend to the socio-technical assemblage, in which conceiving, developing, marketing, auditing, competing, and regulating agents interact with, experience, challenge and support each other. Institutions are formed and categories (of algorithms) emerge that support trust by evoking expressions that portray algorithms—even though potentially opaque—as essentially based on good (or malicious) intentions, as trustworthy or not. Perhaps rarely will multiple agents consciously flog towards a common idea of advancing a specific product actively through the means of responsible innovation. But if this happens, an assemblage can be identified. Different from an indifferent, almost Kafkaesque, pursuit of an engineering career, acquiring a world view in terms of assemblages will hopefully spark the students' interest to contribute to the responsible innovation assemblage.

3.2 Course Structure

An actual engineering ethics course based on assemblage theory may obviously take many forms. We outline one possible concept of a structure that, admittedly, still needs to prove effective. Based on the above rationale, however, we believe it best to split the course into two parts: A first part is driven by case studies and works towards establishing the main concepts of assemblage theory one by one. A summary can then outline the theory itself and retrospectively link concepts and terminology to the case studies that were discussed in the first part. Its purpose lies in highlighting conceptual similarities and patterns as a concession to student expectations of take-away messages, which needs to be balanced with the open-ended nature of assemblage theory. A second part could task students to penetrate a new case study along the conceptual lines taught in the first part. More ideally than ready-made case studies as hand-outs even, a current situation from the news or reports could provide an analytical challenge a group of students could work on.

4 CONCLUSIONS

In this contribution, we have advocated the adoption of assemblage theory as a conceptual approach for ethical analyses in an engineering ethics educational context. We have outlined the limits of teaching ethical theory to increase commitment to responsible innovation practice in engineering students as a core motivation for approaching engineering ethics education differently. Instead, we believe that assemblage theory's focus on conditions, relations and events is well suited to shed light on the ethical challenges that innovative technologies, the perpetuated use of algorithms and artificial intelligence first and foremost, bring about. However, even though assemblage theory is a viable engine for ethics education, its conceptual intricacies may be best introduced in a step-by-step fashion without overbearing terminology.

Conference Key Areas: *Mathematics at the heart of Engineering, co-creation with students*
Keywords: *peer teaching, math lecture for engineers, engineering teaching, student participation*

ABSTRACT

Engineering students often miss the connection between mathematics and the engineering disciplines. One solution to this problem is to integrate application examples into the math lectures. However, it is challenging for mathematicians to find adequate applications and to present them in an authentic manner.

We describe a concept of integrating application examples through peer teaching: A student who has already completed the mathematics course is involved in the preparation and presentation of such examples. As a result, the examples are very authentic since they are developed and presented by a person knowing the applications, the learners' motivation is high due to peer teaching, and the new

doi:10.5821/conference-9788412322262.1418

material is high-quality owing to the supervision by the lecturer. Surveys conducted for each application example reveal that the concept is well accepted.

The paper describes the steps in the development of application examples of different length and mathematical depth and gives recommendations on how to implement the concept successfully into math lectures.

1 INTRODUCTION

Mathematics courses are important for the education of engineers at universities [1], but the link to the engineering disciplines is sometimes missing [2] and the course is seen as a hurdle [3]. This can lead to low motivation and interest in mathematics among engineering students [4].

1.1 Bringing different academic levels together (peer teaching)

Students' motivation and learning effects can generally be strengthened by peer teaching [5]. Several benefits have been documented across the literature for both tutors and tutees. Tutors benefit in particular from the intensive active engagement with the subject matter and from explaining it [6]. An advantage for tutees is a similar cultural and linguistic reference and a more direct speech and confidence between tutor and tutees [7].

In the following we use the term “peer teaching” in the sense that we engage major students as partners in the development and presentation of teaching material. Such concepts are applied in [8] and [9], for example. Croft et al. [8] describe a project where major students are involved as co-creators of screencasts for first-year math lectures. Bovill et al. [9] gives an overview of appoaches where students are involved as co-creators of teaching approaches, course design and curricula. Yet, these concepts encounters resistance from many lecturers as they fear that the quality of the resulting content may be insufficient [7].

1.2 Bringing different disciplines together (application examples)

There are various concepts to establish a closer connection between, amongst others, engineering and mathematics in engineering degree programmes [10]. One possibility is to integrate applications from the engineering disciplines into the mathematics courses. Such material should be as authentic as possible to create a link between mathematics and the engineering disciplines [4]. However, this idea includes the challenge for mathematicians to find appropriate applications [11] and to present them in an authentic manner [12].

1.3 Our concept

The concept presented in this paper combines both concepts, i.e. “Bringing different academic levels together” and “Bringing different disciplines together”: The lecturer and an advanced student together develop application examples, and the student presents them in the lecture. This leads to high-quality and authentic application examples as well as to authentic presentations. With this project we hope to create a stronger connection between the mathematical and the application topics within the given institutional and temporal conditions and in this way making the relevance of mathematics for the engineering programme more explicit.

1.4 Overview over the paper

The concept was conducted during a mathematics course for rescue engineers in the master's programme at a technical university in Germany. Students of this programme "obtain a specialized skill set allowing them to develop innovative and efficient concepts in hazard control and prevention as well as safety engineering" [13]. The mathematics course mainly includes topics in statistics and probability. It consists of a weekly lecture, in the form of seminar teaching using slides, and a weekly problem session.

In this paper we describe in detail all steps of the concept as it was carried out in that course in the winter term 2021 together with a major student (section 2). Then an accompanying evaluation of the intervention regarding the students' perspective on the application examples is described, and results are presented (section 3). Finally, the concept is discussed, and research perspectives and recommendations on how to implement the concept in other educational settings are given (section 4).

2 DESCRIPTION OF THE CONCEPT

In this section we explain in detail the steps that lead to the embedding of an example into the lecture. The steps are shown in Figure 1 and described afterwards. The fourth step sometimes made it necessary to return to the third step.

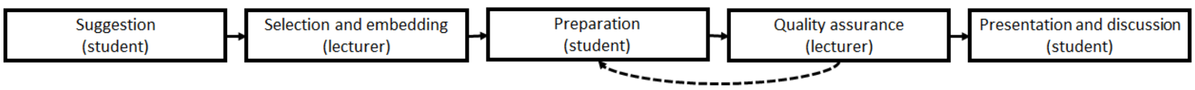

Fig. 1. Steps needed for the successful implementation of the concept

The project was realised with a (male) participant of the course of the previous semester who had achieved a very good grade and who had working experience in rescue engineering. We employed the student as an assistant for the project.

2.1 Suggestion (student)

Before the start of the semester, the student was assigned to search for applications of mathematics from the lectures of other engineering subjects, the related literature, and his work environment. He presented the results of his research to the lecturer.

2.2 Selection and embedding (lecturer)

The lecturer examined the collection of applications regarding the mathematical content and the fit with the lecture material. In the end, six examples were selected. We briefly describe two of the six examples, a short one and a long one, both receiving a very good evaluation by the students.

The example number 3 treated the mathematical topic of transformation of data (statistics). It consisted of a table with deployment data of twelve months for four fire stations, with a large accumulation of deployments in the month March (Figure 2). The task was to decide which of the four stations was unusually busy in March. For a meaningful comparison of the four stations the deployment data had to be transformed into standardised values. The student came up with the application himself based on his experience as a member of the volunteer fire brigade.

Fire station	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
1	7	11	31	12	12	10	10	9	9	11	13	14
2	23	34	56	43	36	35	27	26	24	32	43	41
3	2	3	5	3	4	3	4	3	2	6	4	4
4	3	5	12	6	3	1	3	4	4	5	2	6

Fig. 2. Number of deployments for four fire stations

In another example (number 5), the use of various discrete probability distributions such as Poisson distribution, binomial distribution, geometric distribution and uniform distribution was needed. Deployment data from a rescue service location was provided (Figure 3), and it had to be estimated how many rescue resources had to be kept on hand at what time in order to ensure a high level of operational safety for the missions. The idea for this application came from a standard book for rescue engineers [14].

Total number of missions in 2020	12400
Rescue vehicles provided	3
Average duration of a mission (unit)	58 minutes

Fig. 3. Deployment data from a rescue service location

2.3 Preparation (student)

The student prepared the selected examples for a presentation. He was provided with the slides for the lecture in which the example had to be embedded so that he could fit the example well into the context. Furthermore, he was asked to build on the mathematical knowledge that had already been covered and to use matching notations. In addition, we explained to him in advance how to prepare an example in a good educational way. We used the modelling cycle according to Blum and Leiss [15] as a basis (Figure 4).

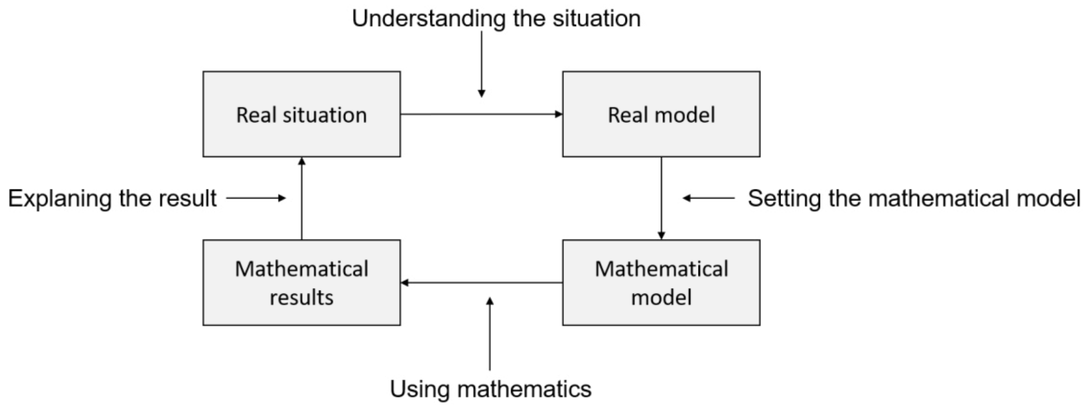

Fig. 4. Modelling cycle for the preparation of application examples ([15], modified)

The example number 3 was initially prepared by the student in a spreadsheet programme (Excel). The sheet included the number of deployments for four fire stations in twelve months (Figure 2) and the calculations for standardising the data. After quality assurance by the lecturer (see the next step), the student additionally prepared slides showing in detail the steps in the modelling cycle (Figure 4).

The example number 5 was also initially prepared exclusively in Excel. The student's approach first was very similar to the presentation in the literature [14]. He didn't show the simplifications and assumptions made for the setting of the model (steps from "Real situation" to "Mathematical model" in Figure 4) or which probability distributions were used ("Using mathematics" in Figure 4). In several cycles (see Figure 1 and see the next step), a number of slides were created that addressed the different steps in the modelling cycle (Figure 4).

2.4 Quality assurance (lecturer)

The student presented his material to the lecturer. The lecturer critically examined the preparation and the presentation, especially with regard to the setting and use of the mathematical model, the mathematical solution in the model, the fit to the course material and the quality of the presentation. In-depth questions by the lecturer on the application context improved the understanding of both and as a consequence also the student's presentation (see step 5). This discussion partly required the student to revise the preparation of the material (back to step 3).

The example number 3 required very little time on the part of the lecturer. The student supplemented his initial presentation via Excel sheet with teaching slides and he added a quiz to activate the students.

Example 5 was more elaborate in its preparation, on the part of the student as well as on the lecturer. All the modelling necessary for the mathematical solution was worked out very carefully. Hidden assumptions made in the applications were explicitely described and discussed and provided with a suitable discrete probability distribution. Several times, we returned to step 3.

2.5 Presentation and discussion (student)

The student explained and presented the examples in the lecture, sometimes with integrated quizzes or independent work phases in smaller groups, and he led the subsequent discussion. Questions concerning the application context could be answered directly by him, the 'expert' for the application. The lecturer was also available for questions (of a more mathematical nature) and for clarifications. The presentation of example 3 lasted about 10 minutes, whereas the presentation of example 5 filled a big part of the session (45 minutes).

3 EVALUATION OF THE CONCEPT

Our subjective impression was that the examples were very authentic and well received by the students who participated in the course. Nevertheless, we also wanted to systematically evaluate the examples in order to learn more about the acceptance of the concept, to better understand the students' perspective, and to obtain ideas for improvement from the students' perspective. In this section we explain the methodological tool of the evaluation and present the results.

3.1 The evaluation instrument

To measure the students' evaluation of the examples, the students answered a survey questionnaire after the presentation of each example. The examples should be evaluated regarding the criteria "motivational", "applicability" and "authenticity" which were developed in [4] and which we adapted to the setting of the examples. Respondents were given options using a six-point Likert scale ranging from 1 (strongly disagree) to 6 (strongly agree) to measure their agreement on the statements of the questionnaire. Five items build the scale "motivational", one being for example "The reference to an application has aroused my interest." The scale "applicability" consisted of three items, one being for example "This example has improved my ability to work on tasks with an engineering context." The criterion "authenticity" is checked with one item, namely "The application reference is authentic: a real engineering problem is solved with the help of mathematics." (All sample items were translated by the authors.)

In addition, we had the following statement rated, on the same scale: "I liked that the example was presented by a student."

3.2 The sample

The study involved 7 to 18 students who were enrolled in the master's programme of rescue engineering. The six examples that were integrated into the lecture were evaluated by a different number of students: The first one was rated by n=18 students, the second by n=17, the third by n=11, the fourth by n=12, the fifth by n=7, and the last by n=10.

3.3 The results of the evaluation

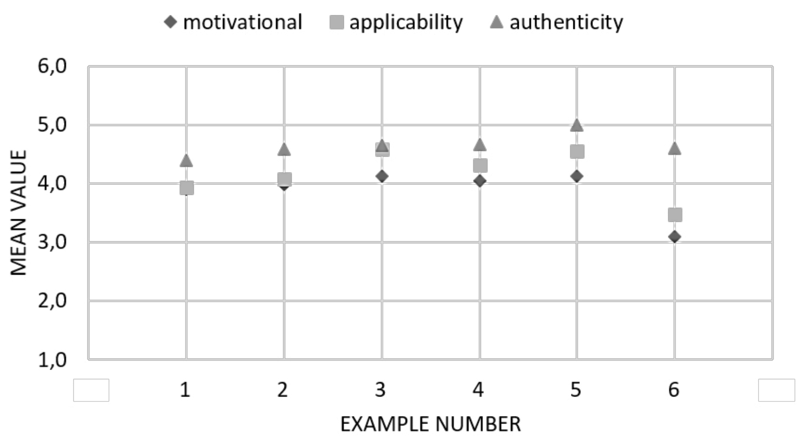

Fig. 5. Mean values of the three evaluation criteria in the six examples

Descriptive analysis for the evaluation criteria (Figure 5) reveals that all examples were evaluated as being very authentic (mean values ranging from 4.39 to 5.00), the one with the highest mean value is example 5. The examples 1 to 5 seem to be quite motivating (mean values between 3.90 an 4.12) and applicable (mean values between 3.93 and 4.58). In the example 6 the criteria “motivational” and “applicability” are rated weaker than in the other examples (3.10 and 3.47).

The mean scores for the examples in the item “I liked that the example was presented by a student” are 4.56, 4.88, 4.55, 4.33, 5.29, and 4.40, so they are consistently well above average (3.50).

4 DISCUSSION AND CONCLUSION

We summarize the concept and describe success factors and challenges, discuss the evaluation of the project and give recommendations on how to implement the concept in other courses.

4.1 The concept: summary, success factors and challenges

The concept successfully combines the ideas of “Bringing different academic levels together" and "Bringing different disciplines together" as explained in section 1, and additionally solves the disadvantages associated with the two approaches, namely the concern for the correctness of a student presentation [7] and the missing authenticity of the presentation by a mathematician [12].

Different levels are brought together by the collaboration with an advanced student during the development of the material and the presentation of the examples. The didactic and professional quality of the presentation is ensured by the the interplay between student and lecturer (in particular step 4, the quality assurance).

This close cooperation also brings together different disciplines: an engineering student and the mathematics lecturer. The involvement of advanced students with an engineering background makes the examples more convincing. The authenticity is reinforced by the fact that the student himself/herself presents the application and is directly available for discussions, especially on the context of the application. This is an important difference to the concept in [8], where screencast videos are developed together with students and then integrated into the course as video material.

The concept is a small intervention that can be easily accommodated within the given institutional framework and requires little time. The cooperation with the student is needed as the mathematician lacks the knowledge of the application context. Remark that short as well as long examples were successfully embedded into the course. A side effect of the project is the learning effect that the tutor has concerning the mathematics and the educational tools – the student’s presentations improved from example to example, and the student also confirmed an increase in understanding in an interview that concluded the project.

Central for a successful implementation of the concept was the collaboration with a student who was enrolled in the same study programme, had a good understanding of mathematics and who had experience in an engineering work environment, thus knowing the work place of engineers quite well.

Other important factors were the close cooperation between the lecturer and the student, the demand for a deep understanding of both the application and the mathematical content (on the part of both the student and the lecturer), the use of the modelling cycle in the preparation of the material and the attention to matching notations and a good fit with the lecture material.

A challenge even before the start of the project was to find a student with the mathematical and engineering background willing to develop teaching material and to present it. During the collaboration, it was challenging to develop mutual understanding, in particular to match the lecturer's 'mathematics language' and the student's 'engineering language'.

4.2 The evaluation: Summary, limitations and research perspectives

The results of the survey show that the examples were perceived by the students as very authentic and that they very much appreciated that a student had presented them. The example number 5 that took the most time to prepare, had the most mathematical input and took the longest to be presented was judged the most authentic. In addition, most of the examples were received as very motivating and applicable. Only the sixth examples was rated worse in these two criteria. A reason for this could be that the mathematical topic used in this example (hypothesis testing) is quite difficult for students.

Limitations of the evaluation result from the small size of the sample. Either the concept should be tested and evaluated in courses with a larger audience in order to gain better quantitative insight into the students' evaluation of the examples and the role of the student giving the presentation, or, with a similarily small sample as here, interviews should be conducted in order to obtain qualitative results.

In addition to a better methodological implementation of the study, it would be interesting to investigate if there is a difference in the evaluation of the examples when they are not presented by a student, whether the concept changes the students' motivation in the long term as a result of the intervention, and which value the tutor found in the intervention.

4.3 Recommendations

The concept can be transferred both to beginners' math lectures and to any other subject where connections between different disciplines can be created. The new material can be used beyond the specific implementation in one semester with a particular student, as the quality is good and the lecturer understands the application well after the implementation.

A challenging step is to find a student from a higher semester, ideally with work experience and good grades in the subject. We recommend asking students who have previously taken the subject.

ABSTRACT

Professional engineering work occurs in dynamic, complex contexts that require engineers to leverage various skills beyond their technical competencies to work productively with different stakeholders. Problem-solving is not merely a technical endeavor; educators and practitioners have long realized the synergistic connection between technical proficiency and complex personal and interpersonal competencies, such as critical thinking and communication skills.

Since the 1990s, the topic of transversal or professional skills has been a common thread in engineering education literature. Engineering accreditation bodies such as Accreditation Board for Engineering Technology (ABET) and Commission des titres d'ingénieur (CTI), and engineering curriculum models such as the conceive-design-implement-operate (CDIO) have highlighted the importance of various transversal skills in professional engineering work. Today, there is a general agreement among engineering educators and scholars about the value and benefits of transversal skills. What is less clear is which specific skills should be considered transversal and how those skills can be categorized and defined. Efforts in settling these issues ultimately help engineering programs to have a clearer picture of which skills are (and are not) well integrated and assessed in their curricula.

This concept paper discusses a framework for categorizing transversal skills. We build on the relevant literature and the ongoing educational practices in prioritizing transversal skills at the École polytechnique fédérale de Lausanne (EPFL) to bring visibility to essential graduate skills and attributes, including those that are often underemphasized.

1. INTRODUCTION

Desired outcomes in engineering curricula for students' learning are often categorized into two groups: technical and transversal or professional competencies (we use the terms interchangeably in this paper). Broadly speaking, the technical competencies are among widely accepted desired attributes for engineering students. Accreditation bodies such as the Accreditation Board for Engineering Technology (ABET) and Commission des titres d'ingénieur (CTI), and popular models in engineering education, for instance the conceive-design-implement-operate (CDIO) approach, point out to outcomes that demonstrate more or less similar attributes regarding technical competencies, among them, emphasis on scientific and technical knowledge and ability to apply knowledge to solve engineering problems, or ability to plan and carry out experiments (ABET, 2021; Crawley et al. 2014; CTI, 2017). Despite engineering educators' familiarity with these competencies, defining specific outcomes, teaching strategies, and ways to assess the outcomes and their respective competencies are the focus of ongoing work in the scholarship of teaching and learning.

Our focus in this paper is on the second group of competencies, transversal skills, which has been a matter of debate. Since the 1990s, the topic of transversal skills has become a common thread in engineering education literature. The emphasis on these competencies in particular was motivated by reports calling for broader education and the observation of inadequate preparation of engineering graduates for work settings (Crawley et al. 2014; Shuman et al. 2005). In the U.S., for example, documentation of misalignment between the level of preparation of undergraduate students in attributes necessary for professional settings, such as communication and teamwork, led to the major changes in ABET requirements on students' outcomes, ABET Engineering Criteria 2000 (Prados et al. 2005; Shuman et al. 2005). Today, engineering programs are more intentional to incorporate various professional skills and competencies, often motivated by changes in student learning outcomes identified by accreditation bodies. Nevertheless, while there has been increasing attention to the importance of professional competencies within engineering education community, the lack of consensus about the breadth and depth of competencies addressed in educational settings as well as ambiguities in guidelines specified by accreditation bodies, for instance on ethics (Junaid et al. 2021), created a complex picture for building a common ground centered around transversal knowledge, skills, and attitudes.

Considering the diversity of the competencies and the complexities in defining them, we believe developing a framework for categorizing is critical for educators to have a clearer picture of which skills are (and are not) well-integrated and assessed in their curricula. This study was motivated by the recent strategic efforts and ongoing educational practices around transversal skills at the École polytechnique fédérale de Lausanne (EPFL) and aims to develop a framework that can bring visibility to essential graduate skills and attributes. This will also help to refine emerging approaches to teaching transversal skills, including the use of tangibles.

2. EFFORTS IN PRIORITIZING TRANSVERSAL SKILLS AT EPFL

With the recognition of the primacy of transversal skills for students, diverse educational initiatives have prioritized different skills in the curricula at EPFL. Notably, teachers are asked to select specific transversal skill learning objectives, for each course, from a list of 32 skills— adopted since 2013. These skills are categorized into five broad themes: (1) communicate, process, manage, and generate information; (2) personal effectiveness; (3) project management; (4) working in the society; and (5) working in groups and organizations; for more details see Kovacs et al. (2020). Some skills point out general statements that focus on behavior or performance, for instance, “write a scientific or technical report” or “collect data”; others emphasize specific processes, for instance, “communicate effectively with professionals from other disciplines”.

As thinking and experience within the EPFL community around transversal skills for engineering students evolved, a working group was set up in 2021 to review our current needs, objectives and resources in order to coordinate the teaching of transversal skills at different educational levels. The working group includes professors and members from several units, among them the Teaching Support Center (CAPE), the Language Center, and the representatives of the Student Association, and is led by Associate Vice President for Student Affairs (Hess, 2021). The working group envisions creating possibilities for EPFL students to develop the necessary skills for highly competent architects, scientists, and engineers.

In the first phase of their work, the group identified a list of competencies and the subjects that address those competencies, as well as a list of high-priority skills that should be taught at different educational levels (BA, MA, and PhD). Table 1 presents the list of transversal skills identified for bachelor students concerning five major themes: communication, interpersonal, intrapersonal, organizational, and enterprise. The group arrived at a consensus on some particular high-priority skills for bachelor level; for instance, giving oral presentation (communication skills), collaborating (interpersonal skills), and learning from feedback (intrapersonal skills).

In addition to the efforts described, there has been a growing interest and commitment to doing research and professional development with respect to transversal skills at EPFL. One such recent initiative is the 3T Play[1] (transversal skills, technical universities, tangible objects) that aims to design interventions for teaching transversal skills using tangibles. The project is a collaborative effort between several units at EPFL, including the College of Management of Technology (CdM), the Center for Learning Sciences (LEARN), CAPE, and the Discovery Learning Program (DLP). The current study is an initial attempt to converge the ongoing efforts and create a common framework for designing the 3T Play Project.

Table 1. List of transversal skills at bachelor level identified by the working group at EPFL

Broader categories	**Skills**
Communication	- Giving oral presentations - Writing reports - Listening actively - Mastering at least two foreign languages
Interpersonal	- Collaborating - Taking the perspective of others - Managing conflict
Intrapersonal	- Learning from feedback - Regulating emotion - Evaluating oneself - Planning learning goals - Managing priorities
Organizational	- Setting objectives - Managing time - Choosing appropriate methodology
Enterprise	- Working with other professionals - Determining relevant societal issues - Applying relevant ethical, legal, and safety goals

3. TOWARDS AN ORGANIZING FRAMEWORK

There are some similarities among different lists of transversal skills proposed by accreditation bodies and/or adopted by various institutions. For example, they often highlight various communication and collaboration skills, which are widely recognized and frequently addressed in engineering education (Cruz et al. 2020). Such recognition implies that there is more emphasis on integrating these competencies. Importantly, there is less conceptual ambiguity in defining such skills and establishing evidence for their improvement. The differences, though, resonate with the diversity of attributes that have been addressed in the engineering education literature (Crawley et al. 2014; Passow and Passow, 2017; Rosén et al. 2019). They further speak to a degree of specificity in defining particular skills and competencies.

We picture a categorization on the basis of specific competencies rather than domains of competencies. That is defining domains of competencies, such as interpersonal skills, may in fact add another layer of complexity in developing a framework. Further, there are interrelationships among various competencies and as such, creating explicit boundaries around different groups of skills is not consistent with the reality of day-to-day practice, which is particularly problematic when considering interactions between personal and interpersonal knowledge, skills, and attitudes. For example, CDIO syllabus v.2 (Crawley et al. 2014) distinguishes between personal and professional attributes and interpersonal skills. The former includes categories such as “systems thinking” and “ethics, equity, and other responsibilities” and the latter includes “teamwork” and “communications”. While it would be perfectly reasonable to prioritize specific skills, within each category, in an educational setting, downplaying the importance of interactions between the two reproduces the predominant practices in engineering education that lacks consideration of broader social factors.

In addition, a useful framework of transversal skills should foreshadow criteria and indicators one could consider in addressing each group of competencies. There might be a diversity of interpretations about the specificity of particular skills; some point towards general descriptions and criteria for addressing the competencies, while others get to a more detailed description of each group of competencies. Moving towards a detailed description of skills and prescribing the attributes may, in fact, simplify the very nature of transversal skills and limit faculty members in operationalizing the skills in their classrooms. The goal is not to copy specific outcomes, as it is the case with learning outcomes identified by accreditation bodies. Here, it is important to distinguish between competencies and the primary emphasis of educational activities. One teacher may prioritize and assess critical thinking for a given intervention, while another may focus on collaboration and teamwork.

Now, the question is what skills and competencies should be considered in building a framework. Our goal is not to provide an exhaustive list of skills but to prioritize an initial list of broader themes and emphasize the interactions among them, which can help us identify specific criteria and indicators. There is a consensus about the importance of collaboration and communication skills for professional engineers. The abilities to effectively work and interact with stakeholders and individuals with different backgrounds are often integrated into engineering curricula. In addition, in agreement with theoretical and empirical works around transversal skills, we posit any set of proposed skills should prioritize fostering students' moral values. We use ethical reasoning as an umbrella term to describe skills for moral deliberation process, among them, considering and evaluating different perspectives, and insight into intended and unintended consequences of courses of action.

The last two broad categories we propose are thinking and management skills. By thinking skills, we mean reflective ways, cognitive, emotional, and social, by which we approach and engage in problem-solving and the process of inquiry. It emphasizes the skills needed to deal with ambiguity and uncertainty, which is the very nature of real-world problems. While different frameworks specifically address indicators of thinking skills, for instance, critical thinking, these competencies have remained underemphasized in engineering education. Not only is there less clarity about these skills, conceptually, but they are often treated fundamentally as problem-solving in ways that reinstate the status quo of technical rationality. Lastly, by management skills, we refer to the ability to organize taskwork or a change process individually and as part of a group.

As we move to spell out broader categories of transversal skills, it gets more clear that specific skills may interact. Considering such dynamics, we propose a different framework to organize various transversal competencies. We envision a more holistic representation of transversal skills considering overlapping relationships between five general themes: thinking skills, ethical reasoning, collaboration (teamwork), communication, and management skills. Readers may imagine a Venn diagram presenting relations between different themes. Such illustration emphasizes five broad themes of transversal skills that have been highlighted as critical graduate attributes for engineering students.

We intentionally avoid treating interpersonal and intrapersonal skills as broader categories to organize professional skills and therefore drawing boundaries between various skills on such a basis. We posit that competencies that are often defined at the individual level, such as critical thinking and ethical reasoning, interact with interpersonal communication and the dynamics of relationships between individuals. While this claim might seem obvious to the readers, its practical implication demands moving beyond the picture of thinkers as merely isolated individuals. Further, the interactions among the various skills, for example the overlap between ethical reasoning and thinking skills, demonstrate how interventions focusing on one may influence another. Treating imagination as the primary constituent of thinking skills and ethical reasoning, for instance, and providing opportunities for students to practice at imagining (Jalali and Matheis, 2017; Jalali et al. 2022) may work to simultaneously develop both. Put differently, the overlap between the themes can also be considered a guide for designing classroom interventions. The description of all reciprocal interactions is beyond the scope of this concept paper.

4. DISCUSSION AND CONCLUSION

This work-in-progress paper presented an initial work towards developing an organizing framework for transversal skills. While technical and transversal skills are important for professional engineering practice, transversal skills are often not adequately taught and learned (Graham, 2018; Kovacs et al. 2020; Sarrade et al. 2021). Kovacs et al.'s review identified that while some transversal skills are addressed relatively frequently, others are rarely addressed (Kovacs et al. 2020).

Our future work considers exploring the categories of transversal skills developed in other technical universities and next to the two lists developed at EPFL. In addition, we intend to examine the state-of-the-art in the categorization of transversal skills to clarify the discourse on differences among skills and categorizations. The outcomes help us reflect further and refine the initial framework of transversal skills proposed in this paper and define specific indicators. Further, there is an empirical component in working with teachers once we put forward the framework. It is essential to explore how it can be used in different settings and how its specificities, such as relationships between skills, are translated into practice.

The model proposed in this paper is an attempt to simplify the complexities around transversal skills and facilitate communication with a range of stakeholders, primarily engineering instructors. Our goal is ultimately to develop critical indicators for each theme, informed by the literature, and clarify the key synergies or overlaps between different groups of skills, which will improve understanding of what each attribute/competency is and what it entails. It also provides a springboard for successfully implementing these competencies in practice.

Recognizing the need to converge different approaches at EPFL into a coherent list for transversal skills, we aim to reduce the ambiguities around transversal skills and bring more visibility to these essential skills for faculty and students. We hope that the current study serves as an invitation to discuss how we can better communicate, further develop and implement a somewhat different model of transversal skills in our institution and potentially beyond.

ACKNOWLEDGMENTS

We would like to thank the anonymous reviewers for their review and helpful comments. Special thanks to Natascia Petringa for provindg feedback on the paper.

Keywords: European University Alliance, multilingualism, multiculturalism, global competence, engineering education, Internationalisation, English as a lingua franca

ABSTRACT

With the ultimate aim of finding ways to improve the systematic integration of linguistic and cultural competencies in engineering education, this paper addresses how culture and language competency education is discussed within a technical European University Alliance and how this discourse is translated – or not – into educational initiatives and activities. By doing this, we aim to put focus on the gap between a certain European Union ideology – "united in diversity" – which is at the very heart of the EU project, and the everyday practices at technical universities, where linguistic and cultural competency education are often considered as marginal activities or elective add-ons compared to the hard core of technical subjects.

The paper is based on European University Alliance documents and the observations and experiences made within one alliance's working group on cultural and linguistic training during 2020-2022. We suggest that the gap between the

rhetoric of multilingualism and multiculturalism and the reality of teaching and learning within the alliance has at least two sources: a tendency to engage in magical thinking where global competence develops “spontaneously” in international settings and a tendency to avoid addressing difficult questions, e.g., what multilingualism and multiculturalism actually mean in contemporary engineering education. This paper will provide some of the crucial questions that need addressing if we want to move beyond the empty rhetoric, as well as some practical suggestions for a systematic integration of cultural and linguistic competency education into engineering education.

1 INTRODUCTION

The European University alliances, exemplified in this paper by one of the first of its kind with an engineering profile, have the potential to systematically strengthen the integration of linguistic and cultural competencies in education, to the benefit of students, staff, educators and society at large. While the ambitious European University initiative in itself can be said to be in line with general trends of internationalisation in higher education [1] as well as older calls for comprehensive internationalisation [2], we would argue that the integrative training of global competence is – or at least should be – at the very heart of this educational endeavour, and also that this has a special relevance and importance for engineering education.

When the European Commission in 2019 announced the first selection of 17 European University alliances, representing more than 100 higher education institutions from all over Europe, this represented a qualitative change to the European educational area. The following year, the second call resulted in a total of 41 European University alliances, representing more than 280 institutions from 27 member states, and with further partner institutions from Iceland, Norway, Serbia, Turkey and the United Kingdom – the aim of the initiative was as ambitious as its scale .On a rather obvious level, the initiative aimed at strengthening the European Education Area, increasing the European Union’s international competitiveness and capacity to deliver the education and research needed to meet present and future economic, societal and environmental challenges. Equally important, however, and in line with earlier EU initiatives for the integration of European higher education, was the initiative’s role in the ideological work to promote official “European values” and strengthen the idea of the European identity – “united in diversity”, as the motto of the European Union has been since 2000.

When answering the call of the European Union, the motivation of individual universities to join and the perceived importance of the initiative and of its different aspects most likely varied from one alliance to another. Motivation and perceptions probably also varied between the different institutions within the alliances, and even within the individual institutions. As the motivation to work as part of a European University varies, so do the challenges involved, and the opportunities.

Engineering education has a special position in the educational landscape as a self-designated producer of "problem-solvers". It works at the interface between basic research and applied research and development, which is increasingly concerned with the grand challenges of our time, working towards a sustainable future while trying to balance the not necessarily aligned needs of the many stakeholders involved. Engineering graduates are increasingly expected, both by society and by industry, to possess the competence needed to effectively and appropriately communicate and work in environments characterised by cultural and social diversity, i.e., intercultural or global competence [3, 4]. The call for more socially skilled graduates is, however, a challenge for engineering universities, staffed foremostly by academics hired on the merits of often highly specialised technical knowledge, working in fields where ever more knowledge and specialised skills are seen as indispensable to already crammed curricula.

For educational leaders at these universities, internationalisation seems to be at least a partial answer to the question of how students can learn to work and communicate among people with backgrounds different from their own. Not only does internationalisation tend to help with the ubiquitous ranking lists, but also seems to be the answer to how students can acquire core competencies of a cultural and linguistic nature through international mobility. Furthermore, the scope of the European University alliances, like the other Erasmus programmes, also includes the mobility of teachers and staff. Given the challenge of many engineering universities to make room for global competence education or for languages beyond the local language and English, the European University alliance initiative holds much potential. This is true also of the alliance studied in this paper, Unite! – University Network for Innovation, Technology and Engineering, which we for the purpose of brevity will refer to as "the Alliance" [5].

The Alliance was created in 2019 between seven universities most of which had a long history of collaboration within the CLUSTER network. The official aim was to "be a model for a European University of innovation, technology and engineering addressing the Sustainable Development Goals through the twin digital and green transition." The member universities were located in Germany, Finland, France, Sweden, Italy, Portugal, and Spain.

In this paper, based on participant observation and document analysis, we explore how culture and language competency education has been discussed within the Alliance, and how this discourse has been translated – or not – into educational initiatives and activities. We will identify a gap between the Alliance's official rhetoric of multilingualism and multiculturalism, and the preparedness to see this translated into systematic and effective educational activities that could help individuals – students, staff and educators – acquire the competencies needed to work effectively with the cultural and linguistic diversity of our globalised world.

We argue that this gap has two likely sources. The first being the seemingly fact-resistant belief that global competence will spontaneously develop in an international work- or study environment. A second probable source is an avoidance strategy when it comes to addressing difficult questions such as what multilingualism and multiculturalism actually mean, or could mean, in engineering education today.

Finally, this paper outlines what we see as some crucial issues to address in order to move beyond the empty rhetoric. It also provides some practical suggestions to systematically integrate global and linguistic competency into a European University alliance such as the one discussed here.

2 METHODOLOGY

The data in this study come from multiple sources, both from official documents related to the EU project call and from observation notes and experiences of the members of the Multilingual and Multicultural Training Centre (henceforth M&M). The consulted texts include three official documents from three phases of the project: the first phase project proposal (2018), the progress report (2019), and the project proposal for the second phase of the project (2022). These documents serve similar purposes, addressed as they are to the grant giving organisation within the EU, and we believe that they can serve as good illustrations of how the concepts of multilingualism and multiculturalism have been framed, presented, and mobilised within the Alliance.

These documents are analysed in two stages: first a keyword search, then a text analysis to better understand how the keywords are used within the documents. In the first stage, a keyword search was performed across the three documents to track the evolution of the use of terms related to language, culture, diversity, internationalisation, skills and the like. In line with Dafouz's [6] study on another European University alliance, a keyword search related to the national languages of the members of the Alliance and English was also carried out. Table 1 includes a complete list of keywords for each document, the number of raw instances in each document, as well as the average times they appear per 1000 words in order to provide a means of comparison. Secondly, in order to investigate how the keywords were used, the passages of the documents including the keywords were analysed. This allowed us to understand the terms within the context of the document.

In addition to observing how the topics of multilingualism and multiculturalism are portrayed in the official documents for the EU grant, we also explore this question internally, based on the experience of members of the M&M-team working within the Alliance. An explanation of the group's goals and consequent experiences within the Alliance are developed in the next section of the paper.

3 FINDINGS

3.1 The Alliance's proposals

The official documentation reveals an evolution in how matters related to multilingualism and multiculturalism in the Alliance are presented within the context of the EU call.

Regarding the keywords *multilingual(ism)* and *multicultural(ism)*, we can clearly see their importance to the Alliance as there is a dedicated working group on this topic that is called the Multilingual and Multicultural Training Centre (M&M). Beyond this group, these terms have permeated the Alliance's communication, with an increase of the terms *multilingual(ism)* and, to a lesser extent, *multicultural(ism)* since the first proposal.

From the beginning, being multilingual and multicultural have been defined as "key to our mission to shape the mindsets of a new generation of European and global citizens and to educate the graduates that contribute to sustainable global Development" (1st phase project proposal, p. 158). Learning a language of one of the partner universities is seen as providing "better access to another European culture, increasing mutual cultural knowledge and understanding and helping students be part of the daily life of their host country" (1st phase project proposal, p. 109). Overall, this promotes "employability across Europe" (1st phase project proposal, p. 8, and 2nd phase project proposal, p. 38) Thereby, multilingualism and multiculturalism are seen to open doors and increase understanding, simply by being present. To acquire these competences, the Alliance intends to provide language courses and create opportunities for mobility and interaction. This communication around the benefits of immersing oneself into a multilingual and multicultural environment to increase linguistic and global competencies continues to be present in the 2nd phase project proposal.

Likewise, d*iversity* and *diversity and inclusion* are also terms that increased significantly throughout the project. A working group separate from M&M is devoted to "diversity, inclusion and well-being", and they have created a "Charter on Diversity and Inclusion". Diversity is understood to promote multilingualism, and as such, is integrated throughout the University Alliance: "Diversity, inclusion and well-being as well as transversal themes with clear goals and activities to promote multilingualism in our education are addressed in various work packages" (2nd phase project proposal, p. 5). Interestingly, the buzzword *cultural diversity* has been all but forgotten since the 1st phase project proposal, and is no longer highlighted as it once was earlier in the project. Yet, it is still referenced indirectly in the text: "The multicultural and inclusive alliance also promotes the diversity and cultural heritage of its countries and regions, thus also supporting visibility of the different institutions in it" (2nd phase project proposal, p. 36).

Also, the use of the term *English*, while almost forgotten in the progress report (2021), saw substantial increase in the second phase project proposal (2022).

English has always been recognized as the official working language of the University Alliance members. At the same time, the national or regional languages of the partner universities are mentioned less often. In fact, the specific languages are mentioned only once in the 2nd phase project proposal. In addition, the keyword *language* is used less in the 2nd project call, probably because the term *multilingual*(ism) is privileged.

Lastly, we also note that while *European* – unsurprisingly – has been used consistently throughout all documents, the use of the terms *international* and *global* have declined in comparison. The focus is placed on promoting European identity and common European values and “strengthening European Identity through Education and Culture” (1st phase project proposal, p. 6). By the 2nd phase project proposal, this has been clarified as “actively contribut[ing] to European citizenship as well as to European attractiveness, resilience and competitiveness on a global scale” (2nd phase project proposal, p. 4).

3.2 The Multilingual and Multicultural Training Centre (M&M)

During its first phase, the Alliance was organised into ten “task forces”. Matters related to language and culture were delegated to a sub-task force known as the Multilingual and Multicultural Training Centre (in everyday Alliance communications and henceforth in this paper referred to as “M&M”), which was associated as part of the task force in charge of “student services”. This positioning of language and culture issues, which caused some internal complaints, likely mirrored the non-academic position of some, but not all, of the language centres at the partner universities. Thus, already from this organisational design there appeared to be a mismatch – intentional or not – between the rather peripheral position of language and culture matters in the overall Alliance structure, and the centrality of the concepts of multiculturalism and multilingualism in the words and spirit of the proposal.

The M&M working group was set up from the start to be responsible for developing and supporting language and global competence offers inside the Alliance. The language training offer includes both language courses (i.e. structured, formal learning) and language tandems (i.e. informal, largely student-led learning), with a view to equipping engineering students for an increasingly internationalised, multilingual and multicultural job market and academic environment.

The M&M team is made up of language teachers, researchers and administrative staff from the seven member universities, with varying degrees of professional experience and training. The members of M&M are themselves multicultural and multilingual due to their personal and educational histories, and include a range of extra-European family backgrounds, expertise and experiences. As in the rest of the Alliance, the working language in M&M is English. A possibly unique feature of this group within the context of the Alliance is that English is also the first language of several task force members. With these professional, cultural and linguistic credentials, the M&M team seem ideally equipped to tackle the complex task of developing a multilingual and multicultural offer inside the Alliance.

The team took shape over the year 2019-2020, adapting quickly to the conditions imposed by the COVID-19 pandemic, and soon established a work approach based on weekly virtual meetings, with only some work done outside meetings. The points on the agenda are dealt with as a whole group or in smaller groups that report back to the team at the end of the meeting. The meetings typically develop through frank and open discussion of the issues, and virtual collaboration tools such as Google Docs are frequently used to produce documents and materials.

Although the team was mostly able to keep to the agreed deadlines, quite a bit of time was needed in the first year to become familiar with and understand the different work modes and local conditions and opportunities of the various universities represented by the team members. Engaging though also complex discussions often took place as a result of quite varying perspectives on the issues at hand. The M&M team very early on produced a joint list of language and culture courses that each partner university was willing to share with the Alliance. Slightly more slowly, the language tandem project was structured and defined, and a variety of global competence initiatives were outlined, including a course in global competence and a series of videos produced by students to present their local cultures to students from other partner universities.

It soon became clear that organisational differences between the partner universities, in terms of academic calendars, administrative processes and the structures of the chain of command, constituted a major challenge to the effective deployment of an M&M language and global competence offer. In the spring of 2022, a small offer of virtual language courses and activities was finally launched, covering the eight Alliance languages as well as English, intercultural competence and including one serious game as an Open Educational Resources (OER). This virtual offer represents only a small sampling of the full language and global competence training offer available at the different partner universities. Nonetheless, it was considered sufficiently varied to be attractive and of use to the Alliance student community, and, given the organisational complexity of providing even this relatively small offer, it seemed a good enough start. To date, however, the uptake of these courses has been quite limited, and enrolments have been fraught with administrative difficulties. A more precise picture of the possible reasons for the scant interest in the M&M course offer is yet to be gained, but it appears that effectively promoting multilingualism and multiculturalism in the Alliance is far more complex than what is suggested by the confidently positive wording of the project proposals and report.

Beyond the organisational challenges outlined above, what ultimately stymied the M&M team would seem to be the fundamental contradiction between the theory and the practice of the Alliance with regard to multilingualism and multiculturality. On the one hand the project proposals apparently support and encourage multilingualism and multiculturalism, to judge from the pervasive use of the terms throughout the documents, as shown in the Findings of this paper. The very fact that a specific task force has been assigned the responsibility for producing a language and culture offer inside the Alliance is a strong indication of intent. On the other hand, however, training in languages and global competence is glaringly absent from joint programmes and content course offers, and even on paper only 3 ECTS are reserved for language learning activities in any given joint programme or content course, obviously not enough to enable any teaching and learning of real substance. Clearly, a way to bridge the gap between the theory (e.g. the proposal rhetoric) and practice (e.g. the material inclusion of effective multilingualism and multiculturalism in the Alliance) needs to be found. Drawing up an alliance policy on language and global competence seems strongly advisable, as is discussed in the next section.

A clarification of the terms used should also be highly useful. It could be the case that “multilingualism” and “multiculturalism” may not be the most appropriate terms for the purposes of materially enacting the endeavours of the European University initiative. Using EU terminology, both terms simply describe the presence of different languages and cultures within a community [7], i.e. the de facto situation when more than two universities from different EU countries interact. It might be the case that the terms “plurilingualism” and “pluriculturalism” are more appropriate for the initiative, as these terms indicate the ability to use a repertoire of diverse linguistic and cultural resources to meet communication needs or interact with people from other backgrounds and contexts, and enrich that repertoire while doing so [7].

Even within M&M a mix of concepts has been used, likely reflecting the different backgrounds and expertise of the individuals involved. Early on, the group decided to do away with ideas found in the proposal and other texts that were seen as building on notions of cultural essentialism, especially in terms of national cultural stereotypes. Instead, the team preferred working with the non-essentialist notion of “small cultures” and proposed as a slogan for its work “the challenge of diversity”. The concept of global competence was also introduced at an early stage as being particularly fitting to an engineering endeavour working in the spirit of the European Union – united in diversity – while not forgetting the importance of connecting intercultural and plurilingual competence to the goal of “act[ing] for collective well-being and sustainable development” in the words used in the OECD definition of global competence [8].

Despite presenting these thoughts at several transnational Alliance meetings – so called Dialogues – and at full task force meetings, there is still a lack of formalised alliance-wide definitions put on print, and it remains highly unclear to what extent and in which way the understanding of central notions like these have been understood by other task forces in the Alliance. This lack of ready results, be it in educational activities or in the mindset of other colleagues working in the Alliance, was from time to time a source of great frustration within the M&M team.

Educational organisations, while sometimes able to respond very quickly to political steering and societal needs, are well known to find change difficult [9], and the frustration that was from time to time felt in the M&M team was most likely primarily related to the everyday red tape and inertia typical of higher education institutions general. In the case at hand, these standard difficulties were compounded due to the need to bridge the administrative gaps between different institutions in an alliance that subscribed to a model of simultaneous top-down and bottom-up agency.

4 CONCLUSION

In conclusion, we see a major gap between the idea of multiculturalism and multilingualism, despite the centrality of the notions in the original proposal, and the systematic integration of teaching aimed at fostering globally competent (or plurilingual/interculturally competent) individuals. As mentioned above, we see two main reasons for this. On the one hand, the “magical thinking” often found in internationalisation initiatives, where the mere fact that people in a group have different backgrounds should somehow spontaneously make them acquire these competencies, without the need for scaffolding and institutional support. On the other hand, the more or less tacit understanding that “English is enough”.

The tendency to engage in magical thinking as described here is as prevalent as it has scientifically been proven faulty, and should rightly be questioned, confronted and dealt with [10, 11]. The idea that English is enough is a more complex one. It should be noted here that this idea is not officially acknowledged but clearly discernible from the fact that the Alliance exclusively uses English as its *lingua franca,* and its learning offers are only provided in English (with the few virtual language courses described above as the sole exception to the rule). That English is enough is also mirrored in the language-related trends seen in the three documents analysed above. The issue of teaching, cooperating and studying using English is not a trivial matter for participants who primarily have English as their second (or third) language. As the Bologna process has set the stage of European education, it is also increasingly feasible for European students to go through higher education completely relying on a combination of their institution’s first language and English. For engineers, this may appear reasonable, seeing as their primary labour market would seem to be either local – using the local language – or in international organisations where English as a rule is the common working language. So is this a problem at all? After all, most of our students, teachers and staff would do well to become even better at using English. We would argue that it is a problem, primarily for three reasons:

- By not actively encouraging language learning beyond the local and national language through the integration in official curricula, the Alliance fails to work towards the EU ambition of all citizens being proficient in their national language plus two other EU languages.
- By ensuring only the language skills needed to complete their studies, the Alliance falls short of realising its potential for fostering true European citizens that can become part and parcel of the principle of free labour mobility. English may be enough to conduct official work duties abroad, but the EU ambition is to go beyond the creation of an “intra-European expat cohort” living in cultural bubbles isolated from the local society.

- The ability to understand the viewpoints of others is a vital part of global competence. Even as we agree that global competence training does not per se presuppose more than one lingua franca, the traditional role of foreign languages as the lenses through which we can experience the world from different angles is by no means outdated. On the contrary, the rise of world English is both an enabler of communication and an enabler of miscommunication, especially considering that this international form of English is not cultureless, but is influenced by the sociopragmatic assumptions and conversational expectations of the speaker [12]. Therefore, English-only education that lacks a focus on the cultural implications of its speakers contributes little or nothing to develop the capacity to function well in linguistically heterogeneous situations and organisations.

European University alliances run a clear risk of succumbing to an overly Eurocentric perspective when it comes to issues of language and culture, and we would like to critique this from the perspective of global citizenship, a concept embedded in the United Nations' Sustainable Development Goals. For the time being, we can only regret, and take part of the responsibility for, the failure of the Alliance in formulating any strong vision of how multiculturalism and multilingualism could be used as a resource for effective global competence education in the context of the Alliance, and to commit to systematically strive to achieve that goal. In combination with efforts to strengthen activities related to internationalisation at home, we believe the potential benefits of the Alliance go well beyond the activities of the Alliance itself, making a failure to act even more lamentable.

5 FINAL REMARKS

We hope that in its next phase the Alliance will manage to rise to the challenge of diversity, embrace a vision of what global and plurilingual competence could mean within the context of the European University, and commit to realising this vision. Should it fail to do so, it will not be for lack of ideas. Between the literature and the expertise in the M&M team, the list of activities and initiatives could easily be made very long. Some examples would be to tweak existing courses and learning activities to ensure they all include a global competence dimension; to initiate multilingual projects in line with higher education multidisciplinary project work; to provide earlier opportunities for mobility in order to increase language learning motivation; to enable bilingual courses; to ensure that students have room in their programmes to study language and culture [13, 14, 15].

First and foremost, however, the Alliance must make up its mind about how to view issues of multiculturalism and multilingualism, taking seriously the fact that global or intercultural competence, and plurilingualism, is not something that comes to people by magic just by being in diverse company, and that not acting is wasting a chance to contribute substantially to the future development of European engineering education.

Thus, the first point on the agenda during the second phase of the Alliance should be to draft an Alliance Policy for global competence, multilingualism and multiculturalism, defining key concepts, laying down the Alliance's overarching objectives and standards in these areas for faculty, staff and students, as well as for joint endeavours, and the means to reach these.

ABSTRACT

The Positive Start Project is a new initiative that is in the process of providing a series of workshops and events focused on academic wellbeing, career development and positive mental health within a large faculty of engineering and applied science in the UK. Aimed at building a scholarly and sustainable research and teaching community of early career academics (ECAs), the project has arisen out of a need to provide high quality professional development activities and frameworks for the ECA community whilst also combatting social and academic isolation left over from the two-year long period of 'lockdown'.

Adopting an Action Research Approach this paper addresses a little considered topic in academic circles, the need to nurture positive wellbeing amongst the Engineering Education academic community. Describing proposed plans for how the Positive Start Project will be developed, disseminated, and reviewed, attention is paid to how 'wellbeing' will be benchmarked at the beginning of the project. Following this a brief overview of some of the planned support and development activities is given whilst the conclusion reiterates the need for a positive and proactive approach to academic wellbeing whilst also noting why Early Career Academics are an important demographic group within our Engineering Education community.

1. INTRODUCTION

Set within one of the UK's largest applied Engineering Education Faculties, WMG employs almost 800 academic and professional support staff. In addition to this, it is home to around 350 postgraduate researchers and over 3,000 undergraduate and postgraduate students studying a range of different engineering, applied science and management disciplines. Tasked with rebuilding the academic community after two years of remote and hybrid working, the Positive Start Project aims to develop a unique Community of Practice for our Early Career Academics[2] [ECAs]. Starting with a two-day long professional development workshop in which the focus will be on colleagues' strengths and attributes (using the Clifton Strengths Tool[1])a fully licenced and fully experienced Clifton Strength Coach / Consultant has been employed to work alongside the academic team leading the project. Following this a series of 'live' face-to-face training workshops and upskilling events will be held alongside peer mentoring opportunities and coaching sessions. Underpinned and evidenced by an Action Research approach this short paper provides an insight into how the Positive Start Project will make a significant impact to the academic culture of WMG by targeting our large Early Career Academic (ECA) community.

[2] Early Career Academics (ECAs): *For the context of this project, the term ECAs refers to the following: PhD students: Colleagues in their first academic post, who have been employed five years or less as an academic, including those on research only, research & teaching or teaching only contracts: Colleagues within 5 years of beginning an academic career (this includes graduates as well as more senior colleagues who have entered academia after a career in industry); Colleagues who have worked in academia for some time but who have changed focus within the last five years (for example, colleagues whose whole career has been research-focused who have within the last five years changed to a teaching contract and colleagues who have previously been employed on a teaching contract who have, within the last five years, changed to a research or research / teaching contract).*

2. BACKGROUND & CONTEXT

One of WMG's key strengths within the University of Warwick is found in its longstanding links with industry. With a leading international reputation for cross-sectoral collaboration and cooperation, WMG has an established record of driving engineering innovation through cutting-edge research. At the same time, WMG's teaching portfolio is built upon a strong emphasis on scholarship and constructive alignment. Colleagues are supported to adopt an applied pedagogy whereby research, learning and teaching, student employability and the needs and expectations of wider society are contemporaneously considered.

Like the majority of academic institutions worldwide, the Covid19 Pandemic has had a marked impact on how WMG operates. Indeed, the past two years have seen a notable change in how the 'day-to-day' operationalisation of learning and teaching is managed and provided. From a teaching perspective there have been a number of changes in the make-up of the academic faculty, with many people leaving the organisation and newer colleagues joining. Many of the new arrivals are Early Career Academics [ECAs] at various stages of their own learning and teaching journey (from Graduate Teaching Assistants to post-doc academics and people new to teaching who are fresh out of employment). A significant number joined the organisation when the curriculum was only offered online, and no one permitted to visit the campus. Joining a large organisation during a global crisis, and then working in enforced isolation, without having an *a priori* relationship within an academic team, it is perhaps not surprising that some newer colleagues, most notably the ECAs have found themselves feeling somewhat isolated.

Yet, as we move towards what is becoming an 'emerging, reformed normality', so the impact of the Pandemic is becomes more evident. One notable issue that is increasingly being reported in the media, is a general increase in mental health problems across the population[2] . Already acknowledged to be a matter of some concern amongst the academic postgraduate research community[3,4], problems with poor mental health are augmented by low levels of individual wellbeing to impair promising academic careers[4,5].

It is in this unique 'reformed normality' that this paper is set. Within WMG itself there is a general recognition across the academic faculty that we need to rebuild and reboot our unique Academic Community of Practice. This is particularly the case for our ECAs, some of whom had limited or no opportunity to get to know their colleagues personally and so are struggling to feel part of an academic community. It is the impact of this 'lockdown gap' that this project will address over the next 12 months.

3. PROJECT OBJECTIVES

The Positive Start Project proactively addresses what is often perceived to be a 'taboo subject' in UK Higher Education, that of *collegial wellbeing.* Starting with a benchmarking survey aimed at gauging wellbeing across the faculty, a series of bespoke workshops and events are being put in place to help rebuild our academic community. To facilitate this the project has a single primary objective:

To provide the means by which WMG's Early Career Academic (ECA) colleagues can become part of a thriving Academic Community of Practice whilst developing their individual transferable professional competencies.

To support this, four sub-objectives have been developed:

- Conduct a detailed and critical literature review about collegial wellbeing in academia with a particular focus on Engineering Education.

- Undertake a benchmarking survey looking at academic wellbeing on which to ground ongoing interventions

- Starting with a number of two-day long 'kick-off' workshops, develop a series of developmental activities and events aimed at supporting the ECA community

- Disseminate knowledge across the university and beyond about how to better support ECAs from a professional development and wellbeing perspective

4. THE KICK-OFF WORKSHOPS

The kick-off workshops will take place over three days, offered in two distinctive themes:

1. **Academic Wellbeing: Balancing Professional 'Health' & Individual 'Wellbeing' (Workshop 1: Days 1 & 2):** *This theme emphasizes the link between academic wellbeing and professional development. Colleagues will be taught how to use tools such as a 'force field' analysis to build up persistence and research stamina*

2. **Academic Apprenticeship: Balancing Research, Teaching and Life (Workshop 2: Day 3):** *This workshop will occur 4 weeks after workshop 1 and will provide ECAs with the tools and strategies needed to move forward as part of a larger academic community of practice.*

In addition to the above, a programme of academic development workshops and events is being put together. This programme will provide colleagues with opportunities to share their experiences of learning and teaching in engineering whilst also providing opportunities for upskilling. Newer Career Academics will be encouraged to present their ideas and also to engage in scholarship; conducting research into their own teaching to identify areas for improvement and development.

5. BUILDING TOMORROW'S ACADEMIC COMMUNITY OF PRACTICE IN ENGINEERING

Whilst the generic benefits of developing an Academic Community of Practice are recorded in the literature[6], this project is distinctive in that it is focused very much on a relatively large single community of early career academics working within an applied Engineering Education setting. In addition to the ‘Kick-Off Workshops’ discussed above, the following activities and interventions will be rolled out of the next 12 months:

1. Peer Mentoring Network: Using an approach developed by two WMG colleagues[7] a Peer Mentoring Programme will be launched through the summer of 2022. It is anticipated that this will provide one-to-one and / or group support for all newer academic colleagues. In addition to the PGR community of 350 individuals, this intervention will be open for newly appointed researchers and teachers to join (those within the first three years of their first academic appointment initially).

2. Professional Development & Teacher Training: The need to train academics to teach has long been acknowledged in the literature[8,9]. Facilitated in partnership with WMG’S Education Innovation Group a series of learning and teaching focused workshops will be offered to all ECAs. Topics covered will vary, starting at a basic level for colleagues joining academia from industry or as graduate teaching assistants, with topics such as ‘An Introduction to Constructive Alignment’. Move advanced workshops will include ‘Curriculum Design’, ‘Developing a Successful MOOC’, and ‘PhD Supervision’. The professional development and teacher training activities will start in the summer of 2022 and continue.

3. Research Methods: WMG currently offers Research Methods training to all PGRs as part of their compulsory year 1 training. The Positive Start Project will expand on this and offer further specialised RM training workshops and events throughout the year open to all ECAs including colleagues who having moved to teaching directly from industry have little or no experience in conducting research.

5.1 Leading by Example: Scholarship in Action

In addition to the professional development focus described above, the Positive Start Project encapsulates an Action Research[10] strand. Adopting a mixed methodological approach, the project will begin with the administration of a survey aimed at gauging general wellbeing amongst the faculty as society begins to move out of the global Pandemic. Adapted from the NHS Staff Survey (2021)[11] the survey begins with a series of demographic and background questions. It is important to note that such questions are for analytical purposes only as all data collected in the survey will be anonymous. Ethical approval has been acquired and steps put in place so that should any sub-group be small enough to risk identifying individuals, the data will be aggregated into a larger classification.

The findings from the benchmarking survey will be used to guide and inform both the Positive Start Project whilst also being disseminated amongst the PGR team to enable future activity planning.

5.2 The Survey Tool: The main themes to be investigated.

In planning the benchmarking survey, a literature review has been conducted to identify the key factors underpinning wellbeing and mental health at work. Seven different themes are to be addressed by the survey:

i. **Number of hours per week spent at work / study:** Whilst occupational resilience is acknowledged to be linked to the ability to be flexible with regards to workload and other employment related demands[12], a small but important corpus of literature focuses on occupational burnout and excessive workload for colleagues working in Higher Education[13,14,15]. Given the focus on early-career academics, the need to gain an insight into the number of hours colleagues spend at work and / or studying is an important factor which will inform future decisions in respect of workload management and work-life balance.

ii. **Sleep:** There exists a considerable body of knowledge about sleep deprivation within younger people amongst university / college students and those in the early part of their (i.e., age 16-30 years)[16,17,18]. Whilst a different, but equally significant corpus of research has examined the impact of sleep deprivation on work performance of people of various ages[19]. In analysing this literature, the link between sleep deprivation, stress, poor work performance and general lower quality of life is evident making this an important variable within the study.

iii. **Exercise & Physical Activity:** Links between poor mental health, stress and a lack of physical activity are widely acknowledged[20,21]. The benchmarking survey will ask colleagues to gauge their level of activity and the nature of their role in terms of physical activity. Given the varied nature of WMG's ECA community this question is particularly relevant. A small handful of colleagues have physically demanding roles conducting primary engineering research, whilst others' time is generally spent conducting desk research. Over the Pandemic teaching has become a somewhat sedentary occupation, mainly taking place online. As we move back towards a more 'usual' pedagogic practice in which students will be taught in classrooms and laboratories the benchmarking survey will look at the physical nature of colleagues roles.

iv. **Individual Perceptions of Physical & Mental Health:** Connected to wellbeing these questions focus on the participants' perceptions of their own health.

v. **Social life / Leisure time:** The relationship between the amount of time spent on leisure or social activities and positive wellbeing and mental health on students and young people in particular has been well-researched[22,23]. In building an academic community of practice, particular amongst the postgraduate research community, the project team are aware of the need to support social activities. The benchmarking survey will look at what colleagues prefer to do outside of the academy.

vi. **Professional Development Activities:** The final quantitative question focuses on the proposed activities planned within the Positive Start Project asking participants to gauge the potential value of each activity. The responses to these questions will be used to guide and inform future activities in WMG.

vii. **Support within the Academy:** Three open questions are asked, one of which focuses on how WMG could better support ECAs professional and academic development. Whilst the second question asks about support for participant's overall wellbeing. The final 'catch all' question is intended to provide participants' with the opportunity to raise any issues pertinent to them.

5.3 Benchmarking Survey: Data Analysis

No identifying data will be collected. The data will be analysed using Qualtrics to produce descriptive statistics. A series of cross-tabulations will be undertaken with a view to gaining insight into any demographic differences in participants' perspectives and experiences. The three open questions will be analysed using an approach based on grounded theory methodologies in which the data will be conceptually analysed using simple and axial coding

5.4 Action Research Qualitative Research.

Following a typical Action Research methodological approach[10], the results of the wellbeing benchmarking survey will be to inform and underpin subsequent academic activities offered under the auspices of the wider project. Following this, the next stage of the research part of the project will be to critically analyse the impact and longer-term outcomes of the planned interventions. This will be undertaken using in-depth qualitative interviews and focus groups which will then be analysed, and the findings used to inform subsequent activities.

6. CONCLUSION

Purposefully designed as a holistic yet multifaceted approach to early academic career support, the Positive Start Project is still in its very early days. The intention in providing a range of opportunities from two-day-long workshops through to smaller professional development activities and workshops is to help the somewhat 'covid beleaguered academic community' to pick itself up and move forward.

In conclusion, the focus on the ECA community is important as newer academics, long expected to simply 'fit in' to the academy, are integral to the successful future of Engineering Education. Left alone to 'sink or swim' for far too long the Positive Start Project will make a significant difference across the faculty; building a cohesive, academic-focused, and supportive community will undoubtedly improve academic wellbeing amongst colleagues which will in-turn, enhance the student experience.

ABSTRACT

This paper discusses the applicability and benefits of self-checking tasks in continuous assessment in an electrical engineering course. The method was implemented in the first-year online graduate course of Advanced Power Electronics. The method uses a two-week cycle, where during the first week a task is accomplished on the topic of that week. The tasks include working with data from

[1] *Corresponding Author*

J. Korhonen

juhamatti.korhonen@lut.fi

doi:10.5821/conference-9788412322262.1219

component datasheets, reading and employing application notes, calculations, and simulations. During the second week, the students self-check their tasks using a rubric provided for them and then turn in a corrected version of the task. To keep the cycle going, during the second week, a new topic is also introduced, and a new task is given. The method was assessed based on a student questionnaire and teacher experiences. The method was new to all students. One of the main findings from the questionnaire was that correcting the original task submission supported student learning more than any other form of teaching on the course. However, there were different interpretations of how this support actually worked. The study also showed that there was significant variation between different types of tasks in how the students assessed the relevance of tasks and their difficulty level. Furthermore, students found that some tasks or their outcomes were more suitable for self-checking than others. This was confirmed by the teacher's insights on the course.

1 INTRODUCTION

The term 'continuous assessment' commonly refers to a practice where students' learning is assessed alongside their entire study process instead of merely at the end of the process. Continuous assessment can take many different forms depending on the nature of assessment tasks, timing of the assessment, formation of the final grade, and many other pedagogical design decisions that the teacher makes. Continuous assessment has been reported to have multiple benefits in various fields of engineering education. Previous studies have found that the use of continuous assessment leads to better grades, higher student satisfaction, a higher passing rate, and improved engagement with overall course activities. These studies were performed in chemical engineering [1], process engineering [2], and civil and mechanical engineering [3]. One of the benefits of continuous assessment compared with the end-of-course exam is that it provides students with information about their learning at the time when they still have a chance to adjust their learning methods, correct some misconceptions, or increase learning. However, the information received by the students relies rather heavily on the nature of the assessment tasks and the resources of the instructor for giving feedback.

Self-checking tasks have gained attention and popularity in engineering education in the past few years. Tasks of this kind have also been called flipped homework [4], self-corrected homework [5], dual-submission-with-reflection homework [6], and a self-evaluation and revision method for homework [7]. Such tasks commonly follow a procedure where the student first submits a solution to a task, then corrects it with the help of materials provided by the instructor, and finally submits the corrected version usually also containing reflection of the corrected mistakes and improved learning. Depending on the method, the instructor grades either both submissions or only the corrected version.

The method has been shown to make students take more ownership of their learning and thus also devote more time to solving the tasks [4], [5]. Students also have less stress about the mistakes in the first submission, leading to more honest attempts and less motivation to rely on solution manuals [8]. With instructor-assessed tasks, there is often a risk that students only pay attention to the grade of the task and do not review the feedback, thereby missing the opportunity to learn from their mistakes [7]. Self-correcting tasks, on the other hand, force the student to face their misunderstandings, thus enhancing their metacognitive skills and learning of the content matter [4], [5], [6], [7], [8].

The instructors also benefit from the self-corrected tasks. Despite the concerns expressed about the effects of continuous evaluation on the instructor workload [9], the users of self-corrected tasks have reported that it does not generate more work for the faculty [4] or even reduces the grading load [6], [8]. Nevertheless, the nature of the grading changes from pointing errors to providing feedback on students' conceptions and learning process, making the assessment process more fulfilling for the instructor [8]. The method also enables the instructor to follow the student understanding (and misunderstandings) of the topic without having to interpret the poorly conducted homework, which gives the instructor more emotional energy to invest in in-depth feedback [6] and the possibility to correct the misconceptions early on, thereby facilitating faster comprehension [7].

Self-checking tasks have been shown to be more effective than the traditional homework model [4]. The method is mostly preferred to the old ways of conducting homework by both the students and the instructors [6], [7]. With clear benefits for student learning and more meaningful use of the instructor's time, the approach appears to be a good choice to pair with continuous assessment practices.

2 DESCRIPTION OF THE METHOD

2.1 Course setting

The method of self-corrected tasks was implemented on a first-year master's level course of Advanced Power Electronics, which takes place during the spring semester. The course was organized for the first time during the academic year of 2020-2021, and it was implemented fully online. When the course was organized for the first time during the 2021 spring semester, continuously assessed weekly tasks were selected for the course. Continuous assessment has been found to be a versatile method, and it can be used with various types of tasks. For the course under scope, the continuous assessment accounted for 50% of the grade, combined with an assignment at the end of the course covering the other 50%.

The spring semester includes 14 teaching weeks, and for 13 of these, a weekly assessed task was given on the topic of that week. Out of the 13 weekly tasks, 11 were simulation tasks with Matlab Simulink. These tasks may require initial calculations or component dimensioning, and the simulation results are used for further analysis. After the weekly task deadline had passed, correct solutions, with at least one implementation method, were given to the students.

Even though a short report was turned in with the calculations and analysis of the simulation results, grading such tasks by the teacher was found burdensome and time-consuming due to the nature of the tasks. The initial calculations and further analysis can be browsed through rather fast, but detecting potential errors in a simulation model would usually require running the simulation in order to find the actual errors. Detailed assessment of the contents of the simulation model and trying to interpret the logic within the simulation is time-consuming, especially when the implementation can be done in various ways.

After the first time the course was organized, it was found that the original implementation was not applicable because of the increased workload for the teacher, and thus, the methodology had to be improved. Regardless of the extensive benefits of continuous assessment, previous studies have also found that the method leads to a significant increase in the workload of the instructors [9].

2.2 Improved method

When the course was organized for the second time in 2022, the approach to overcome the issue of increased workload was to involve the students in the assessment process. A computer-aided assessment process or adaptive homework has been found to decrease the workload of the teacher during the assessment, but may not enhance deeper learning [6]. Moreover, using such tools is not applicable with simulation tasks. Self-checking homework has been proposed previously with positive results [4], [5], [6]. The primary benefits that have been found with the method of self-checking homework are enhanced learning and self-reflecting skills.

Similar to the previous academic year, the weekly topic was accompanied with a task with a deadline by the end of the week. After the deadline for the weekly task, in the second part of the cycle (which overlaps with the topic of the next week), a grading rubric is given to the students. The rubric gives at least one implementation method for the task, and for the majority of the topics, a demonstration video is given to complement the instructions on the grading rubric. The students are instructed to turn in the grade and the corrected task, and the deadline is at the end of the second week. The two exceptions to the cycle used for the method are weeks one (W1) and 14 (W14). For W1, the task was a multiple-choice quiz with automated correction online, and for W14 there was no task, because of a visiting lecture from industry.

The grading of the tasks is split between the initial task and turning-in of the self-corrected task, similar to [6], where the self-assessment accounted for 30% of the grade. With the improved method, all the tasks are graded in the same way. The task that is turned in by the students during the original teaching week is assessed by themselves with a maximum of 8 points during the following week. All the weekly tasks have very different contents, regardless of the emphasis on simulations. For example, the grading is on dimensioning of components, designing circuit topologies, control logic, and analyzing the simulation results. Each week, the students are instructed to turn in a short report with answers to specific questions regarding the results. The corrected task, with the initial calculations file, simulation model, and the short report, are turned in by the end of the second week of the cycle. After the deadline, the corrected task is assessed by the teacher with a maximum of 2 points, leading to 10 points at the maximum per week.

The improved method was built on the tasks that were used during the previous academic year. The tasks were revised slightly based on the student feedback from the past year, but on a larger scale in order to fit the rubric and the 8-point grading system. Therefore, the number of questions or subtasks was increased, which also made it more straightforward for the students to implement the task.

2.3 Student questionnaire

The aim of the research was to find if the method was truly applicable with the task-based continuous assessment, especially with the tasks being simulations that are conducted independently. The feasibility of the method was assessed with a student questionnaire at the midpoint of the course. The timing of the questionnaire gives room for adjusting the method for the rest of the course. To motivate the students to submit answers, extra points were given upon a completed questionnaire. Out of the 34 active students at the time of the questionnaire, 33 answered the questions. The teacher gave the students feedback based on the questionnaire, and some key areas were emphasized for the remaining part of the course.

3 RESULTS

The first question in the questionnaire was: "*1. Continuous assessment with self-corrected tasks was a new form of learning for me.*" All of the 33 students answered this statement to be true. When a new teaching method is applied for the whole student body of the course, it will take some adjusting and effort from the students to orient themselves to the new practices.

The second question was: "*2. The teaching methods described below supported my learning. Use an average value over the first weeks of the course.*"[2] The subquestions and the mean and standard deviation (STD) values of the answers are given in Table 1. The two teaching methods that supported the students' learning most were the demonstration videos and correcting the original task. However, the differences were not statistically significant (two-way t-test, significance level $p<0.1$).

Table 1. Mean and standard deviation of the answers to question 2, n=33.

		Mean	STD
2.1	Video lectures and their lecture material	3.64	0.80
2.2	Demo videos on simulations	3.85	1.08
2.3	Weekly tasks	3.61	0.92
2.4	Self-assessing the weekly task with the rubric	3.66	0.95
2.5	Correcting the original submission of the task	3.88	0.88

[2] scale in questions 2.1-2.5: 1=Strongly disagree 2=Disagree 3=Neutral 4=Agree 5=Strongly agree

Correcting the task is the most important part of the cycle of the method, and it was also acknowledged in terms of learning by the students, both in ratings given for question 2, and in open comments for question 3. These results are in line with the results found in [6].

The next question was: "*3. Briefly describe your learning process when using self-checking tasks.*" Students' answers confirmed many of the findings from prior research. A couple of students pointed out that without self-checking one would not necessarily go through the mistakes and correct ways of doing things at all, as suggested by [7]:

> *"You actually look into your task versus if the points just came by the teacher's evaluation it is possible that you wouldn't ever look the right answer and come back to the task to do it correctly."*

Also learning from mistakes [8] was mentioned often as a central feature of the learning process:

> *"There were "Exactly!" moments when fixing the task. These moments will be remembered."*

In this respect, the strength of the method is not only in that the mistakes reveal misunderstandings and unclear issues both to the students and the instructors, but also that the correction round reduces the pressures of getting things absolutely right in the first submission and thus encourages the students to solve the problems themselves instead of consulting solution manuals or other sources of ready-made solutions [8].

Many students emphasized the learning by doing aspect of the method, and some pointed out that seeing alternative ways of solving the problems develops one's thinking:

> *"It is interesting to compare your own output and task because there are so many different solutions. This is how you can change your thinking. Next time you can evaluate how to do it better."*

Students also perceived that this method takes up more time than traditional homework, but also linked it to learning more or better, as suggested in [4].

Probably the most common challenge in the learning process was related to situations where the student started to solve the problem very differently from the teacher. In these cases, the self-evaluation and correction were perceived difficult:

> *"Sometimes I opt for a different method if I am unable to perform in the suggested way, and in such circumstances it becomes difficult to self-grade the tasks."*

This became particularly evident from the answers to question 7, where students were asked to elaborate on the difficulties they met during the course.

In order to find out the perception that the students have on each weekly task, the following question was asked: "*4. Evaluate the relevance of each task.*"[3]. The follow-up question "*5. Elaborate on how relevant and/or rewarding you found the tasks.*" also provided insight on how the students assessed the relevance of each task. These questions are interesting for the teacher to assess the learning outcomes of the students reflecting on the lectures and the demonstration videos. The mean and STD values of the answers to question 4 are given in Table 2. Clear differences can be seen in the results, yet only the task for W6 stands out with a lower mean value. From the teacher's perspective, all of the tasks are relevant, but the task for W6 was clearly too difficult for the majority of the students. Based on the answers to question 5, the major issue was that the initial knowledge level and programming skills were insufficient for the completion of the task. As a result, a very thorough task demonstration video was given, but the task must be revised for the following year.

Table 2. Mean and standard deviation of the answers to question 4, n=33.

	W1	W2	W3	W4	W5	W6	W7
Mean	3.76	4.03	4.12	4.15	3.94	3.03	3.72
STD	0.91	0.65	0.76	0.71	0.81	1.42	0.91

The following two questions were used to evaluate how difficult the students found each part of the method: "*6. How difficult did you find the following (on average).*"[4] and "*7. If you found some of these difficult, please elaborate on.*" The mean and STD values to question 6 are shown in Table 3, and based on the answers, the most difficult part was doing the tasks. The comments in question 7 highlighted that there were difficulties with the new simulation environment, and certain tasks were found especially difficult. The procedures of self-checking and correcting the tasks were found slightly on the easier side, which can be interpreted in favor of the method. In question 7 there were a few comments on uncertainties with the rubric at places where it did not thoroughly specify certain parts of the task results. These rubrics will be revised for the next year.

Table 3. Mean and standard deviation of the answers to question 6, n=33.

		Mean	STD
6.1	Weekly tasks	3.97	0.63
6.2	Self-assessing the weekly task with the rubric	2.82	0.99
6.3	Correcting the original submission of the task	2.88	0.71

[3] scale: 1=Strongly irrelevant 2=Irrelevant 3=Neutral 4=Relevant 5=Strongly relevant

[4] scale: 1=Very easy 2=Easy 3=Neutral 4=Difficult 5=Very difficult

An interesting point relating to the development and importance of metacognitive skills was illustrated in one student's general comments about the course:

> *"It is not perhaps difficult but it is a bit scary to assign yourself the grade, so it can lead to unnecessary doubting of your own results."*

Although reflection skills are often emphasized with respect to situations in which the student needs to evaluate the soundness of their solution, one could argue that also reflection upon confidence in one's solution is a valuable skill in working life and thus something that should be developed during studies. The self-checking method seems to serve also this purpose and promote self-regulated learning [10].

A mismatch with the workload and grading between tasks can be unmotivating, and therefore, the following question was used to get the students' perception: "*8. Do you feel that the weekly grading principle of 8 points per task and 2 points for correcting and resubmitting the corrected task is fair.*" There were three alternatives:

a) Yes.
b) No, the original task should be weighted more.
c) No, the self-checking should be weighted more.

Out of 33 answers, 25 answered 'Yes', which is 75.8%, while the remaining 8 (24.2%) answered that the self-checking should be weighted more. Therefore, the grading can be found to be in line with student efforts, even though if the initial ratio had been 70% and 30%, the result to this question could have gained an even more positive response.

The final question was: "*9. The feedback provided by the grading rubric and the video feedback were sufficient to enhance my learning.*"[5] The mean value to the question was 3.58 and STD = 0.87. These values still leave room for improvement in the implementation of the method, especially with better rubrics.

4 SUMMARY

The results from the student questionnaire indicate that continuous assessment using self-checking tasks supports well both the learning of the content and the development of metacognitive skills and self-regulated learning. However, the suitability of self-checking depends to some extent on the nature of the primary task.

As for the amount of work effort by the teacher spent on revising the tasks, generating the rubric and the videos took approximately one working day each. This was approximately the same amount of work that was spent on checking the tasks during the previous year. The time spent on checking the short reports and the corrected tasks depends on the week, being nevertheless two hours at the maximum, which was significantly less than during the previous year. As a result, the time invested in modifying the teaching method will be beneficial in the future academic years.

ABSTRACT

In 2013, our university has implemented a new educational model that puts team projects at the core of all BSc programmes, requiring that students develop teamwork skills. On top of this, in 2018, our Chemical Science & Engineering BSc has become an English-taught, international programme. In consideration of this challenging transition, we have developed additional training to facilitate students' acquisition of knowledge, skills, tools, and attitudes to aid conscientious intercultural teamwork. For this, it is paramount that students become aware of, and learn to appreciate, differences in the educational and cultural backgrounds of themselves and their peers. Concurrently, students should practice what they have learned and adjust their behaviour when appropriate.

In this paper, we share our experiences, best practices, and lessons learned. More specifically, our study: i) explores which factors are key to a successful intercultural team, ii) investigates how diversity in teams can be cherished and used for the benefit of the team, its members, and its goals, and iii) how these teamwork skills can effectively be taught in engineering programmes. Building on this, the paper

describes how the new curricular education has been designed, what is taught, and how an inclusive, regardful, and pleasant atmosphere has been created for the intercultural project teams.

1 INTRODUCTION

1.1 Essential skills in engineering education

In this ever-changing society, higher education (HE) institutes should take on the responsibility of preparing students with the necessary skills in addition to their respective disciplines to face the world's greatest challenges. Among these skills, teamwork [1] has been identified as a key characteristic that employers seek in university graduates because workplaces demand interpersonal cooperation and high levels of interpersonal skills. In response to this, since 2013 all bachelor programmes at our university are designed based on a new educational model that enables students to create their development and learning experiences through a variety of projects that weave their way through the programme like a thread.

Furthermore, our Chemical Science & Engineering BSc has become an English-taught, international programme, and in today's globalised environment, intercultural skills are becoming increasingly important and desired [2]. Teamwork involves challenges that might be exacerbated when members come from diverse backgrounds but lack intercultural competence; students must be aware of their roles and of how to cooperate with different peers. Growing industrial interests also require the diverse population of engineering students to develop beyond traditional technical abilities. These challenges call for in-depth research to gain a better understanding of how to foster effective teamwork and intercultural skills in engineering education.

This study recognises the importance of intercultural skills and intends to provide means to train students to effectively work in teams with people from diverse backgrounds. More specifically, this study aims to (i) explore factors that are key in establishing success in intercultural teams, (ii) investigate how diversity in teams can be cherished and used for the benefit of the team, its members, and its goals, and (iii) develop an effective teaching method for these teamwork skills in engineering programmes.

1.2 Underpinning Theory

A team is here considered “a collection of individuals who classify, define and evaluate themselves in terms of a common social category membership” [3]. The core of a team is a shared responsibility for achieving common goals [4], which requires the commitment of each individual team member to work on assigned tasks.

In academic settings, simply getting individuals together is insufficient for effective teamwork. Students need guidance and mentorship to learn how to interact and work together and understand the team roles and responsibility of each member [5]. Teamwork competencies encompass a set of behaviours, knowledge, skills and attitudes from students that contribute to the team’s efforts [6]. Four dimensions of teamwork skills development [7] are identified: (i) identity (goals, sense of belonging, roles, adaptability, teamwork climate, commitment); (ii) communication (information, personal interaction); (iii) performance (planning, decision making, carrying out the tasks, monitoring performance); and (iv) regulation (collaborative problem solving, negotiation, making improvements). From this, one can conclude that the key components of teamwork skills development are:

- why the team exists (objectives),
- what a team does (activity), and
- who is on the team (roles) [8].

Furthermore, being able to work with diverse people is a prerequisite for successful teamwork, necessitating a comprehensive approach to incorporating intercultural skills into teamwork-skill training. Intercultural skills are "the ability to communicate effectively and appropriately in intercultural situations, to shift frames of reference appropriately and adapt behaviour to cultural context" [9]. Respect, openness and curiosity are the pillars [10] around which the competence is based.

From a pedagogical perspective, the development of teamwork skills is a process of learning involving strategies of (i) providing opportunities for the application of knowledge; (ii) structuring opportunities for collaboration and interaction with diverse peers; and (iii) providing opportunities for perspective-taking and reflection [11]. Based on this three-stage process, this study develops the teamwork skills training utilising the framework described in Figure 1.

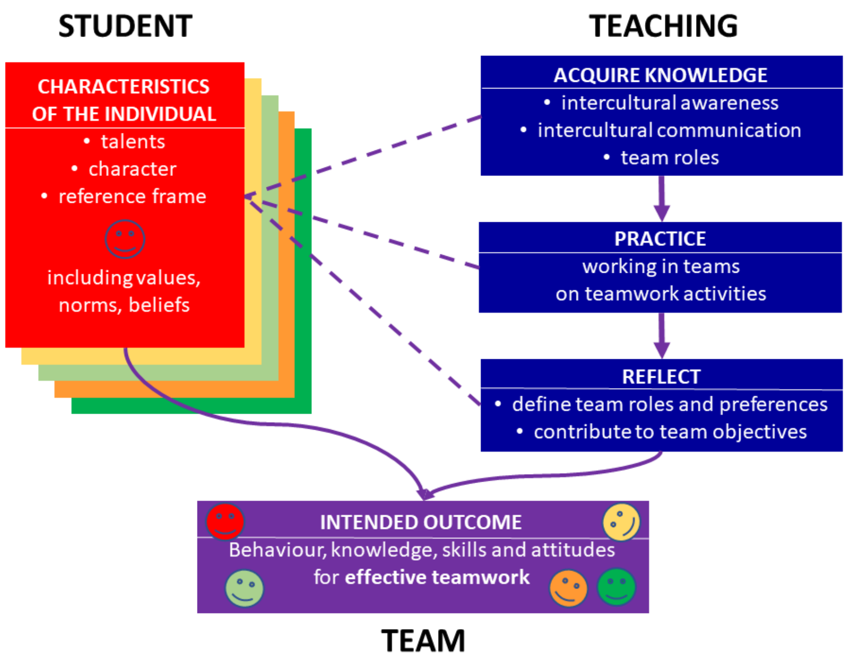

Fig. 1: Intercultural teamwork, from theory to practice in our programmes

2 METHODOLOGY

2.1 Programme context

Originally, our Chemical Science & Engineering programme was only offered to national (Dutch) students. The programme was converted into an international English-taught programme in 2018, with approximately 60% of the current students being international. This development is highly valued, yet a smooth transition from a national to an international classroom can be challenging. Therefore, the teamwork skills training was developed to prepare students to work effectively in project teams with their international peers.

2.2 Design of teamwork training

The training is designed as a four-stage process. Students acquire necessary knowledge and apply it through teamwork activities, while also reflecting on their experiences for future improvement (see Figure 1). The following section details the training setup for each stage.

Freshmen: When students enter our bachelor's programme, we teach them organisation skills, focusing on how to carry out effective meetings in a team of peers they hardly know. Some students have experience with group work, while others were used to working individually in their high school. In their first project, they experience what intercultural group work can be like in their studies. They take their successes and failures in this group work, as well as their individual questions, with them to the second project, where they receive the teamwork training with a new group of students (typically four-six students per team in the first and the second project).

Workshop on cultural diversity: We commence with a workshop on cultural and educational diversity, with the following learning goals: to (a) be more aware of each other's expectations; (b) be able to identify differences in (prior) education of their group mates; (c) devise ways to get the most out of their education at our institution; (d) empower effective teamwork in a (project) group of diverse people.

In a classroom setting, students sit with their new project team and work on assignments. First, they introduce themselves to their peers (with a focus on their name, its meaning, who named them; their upbringing; their high-school experiences; their affiliation with the project). Then, students collectively discuss given cases – situations where individuals have misunderstood each other – and try to identify what was the cause of the confusion. Students continue with collecting keywords that link to 'culture', and try to use these to constitute a definition of 'culture'. Additionally, students practise with an exercise about universal, cultural and personal characteristics, that they discuss with their team. At the end of the session, we teach students about conceptual knowledge on intercultural communication (emphasis on high vs. low context; perception of time as synchronic or sequential; affective or neutral emotions; relationship vs. deal orientation; and hierarchical vs. egalitarian cultures), with an exercise to highlight where on these axes students would position themselves and what the effects might be on the group or group process. After the workshop, the project groups work on an assignment about how they wish to work together, and how they will take into account each other's needs, norms, values, and beliefs, resulting in a project group agreement.

Workshop on team roles: We realise that, when they work in groups, students often define group roles by themselves, while they lack a theoretical background about roles in group processes. Hence, we introduced the Belbin model [12] to improve their understanding of team roles. The students fill out a self-perception inventory and ponder on its possible meanings. Then, they discuss the outcomes within their team, draw conclusions about missing or underrepresented roles in the team, and how to use these insights to the benefit of the team. Also, they are asked to decide who to work with in their next project (small groups of three students), taking into account the outcomes of the Belbin model.

Reflection: Lastly, we have reflection activities. Already early in the project, students give each other feedback on their perception of the leadership qualities, team-player behaviour, fitness for specific tasks and roles, and potential for interpersonal conflicts; students score themselves as well as all their peers from the project group. They discuss, in particular, discrepancies in the perceptions of themselves and the others; e.g., someone may consider her/himself a well-liked natural-born leader, whereas the other group members anticipate this person to induce problematic coacting and conflicts.

At the end of the project, we offer a reflection workshop. We look back at the original group agreement, what worked and what did not, why things did or did not work, and how a group might improve teamwork for the next project.

In the master's programme, we offer similar teaching activities, adapted to the fact that these students often have more experience in teamwork.

2.3 Evaluation

The evaluation input was gathered from multiple stakeholders:

- We asked the participating students after each workshop for feedback to improve the workshops and used that in the next year;
- The training is assessed as part of the regular course evaluation of the Chemical Science & Engineering programme to assure its quality;
- Additional input from teachers and programme management is requested to determine how the training is integrated into the programme's overall curriculum.

3 RESULTS

3.1 Acquire knowledge, practice, and reflect

The teamwork skills training is embedded in the existing programme. This implies that students have opportunities to apply their knowledge to concrete tasks through an engineering project: students have goals to achieve, technical issues to solve, and deadlines to meet while participating in a group process. Students focus on interpersonal qualities and relations in the team, which is separated from, yet in the context of the specific content and aims of the project. Additionally, students are encouraged to engage in meaningful and practical reflections.

The peer-review process revealed interesting insights, as students often have a different perception of their behaviour, strengths, and weaknesses than their peers do. They also needed time to reflect on their own performance for the group reflections to be successful. The introduction of the individual (peer and self) reflections has made the group reflections more meaningful and more thorough.

Students' perspective: Students' feedback provides input on how the training was perceived and what effects were obtained (see Figure 2). Below is a summary:

- The workshops validated that intercultural differences could be a cause of problems in a project group. For many students, working in an international project team at first was overwhelming. The workshops assist students in understanding how norms and values can differ and that there is no ‘wrong’ or ‘right’; just a different basis.
- Due to the workshops, differences among cultures were discussed, which would otherwise not happen automatically. Students claim that confusion and irritations were mitigated because of this approach. Often, groups immediately focus on the tasks they need to work on; now, they would start with the fundamentals of intercultural teamwork instead, and the workshops made it easier to address any teamwork issues.
- The workshops increase self-awareness in intercultural collaboration, especially when students need to decide on a project approach and agree on how they will work as a team (project group agreement).
- Students say that the workshops have massively impacted the way national and international students interact, and group bonding was increased – not just in this project but across the student cohort.
- The workshops were taught playfully, helping students to get to know each other better, on a personal level, increasing the groups’ ability to discuss possible issues.
- Groups were more aware of how they could improve the group atmosphere through better understanding and communication about expectations (from the project as well as from their peers). This also increased the likelihood of success. Success for a project group also was valued more by the students, because it was a true team effort.

Fig. 2: Word cloud of feedback from students after teamwork training: what did they learn?

Course teachers’ perspective: The course teachers of the project indicate that, due to the intercultural workshops, the teams perform and contribute better in their intercultural "Process Plant Design” project. The teams consist of 4-5 students and they sit together in a project room for 2-3 days a week. They need to collaborate intensively for five months to make their project successful. They are now much more aware of differences due to cultural backgrounds which makes it easier for them to discuss issues beyond their personal perspective, especially since this was addressed during the workshop. Potential conflicts are now discussed and solved within the team.

Programme director’s perspective: Although about 60% of our students has an international background, our national culture and norms tend to remain dominant in the classrooms. This workshop is of particular importance to broaden the perspective of international and national students and contribute to a truly international classroom culture. The workshop seems to have a lasting positive effect on mutual understanding and on formal and informal collaborations between students of different cultural backgrounds.

3.2 Future development

We shared our experiences with other programmes at our university. As a result, other engineering programmes also introduced workshops on cultural diversity in teams. On top, this implementation has become a stepping stone for the development of teaching methods for other essential skills in our programme (like academic writing, oral communication, critical thinking, conceptual modelling, and civic engagement including sustainability awareness). We couple these activities with existing courses or projects in the programme, and ensure that we assess students’ development in these essential skills.

The workshops also accomplish that students value and contribute more to global citizenship, as they learn to appreciate different perspectives.

We conclude that with this study, we found factors that are key in establishing success in intercultural teams. The main factor is awareness of the different backgrounds of students’ peers. Diversity in teams can be cherished and used for the benefit of the team, its members, and its goals, which became apparent to the students, who started their projects with more focus on what intercultural teamwork entails and requires, and with more awareness of the needs and backgrounds of their peers. Also, we have developed effective trainings to teach these teamwork skills in engineering programmes.

ABSTRACT

Preparing students for the labour market is an essential part of education, and academic personnel usually influence this process. Students' experiences with leading figures, like supervisors and other professors, can affect their expectations about future leaders. For this reason, our research aims to assess students' beliefs and expectations and make suggestions for higher education representatives who can serve as a leadership model for them.

We conducted focus group interviews mostly with engineering students at a Hungarian technical university in spring 2022. Thirty students participated in our research and were assigned to the focus groups according to their work experiences. After coding interviews, we categorized their answers into three groups: leadership qualities and professional and social expectations. According to them, a leader must be competent, socially active, and have a good personality. His or her behaviour must reflect these qualities to be engaging and a good role model.

Our results showed that school and university experiences are a critical starting point and reference when students formulate their expectations towards future leaders. Therefore, it is important to raise professors' awareness about their leadership roles and develop their leadership skills to be good role models for young people.

In our study, we discuss leadership requirements and suggest developmental methods, respectively, to the university's characteristics. In addition, we recommend integrating leadership development programs into engineering education, from which both professors and students could benefit.

1 INTRODUCTION

1.1 Academic professors as leaders and role models

Considering leaders as role models have been investigated for many years since transformational leadership and charismatic leadership influence leadership theories. They emphasize the leadership role and define it based on behaviour and the effect of leaders on subordinates [1], and even on the leader's capability to transmit goals and values [2]. Although it seems easy to draw a parallel between leaders' behaviour and role modelling, we have to define role models in the broader sense.

Role models are associated with influence coming from one's position and being an ideal person or example someone wants to identify with [3, in 4]. This definition combines two different aspects, one of the identification theories and one of the social learning theories [4]. Gibson [4] broadens the definition and emphasizes the cognitive construction within the modelling process. According to him, individuals want to be similar to those representing social roles and their perceived positive attributes. On the one hand, this construct of role models differs from the mentor definition in terms of development because mentors are usually described from career and developmental perspectives. The mentor helps to learn and develop through involvement. On the other hand, the similarity between the cognitive and behavioural models is that both are based on learning, but the latter focuses on observation and accessibility [4].

Uniting these developmental, behavioural, and cognitive aspects would be beneficial in leadership development since leaders are usually referred to as role models both in the business and the academic sectors [2, 5-8]. Therefore, it is important to raise professors' awareness about their modelling status because students learn from conscious activities where professors emphasize what to do and their observed behaviours, which students might unconsciously begin to copy and internalize [5].

In educational settings – especially in the academic sphere – leadership tends to be seen as a formal, managerial role, e.g., dean of faculty or head of the department. Still, leadership occurs informally, independently from designation [8]. We use the term "professor" in the broader sense, including academic personnel who teach and supervise without designation.

Academic leadership is "a process through which academic values and identities are constructed, promoted and maintained" [9, p. 3]. Educational leaders help colleagues or students to learn academic disciplines through empowering, mentoring, or even role modelling [9]. This form of leadership is usually associated with the work of supervisors because this leadership indicates that leaders guide and support colleagues to focus on research and develop professionally [8].

In his research, Macfarlane [6] summarized the qualities of intellectual leadership. Two main aspects among the six qualities have arisen, the interpersonal and the professional. From the interpersonal aspect, professors care and stand for younger colleagues and give protection and guidance to them. They even motivate students to take intellectual risks and use their hidden potential. Furthermore, they secure resources or other opportunities to facilitate research. From a professional or intellectual aspect, professors serve as role models because of their special expertise in one field and commitment to this discipline, inspiring others. They express their engagement in the way they promote their subject and contribute to scientific development through editorial work and reviewing or as a keynote speaker representing a university at a conference [6].

Both of the above-mentioned leadership forms reflect on a leader as a role model to some extent, which is not surprising since professors, as informal leaders, give a part of themselves to students. At the same time, they educate, inspire, support, and lead them [2] or just fulfil other duties [5]. This indicates that teachers and academic professors can be leaders and role models worth following [2]. This distinction is needed because role modelling is a two-sided phenomenon. Some people are motivated to identify themselves with the exemplar, and others are decided to avoid being like the modelling person. To be effective role models, academics need to demonstrate competence in the desired field, teaching, and good personal characteristics [5].

1.2 Student engagement and expectations

Even though academic professors are usually not identified as leaders or role models explicitly by students, they affect students and their engagement [10-12].

Wright, Wong, and Newill [10] found that role models and their personalities – sometimes different traits or values from other models – and students' relationship to them influence students' career choices. According to their research, students consider important the attitudes of the modelling person, his or her compassion and enthusiasm for work, the integrity of his or her personality, and the ability to be objective and use the power of humour if needed. Above this, students expect these role models to be socially active, have good leadership and communication skills, be patient, conscience, and aware of their capabilities [10].

The strong association between career choice and role model is also supported by examining the engagement and retention of STEM (science, technology, engineering, and mathematics) students in their selected major with the help of role modelling [12]. Shin and her colleagues [12] found that stereotypes can determine engagement, and these can be modified or replaced with the help of role models, in their case, role model biographies. The exposure to hard work and success of those typically underrepresented in STEM majors strengthened students' interest due to perceived compatibility with models. Students reframed their stereotypes because counter-role models were considered competent and inspiring. Their success based on effort and hard work showed another feasible way to be outstanding within these majors [12].

Competence and inspiration are essential factors in the case of university professors too. Tam and his colleagues [11] examined what makes a good teacher, and their participants formulated important aspects and requirements. They identified two main categories associated with expectations. Teacher quality includes caring for students, providing help and safety, having a democratic, humorous, open personality, and being competent, well-balanced, and knowledgeable. Appropriate use of assessment, student-centered and various teaching methods, openness to their opinion and feedback, and free choice in learning cover the category of teaching approaches. Favourited teachers served as role models thanks to their inspiring character and passion for teaching and learning. Students expect them to guide them and be available and open to the affective and social dimensions of education [11].

Cadwell and Anderson [2] highlighted seven factors influencing students' openness and willingness to learn from professors and achieve higher performance. Similar to Tam and his colleagues' results [11], if professors show inherent virtuousness and sincere feelings, they can reach students. Because students understand moral messages, realize how important it is to achieve more in life, appreciate support and care, and are aware of their role in changing the world and their moral responsibility [2].

All these results support that the influence of leaders is inescapable. Different leadership aspects brought different views and expectations. Still, they agreed that leaders – even teachers and professors – influence followers, which can result in identification with them as role models. Based on this influential relationship, our research aimed to understand the personal expectations towards leaders, especially how they can motivate and engage university students today.

2 METHODOLOGY

2.1 Participants

This research is part of doctoral research that aims to profile engaging leaders and the expectations of university students for leaders. We conducted focus group interviews in March and April 2022. Students mainly from a Hungarian technical university participated in focus groups. Some of them were offered to get extra points on a course for their contribution.

37 students applied for focus groups. From them, 30 students (20 women and 10 men) answered our questions. 17 are engineering students, and the others are studying economics, IT, or social studies. The youngest participant was 19 years old; the oldest one was 45, with an average of 23,9 years. 10 students are currently working for more than six months and spoke about their recent experiences with organizations, leaders, and work. Those with less than six months of experience or no experience answered our questions about ideal work, organizations, and leaders.

2.2 Procedure

Candidates were allowed to register on a Google Form after answering demographical questions. We assigned applicants into two groups based on their work experiences, considering whether they have been working for a company for more than six months or not. We decided to cut at this timepoint because it usually takes half a year to get acquainted with a new role, new group, and organization.

We worked with semi-structured interview questions. These questions were formulated considering the engagement influencing factors based on the results of Firouznia and her colleagues [13]. Our general questions were:

- What would you like to work in the future? In which position do you imagine yourself? or In which position and where do you work?
- What motivates you? What is your aim with this work or major you are learning now?
- What do you expect from work? How do you imagine your work, workload, and so on? (It was a question just for those who were currently not working.)
- What is your team like? How do you work together? or What kind of teams do you want to work in?
- What is your organization like? How do they motivate or engage you? or What kind of organization do you want to work at?
- What can or should the human resources department do for you to motivate and retain you for a longer period?
- What makes a good leader? How can they engage you? What characterizes them?

The personal interviews were recorded with a dictaphone, the online ones with the help of Microsoft Teams. We used online software to transcribe these interviews and corrected the transcripted text.

We used the desktop version of Atlas.ti 22 to analyse qualitative data. First, we generated a word list based on the interviews and listed words containing “leader” or “boss”. After this selection, we searched through the text and generated automatic codes for phrases including “leader” and “boss”. Second, we exported the labelled phrases into excel and categorized the answers into three categories based on the requirements of effective role models [5]. We also asked an independent leadership developer professional to assess and classify the responses from the focus group interviews. Finally, we compared the categorizations, and in case they were different, we consulted with the expert and decided on a category by common consent.

3 RESULTS

3.1 Frequency analysis

Frequency analysis showed that those with work experience used more words related to leadership.

The leadership code distribution of the documents is listed in Table 1.

Table 1. Distribution of “leader” and “boss” codes

Code	WE1	WE2	WE3	NWE1	NWE2	NWE3	NWE4	NWE5	TF
“boss”	4	8	42	10	3	18	2	8	95
“leader”	65	89	34	42	40	47	55	62	434
Total	69	97	76	52	43	65	57	70	529

Note: WE=group with work experiences, NWE=group with no or minimal work experiences, TF= total frequency

3.2 Text analysis

Our participants highlighted leadership, personal qualities, and professional and social aspects associated with leaders. Those expectations which appeared in more groups are marked in italic and presented in Figure 1.

The qualities of a leader should be: “a protecting wall”, *a good judge of character*, *accepting*, an *authority figure,* authentic, *available*, careful, *charismatic*, *confident*, *consistent*, *dedicated* to working and subordinates, democratic, *determined*, *direct*, *empathetic*, engaged, *exemplary*, fair, goal-oriented, *good communicator and mediator*, *good in problem-solving*, *helpful*, *honest*, *humane*, *human-oriented*, humble, humorous, in a *positive* mindset, motivated and able to motivate others, *open* to new ideas and people, resilient, *respectful*, straightforward, *supportive*, the one who not just speaks but does things, *the one who sets the course*, *trustful*.

The professional expectations towards leaders are that they must: *admit mistakes*, be clear about *what (s)he expects in work* and this should be the same as *what (s)he did or does also*, be *clear and realistic about expectations and articulate them*, be competent both vocationally and to leadership, be *good, skilled, and experienced at what (s)he does*, coordinate and *delegate* tasks, emphasize common plans, goals, and development, focus on realistic goals, have *earned the leadership position*, have good time management, keep his/her word, make decisions about workload based on the skills of subordinates, *organize regular meetings*, *participate* in projects, *plan and allocate work rationally*, qualified and up-to-date in his/her field, so one can trust in him/her, *share information and knowledge*, *show the added value of one’s work and its effect*.

The following criteria belong to the social expectations according to which leaders should: acknowledge and motivate team members, appreciate autonomy, ask and listen to the answers, be a *part of the team*, be an active participant who knows the inside jokes and stories, be like the team members, *be motivated to get to know better his/her colleagues*, be open to be friends and have programs together outside the workplace, be understanding and give comfort, *bring the team together*, *give feedback* and ask for it, give *individual attention* to everyone, have similar values and interests like the team, *involve* them and be open to ideas, *know the qualities and skills of team members*, organize programs and facilitate common experiences, protect and serve others, show *mutual trust and respect*, *stand for the team*, support learning and *development*, *treat everyone equally*.

Fig. 1. Students' expectations in a word cloud

Some groups mentioned experiences with teachers or professors in association with leadership experiences. We cite them:

"- And then I come to work and do the same as in elementary school and high school. (…) And the leader is similar to a class teacher in this way, and I think the class teacher has had five years to get to know the students, and I guess everyone gets along well with their class teacher in the fourth year and the fifth year. And I think it needs to develop with the time in a workplace too.

- I would say that my bosses are not class teachers but rather practicing teachers who come to us, who don't fully know what team dynamics are like, but they try to recognize it as well as possible, and they evolve with the team."

"When I went to college, and the teacher didn't even introduce herself, she was already telling me about an 80 percent dropout rate for a subject."

"It's even quite an interesting experience to go out with a professor for a beer outside of class and then get to know him from a completely different side. You see someone standing at the chair and just giving a lecture, and you are sitting at the table together. It is completely different when you are having a beer in the city and then talking about something completely different from the material in school. You get to know a completely new side of your professor."

"There should be no collective punishment. I always hated to get the punishment because others were stupid. (…) they're not motivating me by punishing me; they motivate me by acknowledging me for performing well. It's a problem going back to school. And it left a strong effect on me."

"Don't always stand behind me to see if I'm doing the job well. And stare. I don't know, for example, when you write an essay and then write and think. And then the teacher goes round and round. (…) So, I didn't like it that way, but the occasional feedback here is critical. But not by standing behind you and staring."

"…teachers have full power over students, so to speak, and expect full attention and full respect, and I don't think that's a good attitude. Of course, you need both, but I don't think so hard. For example, there has been no mutual respect in the teacher-student relationship, and I think this often happens in the workplace."

"And this attitude that the bell is ringing for me. So, if there is one thing that is true for everyone. Then why would it be true just for one person, regardless of whether he or she is in a leadership position? So that's so unfair."

4 SUMMARY

The role of education is to show students alternatives to thinking and views and teach them acceptable values and behaviours [14]. In this process, academics play an enormous role as leaders or role models. There has been little research on academic leadership. Still, some researchers have already emphasized the importance of leadership in education, independent of whether it is a formal position or an informal, supervisory relation [6, 8].

The expectations towards leaders, especially academics, were usually grouped into two categories, i.e., personality and relationships [10] or teacher quality and teaching approaches [11]. Macfarlane [6] brought the professional and interpersonal aspects together, and Cadwell and Anderson [2] highlighted the personality of a teacher and the responsibility and capacity of students. Our results indicate that three categories could describe better good and influential leaders and professors because personality, professionality, and even social skills and intentions are equally important for students, which are consonant with the criteria of effective role models [5].

The answers of university students from Hungary overlap to some extent with previous results [2, 6, 10-11]. Furthermore, they give new perspectives on these three categories. Appreciated leadership qualities are directive (e.g., determined, direct, the one who sets the course), practical (e.g., goal-oriented, exemplary), and emotional characteristics (e.g., empathetic, resilient, positive mindset). Rationality (e.g., rational plans, realistic goals and expectations), presence (e.g., participate, organize meetings), and experience in a broader sense (e.g., earned leadership position, expects what (s)he did or still does) are additional demands of students. Finally, university students wish leaders to be socially active (e.g., active participants, open to having programs outside the workplace), be team members and leaders or facilitators at the same time (e.g., part of a team, mutual trust, and respect, organize common programs), be good reading people (e.g., know better colleagues, know the qualities and skills) and be personal support (e.g., individual attention, give feedback, support learning and development).

Our results highlight that positive and negative role models can influence later expectations and relationships with leaders. Although they are congruent with previous results, we worked with a relatively small and diverse sample which does not allow us to draw an extensive conclusion. Even though we tried to ensure objective categorization, other independent raters could have secured a higher validity of our results. Additionally, more extensive research involving different universities, majors, and students could give us better insights into the expectations associated with leaders and let us understand better and compare the academic and business characteristics.

Taking everything into account, theory and practice are key elements to the successful education of young engineers or other professionals. But we should not neglect the influence of academics who support and guide them. For this reason, we recommend that universities promote leadership development which might be helpful and fit both professors and engineering students. Since role modelling can be experienced on formal, informal, and hidden, institutional levels, interventions would be needed not just on a personal but on an institutional level too to ensure leadership development and through this positive role modelling [5].

5 PRACTICAL IMPLICATIONS

There was a shift from basically research-oriented education to applied science and practical engineering [15]. It requires leadership skills from engineering students who can learn these from practicing those skills [16] and internalizing the behaviour of role models, mostly their professors. Professors are expected to be researchers and leaders simultaneously, which requires different skill sets [6]. Sometimes, their job description does not clarify the variety of tasks and emphasizes the managerial part of their work [8]. This entails that they do not usually get prepared or just too little for their career as an intellectual leader [17]. Because of this, we would suggest a complex developmental program that aims at all the three levels of modelling influence defined by Cruess and her colleagues [5] to raise professors' awareness about their influential power and modelling status and help them develop leadership skills.

First, academics need to acknowledge the importance of leadership development [15] on an institutional level and facilitate cooperation between faculties and departments to raise awareness about the importance of non-technical, interpersonal competencies [15-16]. A developmental program could effectively reach its goal in such a supportive culture with clear expectations about leadership.

Second, we suggest a reform of the curriculum too. Farr and his colleagues [16] emphasized that building in some new topics or methods is easier than creating a specified course for them. Engineering curricula and even Ph.D. curricula should be revised and extended to leadership theories and practice. Engineers at our university have mandatory psychology lectures without practicing social skills, which could be incorporated. The Doctoral Student Union provides optional workshops for Ph.D. students about academic, business, financial, and psychological topics. Professors are also allowed to participate in these workshops. This training could be built into the education regularly, not occasionally, and optionally.

If the university supports leadership development and the curricula are revised, then the informal level should be addressed intensively with the help of training and workshop series. Based on the developmental program of Rutgers Leadership

Academy, the series should cover organizational and leadership theories, the development of social skills and leadership competencies, and specifics of higher education [17]. The awareness of one's leadership function can increase with the help of projects, interactions, and reflections on teamwork [16-17]. These contribute to developing the most important engineering leadership skills (i.e., communication, teamwork, cultural awareness, and ethics) [15].

Although these suggestions are made on a theoretical basis and need to be tested and examined widely, they can contribute to the preparation and development of professors for formal and informal leadership roles. This is important because they can significantly influence students besides soft skill training and theoretical education. Professors should set an example that engages students, helps them internalize leadership skills, and prepares them consciously or unconsciously for their future leadership position, which usually comes fast in the case of successful graduate engineering students.

ABSTRACT

During the past years we have witnessed various development trends in learning. More and more the learning has moved online thus making it independent of time and place, students' responsibility of their own learning has increased, methods that promote active learning have gained more interest as they result in better learning results, and the role of a teacher has shifted towards a facilitator of learning. Consequently, the flipped learning pedagogical approach has become more common in recent years as it is one way to answer these trends.

This concept paper introduces two studies of practice in which flipped learning approach was implemented for the first time in a bachelor level university course of

electronics at Tampere University (TU) during the academic year 2021 – 2022. The structure of the flipped courses consisted of online pre-class study materials and assignments, face-to-face learning events, various individual and group learning assignments and so-called prime time small group meetings with the teacher. Flexibility and versability of the learning experiences, both-way feedback possibilities as well as a combination of individual and collaborative face-to-face and online learning were emphasized in the course design.

According to the feedback many students felt that this flipped learning approach promoted learning and encouraged to study evenly throughout the entire course. Furthermore, the teachers' thoughts after the first implementation round are considered e.g., which parts and practices were successes, and which need further development. In addition, thoughts about teachers' workload and institute's support in utilizing flipped learning method are shared.

1 INTRODUCTION

In the flipped learning method (FLM) the students familiarize themselves with and learn the new course material first outside the face-to-face (F2F) learning events. Students can learn the new material at their own pace independent of time and place individually or in small informal groups. This is often referred as individual space meaning that students mainly work themselves and the work done is focused on the individual student’s efforts. In the F2F learning events, so called group space, students then learn with the entire class or in intentional small groups and the focus is on higher-level tasks and in active learning. [1] By creating such an autonomy-supportive learning environment in which the pre-class online materials meet students’ autonomy and competence needs and the interactive F2F learning events foster students’ competence and relatedness needs, active learning, self-regulation and engagement can be promoted, and students’ academic achievement may increase [2].

1.1 Designing Flipped Learning in Engineering Education

When designing flipped classroom, it is important to include there two components that can be seen in Figure 1: human interaction component (in-class activities) and computer-automated component (outside activities) [3]. Video lectures are a typical example of the outside activities and them being mainly teacher-centered they can be automated through computer technology. The in-class activities, on the other hand, should be designed based on student-centered learning theories, such as problem-based learning, active learning and collaborative learning to foster the success of the flipped classroom [3].

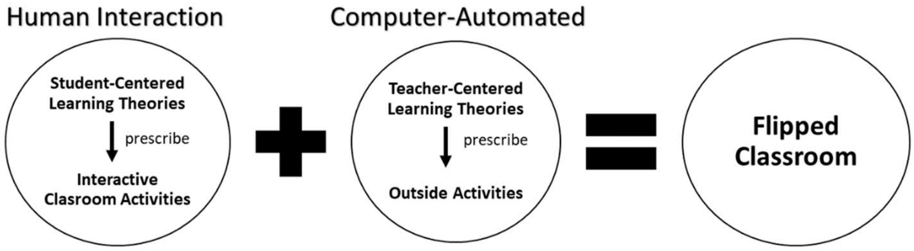

Fig. 1. Components of the Flipped Classroom [3]

It has been shown that the problem-based learning can offer students learning experiences in real world context and thus help them learn how to approach and solve challenging problems and improve students' ability to work in a team [4]. When designing flipped learning it's important to consider the collaborative learning as well as the collaborative environment of F2F learning events can strengthen students' critical thinking and problem-solving skills [5]. These higher order thinking skills, critical thinking, problem-solving skills and teamwork skills are core competencies that engineers need in the work life. The flipped learning setting of pre-class videos, in-class discussions and hands-on activities can furthermore contribute to a deeper synthesis of concepts and it enables more course content to be covered in addition of students learning more efficiently. Carefully designed flipped learning method has the potential to result in better learning outcomes, increase student engagement and enhance students' interest in engineering. [5]

2 FLIPPED LEARNING IN ELECTRONICS EDUCATION AT TU

Two electronics courses, Electronics and Circuit Theory and Product Design of Electronic Device, were designed and implemented using the FLM based on the above-mentioned components. Outside activities utilized the Moodle learning management system and the parts of the courses that required human interaction were designed to reflect student-centered learning theories. The target group of both these courses are bachelor students of the second and third years respectively, and both courses were implemented as seven-week implementations during the academic year 2021 – 2022. In addition to the technical core subjects, the target of these courses is to develop students' work life skills, such as documentation, presentation, critical thinking, argumentation, problem-solving and team work skills.

Both the courses had the same task and session types: pre-class materials and assignments, face-to-face learning events, and prime time meetings. Even though there were some differences between the course implementations, the basic idea in the design and implementation was similar.

With the online pre-class study materials that included short video lectures (duration 3,5 – 21 minutes) and online book materials the students learned the new topic and were able to work at their own pace independent of time and place. In both courses it was assumed that the students had studied the pre-class materials and completed the pre-class assignments before the F2F learning events. In this way the assignments to be done at the F2F learning events could be designed so that they promote students' higher order thinking skills, such as design, compare, analyze, estimate and choose.

The prime time meetings were an important feedback channel both ways, from teacher to student and vice versa. The feedback discussion on the meetings was based on the students' answers regarding questions like, how did you accomplish the learning outcomes of the module, what was the most interesting topic this week, what did you learn / didn't learn this week, what was the most difficult topic this week. At these prime time meetings students were thus able to furthermore deepen their understanding on the topic, make their learning process apparent, understand what they need to learn more and adjust their learning process accordingly. Feedback from students also helps the teacher to visualize e.g., the weak points in students' learning and make possible adjustments accordingly.

In both courses the final course grade was determined based on course points students gathered during the course. The pre-class assignments, or the F2F learning events were not compulsory, but by completing the assignments and taking part in the F2F learning events students were able to gather course points.

2.1 Electronics and Circuit Theory

The Electronics and Circuit Theory course is the very first course in electronics for the students to whom this course is targeted to. The students have some basic knowledge of basic circuit theory already from previous courses, but mostly the topics in this course are totally new to the students. The FLM in this course was designed to follow a weekly schedule which is presented in Figure 2.

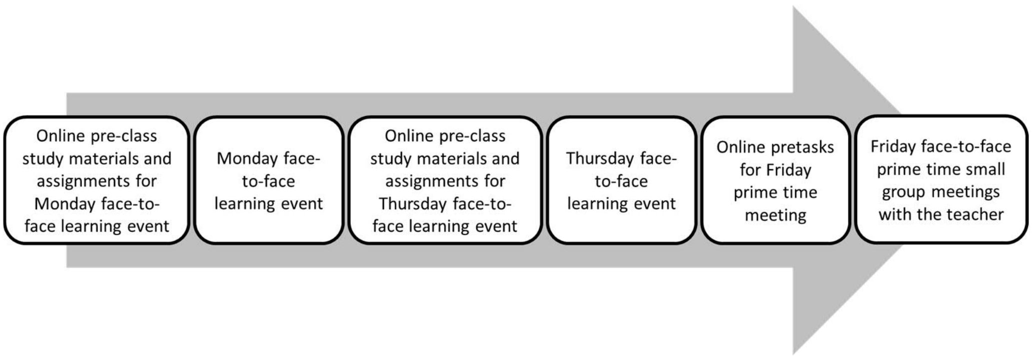

Fig. 2. Weekly schedule of Electronics and Circuit Theory

The assignments were Moodle tasks based on the pre-class study materials. Mostly the Moodle tasks needed teacher's checking, only some of them included automated checking. The future plan is to increase the amount of automatically checked assignments. The pre-assignments had a deadline, and the students had about two to three days to do them. The F2F sessions were for deepening the understanding of the issue at hand by doing various tasks, which mostly included paper and pen part, simulation part, and circuit prototyping part. The circuit prototyping in this case means that the student constructs circuits with through hole components on breadboards and measures and analyses them using a BYOD (bring you own device). Short mini lectures (about 5 to 15 minutes) were included to F2F sessions occasionally, especially when the topic was more demanding for the students.

The prime time meetings were mainly for feedback from the week, and also for clarifying the issues that needed further clarification.

The students gathered course points from all the course parts: pre-assignments, F2F sessions, prime time meetings, and four miniexams. The miniexams were small exams containing calculations, simuations and prototyping. Only the miniexams were compulsory, but for each grade the students needed a certain amount of course points.

2.2 Product Design of Electronic Device

The core contents of the Product Design of Electronic Device course are the different hierarchical levels, production processes and design perspectives of an electronic product. For the FLM implementation the course contents were divided into five flipping modules each of which lasted one to two weeks depending on the extent of the module. Each module followed the same structure presented in Figure 3.

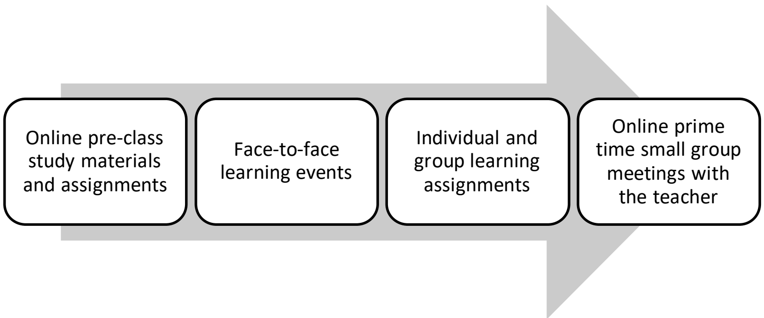

Fig. 3. Structure of one flipping module in the Product Design of Electronic Device course

The online pre-class assignments consisted of self-correcting multiple-choice tests that offered the students the possibility to test their learning and to make notes of questions or problems they may have.

The F2F learning events consisted of collaborative and active learning through various problem-solving and design exercises, calculations, presentations and group discussions in the classroom. In case of a difficult topic or questions from students the teacher explained the pre-class study material shortly anew. Students worked mainly in groups in order to enhance the collaborative aspect of learning as well.

The individual and group learning assignments were designed to deepen students' knowledge on the issue at hand, to promote collaborative learning and to increase students' work life skills. The individual assignments included a calculation exam in the Moodle and the group assignments included e.g., decibel meter construction work, a wiki assignment and a forum discussion assignment in the Moodle. The assignments were compulsory to complete the course and graded passed/failed or on a scale of 1 – 6 points.

The compulsory 30-minute prime time small group meetings after each flipping module were realized via Teams in groups of three students. In addition of the feedback discussion students' knowledge on the topic were tested via small group problem solving tasks. Points were assigned from an active participation.

3 RESULTS

During the academic year 2021 – 2022 a total of 28 students completed the Product Design of Electronic device course approvingly. At the end of the course student feedback was gathered with a questionnaire consisting of open questions. Although about ten students were expected, only one student completed the Electronics and Circuit Theory course. It seems that many students have postponed this course to the next academic year. Thus, we cannot draw any conclusions about this course from the student perspective.

3.1 Final Grade of the Product Design of Electronic Device

For the final grade of the Product Design of Electronic Device course the student was able to gather points from the self-correcting multiple-choice tests, F2F learning events, learning assignments and prime time small group meetings. The final grade scale was 0 – 5 and for a grade one student had to gather 27 points out of 56 points. Grade three required 39 points. Grade five required 51 points and in order to gather this amount of points, the student had to take part in a voluntary electronic exam of the course topics. The final grade distribution can be seen in Figure 4.

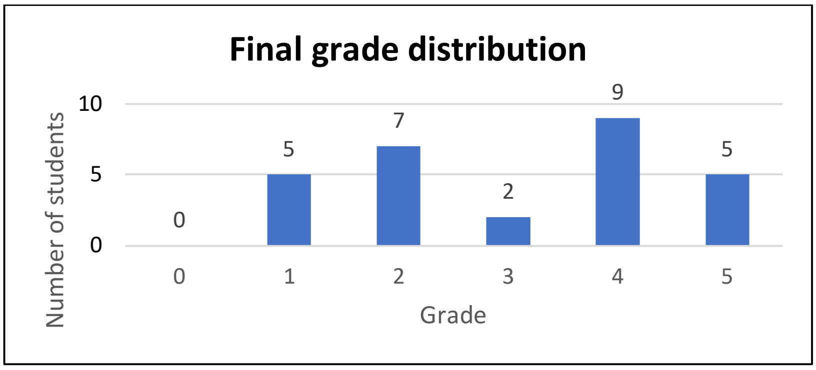

Fig. 4. Final grade distribution of the Product Design of Electronic Device course

As the Figure 4 shows many students (50%) performed very good (grade 4) or excellent (grade 5) at the course. This was expected as flipped learning often results in high student satisfaction and increased performance [5,6]. On the other hand, many students also received grade 1 (17,9%) or grade 2 (25%). There can be many reasons behind this, but these students might have lower self-regulation skills, as it has been shown that high self-regulation skills can be related to high learning achievement [7]. Overall, the grade distribution is consistent with other flipped courses [5].

3.2 Course Feedback of the Product Design of Electronic Device

The open questions in the feedback form asked students' experiences and opinions regarding the flipped classroom model, pre-study materials, learning assignments, F2F learning events, prime time group meetings and the grade formation. Many students believed the FLM promoted learning and made them learn throughout the entire course. This is indicated in Table 1 in the freely translated quotations regarding the question “What are your thoughts about implementing the course by the flipped learning method? Did the implementation method work? Did it promote your learning?”

Table 1. Student feedback on the flipped learning method

“The implementation method worked well ja promoted learning compared to traditionally implemented courses.”
“One had to out of necessity familiarize with the subject and (the method) encouraged to learn through the entire course.”
“In my opinion studying with the short videos and applying the knowledge in the learning events was a functional arrangement. The course didn’t feel too heavy, but one studied regularly during it.”
“I felt I learned well, but I’m not sure whether it was because of the implementation method or because of well and interesting materials.”

The short lecture videos used as online pre-class study material received very positive feedback and many students felt that the F2F learning events deepened their learning, although some students experienced the pace of the events too slow (see Table 2).

Table 2. Student feedback on the pre-class videos and F2F learning events

Pre-class videos	Face-to-face learning events
“The videos were excellent, the most important things were summed up to suitable packages.”	*“The assignments in the learning events visualized and deepened the topics.”*
“The videos were good and it was nice that one was able to watch them several times.”	*“The assignments in the learning events made one consider the topic at hand, and as the assignments were often applied, they were meaningful.”*
“The videos were of suitable length and of suitable amount.”	*“In the discussion assignments one was able to work on the subject together.”*
“Study materials were useful. The videos summarized the main points and from the e-books one could read more detailed facts.”	*“The learning events specified the topics in the videos. Although, if one had watched the videos, the learning events proceeded slowly.”*

There were also some comments in the course feedback about the workload of the flipped learning method being too heavy.

4 EXPERIENCES AFTER THE FIRST IMPLEMENTATION ROUND

In this paper we have introduced our way of implementing FLM to two BSc level electronics courses. The purpose of is to shear our experiences and thoughts about FLM, and this way boost the implementation of FLM also in other higher education institutes.

The design and implementation of the FLM requires time and careful design. Making and editing video lectures is really time consuming and the in-class activities and facilitation need to be planned so that they enhance students’ higher order thinking skills. Furthermore, the design and actual implementation of online self-correcting Moodle assignments were surprisingly time consuming. Teacher's workload is the highest during the first implementation year, but it is expected to be lower after that. Organisation's support for the teacher, such as time allocation, equipment acquisition, possibility to ask for help and peer support, are valuable assets and can greatly promote teacher's interest and success for the FLM implementation. In the structure of the flipped course flexibility, versatile learning experiences, feedback possibilities, individual and collaborative learning possibilities and learning of work life skills should also be considered. Skilled professional instructors are thus important in the FLM and the course content division between outside activities and interactive classroom activities need to be thoroughly planned [6].

The findings of the FLM studies of practise are encouraging for electronics teaching. The short video lectures accompanied with the self-correcting multiple choice tests worked very well as online pre-class study material offering students flexibility and possibility to work themselves mainly independent of time and place. The F2F learning events seem to have worked as well with the aim of learning actively together, deepen the learning and enhancing skills, like design, analyze and compare. Learning of the topic was further deepened with the versatile learning assignments that also offered students collaborative learning possibilities and taught work life skills. The prime time meetings wrapped up the topic and were an important feedback point. Some students felt that these prime time meetings were not useful and that there were too many of them, but from the teacher's point of view the meetings offered valuable information regarding students' learning and possible stumbling blocks. However, in future a prime time meeting after each module or every week it not absolutely necessary, fewer wrap-up and feedback points are adequate as the courses last only seven weeks.

When designing and implementing the FLM students' readiness and experience on working actively according to the method should also be taken into account. Students' readiness and self-regulation skills vary and this can result in disperse learning results as stated above. Course workload can also easily build up overloading or divide unevenly between the different modules or weeks. Careful design of the course workload and introduction to the teaching method are thus things to consider [6].

The findings of these studies are only preliminary since the FLM implementation of these courses were during the academic year 2021 – 2022 and the number of students attending the courses was 29. No absolute conclusions from the grade distribution or from the student feedback can thus be made, but these first implementations clearly showed that video lectures and self-correcting multiple choice tests as online pre-class study material can be automated them being mainly teacher centered. Carefully designed and facilitated student-centered F2F learning events and learning assignments are then needed to enhance students' higher level learning and work life skills not to forget important both-way feedback possibilities. In future the FLM structure of these courses will be continued and more experiences and feedback will be gathered in order to draw more conclusions on e.g., grades and students' self-regulation skills and to improve the courses accordingly.

ABSTRACT

In face of the omnipresence of digital technology in all aspects of life, education and training players are encouraged to adapt to digital tools. This should enable learners to grasp and take advantage of the potential it offers, while developing the various dimensions of digital skills. However, the introduction of digital tools in education and training environments still raises many challenges, especially because any new technology requires from all actors, teachers and learners in particular, a change in their habits and postures. This action research takes as a theoretical analysis framework the model of instrumental acceptance applied to information and communication technologies developed by Caron and Heutte (2017). It focuses on

[1] Corresponding Author, A. Lanthony, antoine.lanthony@isae-supmeca.fr

doi:10.5821/conference-9788412322262.1298

the factors of acceptance and use of a digital tool in general, in particular the 3DExperience platform, by learners involved in applied collaborative projects. It is based on several experiments carried out with students from ISAE-Supméca, a French engineering school, and other students from partner institutions as part of the EXAPP_3D educational research project. With a methodology that focuses on interpretative phenomenological analysis (Restivo et.al., 2018), it provides scientific support for the sometimes complex challenges of integrating new tools in engineering schools.

1 INTRODUCTION

ISAE-Supméca has been involved in educational research for a decade through concrete students' projects involving several stakeholders, from industrial partners to academic partners. In the global framework of the integration of technological tools in the world of education and training in order to improve the transversal skills of learners thanks to the opportunities offered by information and communication technologies, ISAE-Supméca has been introducing for years the 3DExperience platform (Dassault Systèmes).

Several students' projects use this tool as a support and learning tool for the management of collaborative engineering projects and gaining a feedback about their use is of concern and interest, especially in the framework of collaborative projects realized within the EXAPP_3D project[2].

It is therefore in this context of increased use in the process of training learners that this study is located. This work highlights the first results of a qualitative study carried out with ISAE-Supméca students. Our research is essentially focused on the use of the 3DExperience platform. This work with a comprehensive aim seeks to analyse the real uses of the tool and the conditions of its appropriation by the learners.

After a broad review of the theoretical frameworks, we present the context of the study, the characteristics of the target population and the methods of collecting and analysing data. Finally, we present the results of our analysis and conclude.

2 THEORITICAL FRAMEWORK

The explanatory factors for the successful use and integration of technological tools in an educational context have been the subject of many studies in recent decades. The scientific literature indicates the existence of a variety of models to account for the integration of digital tools in teaching (Fievez, 2017; Bauchet et al. 2020) [1] [2].

[2] EXAPP_3D (Experiment Learning by Problems and Projects via 3D Design) is an ongoing so-called e-FRAN project coordinated by ISAE-Supmeca and co-funded by the French Fund Deposits, from September 2016 to December 2022. Among other things, the project aims to promote active learning involving students from secondary school and/or high school and/or Bachelor's degree and/or engineering school in common dedicated projects.

Bobillier-Chaumon and Dubois (2009) [3] group them into three main categories, including theoretical models of the social acceptance of Information and Communications Technology (ICT).

Social acceptance basically refers to the way individuals behave when faced with the introduction of new technologies in both their professional and domestic lives.

Overall, we can distinguish four different approaches to the social acceptance of ICT. We will be particularly interested in the technology acceptance model (TAM) modelled by Davis (1986) [4] during his doctoral research at IBM. It has indeed its roots in social psychology and is inspired by Fishbein and Ajzen's Theory of Reasoned Action (TRA) (1975) [5].

2.1 Theory of Reasoned Action

The TRA rejects the idea that the actions of individuals are underpinned by unconscious, capricious and unpredictable motivations. Thus for Fishbein and Ajzen (1975) [5] human beings consider the implications of their actions before deciding whether or not to engage in them. "Behavioural intentions are indications of an individual's willingness to perform a behaviour" (Fishbein and Ajzen, 2010, p. 39) [6]. Therefore TRA is based on the assumption that behaviour (the adoption of new technology, for example) is under the total control of the individual (Giger, 2008) [7].

This theory analyses the intentions of using a tool based on three social determinants:

- the attitude, which refers to a set of values and beliefs, which leads a user to evaluate favourably or not the fact of adopting new technologies,
- the subjective norm corresponds to the social influence or the social pressure perceived by the individual to adopt the tools (perception of the expectations of others),
- the degree of motivation of the subject to comply, to follow or not the incentives for adopting the tool.

The theory of planned behaviour proposed by Ajzen (1991) [8] is an extension of the theory of reasoned action by adding a new component: perceived behavioural control (perceived self-efficacy, expectation of success).

Both of these theories hold that social behaviour is eminently voluntary, because it implies a choice based on deliberation (Ajzen & Fishbein, 1980) [9].

2.2 Technology Acceptance Model

The Technological Acceptance Model (TAM) of Davis (1986) [4] was inspired by the work of Fishbein and Ajzen (1975) [5] by taking up the variables of the Theory of Reasoned Action (TRA) to which he integrates new elements.

The TAM postulates that attitude in forming the intention to accept a technology is based on two fundamental determinants: perceived usefulness and perceived ease of use. Davis, Bagozzi and Warshaw (1989, p. 985) [10] state that the perceived usefulness refers to “the prospective user’s subjective probability that using a specific application system will increase his or her job performance within an organizational context" and the perceived ease of use refers to "the degree to which the prospective user expects the target system to be free of effort". Thus, according to this model, the perception that individuals have of usefulness and ease of use determines their attitudes and subsequently their behaviours in the use of technologies (Brangier, Hammes-Adelé & Bastien, 2010). [11]

The TAM had a resounding success and is even considered to be the dominant model for studies on the acceptability and adoption of ICT (Sanghee et al. 2013) [12].

Thanks to this success, other derivative models have been developed, integrating a multitude of external and moderating variables.

Faced with the diversity of enrichments to which the TAM has been subjected, Venkatesh et al. (2003) [13] proposed a "Unified Theory of Acceptance and Use of Technology (UTAUT)" from a synthesis of several behavioural models to explain the use of technology.

2.3 The instrumental acceptance model applied to ICT

The UTAUT has made it possible to identify four determinants on which the intention to accept a technology is based; namely the performance expectancy, the effort expectancy, the social influence, and facilitating conditions.

Caron and Heutte (2017) [14] adopted this model by necessarily adapting it to their context of study. The authors use therefore these four direct indicators of the intention to use (performance expectancy, effort expectancy, social influence, facilitating conditions). They match respectively the first two indicators (performance expectancy, effort expectancy) to the utility and usability dimensions. In order to understand the use of the prescribed tool, they propose that the perception of utility is broken down into the perception of general utility and projected utility. Their adaptation of the technology acceptance model is presented hereafter.

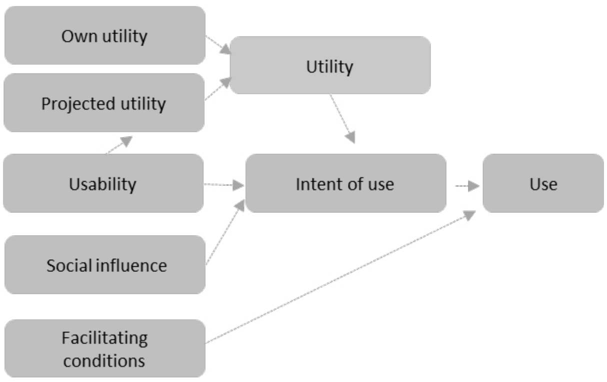

Fig. 1. The instrumental acceptance model applied to ICT (Caron and Heutte, 2017) [14]

The self-utility concerns the learner's assessment of the usefulness of the tool for him/herself. The projected usefulness concerns the learner's projection of the usefulness of the tool for his future, professional activities (in the context of this study, it is about the learners' perceptions of the requirement of mastery of the tool for professional issues). The usability is linked to design, efficiency and satisfaction. According to Davis (1986) [4], it influences utility. The social influence and the facilitating conditions are intended to address the use of the device in its context, by evaluating the social reasons and the conditions (institutional, environmental in the broad sense, etc.) pushing to use the tool.

3 OUR STUDY

3.1 The context

ISAE-Supméca being a French engineering school involved since many years in problem-and project-based learning (PBL) and in educational research, many issues emerged at the confluence of research and practice. Our study is therefore positioned at this confluence, in other words, in a space that meets “both the challenges of knowledge and those of action” (Carré, 1998) [15].

This work was carried out as part of an evaluation following the implementation of the EXAPP_3D project led by ISAE-Supméca and involving several academic and professional actors. This educational project uses the PBL approach in the training of engineers, based on the most innovative digital chain tools, in particular the systems and collaborative animation modules of the 3DExperience from Dassault Systèmes. 3DExperience is a platform that has the advantage of capturing all the activities of an organization and its partners in one place. The use of this tool aims on the one hand to promote greater interactivity and learning of collaborative work in project mode by using digital as an opening to new actors and new know-how for our learners. On the other hand, it promotes the development of monitoring strategies, methods and support tools by and for teachers using digital as a teaching tool.

The objective of our work is to assess the contribution of the project as a whole to pedagogy and its impact on the development of learners' skills.

We will only report here on part of this work: based on a qualitative study, we questioned the feelings of learners about the contribution of digital technology and mainly the use of the 3DExperience platform in the context of collective projects they had carried out.

3.2 Population of our study

We contacted the learners from the 2021-2022 class of ISAE-Supméca who worked on collaborative projects with partners and involving the use of the 3DExperience platform in order to obtain their active collaboration in this research work, through a personal interview. Among the people contacted, 6 showed their interest in participating in the project. We were finally able to interview 4 people, 3 men and 1 woman, from 22 to 24 years old. The concerned learners all used the 3DExperience platform for the first time during the project period, as this use is for the moment experimental for students within some PBL modules, especially in the framework of EXAPP_3D. So, our study is a first qualitative approach of students’ feedback and complements another study published in 2021 [16]. The limited number of people in the sample makes this study an example that cannot be generalized.

3.3 Data collection and methodology

Data collection began with a phase of observations in contexts. It aimed to better understand the overall portrait of learners and their training environment. This ethnographic approach, which consists of observing in contexts, was omnipresent throughout the investigation. Subsequently, a corpus of 6 semi-structured interviews was collected from ISAE-Supméca learners who had worked with the aforementioned platform. Proceeding with semi-directive interviews allowed us to give an orientation to the discussions with regard to the main themes of our research while leaving the necessary latitude to the interviewees for the nuance and explanation of their positions (Michelat, 1975) [17]. We were interested in analysing the conditions of use of a tool, the 3DExperience platform, among learners. The method that seemed suitable for capturing the observed phenomenon is induction.

For data processing, we used interpretative phenomenological analysis, a method proposed by Restivo et al. (2009) [18]. Thematic analysis was also used during this step. It consisted of identifying, story by story, the themes addressed, checking their recurrence from one interviewee to another. The thematic analysis was done using RQDA software. This tool allowed us to automate the identification and extraction of themes (coding) from each story. Coding facilitates the work of comparison because it allows the connection of passages dealing with the same subjects. Our corpus of texts was therefore imported into RQDA in order to carry out this thematic coding.

4 RESULTS

In this part, we present our results according to four categories: general utility, usability, social influence and digital environment of the institution.

4.1 General utility

The data analysis shows a positive perception of the usefulness of the 3DExperience from all the interviewees. They generally recognize the indispensability of this tool for certain aspects of their work, in particular the collaborative aspects given the geographical dispersion and the physical distance between all the actors involved. As a result, learners show a positive attitude to the use of the 3DExperience. For them, the tool is “very practical” and has an undeniable advantage because they can do everything with it: easy access to the work of each member of the group, communication with academic and professional tutors, etc.

The use of the tool for their projects determines the usefulness they perceive of it. The 3DExperience platform arouses their interest in view of the results of the analyses.

However, they use it very sparingly. For them, use is limited to the scope of collective projects. This is a relatively short period (even if each student works around 200 hours, only 2 months are almost full time) during which learners primarily use the tools they master and use with their teachers. Indeed, as already stated, these learners involved in the study used the 3DExperience platform for the first time during this PBL period. ISAE-Supméca students use it for the moment only during some projects modules, whereas all apprentices use it. So, one could argue that the use of this tool has a small impact on the general training of the learners of our study.

4.2 Usability

The 3DExperience is perceived as a complex tool because it brings together in a single place a set of 3D applications to which are added other functionalities that seem close to an educational platform. As a result, its usability is closely linked to it being used by our learners. The various functionalities of the platform are not mobilized in the same way according to the individual commitment of the students and their agency.

At the exception of students from one group, who used extensively the 3DExperience applications and used it for topology optimisation, our students mainly used it as file storage (access to resources) and communication (to a large extent) on the dashboard dedicated to the different groups and projects; to which only members have access. These uses are perceived as being very simple and intuitive. Thus, the majority of interviewees find the usability of the 3DExperience satisfactory. They then express a feeling of self-efficacy on these uses.

On the other hand, the design, optimization and simulation activities required self-training on the part of the students to improve their knowledge and have a greater mastery of the tool. It is here that the concept of agency used above finds its full meaning, insofar as it calls on the self-training activity of individuals as a self-directed learning process. Although all the learners expressed their training needs, the data show that only a few showed agency in implementing learning strategies to increase their effectiveness in using the tool through tutorials or other types of resources.

It could therefore be argued that the perception of the usability of the tool is variable and depends on the functionalities implemented, given the polymorphic nature and the richness of its functionalities.

4.3 Social influence

The social influence associated with the use of 3DExperience seems mainly linked to the injunctions received from academic and professional tutors and seems linked to a relative mastery of the tool on the part of the latter. The data analysis reveals that the interest given to the use of the platform was not the same in all the projects. In some cases, the use was perceived by the learners as an imposed or prescribed decision. The strategies for adopting the tool on the part of the interviewees were linked to their perception of the injunctions issued by the various tutors to use the tool. These learners perceive the first getting started tutorials provided by the tutors as a prescription for use. As a result, the deepening of the functionalities of the tool is nourished and supported by the connotations linked to the profile of the model learner, a determined individual-learner.

4.4 Digital environment of the institution

The analysis of the data brings out the theme of the institution's digital environment. It is present in the remarks of all the interviewees and concerns the digital tools used during their training. Their remarks are mainly structured around the determining elements put in place by the school in the training of students: the class, the courses, the modules.

The learners interviewed describe an environment that is not conducive to the full use of the tool set up for the projects. Indeed, as already stated, the 3DExperience tool provided for the projects is for the moment experimented only in several PBL modules and is not the subject of any training before the projects and is not used as a learning tool in any training module either (for the students, contrary to the apprentices in our institution). These results highlight the existence of a correlation between the discourse on the lived environment and the real practices of the learners during the projects. The use of the tool does not go beyond aspects perceived as intuitive and related to their digital skills. It could be argued that there is a strong correlation between the training received and the uses implemented. We note that the little training received in some groups thanks to tutorials from academic and/or professional tutors is positively correlated to the learners' feeling of self-efficacy and is the basis of the self-training strategies implemented.

5 CONCLUSION

At the end of this study, it appears that the 3DExperience platform is mainly used to access project resources, to store them and to provide access to them anywhere and at any time to other members of the work group. It is spontaneously used by all learners when it comes to communicating with other geographically distant actors and receiving feedback from their various tutors. On the other hand, it is often neglected when it comes to implementing more advanced functionalities such as design or simulation. In this sense, the functionalities that seem perceived as the most useful, even if more professional, are similar to that of an educational platform: space dedicated to each project where the project's resources are stored and are accessible, a space for coordination, mutual aid and communication between learners and between teaching staff/professional tutors and learners. It means that the real power of the tool was not really used during these projects.

The study highlights a discourse accounting for the uses of the platform and highlighting some components of instrumental acceptance (general utility, usability, social influence). It also makes it possible to understand that for learners, the in-depth use of a tool essentially involves institutional prescription, through training or the implementation of modules related to the skills for using the tool. Training in the perspective of supporting the appropriation of tools, even minimal, increases the sense of self-efficacy of learners and leads them to show agency.

Finally, we want to stress that we will use this feedback and then intend to conduct new studies like this one in the coming years, on broader samples, in order to be able to progressively implement more gradual changes.

ABSTRACT

In a context of transformation and increasing complexity of work due to the development of information technologies, communication and digital networks, the question of the acquisition and development of collaborative skills of engineers in training arises with a particular sharpness. Achieving their acquisition in practice is a major challenge. In France, although included in the training programs for students, the world of training is struggling to find the teaching and learning adapted and capable of developing collaborative skills in engineering students. Thus, the practices and methods implemented are different from one institution to another. It

[1] *Corresponding Author, A. Lanthony, antoine.lanthony@isae-supmeca.fr*

goes without saying that the acquisition and development of collaborative skills that are highly sought after on the labor market are unequally distributed among graduates of the major engineering schools. Thanks to a recombination of theoretical approaches, a qualitative and quantitative study conducted at ISAE-Supméca, a French engineering school, in order to obtain an overview of the collaborative skills developed by the students during specific problem- and project-based learning modules, and also in order to provide a critical analysis and feedback about the development of collaborative skills into the students' training program through these applied professional projects that immerse them in work contexts close to the future professional realities. The results show a strong gap between skills development and a focus on the development of skills from the “Process – Deliberation” category.

1 INTRODUCTION

ISAE-Supméca has been involved in educational research for a decade through concrete students’ projects involving several stakeholders, from industrial partners to academic partners. Among other issues, skills is a topic of interest, especially collaborative skills.

Our study focuses on the feedback on collaborative skills from ISAE-Supméca’s students project realized in collaboration with students from other institutions. More specifically, the aim of the study was to obtain an overview of the collaborative skills developed by the students duting these projects.

Our paper is organized as following. Section 2 provides the theoretical framework in which the study took place. Section 3 presents the specific projects analyzed in-depth in order to provide the feedback. Section 4 exposes the methods. Finally, section 5 presents the results and section 6 concludes our paper.

2 COLLABORATIVE SKILLS: ESSENTIAL FEATURES AND ANALYSIS GRID

Although there is a lot of work in the scientific literature on cooperation and collaboration and a keen interest in exploring this concept, no single theory can help to understand the complexity of what is at stake in these dynamic. We will briefly present the theoretical contributions that make it possible to analyze collaboration and cooperation as a process evolving over time.

Collaborative skills result from a social construction within a formalized framework or not (D’Amour, 1997) [1]. We see it as the capacity for the subject to synergize with others by building links in order to achieve a common work (Dejours, 1993, Policard, 2014) [2] [3]. To understand the dynamic nature of the collaborative process, it is necessary to determine the main anchors in which the temporal perspective of the collaborative process is rooted. The approaches taken into account in this work make it possible to account for the dynamic dimension of the collaborative process.

The work of Mattessich and Monsey (1992) [4] offers an explanatory reading of collaboration phenomena. They identified 19 factors influencing the success of a collaboration, which they classified into six groups, related to six topics:

- Related to the environment,
- Related to group membership,
- Related to process,
- Related to communication,
- Related to purpose,
- Related to resources.

Thomson and Perry (2006) [5] present a similar classification. They propose a scale of the collaborative process that covers 5 key dimensions of collaboration, each involving activities related to this process:

- Governance,
- Administration,
- Organizational autonomy,
- Mutuality,
- Norms.

According to Thomson and Perry (2006) [5], the black box of the collaborative process includes three sequences whose structure resembles the models commonly used to illustrate the dynamics of the activity: antecedents – process – results.

The sequential analysis of collaboration proposed by Thomson and Perry (2006) [5] is close to the collaborative skills model of Morse and Stephens (2012) [6]. The latter maintain that the prior analysis of the type of activity carried out collectively by the actors involved in a collaboration makes it possible to identify the different phases of the collaborative action (Sanojca, 2018) [7]. They associate specific skills drawn from the literature with the different stages of the identified collaboration. The originality of their work was to consider that the type of skills used in the collaborative process stems from the very structure of the project. As a result, the authors argue that collaborative skills are skills that adapts to the dynamics of the process in which they are exercised.

According to Sanojca (2018) [7], the term "meta-competencies" (in which they include for example "collaborative mindset) given by Morse and Stephens (2012) [6] is not appropriate with regard to the constituent skills of this group, which are more akin to transversal skills. The "meta-competences" described here can rather be considered as attitudes or predispositions that can influence the choice to collaborate or not.

Sanojca (2018) [7] therefore proposes to establish a correspondence between them and the "antecedents" of the collaboration identified by Morse and Stephens (2012) [6].

By reorganizing all the skills identified in these approaches (Morse & Stephens, 2012; Mattessich & Monsey, 1992) [6] [4] according to the model of Thompson and Perry (2006) [5], Sanojca (2018) [7] obtains a scale of collaborative skills mobilized for the identification of the nature of the collaborative skills implemented by our students.

These three models constitute a theoretical framework of reference for the analysis of our data.

3 CASE STUDIES

For several years, ISAE-Supméca, a French public engineering school, has been offering its last-year students the possibility of carrying out a so-called “synthesis project”. These projects are done in a problem- and project- based learning (PBL) approach and are more precisely based on the socio-constructivist approach and give a central place to the individual in the co-construction of his knowledge from personal experiences and in his interactions with his environment (Vygotsky, 1978) [8]. Students work in teams of three (sometimes in teams of two), during around 200 hours (for a group total of around 400 to 600 hours) on a three-month period (and are almost full-time at the end of the period) on situations requiring the confrontation of points of view and the joint resolution of problems. The particularity of this PBL module is that it allows students to work on a subject proposed by companies on industrial issues, with all their complexity and richness. Some of these PBL include in these working groups at least two second-year BTS (French 2-year studies technician curricula) students, in the framework of the EXAPP_3D[2] project. These projects have run under the following collaborative projects model.

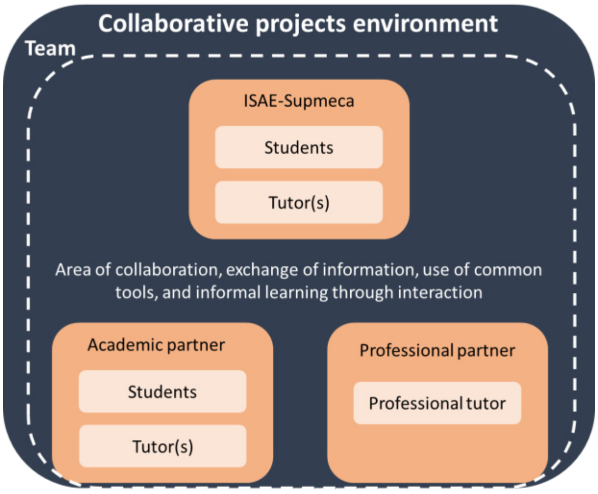

Fig. 1. ISAE-Supméca collaborative projects model [9]

Here, we study projects conducted with two partners: Lycée Voillaume and Lycée Louis Armand, both located in the same region (Ile-de-France) as ISAE-Supméca. As a result, these PBL involve many stakeholders and are focused on collaboration and 3D design and lead to concrete deliverables. A paper published in 2021 presented the frameworks of these projects and focused on academic and industrial tutors feedback in order to highlight some best practices [9].

[2] EXAPP_3D (Experiment Learning by Problems and Projects via 3D Design) is an ongoing so-called e-FRAN project coordinated by ISAE-Supmeca and co-funded by the French Fund Deposits, from September 2016 to December 2022. Among other things, the project aims to promote active learning involving students from secondary school and/or high school and/or Bachelor’s degree and/or engineering school in common dedicated projects.

The present works is a new block in the studies of these projects, especially their collaborative aspects.

4 RESEARCH METHODS

An exploration method appeared to be the best way to account for the social interactions between each student and actors involved in the projects, insofar as it induces the use of a qualitative data collection method (Fortin and Gagnon, 2016) [10].

The approach we have favored in this study is comprehensive and inductive. This inductive approach makes it possible to take what can be learned from the data as a starting point.

A collection of data by non-directive individual interview lasting an average of 30 minutes was conducted with eight students (five men and three women aged 21 to 23) contacted with regard to the activities they carried out in groups of two or three. Were excluded from our panel the groups in which we could not interview all the members.

Each of the participants was invited to express themself on the existing social interactions and the way of working during the project.

The qualitative data collected was analyzed using a computerized tool for processing textual data: RQDA (R package for Qualitative Data Analysis) from the items of our scale. It was a question of assigning to code the corpus when it was obvious to establish its correspondence with one of the items of the scale.

We have also opted for a mix of analysis methods, which combines quantitative and qualitative analyzes according to our progress in understanding the phenomenon studied.

5 RESULTS

The aim of our study was to understand a phenomenon: the acquisition and development of collaborative skills of students involved in collective projects, according to the point of view of students who experience it.

5.1 Overview of declared collaborative skills

In this part we present the action verbs and expressions used by ISAE-Supméca students, from the eight interviews conducted. The interviewees had to describe their collaborative practice based on a broad question: “What exactly do you do when you collaborate?”

The data collected was related to the different items of our scale, made up of skills rewritten and reorganized using the approaches of Morse & Stephens (2012) [6], Mattessich & Monsey (1992) [4] and Thompson and Perry (2006) [5].

These data, presented in Figure 1, are organized according to the different categories of our scale, highlight the average number of expressions listed in the verbatim statements and analysed as well as the number of people for each skill.

The general average occurency of the statements corresponding to the skills of the scale is just under 4. As a result, only the skills cumulating a number of statements greater than or equal to this threshold were considered significant. They are the lines in bold blue in Figure 1. Skills rarely or very rarely quoted by the students are the line in dark orange.

5.2 Data on the nature of the collaborative skills implemented

These data presented in Figure 2 allow some analysis on the nature of the skills the students pretend to develop through the occurency of the speech about them.

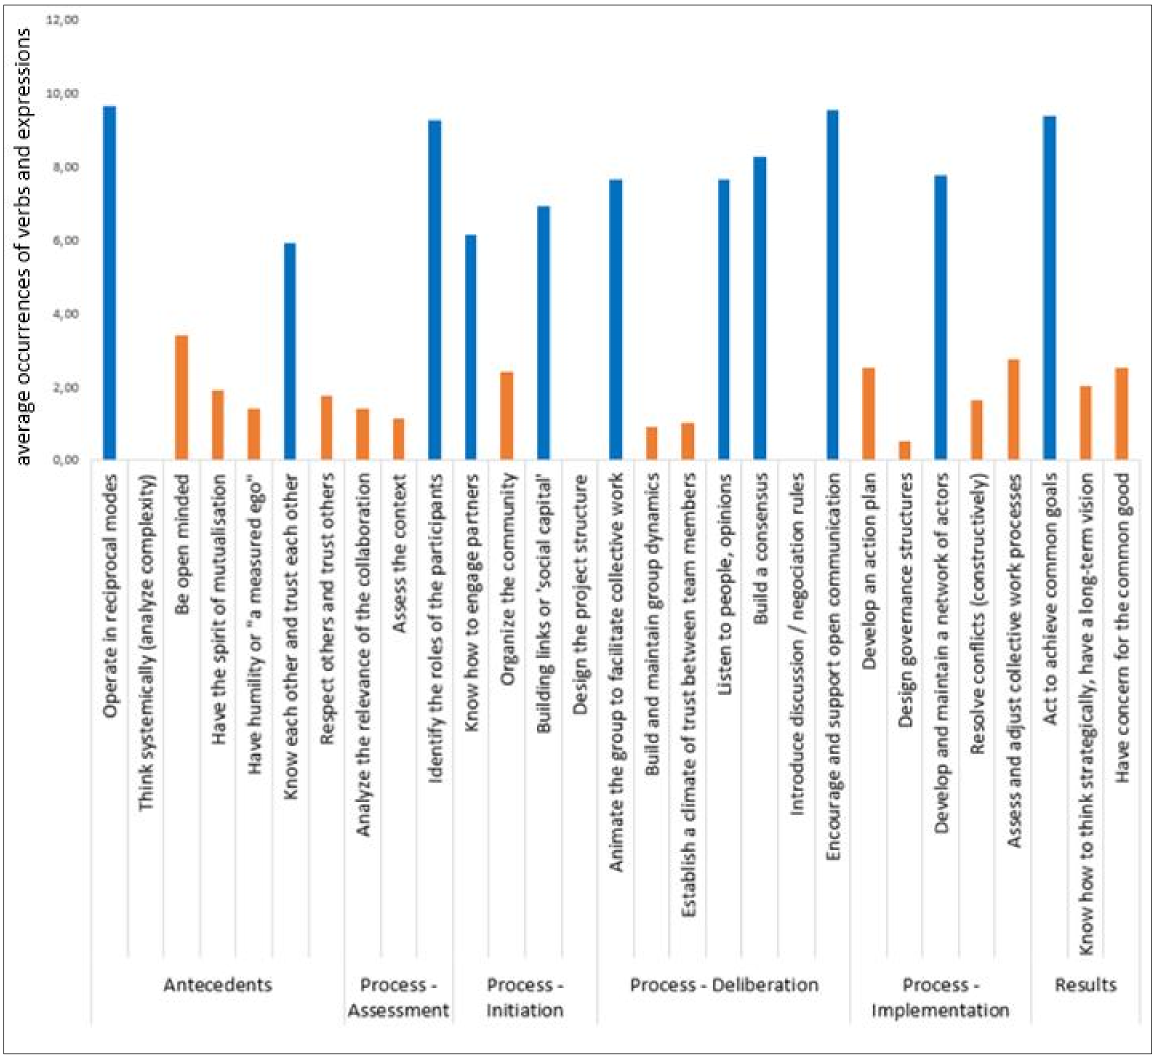

Fig. 2. Average occurencies of action verbs and expressions used by students in reference to each skill as re-written taking into account and reorganizing Morse & Stephens, Thomson & Perry, Mettessith & Monsey approaches

Among the skills with an average occurency over 4, four items have an average occurency over 9: these items are : “Operate in reciprocal modes”, “Identify the roles of the participants”, “Encouraging and supporting open communication” and “Act to achieve common goals”, all belonging to different categories. In terms of category, We note that the skills relating to “Process – Deliberation” are numerous to be considered developed (4 out of 7) and among them, “Encouraging and supporting open communication” stands out slightly, just above “Building a consensus”.

On the opposite, some skills are very rarely or even not quoted, but it should be highlighted that although these skills are rarely mentioned, the fact remains that they are the subject of development for some students.

We will now focus more on several significant data with regard to the threshold of 4 already explained. More precisely, we will highlight four other results of our study.

5.3 Development of attitudes related to the collaboration developed

Collective work is facilitated by the knowledge of the members of the group, which is acquired through interactions. This knowledge makes it possible to establish a balance within the group, based essentially on “trust”. In a context of collective work, knowing others is an undeniable asset. Indeed, knowing the members of your group means having knowledge of their skills, the way they work and the soft skills that characterize them. “I knew that we didn't have the same skills at all,” underlined one of the interviewees. So, even if the “Know each other and trust each other” skill received an average occurency of less than 6, it was quoted by all students and seems important for them.

5.4 Skills related to the implementation process and the achievement of goals

These collaborative attitudes are necessary to enter into collaboration and prove to be very judicious for the collective mode of work. To know is also to adopt a collective work organization which consists of a sharing of tasks by identifying the roles of each. This knowledge of others makes it possible above all to accommodate diverse personalities, accept other points of view and be attentive to each other: to listen to people and opinions.

Consensus building emerges also in parts of students statements; that is, the fact that the members of the group must succeed in converging their ideas to reach an agreement that satisfies everyone, when they discuss the activity.

To reach a consensus, everyone must speak up and communicate. Here the notion of communication refers on the one hand to the interactions relating to the task which are aroused during collective work and the confrontation of points of view and on the other hand to the fact that everyone is encouraged to freely express their ideas without embarrassment.

The items "Know how to engage partners" and "Building links or ‘social capital’" in the category “Process – Initiation” see an average occurency above 6 and refer to the way students proceed to achieve the goals they have set themselves and which are linked to the concrete organization of collective activity on an equal distribution of tasks within the group. But even by following this modality, students are aware that they must establish links allowing a certain proximity between members of the same group. These goals emanate from a desire to “succeed” in collective activities and to rely on the strengths of the group to achieve them.

5.5 The emergence of a new attitude: benevolence

The analysis of the data also reveals skills acquired by the students and not appearing on our scale. This is the case of benevolence perceived through the expressions “listen”, “attention”, “comfortable”, “benevolent” used by the interviewees. They emphasize the idea that students strive to interact with members of their group in a respectful and caring way and expect reciprocity from them. Benevolence is a state of mind that promotes the establishment of a healthy work environment.

5.6 Skills not developed according to the students

The analysis of the data also show that 3 skills were not quoted at all by the students in their speeches. These are “Think systemically (analyze complexity)”, “Design the project structure” and “Introduce discussion / negociation rules”. If the latter could maybe seem not so surprising, the two first ones can be surprinsing, especially in an engineering school. Also, only 3 students quoted the item “Design governance structures”, making this skill far from a priority. This result about skills not or barely mentioned is a small matter of concern about the development of some of these skills in the kinds of PBL modules studied, even with an academic partner and with many situations close to the professional environment.

6 CONCLUSION

We mentioned the importance for training structures in general, engineering schools in particular, to develop the collaborative skills of students. Data from interviews with students show that the collective projects offered to students promote the development of collaborative skills in action.

The development of these skills in situations close to those experienced in a professional situation corroborates the idea that the work situation conveys knowledge and generates skills (Schön, 1983; Orlikowski, 2002) [11] [12].

As a result, by focusing on what students do during collective projects and how they do it, we have managed to highlight the skills constituted by their collaborative practices. Although the data analysis has made it possible to observe the emergence of new skills, it should be specified that it is also important to note the analysis of the data reveals new skills not present in our scale. Indeed, our semi-directive interviews brought a reflective posture from the learners towards their practices and it brought more student awareness of skills practiced and learned.

We can therefore argue with Sanojca (2018) [7] that “There is a strong link between the development of collaborative skills and activity” (p.355).

Also, we can propose the hypothesis, especially because the understanding of each other and their roles in the project was highlited, that the length is important. For this reason, in order to compare results, we intend to conduct a similar study on groups of students working on a shorter period and studying one grade earlier.

ABSTRACT

In Engineering, the construction of informed, persuasive and convincing arguments is at the very core of everyday practice. However, in taught postgraduate education there is often an excessive focus on assessment of these skills through written arguments or oral presentations that are usually in the form of long uninterrupted monologues, where the construction of the arguments themselves is almost never challenged. To change this status quo, we have successfully pioneered the use of oral debate as a dynamic and engaging mechanism to develop and assess this skill in our Chemical Engineering MSc students.

Debate is an ideal mechanism to assess our students' ability to construct arguments as it actively encourages them to (1) think about both sides of an argument, (2) consider how they can persuade others and (3) express their viewpoint

i.mackay@ucl.ac.uk

professionally but with conviction. For this reason, the debates undertaken were linked to important engineering ethical dilemmas, by discussing topics such as "should developing countries prioritise the shift to clean energy over economic growth".

The development of this debate-based training and assessment has had numerous positive outcomes on the students' learning experience and vital skills development. Importantly students found the debates to be both an interesting and enjoyable method of assessment and noted that the skills learned would be useful in their future careers. In this concept paper we present our experiences in delivering debate assessments to engineering students along with recommendations for practitioners wishing to implement similar styles of performative assessments in their own pedagogy.

---

1 INTRODUCTION

1.1 Problem

A core part of everyday practice as an engineer, whether in the classroom or in industry, is the ability to construct persuasive and convincing arguments [1]. Despite this, we very rarely see the skills being actively developed in taught undergraduate and postgraduate engineering courses. It is rarer still that they are directly assessed, and if they are there is commonly a major focus on written arguments within larger reports. Whilst oral presentations do appear to allow the assessment of spoken arguments, they are usually in the form of pre-prepared, long and uninterrupted monologues, in many cases read from text or bullet points, followed by technical questions. Although these methods do allow technical expertise to be demonstrated, the quality of the argument structure and its impact, i.e. its construction, is almost never appraised. Possibly more importantly, arguments are also rarely challenged, particularly in the spoken form, despite this being a common feature of an engineer's everyday professional experience.

It is clear that in engineering education we must develop teaching and assessment methods that promote team working and effective communication, actively engage the students and allow them to improve their ability to develop, present and adapt arguments. To achieve this we would ideally pair any new pedagogical practice with subjects that allow for nuanced, complex and two-sided thought and discussion, as this will help to meet the requirements of classroom assessment as presented by the National Research Council [2]: to "give students the opportunity to think critically as they apply their understanding under novel conditions to solve new problems or to explain novel phenomena."

1.2 Ethics in Engineering

Ethics is an area, unlike most others in engineering, where there is no 'right' or 'wrong' answer to a question, rather we must use ethical frameworks to form views on which is the optimal path to follow. Nonetheless, it is a topic that it vital that engineers both engage with and understand; It is mandatory that ethics is taught for IChemE [3] accreditation. When discussing ethics in practice we must persuade and convince others, within our team and more widely, that our choice is appropriate, potentially adapting and reframing our arguments based on their unique perspective. Although written essays may be utilised to assess these skills to some degree, they primarily assess slow cognitive argument formation and presentation. Yet, in a non-educational context (e.g., employment) making fast-paced decisions that must instantaneously be justified, and are frequently challenged, is a common, if not every day, occurrence. Performative assessment methods, like debate, are better placed to develop and assess these skills.

1.3 Debate as a form of assessment for engineering ethics

The term debate finds itself applied to describe a broad and diverse spectrum of activities, ranging all the way from formalised parliamentary proceedings to chaotic online forum threads. In the context of utilising debating as a pedagogical tool, leading practitioners have defined a debate as referring to, broadly, “an equitably structured communication event about some topic of interest, with opposing advocates alternating before a decision-making body” [4].

There are several published examples from higher education where in-class debates have been used successfully, both as formative and summative assessments, yet the majority of the cases have been within humanities subjects with only a few examples from STEM subjects [5]. Debates encourage students to focus less on the facts, but more on how they use them to construct robust arguments, by conducting thorough independent research to develop a deeper understanding of the technical knowledge in order to be able to present that information robustly [6]. The development of such argument construction skills, alongside having to consider alternative viewpoints, is particularly useful for students’ to be able to discuss ethical dilemmas [7]. Debate has been clearly shown to be a successful tool for building student’s confidence in handling ethical dilemmas, particularly in relation to the health care sector where debate has been shown to improve nurses moral judgement [7]. However it has yet to be shown that this will work in an engineering context.

For many students, a debate may be the first time that their ideas have been critically challenged and so students are encouraged to think critically about the material in order to actively engage with the other side and present dynamic and robust arguments. In the few examples of debate being used within STEM subjects [5], the studies that have been discussed have clearly shown that debate-based assessments are beneficial to the student experience. Hence in the 2019/2020 academic year we piloted the use of oral debate as a mechanism to assess our Chemical Engineering MSc students’ understanding of ethical issues – a vital part of Chemical Engineering education [3]. As per the definition earlier stated given by [4], in our assessments we made use of a style of formalised debating which is standard at many competitive debating tournaments in the UK, making a few minor adaptations to simplify the rules for our students’ benefit. Borrowing from competitive standards ensured that as a means of assessment our debates were suitably structured, equitably-balanced and involved direct communication towards the assessors as the adjudicating decision-making body.

1.4 Objectives

Given the clear benefits of debating as a form of assessment that have previously been discussed, in the 2019/2020 academic year we piloted the use of oral debate as a mechanism to assess our Chemical Engineering MSc students' understanding of ethical issues – a vital part of Chemical Engineering education [3].

The aims of this pilot were to: a) determine if debating would provide valuable skills to engineering students, b) determine the best way of assessing debating skills and c) provide a framework for debating in engineering education that can be implemented by other teaching practitioners

In this concept paper we will discuss how effective the pilot year was and what impact it had on our students. We will also discuss how we have since developed the debating assessment, with a view to providing recommendations and encouragement for other teaching practitioners who wish to implement similar assessment techniques in their own courses.

2 METHODOLOGY

2.1 Student Background

This study was undertaken in a Department of Chemical Engineering at University College London, as part of the development of a new MSc level module on 'Research Skills' with an annual enrolment of 22-40 students. The students taking this course all have an undergraduate degree in Chemical Engineering, Chemistry or similar, however come from institutions across the globe. This lecture course was designed to ensure that they all have the same training to successfully undertake their final research projects. Alongside more traditional skills topics including literature searching and academic writing, research ethics is taught. Ethics was a subject that had not been explicitly taught as part of either undergraduate or postgraduate courses prior to 'Research Skills', instead different aspects had been covered in various modules. 'Research Skills' is fully assessed via coursework (both written and oral), with no examination component. Prior to the conception of this course, any preparation for the MSc research project was presented via traditional didactic lectures or in written texts.

The debate assessments were piloted in the first term of the 2019/2020 academic year. After their success this was continued, despite the pandemic, through the subsequent two academic years. These debates have had remarkable success in both in person, and remote teaching environments.

2.2 Debate Assessments

As previously discussed, debate is an ideal mechanism to assess our students' ability to create strong arguments, a valuable skill for the workplace, and especially for discussing the numerous ethical issues we face as engineers. However, for the majority of students debating is a novel form of communication which they are unlikely to have any significant prior experience of. Hence, we recognised that we would first need to provide the students with debating skills training before we utilised debate in any assessment.

In the pilot year, 2019/2020, bespoke hands-on training workshops were developed, in collaboration with the leading UK debating charity Debate Mate [8], to teach debating skills to the students, as well as providing opportunities for cohort building and increasing student confidence in public speaking. This training included sessions of information transfer from Debate Mate mentors to students (direct teaching), student-led activities, and scenario based applied learning via mini-debates. They therefore developed the students' critical and creative thinking skills for problem solving and encouraged the students to think on their feet and build dynamic arguments. This debate training was vital in improving the communication skills of the students and enhancing their ability to influence others and create impact with their arguments.

The students were then split into small teams for the final assessment, participating in a structured debate on an ethical issue related to science and engineering. The students were given their motion and whether they would be for or against the motion, one week to prior to the assessment for them to adequately prepare background research. An example debate motion is:

"*This house would punish workers who do not blow the whistle on malpractice, corruption or negligence as if they had carried out those acts themselves*."

In the debate, students presented their arguments (and rebutted arguments from the opposing team) using techniques learned in the training sessions. Teams could interrupt each other through requests for 'points of information' (POIs) and questions could be asked by the audience, responses to these had to be integrated into the final speaker's summary. This meant students could not prepare a static speech, but instead needed to reactively adapt their argument as the debate progressed, in order to be more persuasive.

In the assessed debates our students were evaluated on three key areas. Firstly, Style, the extent to which they were communicating clearly, confidently and utilising the persuasive techniques covered in the training sessions. Secondly, Content, the strength of their argumentation and rebuttal in terms of logical construction and analytical sophistication. And thirdly, Strategy, which covered a broad range of criteria including role fulfilment, time management, teamwork and engagement with POI's and questions from the audience where relevant. A representative from Debate Mate with a background in adjudicating competitive debating tournaments moderated the debates and functioned as a second marker.

2.3 Remote Learning

The pilot year was a great success and so the teaching team were highly motivated to continue to develop and optimise debating as an important training and assessment tool for the 2020/2021 academic year. However, in the 2020/21 academic year debates and training were moved online due to the Covid-19 pandemic. All teaching and assessments were undertaken via an online platform (Zoom). Online debate training sessions had very similar content to that of the previous year, ensuring that the vital aspects of communication for leadership were still practiced. For the debates, functionalities of the platform helped to maintain the dynamic and high energy feeling for this highly engaging form of assessment. The whole class was present on the Zoom call, and they were encouraged to use the ‘reactions’ emojis (e.g. applause) to praise or support well-made arguments (in place of in-room applause). Participants could make POIs via the ‘raise hand’ function and the moderator ensured the speaker was aware.

3 RESULTS

3.1 Student Feedback

When implementing a new form of assessment, it is important to evaluate how the students perceived the task and whether they found it useful. Over the past years we have actively gathered feedback from students on how they found the debate assessment. We conducted a non-compulsory anonymous survey asking the students if they believe that the debating had a “positive impact on their learning experience”. The results of this survey for the past three years are shown in figure 1, with all students indicating that they agreed with the statement.

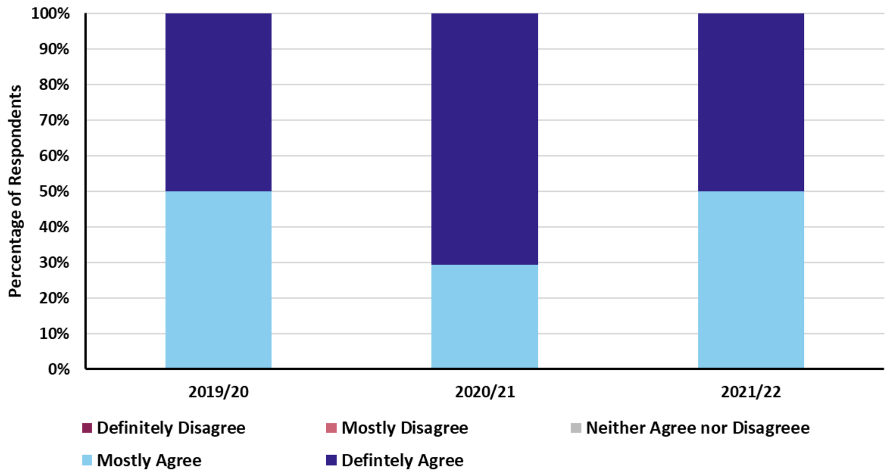

Fig. 1. Number of students surveyed as to whether debating had a “positive impact on their learning experience”

In addition to the survey, we also contacted students from the pilot year, 6 months after they graduated, to gain an insight into how the debating has helped them in their career. They were asked “Do you believe the debate skills you learned at UCL have been helpful for you in your career since your MSc finished? If so please briefly detail how?” All responses received were positive with key comments including:

- “I have now noticed that I am a lot more comfortable presenting to groups in my current graduate scheme”
- “During the interview, some interviewers gave a topic for interviewees to debate and then made a judgment from their performance in debating”

- "It has enhanced my ability to make a point sound convincing"
- "The debate class has improved my communication and presentation skills, in particular it inspired me the method to appropriately respond the challenging questions raised from the investors"

The final way we have received feedback from the students regarding the debates is through the national Postgraduate Taught Experience Survey (PTES). This is a general survey asking about their experience on their MSc, and as such none of the questions specifically focussed on the debates. One of the questions on this survey is "what was the most enjoyable part of the course" and multiple students highlighted the debates here with comments such as "it has improved my oral English and teamwork ability". This clearly shows that the students found the debate activity to be a highlight of their course.

3.2 Staff reflections

Whilst the pilot year was a resounding success, especially in terms of student feedback, the teaching staff discussed their reflections of how the assessment had gone from a pedagogical perspective and made some minor modifications to the way it was run to improve the experience.

The first observation was that whilst the requirement to form a rebuttal of the previous speaker's point and use of POIs meant that there was some element of students creating responsive arguments, it was still felt that this was done superficially, and students had overprepared speeches. In order to discourage this level of detailed preparation in the 2020/21 academic year, the students were given their motion one week before the assessment but were only told which side they were arguing for on the day of the assessment. They were then given 10 minutes to discuss their strategy as a group before the debate started. We saw that the quality of responsive engagement in these debates were much higher than those of the previous year.

The second key observation that we made was that the students were quite tentative about undertaking an assessment that involved such a high level of group work at the beginning of the academic year, when they were not quite comfortable working with each other. To address this we moved the debates from the first academic term to the second. This allowed the students to become more familiar with each other before being presented with a completely new style of assessment. We saw that this was effective as there was a greater interaction from all the students in the debates, with more POIs and more questions from the audience.

4 SUMMARY AND INSIGHTS

The development of this debate-based training and assessment has had several positive outcomes on the students' learning experience and vital skills development. Importantly students found the debates to be both an interesting and enjoyable method of assessment and noted that the skills learned would be useful as they look for jobs (e.g., at assessment centres). This can be attributed to the fact that, compared to typical technical presentations, the students are required to do more thorough research in order to consider both sides of the argument and work convincingly as a cohesive team, rather than a group of individuals, in order to strengthen their overall argument.

Not only were the debates high quality, but the practice of having to fully engage with what others are saying and being able to respond dynamically has enabled the students to improve their communication skills in other aspects of their learning. For example, in a subsequent presentation assessment the quality of the responses to questions was much higher than expected, with students providing well-reasoned responses rather than just rephrasing what has already been said. Students were also much more willing to ask their peers sensible questions, rather than it only being academics asking them.

The success of the pilot and onward implementation of debate training and assessment for MSc students has led the Chemical Engineering Department to begin work to expand this training across the other students across the postgraduate taught and undergraduate cohorts, as it has been seen that the communication skills that the students develop are invaluable for them in their future careers.

4.1 Recommendations

Due to the success of implementing this debate assessment we strongly encourage other engineering education practitioners to implement similar styles of assessment in their own teaching. Having run this assessment for the past three years we provide here a series of recommendations:

1. It is vital that there should be adequate training on how to construct arguments and particularly the structure of a debate as this will likely be completely unfamiliar to the majority of students.
2. How the assessments will be graded should be clearly communicated to the students from the beginning. It is important to be clear that their grades will not be directly related to whether or not their team win the debate, and also that the assigned debate topics are fair and balanced, to ensure that the students on both sides can reasonably be expected to offer strong arguments.
3. Having one student on the team in a non-speaking role helps students with lower confidence, especially those with a different native language. This student will still assist their group with their pre-debate preparation and will still have the opportunity to take an active role in the debate if they wish to offer points of information to the other side.
4. The quality of the arguments being presented is higher if students are only told the side which they are arguing 10 minutes before the debates occur, as this further limits the chances of students presenting pre-prepared speeches.

4.2 Acknowledgements

We gratefully acknowledge the charity Debate Mate, for working with us to design and deliver the training workshops and assessed debates.

ABSTRACT

Engineering education today is often organised in discipline-specific modules. Although it is essential to build up basic knowledge, cross-disciplinary knowledge is fundamental for solving complex problems. Transdisciplinary approaches can provide the necessary hard and soft skills, improve self-determination in education and broaden personal competence profiles.

The experience gained is conveyed using the example of project-based modules on the topics of a) AI applications to minimise racial biasing in medical technology and b) construction of microfluidic systems to avoid animal testing. These were developed over several semesters by interdisciplinary student groups involving industry and research partners. The concept was initially carried out online in an interdisciplinary project module focusing on individual learning objectives, composed of the disciplines "Mechanical Engineering", "Computational Engineering Science", "Physical Engineering Sciences" as well as "Biomedical Engineering" and is being expanded in a hybrid-transdisciplinary manner through gradual additions including systems engineering, philosophy and sustainability in technology, ergonomics and human-machine systems.

Through active participation in researching and solving real challenges, collaboration of transdisciplinary teams over several group generations and setting individual learning goals, profound knowledge and new methodological competences can be acquired beyond engineering disciplines. The integration of non-technical methods and approaches allows students to recognise complex problems and identify the necessary competences in order to realise a successful project. To further expand this approach, a new module concept for interdisciplinary cooperation in production engineering was developed. It takes up the aspects of individual, project-based learning and brings together all the competences of the institute in transdisciplinary exchange.

1 INTRODUCTION

1.1 Current situation

Constant technological change, the increasing acceleration of innovation, and changing work environments are changing the context in which science and teaching take place. However, adaptation to changes can be achieved through tailored teaching and dynamic teamwork. Higher education institutions should prepare students for lifelong learning and social interaction, involving those complex, rapidly changing social and socio-economic team structures. To meet these challenges, appropriate teaching concepts are needed that offer choice and flexibility, promote multi- and interdisciplinary learning, but also teach responsibility, methodological skills and ethical foundations. In an increasingly interconnected world, there is a need to provide the basis for taking global perspectives and experiences that go beyond the learning of engineering disciplines. Being prepared for career and the mixtures of disciplines that come along with it means having the capability of holistic thinking, initiative, self-confidence, creativity, lifelong learning, agility and corresponding methodological competences which should be taught as key components [1].

Transdisciplinary teaching formats represent one approach to this. The greatest challenge at present is to break down the prevailing, discipline-bound specialisation and, thus, fragmentation of thought and action. However, there is still a large gap between the advocacy of cross-disciplinary teaching and reality. Disciplines composed of specialist areas, disconnected modules and methods, each with its own concept of research and learning, have become the fundamental structures of modern universities giving only little space to different formats [2].

In the following, two examples demonstrate how interdisciplinary and transdisciplinary teaching approaches in small project groups of students that have been developed across different generations can look like. The work includes socially relevant problems, with focus on industry involvement.

1.2 Inter- and transdiciplinar teaching approaches: A way to strengthen individual learning goals?

In the 1970s, models have been postulated to promote measures to integrate research across different disciplines and sectors, with intensive collaboration between all participants. Transdisciplinarity has emerged as an approach best suited to enable the integration and implementation of research across disciplines and societal sectors, linking it to intensive participatory processes. Transdisciplinary work in teams is characterised by highly participatory, mixed methods involving science and industry from different disciplines and sectors of society, including those who are expected to benefit from the interventions. These stakeholders are brought into focus from the outset and on an ongoing basis. Although some interdisciplinary and transdisciplinary models overlap, transdisciplinary approaches typically go beyond an interdisciplinary contribution: they involve a transcendent approach, where students create a shared definition of a problem that goes beyond their own disciplines and even create new paradigms and methods for solving real-world problems [3]. For optimal collaboration, a synergistic combination of values, attitudes, skills, knowledge and behaviours must be communicated and taught to students. In particular, values are guiding principles that make team members want to participate, collaborate with others, and become comfortable with unfamiliar theories and methods. Attitudes include a willingness to invest time in learning as well as to adapt individual disciplinary thinking patterns to the demands of teamwork. Behaviours, in turn, include learning activities such as participation in team projects [4].

Further studies reveal what individuals need in order to work together successfully. Research on learning in psychology and education shows three main categories of competencies for successful outcomes: 1. Team knowledge (e.g. task understanding, shared mental models, role knowledge), 2. team skills (e.g. communication, assertiveness, situational awareness), 3. team attitudes (e.g. team orientation, trust, cohesion) [5]. These competences should be aligned with a cross-curricular approach. Furthermore, the approach of solving industry-related, real-life problems in joint teamwork has proven its effectiveness. It offers students the opportunity to experience how interdisciplinary knowledge can be integrated into practice, as well as the ability to challenge themselves to conduct industry-oriented research, giving them access to further postgraduate research.

2 METHODOLOGY: MULTI-GENERATIONAL PROJECTS FOSTERING CROSS-DISCIPLINARY METHODOLOGICAL COMPETENCES

2.1 Project organization procedure

A prerequisite for the interdisciplinary and hence self-determined tracking of individual learning goals is a high level of motivation to participate. For this reason, a broad spectrum of topics is offered, connectivity to current research projects or topics by industrial partners is given, and student co-determination in the setting of tasks is encouraged.

Below the procedure within the project modules is illustrated, adapted on the basis of experience. The currently preferred procedure is shown in Fig.1.

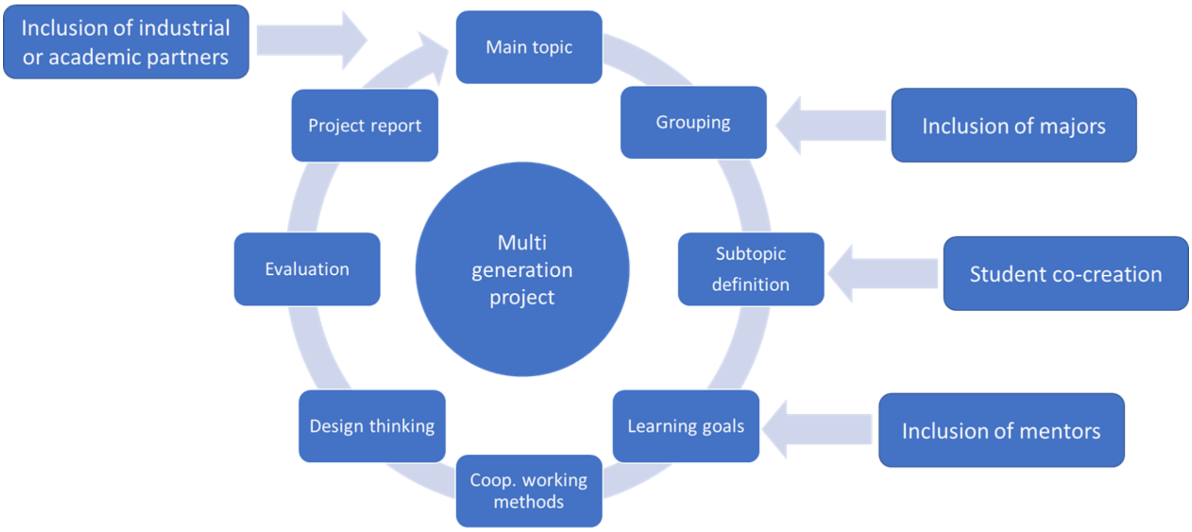

Fig. 1: Currently preferred procedure of the cross-disciplinary project module.

Students are recruited via the ISIS online portal of the TU Berlin. For each main theme, one-minute pitch videos are made available. The topics range from precision engineering, measurement technology, medical technology, micro-assembly, precision machining, micro fluidics, micro-optics, artificial intelligence to teaching topics by and for students. In individual cases, it is also possible for student groups to contribute their own topics. The fundamental requirement is that the task provides socially relevant and practical results that can be further worked on by other groups in subsequent semesters and that the solution requires different subject matter expertise to fulfil a transdisciplinary approach.

Within the limits of possibility, the project is offered to a variance of majors as wide as possible. Involved majors in the past were “Mechanical Engineering”, “Computational Engineering Science”, “Production Engineering”, “Physical Engineering Science”, “Transportation Engineering”, “Biomedical Engineering” and “Patent Engineering”. In the module under way, as well as in a planned expansion, there is involvement of the human factors science, technology assessment, and systems engineering.

On the online portal, students can assign themselves to the respective topic until a predefined group size is reached. The respective group supervisor defines the task in detail in cooperation with the students depending on their abilities, interests and individual learning goals. On this basis the students derive a working plan for the semester.

The following project work is done in regular consultation with the supervisor and progress is evaluated twice during the semester while the evaluation is based on interim presentations. The results of each group will be presented in the presence of the other groups and all supervisors. It is aimed that students actively and critically question their co-students and give hints on possible solutions that can be implemented in the further course. After the second evaluation, the final result is submitted in the form of a project report. This report forms the basis for further developments by subsequent generations of students. Depending on the project being theoretical or practical, the project team additionally presents and explains its results to students from lower semesters taking on a co-teaching part.

2.2 Examples of inter- and transciplinary project modules

The first exemplary student project was originally based on the development of a microfluidic set-up to demonstrate fluidic principles. The system was developed by an interdisciplinary group of students from the fields of biomedical science, production and mechanical engineering being intended to be used by students of lower semesters. The background was to encourage more experienced students to actively participate in preparing and imparting knowledge to other students. Since specific technical subcomponents were necessary for the realisation, industrial contacts to corresponding companies were established through the students' individual contributions. Based on these contacts, further socially relevant research ideas were derived.

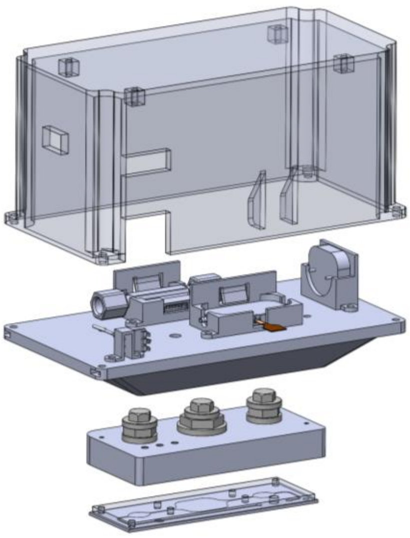

Fig. 2: CAD model of the micro fluidic setup (left) and physical model (right).

The project gave rise to the topic of a multi-organ chip with an integrated heartbeat. Background was to simulate the human body as close to nature as possible with the multi-organ chip, e.g. to determine the influence of drugs or other substances on the body. As part of the transdisciplinary approach, the ethical discussion of the avoidance of animal experiments was a driving motivation for the students. The properties of blood are difficult to reproduce using conventional reference fluids. Thus, experiments with fluids based on a newly developed 2-phase blood by medical and biomedical students of the Charité Berlin in the laboratory for Biofluid Mechanics were conducted. The blood model will further be improved by additional cross-universal investigations of multi-disciplinary groups with similar fluidic systems in the future.

The second project being presented was also developed over several generations of students. In the first iteration, an intelligent spectral measurement system based on low-cost filter sensors was to be built. Students from the fields of computer science and engineering initially collaborated. The students applied basic AI methods to the self-developed electronic system to analyse spectra. On this basis, the possibility of analysing skin pigmentation and vital data analysis was derived by other students' own initiative. The idea was raised to use spectral measurement to actively counteract racial biasing effects in the measurement of vital parameters which still poses a problem in applied systems as well as in consumer products like smart watches.

In addition, to the melanin content as an independent medical parameter, this also acts as a decisive influencing factor for other spectroscopically determined parameters, such as the oxygen content of the blood determined by pulse oximetry. Pulse oximeters are, however, very susceptible to error in heavily pigmented people. This example is frightening when the vital analysis decides on the medical necessity of inpatient or outpatient treatment. These are dramatic examples of racial bias in medicine - the fact that white patients are proportionally more represented in medical studies than people of colour, which leads to a structural disadvantage right from the development phase. This transdisciplinary project idea, thus, should contribute to being able to make statements regarding the melanin content of the skin on the basis of measured values from a non-invasive spectroscopic set-up.

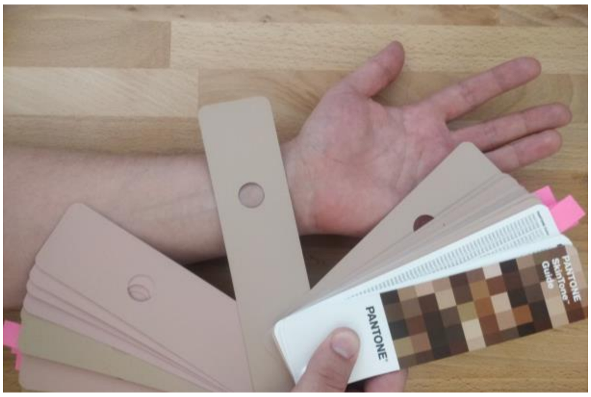

Fig. 3: Measurements of melanin content (left) and comparison with colour charts for the analysis of skin pigmentation (right).

3 RESULTS: LESSONS LEARNED FROM FIRST ITERATIONS

In general, it was observed that the intended motivation for interdisciplinary cooperation, self-determined learning and thematic co-determination could be achieved through the procedure. High-quality results could be derived from this, as well as further final theses, which deepened the students' own learning goal, initiated a self-motivated acquisition of students for subsequent generations by the students themselves and enabled matchmaking with the industry partners.

In the future, however, methodological adjustments will be necessary to promote the achievement of the learning objectives. It was recognized that basic skills for interdisciplinary cooperation are often still lacking and must be taught as part of the project. This is done in the new generation by integrating system engineering approaches. In particular, the continuation of the work over several generations is positively received by the students, as the work carried out forms a basis for future students. In addition, the connection to actual research projects and industry partners leads to an increased appreciation of the results achieved, which is perceived as motivating by students. In the survey mentioned below, students indicated that the interactive and interdisciplinary collaboration increased their motivation and personal and subject-specific development.

The findings formed the basis for several already funded research projects in collaboration with industry, medicine and engineering to address the problem of racial bias and questionable animal testing. The trans-industry and trans-university cooperation, thus, not only offered students the opportunity to gain new knowledge from other, related disciplines, but also enabled the departments to develop long-term research interests. Since its introduction, the module has seen a steady growth in the number of participants. A quantifiable evaluation of the development of the content and the achievement of the learning objectives of the students on the basis of a survey has already being conducted. In an anonymous survey, it became apparent that the students' motivation to learn has decreased due to the pandemic. 50% of the students reported being more demotivated, while 37.5% experienced no change. For the future, the larger proportion of students (61%) would prefer hybrid teaching models to classroom or online teaching. There is a desire to participate more actively with regard to the design of teaching, particularly with a stronger focus on interdisciplinary and socially relevant content. 75% of the participants wish to participate more individually in teaching according to their own learning goals, but currently do not see the capacity to do so in existing teaching concepts (28%). 39% report that they lack the time to pursue their own learning goals in current teaching models. The realisation of these needs through a transdisciplinary, hybrid platform that promotes interaction and individualism corresponds strongly with the initial survey results.

4 DISCUSSION AND FUTURE DIRECTIONS

Implementing transdisciplinary group work requires opening the modules to a range of curricula as wide as possible. In principle, this can be easily implemented with the procedure described. Supervision by several departments to support the individual learning objectives would be useful, but requires adaptation and synchronisation of the curricula as well as improved communication between the departments.

The combination of several disciplines requires a high level of self-motivation, as the high supervision ratio leads to a lower creditable individual teaching performance. The added value arises first and foremost for the students and only secondarily for the departments through better trained students. In addition, the respective disciplines must acquire a good knowledge of the contents of the other disciplines in order to synchronize the offered teaching contents, from which the students can derive their individual teaching paths. Experience shows that this can only be achieved through an intensive exchange of motivated and leading protagonists from the disciplines who actively involve other disciplines and convince them of the added value. In order to promote interdisciplinary and transdisciplinary teaching, administrative conditions must be created that adequately value this teaching performance - the current practice of only partial credit, i.e. proportional distribution between lecturers, sometimes restricts such projects.

The experiences of the ongoing project module will be implemented in a collaborative module of all departments of the Institute for Machine Tools and Factory Management-TU Berlin. The methodology for interdisciplinary collaboration is taught at the beginning of the seminar. In addition to the established evaluation, consultations are held with mentors from all disciplines providing subject-specific tips that are implemented by the respective responsible students according to their own learning goals. Part of the seminar is an initial and a final discussion on technology assessment and sustainability approaches, as well as an initial professionally guided design thinking seminar. In recent semesters, the students have worked together in a mixture of online and face-to-face sessions, which will continue to be used in the future. The creative process and the exchange with mentors and supervisors as well as the evaluation with all students took place online. On site labs, production capacities and a budget were made available for the realization of the project.

As described, the extended transdisciplinary expansion of the project module is an ongoing process. It is planned to expand the spectrum of disciplines in collaboration with other disciplines, also across universities. This will be implemented, in particular, on the basis of the transdisciplinary consortium of the Berlin University Alliance project GlobalRestist. In addition, the human factors science is to be integrated.

Particularly considering the resulting complexity of the disciplines, it is essential that the methodology for collaboration continues to be part of the module in the future. Cross-university collaboration also requires a platform on which transdisciplinary content can be made available and interactive collaboration of different disciplines is made possible online. The materials and technical competencies developed during the pandemic provide an excellent basis for this kind of implementation. The aim here is to create a virtual space that expands the students' individual learning goals to transdisciplinary subject areas by having various disciplines like ethics, gender studies or medicine offer their courses there as basic and in-depth courses.

ABSTRACT

Within the offer of core courses of the Bachelor's Degree in Industrial Electronics and Automation Engineering of the Technical University of Catalonia (UPC), which appeared as a result of the current undergraduate study program, within the European Higher Education Area (EHEA), there is a course, Analog Electronics (EAEIA), which allows the Electronic Engineering student to delve into the knowledge of this content. This paper exposes the philosophy of this course, in such a way that it analyzes the orientation that is intended to be given, especially within the new framework of courses offered at the EEBE where, in addition to the hours of lectures and laboratory sessions, there must be room for to the guided activities (GAs) that the current syllabus contemplates.

1 INTRODUCTION

Despite the indisputable progress and development of electronics and digital systems, it is quite true that analog electronics, and especially that which directly affects the operational amplifier and its applications, is one of the fundamental pillars on which they establish the modern curricula for electronics students in different fields of engineering (industrial, telecommunications, etc.).

Within the offer of core courses of the Bachelor's Degree in Industrial Electronics and Automation Engineering (EIA) of the Eastern Barcelona School of Engineering (EEBE) of the Technical University of Catalonia (UPC), which appeared as a result of the current undergraduate study plan, within the EHEA framework, there is a course, Analog Electronics (EAEIA), which allows the Electronic Engineering student to delve into the knowledge of this content.

In this course's guided activities (GAs), the professor introduces a series of topics to the students (for example, audio amplifiers and equalizers, the control of a small DC motor, etc.). Then, the students, usually in groups of two or three people, work together, cooperatively, according to the puzzle technique, to design, simulate, assemble, solder and test in the laboratory the circuit proposed that fulfills the design specifications.

The current communication exposes the philosophy of this course, in such a way that it analyzes the orientation that is intended to be given, especially within the new framework of courses offered at the EEBE where, in addition to the hours of lectures, problem classes and laboratory sessions, there must be room for to the aforementioned 'guided activities' (GAs) that the current syllabus contemplates.

2 EVOLUTION OF THE TEACHING OF ANALOG ELECTRONICS WITHIN THE BACHELOR'S DEGREE IN INDUSTRIAL ELECTRONICS AT THE EEBE.

The student of Electronic Engineering, within the modern curricula, must not only acquire a solid base in the knowledge of electronics and digital systems for the control of industrial plants in its different fields (microprocessors and microcontrollers, programmable logic devices, automata programmable, etc). Indeed, he must also know those analog electronic systems that will allow him/her, in his subsequent professional career, the acquisition of data or information, the control of systems and industrial plants, and communications in said environments. Under this premise, and within the degree of Engineering in Industrial Electronics and Automation (EIA), offered at the Eastern Barcelona School of Engineering (EEBE) in its study program, in the framework of the European Higher Education Area (EHEA), the courses of the area of Analog Electronics, have a key importance for the training of the future Electronic Engineer [1].

In the now extinct Study Program 72, Analog Electronics was part of a compendium of compulsory courses within the study program that formed the electronic engineer (Industrial Electronics section, within the Electricity specialty). Basically these were two: On the one hand, Basic Electronics, and, on the other, Industrial Electronics.

Once the first year of the Degree with common courses had been passed ('***Linear Algebra***', '***Infinitesimal Calculus***', '***Physics***', '***Chemistry***' and '***Technical Drawing***'), '***Basic Electronics***' was an annual 2nd year compulsory course, formed by a total of 21 credits, simultaneously with '***Circuit Theory and Electrometry***', of 15 credits (Fig. 1). It developed the necessary knowledge that must be addressed in a university course on electronic engineering: Basic electrical laws (Kirchhoff's laws, Thévenin and Norton theorems, etc.), basic discrete components and their application circuits (diodes, transistors bipolar, and field effect transistors), the basic analog systems, around the voltage feedback operational amplifier (VFOA), the basic digital systems (simplification of functions, typical combinational and sequential circuits), and the static power converter structures basic (controlled and uncontrolled rectifiers, and voltage choppers).

In addition, '***Industrial Electronics***' was an annual 3rd year course, made up of a total of 18 credits, and where the horizons of Electronics were broadened in its different fields. In particular, topics related to microprogrammed digital electronics (microprocessors), analog and digital communication techniques, power electronics, and filtering techniques, mainly analog, were discussed.

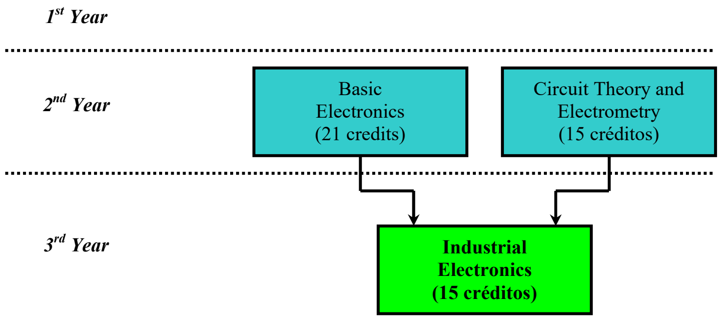

Fig 1. Teaching of electronic systems within Study Program 72 for the specialty of Industrial Electricity (Industrial Electronics section) at the EEBE.

This immense range of topics related to electronic science made that these two courses represent a difficult handicap for the student to overcome. In addition, the main teaching load was focused on lecture blackboard developments and not on practical or laboratory classes, generalizing the idea that, despite the interest aroused by the syllabus of the two courses, the knowledge of electronics taught in it was highly dense.

As a result of the implementation of the Study Program 95, a better rationalization was thought in the teaching of the courses related to Electronics. Indeed, the Electronics student, within an environment of four-month courses, was introduced to the world of Electronics with the compulsory course of 3 credits of the 1st semester '***Introduction to Electrical Circuits***' (Fig. 2.*a*), and '***Electronic Technology – 1***', this one of 6 credits. Once these courses were completed, the student's next encounter with the world of analog electronics was in the 2nd semester of the degree with the 6-credit four-month core course '***Analog Electronic Components and Circuits***', which was combined with the 6-credit courses '***Circuit Theory***' and '***Electronic Technology – 2***', this one of 3 credits. In this course, in addition to studying the basic discrete components and their application circuits (diodes, bipolar transistors, and field effect transistors), an introduction to systems based on operational amplifiers was made. Next, in the 3rd semester, the student faced the course of ‘***Analog and Filtering Techniques***’. In it, the knowledge related to the analog theme was expanded, such as topics related to the analysis and design of analog filters, power amplifier stages, sinusoidal oscillators and PLL (Phase–Locked Loops) systems.

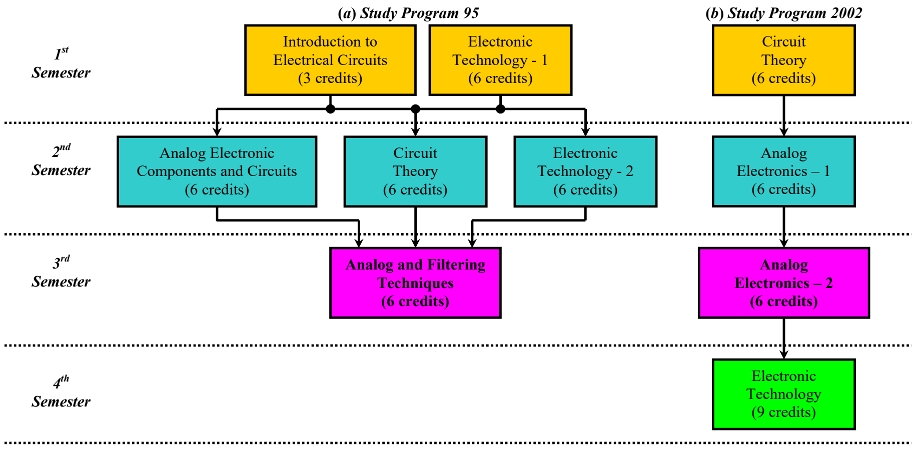

Fig 2. Teaching of analog electronic systems for the specialty of Industrial Electronics at the EEBE. (a) Within the Study Program 95. (b) Within the Study Program 2002.

In 2002, with the revision of the Study Program 95, the new Study Program 2002 was implemented in the old EEBE (the EUETIB), where an attempt was made to correct the most significant anomalies of the existing courses in the different degrees of the School. This revision also affected the courses related to Analog Electronics for the specialty of the Bachelor’s Degree in Electronic Engineering. One of the main anomalies detected in relation to them lay in a certain disorder in terms of the courses taught.

In this regard, and trying to correct this anomaly, in the new 2002 Study Program, the 6-credit compulsory course ‘***Analog Electronics – 1***’ was presented in the 2nd semester, once the course ‘***Circuit Theory***’ had been completed in the 1st semester, also from 6 credits (Fig. 2.*b*). In this course, in addition to delving into the basic laws (Kirchhoff's laws, Thévenin and Norton theorems, etc.), the behavior of passive RLC networks, the basic discrete components (diodes, bipolar transistors, and field effect transistors), as well as their application circuits (rectifiers, power supplies, amplifiers, etc.) were studied.

Once the course ‘*Analog Electronics – 1*’ was passed, in the 3rd semester the student studied the compulsory course, also of 6 credits, ‘***Analog Electronics – 2***’. This was focused on a course around the operational amplifier and its applications in different fields. Due to the course idiosyncrasy, its design was made to be approached from a highly practical point of view. This course was taken simultaneously with other courses of Electronic Engineering such as ‘***Power Electronics***’, ‘***Industrial Informatics***’ and ‘***Electronic Instrumentation***’.

3 CONTEXTUALIZATION OF THE TEACHING OF ANALOGUE ELECTRONICS WITHIN THE DEGREE OF ENGINEERING IN INDUSTRIAL AND AUTOMATIC ELECTRONICS AT THE EEBE.

With the new curricula within the European Higher Education Area (EHEA), the Bachelor's Degree in Engineering in Industrial Electronics and Automation appears in 2009. The course of '***Analog Electronics***', of 6 ECTS credits, is in the 6th semester (6Q) of the degree (see Fig. 3), coexisting with courses related to Analog Electronics such as '***Electronic Instrumentation***' and '***Industrial Informatics***' and other basic training for the electronic engineer, such as '***Power Electronics***' and '***Control Techniques***' [1].

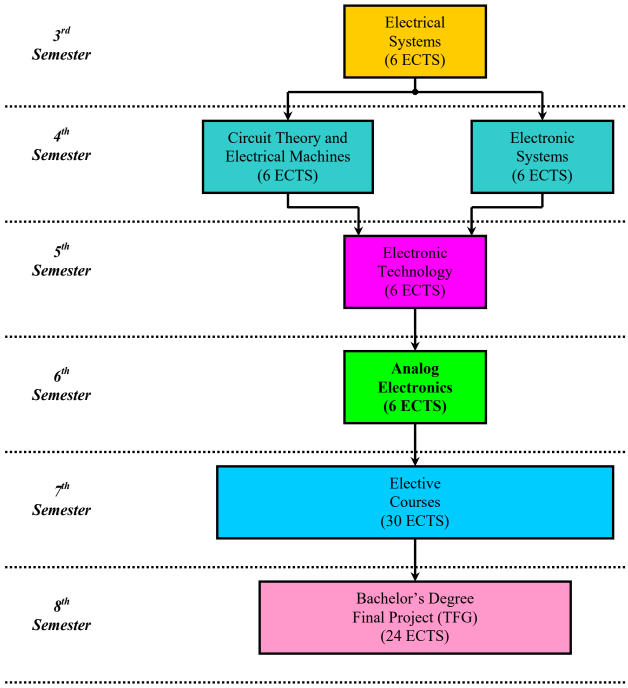

Fig. 3. Teaching of analog electronic systems for the Bachelor's Degree in Industrial Electronics and Automation Engineering at the EEBE within the current study program within the framework of the European Higher Education Area (EHEA).

4 KNOWLEDGE TO BE TEACHED IN THE COURSE 'ANALOG ELECTRONICS' WITHIN THE BACHELOR'S DEGREE IN INDUSTRIAL AND AUTOMATIC ELECTRONICS ENGINEERING AT THE EEBE.

Bearing in mind the idea mentioned in the previous section, the knowledge to be taught in this course has been divided into 5 large blocks, each with its own entity, but which together allow the student to obtain a clear idea of analog based systems based on operational amplifiers. These five blocks or chapters treated in this course are the following (Fig. 4):

1. The operational amplifier working with negative feedback.
2. The operational amplifier working with positive feedback.
3. The real operational amplifier.
4. Sinusoidal oscillators and signal generators.
5. Signal active analog filtering (continuous time and switched capacities).

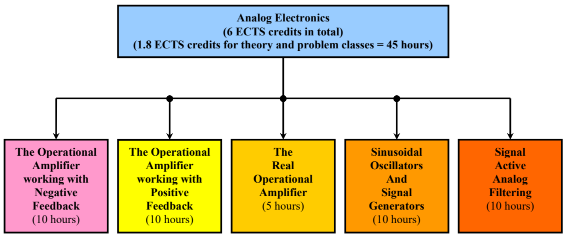

Fig. 4. Thematic distribution of the course 'Analog Electronics'. The indicated hours correspond to those of lectures and problem classes.

5 TEACHING METHOD: THE RIGHT BALANCE BETWEEN LECTURES, PROBLEM CLASSES, LABORATORY SESSIONS AND GUIDED ACTIVITIES.

With the implementation of the current Plan for undergraduate degrees within the EHEA at the EEBE, it is committed that a large part of the courses of the Bachelor's degree, especially those electives that lead the student to follow an intensification within a certain specialty, entail a percentage of credits referring to the so-called 'guided activities' (GAs). In them, it is proposed to carry out different activities (theoretical, practical or information search), in which the professor and student should not coincide in space or time. Of course, the professor tutors, guides and, if necessary, introduces elements of correction of these activities to finally assess them properly. The number of these credits is variable, depending on the course, but it ranges between 10 % and 25 % of the total credits of the course in most of them.

In particular, for the EAEIA course, of the 6 ECTS credits in total that the course has, 2.8 ECTS credits correspond to face-to-face activities in the classroom (70 total hours throughout the entire semester). Of these 2.8 credits, 0.4 ECTS (that is, 14.3 % of the face-to-face activity in the classroom) correspond to guided activities (10 face-to-face hours in the classroom throughout the semester). The other 85.7 % is divided between lectures and problem classes, with 1.8 ECTS credits (45 total hours throughout the semester), and 0.6 ECTS credits for laboratory sessions (15 total hours throughout the semester), always related to the lecture contents presented in the previous sessions of the course (Fig. 5).

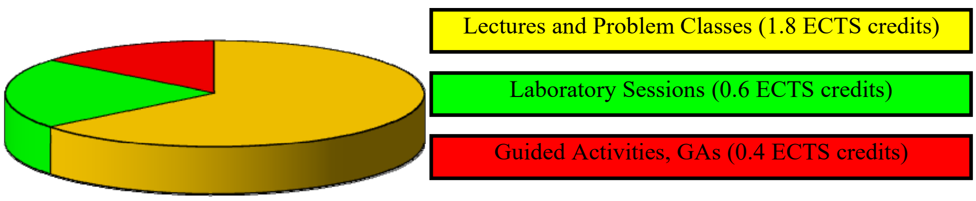

Fig. 5. Percentage distribution of face-to-face hours between lectures and problem classes (62.5 %), laboratory sessions (25 %) and guided activities (12.5 %) of the course 'Analog Electronics'.

This distribution of credits means that three hours of lectures and problem classes are taught weekly, and fortnightly laboratory sessions of two hours throughout the entire semester (considering semesters of fifteen weeks). Thus, there are available about 10 hours per week for each student to carry out the proposed guided activities during the semester.

In the guided activities of the course there is a first part of activities where the student, individually or in pairs, must analyze and simulate different circuits using the OrCAD-PSpice® program.

The second part of the guided activities proposes to the student the physical implementation of a project, using a cooperative work learning technique, in which an analog system is implemented using low-cost electronic circuitry. In effect, the teacher introduces a series of titles to the students (for example, audio amplifiers and equalizers, the control of a small DC motor, etc.) and the students, usually in groups of two or three people, ***work together, cooperatively according to the puzzle technique***. They must design, simulate, assemble, solder and test in the laboratory the circuit proposed by themselves on a test board that fulfills the task specified in the title of the work (Fig. 6).

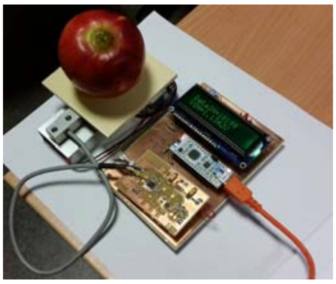

Fig. 6. Example of a prototype implemented in the Analog Electronics course as a part of the guided activities (GAs). In this case, an electronic scale.

In the 10 hours considered face-to-face of the guided activity (GA), the group of students is guided in the classroom by the professor so that the work is developed within the framework marked and scheduled in class. Now, outside the classroom, the group of students must continue working on the project, so that, in addition to the 10 “face-to-face” hours, a series of hours (around 30 more) are contemplated, where the group of students must continue with the guided activity outside the classroom (that is, “not in person”).

It has been seen in the last quarter of the course that the presentation of the prototype in front of the class as a whole is highly positive. The procedure consists of dedicating a few hours to this purpose at the end of the semester, so that for about ten or fifteen minutes the group exposes (we could even say ‘sell’) the design made by them, through the use of some slides. Once this explanation is finished, the rest of the students in the class and the teacher himself can ask the questions they deem appropriate in this regard. The evaluation can be done by the professor himself or even the students themselves can participate, personally issuing a note from the rest of the class groups. The interaction of the groups with the class as a whole, as well as the motivation due to the fact that it is the students themselves who have to defend 'their' design, are high.

6 DISCUSSION AND CONCLUSIONS

Although in general the students start the course with some reluctance regarding its content, it can be said that students’ satisfaction with the course is highly satisfactory. This is an important point despite the ambitious proposed syllabus, which entails an important work of study and assimilation of knowledge by the student, due to the relatively high load of content.

The introduction of software tools is also an important factor to consider. Especially, OrCAD-PSpice® is used for the simulation and analysis of the circuits studied both in the lecture and problem sessions as well as in the laboratory classes. However, the doors are left open for the use of different computer programs for specific course matters. This is the case, for example, of analog filters, where tools such as FilterPro, FilterLab or Filter Wiz PRO are incorporated for the synthesis of analog filters, without having to use the commonly cumbersome analytical methods or using tables for this purpose.

Regarding the guided activity (GA), and despite the considerable number of hours involved in making an electronic prototype that performs a certain task, practically all the students consider that it provides direct contact with the electronics laboratory and with the assembly, soldering and implementation of circuits, essential for future Electronic Engineers. The personal satisfaction of each of the members that make up the work groups is more than satisfied when they manage to make the prototype designed and implemented by themselves work.

With regard to what is indicated in the preceding paragraph, it should be noted and emphasized that, despite the fact that students dedicate 10 ‘face-to-face’ hours per semester to the GA, at home they dedicate a considerably greater number, in order to carry out the guided activity successfully.

As we have commented previously, let us think that these hours of “non-contact” activity of the GA outside the classroom are considered in the ECTS credits of the course. Specifically, of the 6 ECTS credits of the course, only 2.8 ECTS credits correspond to face-to-face activities in the classroom (70 total hours throughout the semester). As we have also previously mentioned, of these 2.8 credits, 0.4 ECTS correspond to guided activities (10 face-to-face hours in the classroom throughout the semester); 1.8 ECTS correspond to lectures and problem classes (45 total hours throughout the semester); and 0.6 ECTS credits for laboratory practices (15 total hours throughout the semester). The other 3.2 ECTS credits correspond to 80 hours of activity outside the classroom, divided between the study of the lecture material of the course, preparation of reports and previous laboratory questions, and the continuation of the guided activities.

Despite this workload for the student, the number of passes is highly satisfactory, thanks in large part to the completion of these guided activities. In the last calls of the course, the percentage of students approved in the course is around 75 % – 85 % of the total number of students enrolled.

Finally, it should be noted that the fact of carrying out the guided activities in groups entails putting into practice one of the objectives of the course and, in general, of all the courses of the Degree curriculum put into operation at the EEBE: Personal and student motivation for group work and cooperativism in learning.

ABSTRACT

This paper describes the experience carried out within the Bachelor's Degree in Industrial Electronics and Automation Engineering taught at the Eastern Barcelona School of Engineering (EEBE) of the Technical University of Catalonia–BarcelonaTech (UPC). Specifically, the experience is based on the realization of a cross project that is under the framework of the degree intensification named *Application Design in Electronics Engineering* (ADEE). This intensification, consisting of a block of two courses, taught in the Fall and Spring semesters, and offered for students in their final year, allows the fulfillment, for two semesters, of the aforementioned project. This includes the design, simulation, implementation (assembly), testing and experimental results (corroboration) of an electronic system or equipment within the field of Electronic Engineering.

1 INTRODUCTION

As is well known, technical studies, especially those concerning engineering, require a highly recommended (and, indeed, almost necessary) practical aspect. It serves not only as main key from a practical point of view of this typology of University degrees, but also it can be used as a motivational tool to current students and future engineers. The idea of cooperative learning-based activity that is shown in this paper started as a result of the detection by course professors of a lack of students' motivation and academic level and ability the Bachelor's Degree in Industrial Electronics and Automation Eng. In particular, this degree, which started in September 2009, was launched along with the Bologna Process. It is offered at the Eastern Barcelona School of Engineering (EEBE) of the Technical University of Catalonia (UPC) in the European Higher Education Area (EHEA) framework.

This lack of students' motivation, stimulation, encouragement, academic level and ability was not only detected at first level courses, where sometimes the motivation is limited due to the large number of common courses to be taken, but also (and worse) in students that are finishing their studies in Industrial Electronics and Automation Engineering and courses related to their own specialty.

The detection of this problem led to Professors of elective courses (taught in 4th year) of this Bachelor's Degree to implement an experience object of this article. This experience covers the fourth last-year course of the aforementioned degree intensification, named *Application Design in Electronic Engineering* (ADEE), which has the current degree. Indeed, these low expectations have led professors of these intensification elective courses to carry out different activities in recent years, including those related to cooperative learning and project-based learning (PBL). These activities could motivate alumni and make them interested in the contents of the mentioned courses, including those of the aforementioned ADEE intensification.

2 GUIDED ACTIVITY (GA) AT THE EASTERN BARCELONA COLLEGE OF INDUSTRIAL ENGINEERING (EEBE)

At the EEBE, current curricula courses are divided into 6 ECTS biannual courses, except for some very particular courses. As a consequence, a 6 ECTS course, especially those that are part of the degree specialty (core or elective), has their structure divided into the following four blocks:

- 1.2 ECTS credits for lectures (corresponding to 2 h/week).
- 0.6 ECTS credits for classes concerning problems (corresponding to 1 h/week).
- 0.6 ECTS credits for laboratory sessions (also corresponding to 1 h/week, but grouped into fortnightly sessions of 2 h).
- 3.6 ECTS credits of non-presential off-site (NP, or non-classroom) activities, and guided activities (GA) (corresponding to 6 h/week).

It can be seen that good workload involved in a particular course, and that students must perform throughout the semester, is framed within 3.6 ECTS credits for non-presential off-site activities (NP), and guided activities (GA). In general, in these credits, course students must perform activities, tasks, works, etc., relating, among others, to the following points:

- Making activities, problems, etc., concerning topics explicitly explained or not by course professors in lectures, problems and/or laboratory session.
- Research, development and/or preparation of activities by students of some topics that are not explained in lectures by course professors.
- Writing laboratory reports.
- Implementation of physical prototypes of electronic circuits, systems or equipment within the field of industrial engineering that is being considered in the course throughout the semester.

Concerning undergraduate studies in Industrial Electronics and Automation Engineering, within this workload of guided activities, special emphasis is focused on the design, simulation, physical implementation and laboratory test of a prototype electronic circuit, system or equipment. Indeed, all this process involves different stages which refer to all the actual process of developing electronic systems or equipment in an industrial or professional environment that students will encounter in a near future in their professional career:

- Design of the different single blocks of the electronic circuit, system or equipment to be carried out.
- Simulation of the aforementioned blocks individually, and simulation of the complete set when they are interconnected.
- Physical implementation of the aforementioned individual blocks that form the system that should be implemented.
- Testing of these individual blocks and experimental corroboration of their operation.
- Assembly and installation of the blocks in order to obtain the complete system or equipment.
- Test, experimental corroboration and obtainment of experimental results of the complete system or equipment carried out.
- Creation of a technical report covering the entire process carried out, simulation results, experimental measures, cost estimation, etc.
- Oral dissertation, within a limited time, of the carried out cross project.

3 COURSES RELATED TO ELECTRONIC SYSTEMS IN THE BACHELOR'S DEGREE IN INDUSTRIAL ELECTRONICS AND AUTOMATION ENGINEERING AT THE EEBE

Within the Bachelor's Degree in Industrial Electronics and Automation Engineering at the EEBE, courses that refer to the study of electronic systems are shown in Fig. 1. Bachelor’s students begin in the Electronic Engineering area in the 3rd semester. In the 6th semester, the degree continues, among other subjects, with Analog Electronics, which allows delving, as similar to the previous one in the digital area, in this case into the analysis and design of analog electronic circuits, mainly based on the operational amplifier. Once passed this semester, in the 7th semester, students enter the phase of elective courses, in which they should choose five 6-ECTS subjects (the current curriculum includes a total of 30 ECTS credits for elective courses). Finally, for undergraduate student, the Bachelor's Degree in Industrial Electronics and Automation Engineering at the EEBE ends with the development of the Bachelor's Thesis (BT) during the 8th semester.

This paper focuses on one core (compulsory) course and one elective courses shown in Fig. 1: ***Analog Electronics*** (EA-EIA), and ***Implementation of Arduino-Based Acquisition Systems*** (ISABA). However, it is also important to highlight that each of the two courses are considered «self-contained». Therefore, the order in which students can take them is not significantly important.

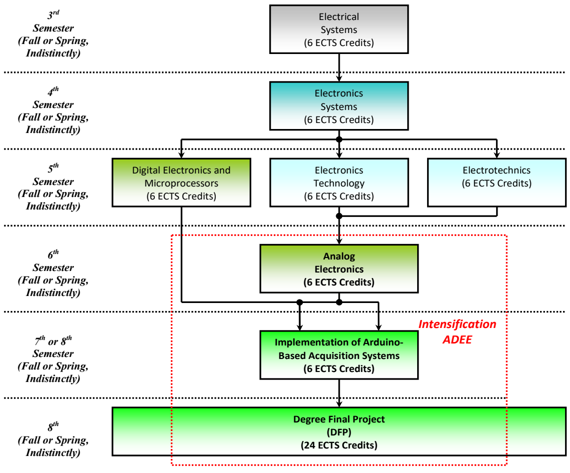

Fig. 1. Map of courses in the field of Electronic Engineering and degree intensification Application Design in Electronic Engineering (ADEE) for the current curriculum of the Bachelor's Degree in Industrial Electronics and Automation Engineering taught at the EEBE.

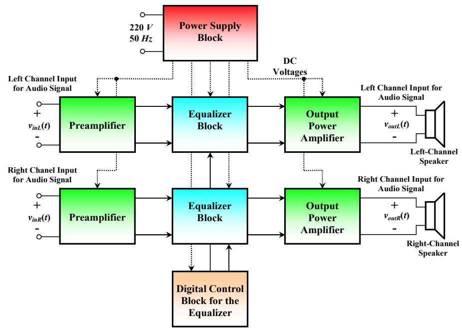

Fig. 2. Overall block diagram of the equipment to carry out in the cross project.

4 EXPERIENCE CARRIED OUT IN COURSES UNDER STUDY

As already mentioned, the idea of cooperative learning activity that is set out in this paper starts when low academic results are observed by degree staff since the introduction of the current curriculum level in September 2016. These course students' low academic results worry and even alarm lecturers, especially because they are in core courses of the Bachelor's Degree, just before ISABA course. Moreover, in recent years, these low expectations have led professors of different elective courses in Electronics area, to consider different activities, including those related to cooperative learning and project-based learning (PBL) to motivate alumni and make them interested in the contents of the mentioned courses, including the subjects included in the aforementioned intensification ADEE.

This paper focuses on what the authors have called "***cross project***" as part of the GA activity. This cross project is included in the two courses previously mentioned (and, obviously, their materials) that define such intensification. To carry out this cross project, it is required that mind-preferred (although not essential), undergraduate students enroll in these two 6-ECTS courses; compulsory course (EA-EIA) in the Fall semester, and the elective course (ISABA) in the Spring. Thus, they can obtain 6 ECTS credits of a total amount of 30 ECTS required to complete their Bachelor's Degree. The activity focuses on the development (which includes the design, simulation, implementation, testing and experimental corroboration) of an audio equipment based on the following five blocks (Fig. 2): Audio equalizer stage, audio preamplifier stage, audio power amplifier stage, digital control module for the equalizer stage and power supply subsystem.

In particular, focusing on the experience on which this paper deals, the activity under study mentioned before consisted of all the process (design, simulation, implementation, testing and experimental corroboration) conducted. To do this, this is carried out in face-to-face sessions, where lecture (2 hours/week) and problem (1 hour/week) sessions are merged in a single 3-hour weekly session. Thus, the cross project is divided into the two semesters (Fall and Spring) mentioned above.

5 PART I OF THE EXPERIENCE CARRIED OUT (COURSES IN FALL SEMESTER)

As a first step in the realization of the cross project during the Fall semester, advanced the course ***Analog Electronics*** (EA-EIA), detailed guidelines (that is, design specifications) of said equipment are presented in class (required output power, frequency bands working, input and output impedances, etc.). From these specifications, and from week 10 of the course (remember that the academic semester includes 15 weeks), in parallel with the progress of this first course, students also advance in the design of part of the different blocks that constitute the system. In particular:

- The design, simulation, assembly, testing and experimental corroboration of the equalizer stage. This process includes the design and calculation, simulation (by means of OrCAD-PSpice®), etc., of the different cells that form the required equalizer.
- The same process for the preamplifier stage is performed. This serves as a support for the student to do the transistor level simulation of such blocks based on the initial design specifications (simulation of the operational amplifier used in different sub-blocks, simulating the preamplifier stage performed around this operational amplifier, etc.). In addition, the student implement theoretical knowledge explained in theory classes.

During the final five sessions of the course, they (considering 3-hour classes) were divided into different parts:

- The first session (that never exceeds 50-55 minutes) has been devoted to explaining (through lecture) those theoretical contents that the course professor must develop so that students can delve into the different topics required for the proper development of the cross project. Students, in this first hour, had a passive role, listening and note-taking or, where appropriate, monitoring the corresponding transparencies previously delivered to them.

- Then, in the next two hours of the session, students, in groups of three, worked on the stages design, simulation or/and assembly directly linked with the theoretical stage explained by the professor in the 1st hour of the session.

In general, the time available in the last five weeks of the course is insufficient to carry out all the process design in class. However, it is important to highlight that this cross project is framed within the non-attendance of the course workload. Therefore, course students should continue working in it outside the classroom, as part of the 3.6 ECTS credits that correspond to non-presential off-site activities and guided activities (corresponding to 6 h/week) referred to both courses. This Fall course ends with two full prototypes developed by the working group (Fig. 3):

- First, the design, simulation, implementation, and testing of the experimental audio equalizer stage.
- In addition, the design, simulation, implementation, and testing of experimental preamplifier stage.

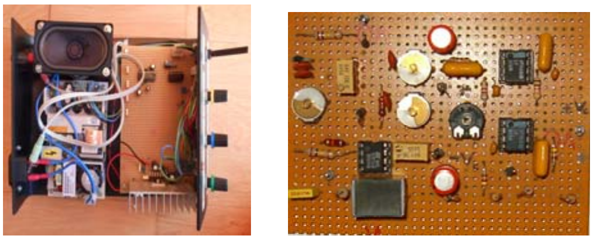

Fig. 3. Examples of different prototypes of some of the partial blocks implemented by students.

In addition, depending on the number of students enrolled in the course, some semester, course professors have also opted for a 15-minute oral presentation. With this presentation, every group can present the work they carried out to course professors, and their classmates.

The project ends this semester transiently with a numerical score which is incorporated into the course EA-EIA of this semester. The weight of this part in both courses is 30% of the total.

Note that each block of the implementation could be self-contained (an amplifier stage, for example, is already a system that allows to be used in many applications). However, the student should keep the key idea that this block is part of a more complete system, whose objective goes beyond that one of these single courses. Notice that here, the idea of globalization, content integration and course coordination are key.

6 PART II OF THE CARRIED OUT EXPERIENCE (COURSES IN SPRING SEMESTER)

In this case, the courses where it continues with the realization of the cross project consist of the elective course of the ADEE intensification taught in the Spring semester: ***Implementation of Arduino-Based Acquisition Systems*** (ISABA).

The mechanism, procedure and routine of the courses are similar to the first one taught in the Fall semester: In the first sessions of each course, the cross project remains stopped, and theoretical and practical elements and contents of both courses evolve. Then, from week 10 on, approximately, students pick up the project with the realization of the missing blocks to complete the overall system:

- The design, simulation and assembly of the digital control stage for tuning the audio equalizer is performed. It serves as support for the student to perform the design, simulation and implementation of control system for the equalizer stage implemented in the previous semester.

- The design, simulation and assembly of the power amplifier stage, and the power supply subsystem of all equipment is made. It serves as support for the student to perform the design, simulation and implementation of the power amplifier stage and power supply that provides power for the entire equipment.

Thus, when optional ISABA course ends, in a similar way that in the compulsory course EA-EIA, with two full prototypes made by the working group:

- On the one, the design, simulation, implementation and test stage of a digital control sub-block for the audio equalizer, developed in the course EA-EIA.
- In addition, the design, simulation, implementation and testing of the power amplifier stage and power supply subsystem carried out in the course EA-EIA.

7 PART III OF THE CARRIED OUT EXPERIENCE (COURSES IN SPRING SEMESTER)

Completed the two semesters (Fall and Spring) and, therefore, having made the student group's cross project framed in the two courses under study (EA-EIA, and ISABA), finally, to overcome the activity and finish it, the students' groups must:

- Assemble the different circuit blocks that make up the complete prototype of the overall project.
- Test of the global equipment in the course laboratory, taking appropriate experimental measurements of the whole, corroborating the proper functioning of the whole system.
- Submit a technical report that highlights everything done in relation to the cross project along the four courses (detailed explanation of the project, process design, simulation and experimental results, etc.).
- Present the project to the group of professors of the four courses as well as the set of classmates.

The project ends with a numerical score. This mark is incorporated into the ISABA course. The weight of this part in the subject is 60% of the total.

8 EVALUATION AND CONCLUSIONS OF THE CARRIED OUT EXPERIENCE

Regardless of qualifications, to assess the activity, information reported by the ‘affected’ people (i.e., course students) was used. It is important to highlight, after several detailed talks subsequent to the presentation and defense of the cross project, the good reception of the experience by students. For the article authors, this aspect is very important, even though, in some groups, results and marks were not fully satisfactory (marks below 7 on a total of 10 points).

For most students, it was not the first time that they performed an evaluation experience of this kind. In fact, in different core courses exposed in Fig. 1 (e.g., Analog Electronics), a part of the course includes the design, simulation, implementation, and experimental corroboration of the operation for a more limited circuit. In them, the goal is that the circuit has a well defined purpose, within the scope of the course itself, but its magnitude is generally dimensioned so that the same dedication from the student is limited. In this case, however, the cross project has a much larger dimension. In addition, it is contained in different courses that, although they are in the same area, they deal with different topics within the field of Electronic Engineering.

However, despite the difficulty and great dedication that students said in their opinion of the course, they expressed a number of strengths of the activity. From these collected opinions, three should be emphasized:

- For students, the proposal of the cross project resembles projects that would take place in a company by a group of engineers. This put the involved courses, and their contents (and, of course, especially, the degree) closer to the imminent actual professional world for these students.
- The *cross project* removes the «tightness» that currently have many courses taught in Spanish University. Our undergraduate students often see the degree courses as separate from other courses. This separation is perceived not only for courses in different semesters, but even for courses taught simultaneously in the same semester. They find it difficult to integrate and globalize different degree courses (core or not) in a common framework of the degree. According to students, the cross project largely eliminates this sealing. As mentioned here before, the idea of globalization, content integration and coordination in the cross project is key point.
- It allows students to focus their Bachelor's Thesis (BT) on a topic close to the cross project or close to contents of the courses included in the intensification that serves as framework for the transversal project. This idea is also a key point to many students who are intensifying as a way to focus their careers in a certain area within the wide field of Electronic Engineering.

Finally, as future research by part of the coauthors of this study, we want to make a series of progressive improvements in the carried out procedure, which involves the following points:

- Mount the cross project as a learning system based on project-based learning (PBL) by technical puzzle. This will imply considering a greater time commitment within the course to carry out the project (sessions will be needed to make the expert meetings, to take time for explanation of an expert to the other members forming the group, etc.). However, in the article authors' opinion, it will result in an improvement from the point of view of learning.
- Conduct a peer assessment set by the students enrolled in the course. Until now, assessment has been carry out by the course professors involved in the project. It is not excluded, however, that part of the final grade of the cross project is carried out by course students themselves.
- Open the project presentation to students of previous semesters, in order to see what advanced students of the same degree have done. This would undoubtedly incentive and motivate these students less advanced, who would firsthand see the «applicability» of their Bachelor's Degree.

ABSTRACT

Tests are an essential tool to assess students' ability. In online education these tests are mostly of static nature with the same items for each student. In contrast computerized adaptive testing concepts take into account the information about the test user automatically collected in an online test. The aim is a comparably precise test result with fewer test items (questions). An implementation of such a computerized adaptive test (CAT) is presented here. The adaptation process is based on the precise knowledge of the item parameters, e.g. difficulty, in the item pool. An estimation of the knowledge level of the test user has to be performed in real time after each answer. With this information the next item can be selected accordingly. This leads to a highly individualized test for each test user. For all items the parameters were determined with methods of the item response theory (IRT) in the framework of the probabilistic test theory. For that real test results of former first year students in engineering science had been analyzed. The prototype of such a CAT has been developed. It focusses on a physics test for prospective students in the STEM fields. In fall 2021 the pilot phase was conducted with first year students in engineering science. The CAT shows that the same precision can be achieved with a mean of 9.3 items compared to 12 in the static test. The acceptance among the students is high. The correlation between the static test and the CAT is satisfactory.

1 INTRODUCTION

1.1 Starting Point

At the transition from school to university the knowledge level of prospective students in STEM – which stands for the academic disciplines "science, technology, engineering and mathematics" – is very heterogenous. In Germany about one-third of all STEM students (one in two in mathematics) drop out of university or change the subject before graduation [1]. The lack of basic knowledge is one of the most important reasons for dropouts. As one of the primary goals of current German education policy is to increase the number of graduates in the STEM fields, not only the number of beginners has to be increased but also the number of dropouts has to be reduced. As the first year at university is crucial, support offers should start as early as possible guaranteeing a smooth start.

1.2 The Project MINTFIT Hamburg

In 2014 the project "MINTFIT Hamburg" [2, 3] started to give support with a free-of-charge online service. The MINTFIT platform aims at prospective students who are interested in independently reviewing their knowledge in mathematics, physics, chemistry and computer science. One can check if the current level of knowledge fits the basic requirements of a STEM study in Germany and at the same time receive information about which gaps need to be filled. MINTFIT focuses specifically on the transition from school to higher education, since there are good opportunities to identify and fill knowledge gaps before problems occur in the first year. Within the MINTFIT learning platform an online test is always the starting point. That far all tests have a static character. For three tests (physics, chemistry and computer science) the questions do not have any variation whereas the math test randomly chooses questions from an item pool or varies values within one test item.

1.3 The Static MINTFIT Physics Test

For the CAT development, described in the following, the physics test was chosen from all MINTFIT tests. The static MINTFIT physics test, that is the current standard, consists of 40 basic test items in the subdomains mechanics, electricity, energy, and optics. While the contents correspond to the intermediate school level, the (re)presentation as well as the mathematical methods (e.g. vector analysis or integral calculus) are oriented to the university level and serve therefore as a well fitted preparation for higher education.

Based on the main topics and subtopics in school about 200 items had been developed. Different question types are used: multiple choice, drop down menu, cloze, short answer, and algebraic questions. For the final test 40 out of these 200 items have been selected to accommodate the test total length to about 60 minutes. The selection was done in several iterations. The items were tested in target-group schools and with first-year students. The final test has been adjusted to allow an optimal assessment of the level of knowledge as well as to offer suitable learning recommendations.

For the comparison to the CAT development described in the following only the mechanics part of the static test was used.

1.4 Alternative Test Ideas for the MINTFIT Physics Test

As the physics test is voluntary, the duration time of 60 minutes is quite long and seems to be one of the reasons for the high dropout rate. It shows up that only one third of the started tests are finished regularly. In about 20 % of the finished tests users stop answering after the first 10 out of 40 questions. The aim for a new test type is therefore to significantly reduce the number of questions or the test duration while maintaining the quality of competence assessment at the same time. To accomplish this, MINTFIT experiments with so called computerized adaptive testing methods [4]. This approach resembles more an oral than a written exam and is related to the expectation to achieve a better or equivalent assessment of participants' competences with fewer questions.

2 METHODOLOGY COMPUTERIZED ADAPTIVE TESTING

Computerized adaptive testing (CAT) is a form of testing, where the next administered question (item) depends on the answer of the already administered items. If, for example, a student answers an item correctly, the next item could be more difficult. Here CAT is used within the framework of the item response theory (IRT) [5]. More precisely the Rasch model [6] is used. The Rasch model defines every item with a single parameter, the difficulty b, and also every student with a single parameter, the ability θ. The probability of answering an item correctly is then determined by:

$$P(x = 1|\theta) = \frac{\exp(\theta - \mathrm{b})}{1 + \exp(\theta - \mathrm{b})} \tag{1}$$

One of the advantages of this model is, that ability and difficulty are measured on the same scale and can therefore be compared. Note that in this model, if a person has the same ability as an item's difficulty, the probability of solving this item is only 50%. The maximum of the slope is at exact this point, where θ and b are equal. The slope is of special interest. The higher the slope is, the better an item can differentiate at this point between higher ability and lower ability students. To make this point clearer, imagine an item with difficulty 0, and four students with abilities of -0.5, 0.5, 1.5, and 2.5. The Rasch model then yields the following probabilities of solving the item: 0.38, 0.62, 0.82 and 0.92. See how the differences between the students shrink: From 0.24 between the first two students, to 0.1 between the last two students. It can be seen therefore, that the most information can be gained from an item, when the student has the same ability as the item difficulty. CAT tries to make the most efficient test by re-estimating the student's ability after every answer and presenting the best fitting item. There are different stopping criteria possible. A stopping criterion that relies on the precision of the measurement is used. This means, the test ends as soon as a certain precision is reached and a statement about the student's ability can be made with sufficient certainty. The precision of a test is also called the test information. It is defined as the sum of the item information. The item information for an item i is defined as the product of the probability of solving the item (p_i) and the probability of not solving the item (q_i). The standard error of estimation SE is then defined as the square root of the inverse of the test information, or as a formula:

$$SE = \frac{1}{\sqrt{\sum p_i q_i}} \tag{2}$$

As many people are more familiar with the term standard error, it will be used throughout this paper. Note, that the Rasch model is a rather simple model. More complex models, like the 2PL model [5], describe an item not just with a difficulty parameter b, but with a second parameter a that has an influence on the slope. This parameter is called the discrimination parameter. The Rasch model can be seen as a special case of the 2 PL model, where the discrimination parameter is fixed to 1 for every item.

3 CAT PROTOTYPE

3.1 Concept

For the CAT prototype an algorithm is implemented that is based on the 2 PL model considering the difficulty and the discrimination parameter for every item. For the pilot phase described here the discrimination power of all items was set to 1. This is equivalent to using the Rasch model.

Initially, a test user's ability is estimated with the value 0. A new question is always added to the test based on the current estimate. For the selection of the next question the item information of all unanswered questions is calculated. One of the questions with (almost) maximum (> 99% of the maximum value) item information is randomly chosen next. Questions are excluded from which it can already be predicted with a probability of 95% or more whether they will be answered correctly or incorrectly.
Always after a question has been answered, an estimate of the ability is calculated for the respective test user and the standard error is determined. For this purpose, the highest maximum a-posteriori probability is taken. This is done by multiplying the discrete standard normal distribution between the minimum and maximum possible ability (-3 and 3) by the respective probabilities that a person with that ability answers the question in that way. The maximum value is the estimated ability. The algorithm terminates if, after answering a question, the standard error falls below the specified threshold. The determined ability after the last question gives the score for the whole test. For better understanding and consistency with the other MINTFIT tests, this value is converted into a scale from 0 to 3 stars and is given as feedback to the test user.

3.2 Realisation

The adaptive test is implemented as a Moodle plugin [7]. The implemented plugin borrows some ideas from a publicly available Moodle plugin for adaptive tests [8], but is not based on that, as a more general approach is used for the ability estimate and the selection of the questions.

A test can be configured with multiple subdomains, but in our test run the CAT was limited to mechanics. For each subdomain a question pool must be specified and a minimum number of questions has to be configured. Each question in the question pool needs a corresponding question difficulty and discrimination power (here set to 1), which are specified using tags in Moodle. The termination threshold for the standard error has to be specified and a maximum number of questions is also set as an alternative termination criterion for the entire test.

From a test user's point of view, the CAT has the appearance of a regular Moodle test. Due to the adaptive concept, the questions have to be answered in the given order and it is not visible in advance how many questions the test will contain.

3.3 Question Parameters

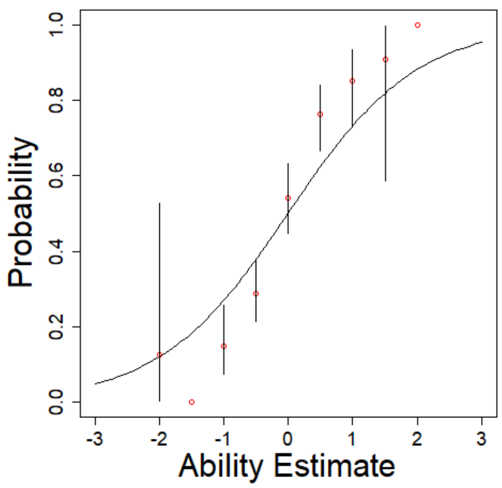

Fig. 1. Excellent fit to Rasch model

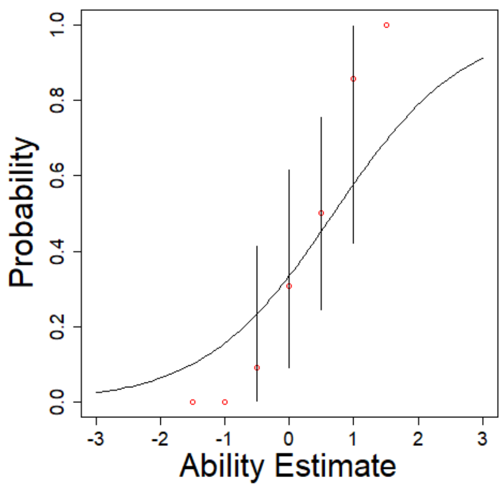

Fig. 2. Acceptable fit to Rasch model

As described above, for the physics test an item pool of 200 items had been developed. To determine the parameters as e.g. difficulty all items were investigated in the winter term 17/18 in a pretest with approx. 350 first-year students at the Hamburg University of Technology (TUHH) and the Universität Hamburg (UHH). The items were split into 8 test sets. 12 so-called anchor items (3 from each subdomain) were included in each test. Afterwards an IRT analysis of the items was performed. As the number of given answers for some items was quite limited the fit of the 2 PL model did not satisfactorily converge. Therefore, the discrimination power was fixed to 1 for all items and the fit was performed within the framework of the Rasch model. An important quality criterion for the procedure is the empiric match between data and Rasch model. Two examples of the model agreement after the fit are shown in figures 1 and 2.

From the complete question pool 72 questions are in the mechanics subdomain and have been used in the CAT.

4 PILOT PHASE

The test setup for the pilot phase consisted of two tests, the mechanics part of the static MINTFIT physics test and the new CAT. Two questionnaires, one after each test, evaluate the respective tests. Also, in the second questionnaire personal information of the test user is included, e.g. the final grades in math and physics before university as these had been identified as important predictors for academic success [1, 9]. The idea is that each test user starts with the static test followed by the first questionnaire. Next is the CAT followed by the second questionnaire (see figure 3). The test feedback and example solutions for the CAT are given right after the test whereas the feedback of the static test is only available after the whole procedure not to give any support for solving the questions in the IRT-CAT test.

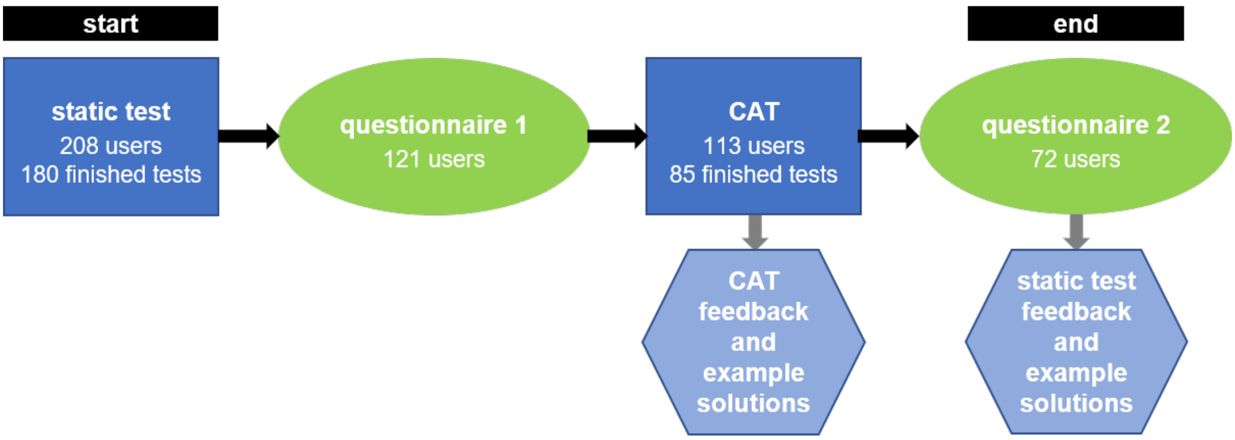

Fig. 3. Overview of test setup

In November 2021, 208 first year students in engineering science took part in the pilot phase. The students worked individually during a 90 minutes presence exercise session that complements the module in mechanics.

Out of the 208 test users that started the static test, 85 users got a converging result for the CAT. Finally, 72 test users also filled in the two questionnaires and thus completed all 4 stages.

To get an impression on how the IRT-CAT-test works in practice for a single user the development of the difficulty of the questions and the estimate of the personal ability and confidence intervals are shown in figure 4.

The items of the static test were not excluded from the item pool for the CAT. 70 % of the converged CAT runs had no overlap at all and 29 % of the tests had one question from the static test included in the CAT. This has no impact on the analysis and will be neglected in the following.

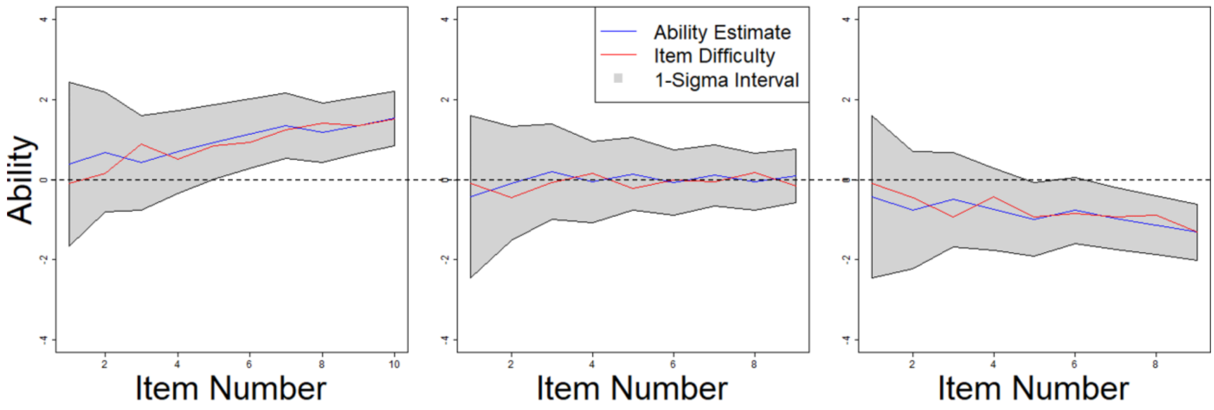

Fig. 4. Development of personal ability estimate and question difficulty versus item number for a test user with high (left hand), mean (middle) and low (right hand) personal ability

5 RESULTS

5.1 Comparison between CAT and Static Test

For the following analysis only the test results have been used where all four steps of the test procedure had been completed. As in the static test each user is forced to complete all 12 items, the number of items in the CAT depends on how many questions are necessary to fall below the error threshold. This leads to the distribution of the number of questions shown in figure 5. The mean value is 9.3 items. So, the number of items could be reduced by 23 % on average compared to the static test.

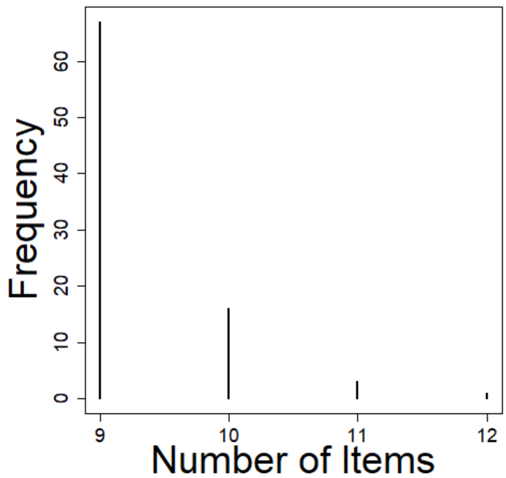

Fig. 5. Distribution of number of items in CAT runs

The comparison of the standard error of the personal ability versus the personal ability for the static test and the CAT is shown in figure 6. The error threshold for the

CAT is constant over the whole range of the personal ability whereas the error in the static test is a little bit lower around the mean value for the personal ability but rises to low or high values of the personal ability. Over the full range the error is comparable on average.

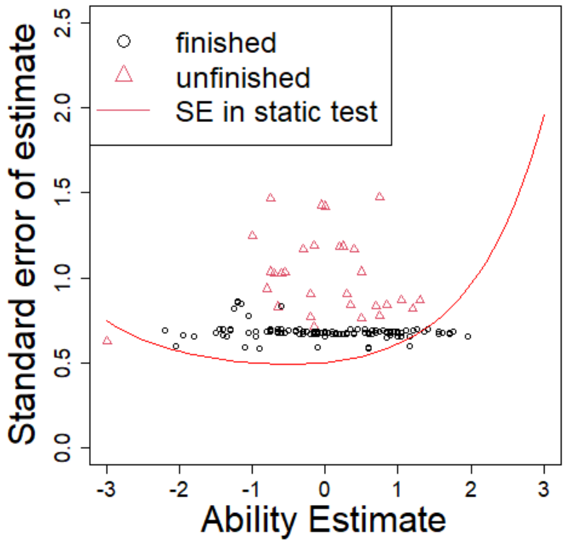

Fig. 6. Standard error versus personal ability estimate for static test (solid line) and CAT (finished and unfinished test runs)

As a quality check if the static and the CAT measure the same ability the correlation of the test results was determined. A satisfactory value of 0.56 was achieved (see table 1).

Table 1. Correlation between static test, CAT and school grades

	Static test	CAT	Grade in math	Grade in physics
Static test	1			
CAT	0.56	1		
Grade in math	0.46	0.49	1	
Grade in physics	0.56	0.35	0.47	1

For the correlation between the grades in math and physics a difference shows up for the two tests: the static test has a stronger correlation to the grade in physics whereas the CAT has a stronger correlation to the grade in math. From the social parameters only the academic background of the parents leads to a significant difference between the tests. The correlation between the test result and that at least one of the parents has an academic background is 0.12 for the static test and 0.31 for the CAT. Together with the difference in the correlation of the school grades this might be a hint that the two tests do not measure exactly the same ability of the test user. For a detailed understanding further investigation is needed.

5.2 Evaluation Results of CAT

In addition to the outcome of the test results the acceptance and judgement of the test users was determined with the two questionnaires.

In good agreement with the reduction of the average number of questions the perception of the duration of the test was significantly shorter for the CAT than the static test. On a five-point Likert scale ranging from “very short” to “very long” 45% chose short and 6 % very short for the CAT whereas only 25% selected short and none very short for the static test.

Both the static test and the CAT were rated in general as good by the majority: 58% “very good” and “good” for the CAT, 63% “very good” and “good” for the static test on a five-point Likert scale ranging from “very good” to “very bad”.

Astonishingly also the difficulty of the questions was comparably evaluated. In the CAT, 58% of the test takers rated the difficulty of the questions as “average”, and also 58% did this for the static test. The expectation was that the CAT mostly shows a mean rating as the questions were selected to fit the personal ability whereas the static test always has questions over the whole difficulty range, so weak students should give a feedback as the questions being “difficult” and strong students have the impression that the questions are “easy”.

6 SUMMARY

The prototype of the CAT was successfully implemented and tested. The number of questions could be reduced significantly by 23 % within a comparable error and hereby fulfilled the expectations. The assessment of the test users for the length of the CAT compared to the static test corresponds to the measured reduction. A satisfactory correlation between the results of the CAT and those of the static test was achieved. As the detailed knowledge of the item parameters is crucial, a further reduction of the test length seems achievable when there is more data available and the discrimination power of the items can also be determined.

7 ACKNOWLEDGMENTS

MINTFIT Hamburg is a joint project of the Hamburg University of Applied Sciences (HAW), HafenCity University Hamburg (HCU), Hamburg University of Technology (TUHH), University Medical Center Hamburg-Eppendorf (UKE) as well as Universität Hamburg (UHH) and is funded by the Hamburg Authority for Science, Research, Equality and Districts (BWFGB).

ABSTRACT

This concept paper reflects an ongoing research on designing students' team projects in engineering education with a focus on soft skills development. The core idea is to relate project tasks with relevant team situations and team roles which require and train certain sets of soft skills. The paper proposes: a) a model for developing the relevant soft skills out of project tasks, and b) an approach to relate individual competence profiles of team members with an overall team competence profile. A core assumption is that if a team is formed, individual competences are aggregated in a certain way to form a single team competence profile. However, in the case of soft skills this aggregating is more complex than simply adding skill levels, e.g., soft skills in teams are a result of specific combinations of competences. Understanding these effects is relevant for project management and engineering education. The paper proposes a first draft of a systematic framework for investigating such effects and for making them usable for the design of student projects in engineering education. It also provides insight into an example of an agile cross-border project conducted fully online and using the scrum method. The paper is considered to be a contribution to the development of project-based learning.

1 INTRODUCTION

For being competitive, “tomorrow” graduates would need to demonstrate technical, professional and global competences [1], including knowledge of project management as a part of “technical” competence. Since much engineering work is done in project and teams, the individual competences are the basis of the team’s or project’s competence profile – a kind of competence aggregation. However, the research on competences in project management indicates a more complex concept: individual competences do not just add up to an overall team competence. In general, there are competence profiles of individual team members which cumulatively scale up to the competence profile of the team; but this aggregation, we believe, is connected to the interaction of members’ soft skills. Human interaction is not an option but a necessity to share knowledge, experiences, and lessons within teams and between teams. Whereas technical skills can be acquired by an individual through learning and practice, soft skills require the interaction of others either through mentoring, interventions, or specific trainings to be developed. Consequently, team competence and performance depends on soft skills and team interation while at the same time soft skills are formed and trained in such team situations. Our research should contribute to a better understanding of these effects and to ways to make such effects usable and applicable in engineering education.

2 RESEARCH MOTIVATION AND METHODOLOGY

We aim to contribute to existing research by proposing a concept on how the team member interactions can strengthen or weaken soft skills of the team. This will support the composition of student teams in project-based education and at the same time it will enable the project managers or project team leaders to have awareness of such interactions so they can strategically allocate team members to create team profiles. We acknowledge that technical skills of the team members are also of high importance in contributing to the effectiveness of the team competence.

Based on the structured literature research, this concept paper will:

a) Propose a model for developing a competence profile of a team
b) Propose a model for examining team competence profiles with focus on soft skills
c) Propose an approach of conducting effective student team projects based on the analysis of the competence profiles and with a focus on soft skills development

3 LITERATURE RESEARCH

The concept of competences is a very diverse research area with different approaches towards definition. In their research on soft skills, Marin-Zapata et al. [2] provide a clear taxonomy “competence → competency → (skills, motivation, knowledge)”, where skills are distinguished between soft and hard; in its turn, hard skills refer to technical expertise, and based on the proposed taxonomy, soft skills have two main components as intrapersonal and interpersonal skills. The development of soft skills depends on the interaction between individual innate traits (i.e., personality and abilities) and contextual factors, whereas in organizations the interaction between soft skills and training programs appears to be vital to enhancing employee job performance [2]. According to Matturro et al. [3], soft skills are a combination of the abilities, attitudes, habits, and personality traits that allow people to better perform in their workplace, complementing the technical skills required to do their jobs and influencing the way they behave and interact with others. Based on the systematic mapping study, Matturro et al. [3] provide main categories (including their definition) of soft skills relevant for software engineering; those are: communication skills, team work, analytical skills, organizational/planning skills, interpersonal skills, leadership, problem-solving skills, autonomy, decision-making, initiative, conflict management, change management, commitment/responsibility, stress management, customer orientation, flexibility, ethics, results orientation, time management, innovation, presentation skills, creativity, critical thinking, negotiation skills, listening skills, motivation, willingness to learn, fast learner, team management, and methodical skills category. Furthermore, Tam et al. [4] examined the people/soft factors that contribute to agile software project success, found that societal culture and personal characteristics of the team members can impact the overall capability of the team.

Although various studies have defined soft skills in different ways, there appears to be consensus that individual personality play a major role in influencing soft skills. Several factors can influence a person’s personality like individual attitudes, behavioural habits, personality traits and their individual competences (abilities). In their study, Yilmaz et al. [5] assessed the personality characteristics of software development teams using the Big 5 personality theory; they discovered that effective team structures support teams with higher emotional stability, agreeableness, extrovertsion, and conscientiousness personality traits.

Awuor et al. [6] study skills for teamwork and propose an assessment methodology of teamwork competence; authors highlight that through teamwork and project-based learning, students improve their knowledge in technical, behaviour and contextual competence areas of project management, and the study revealed that thanks to teamwork, student competences in creativity, leadership and negotiation were sufficiently improved. In their study on project management learning and teaching challenges, Ojiako et al. [7] revealed key components of students' experiences: transferable skills (interpersonal skills, time management, curriculum coherence, critical thinking and communicating) and virtual learning (quality of e-resources, accessibility of information managed online); due to the nature of the study, the paper provides a detailed self-evaluation survey on transferable skills. The authors conclude that institutions and educators need to re-think an integration of transferable skills into education agenda and allow engagement in project-based modules, where students become proactive problem solvers and critical thinkers [7].

To improve students’ performance in a project-based learning, Aranzabal et al. [8] propose a methodology to build a balanced project team. Using the Belbin’s role theory to raise student awareness about the benefits of teamwork, authors confirm that teams formed based on one-of-nine roles performed better than self-selected teams. The role theory developed by Belbin in 2010 states that a team role is a “a tendency to behave, contribute and interrelate with others in a particular way" and it is influenced by personality, mental abilities, current values and motivation, field constraints or external working environment, personal experience and cultural factors, and role learning. The authors highlight, that using the role theory, students realised a positive contribution to cooperative learning, interpersonal relationships, social skills, and abilities to work in the roles- and skills-based environment [8].

4 PROPOSED CONCEPTS

In our first concept (Fig. 1) we want to highlight different aspects influenced by hard/technical and soft skills. If we look at competences from a technical skills' perspective, then we believe it is enough to add up such skills to compose a project team competence profile. Whereas when we consider competences from the soft skills' perspective, it is not possible to add up soft skills of team members and a more complex interrelation among team individuals should be considered. Based on the task deliverables to be achieved (see (t_1 … t_n) in Fig. 1), we may define roles (r_1 … r_k) and relevant competence profiles (CP_1 – CP_m). Based on taxonomy given by Marin-Zapata et al. [2], competences are composed of soft and technical skills, and since the soft skills do not complement each other between team members in a simple way, we assume that deriving the interpersonal team aspects and soft factors from the individual soft skills is an unsolved scientific problem. While we assume that accumulating the technical skills (see "+" in Fig. 1) of the individuals into a technical team competence profile is adequately done by really just adding skill levels, we expect that accumulating the soft skills (see "++" in Fig. 1) is not possible by just numerically adding skill levels but only by an expert review and assessment, based on the experience of good managers.

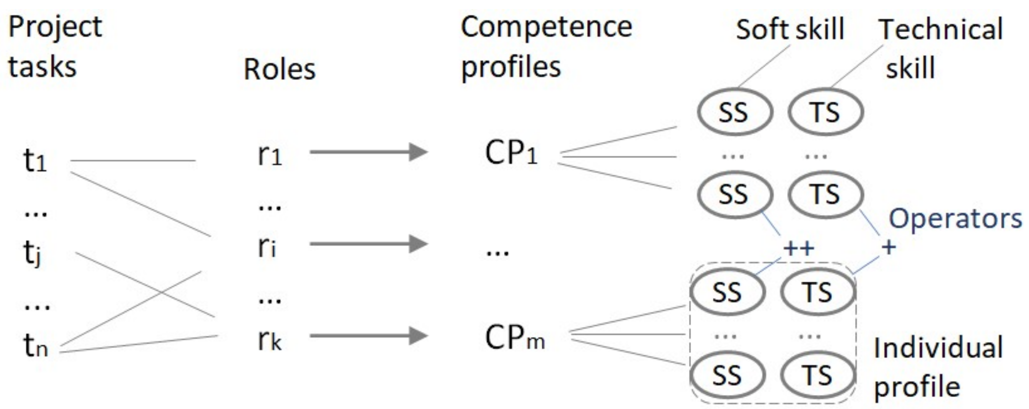

Fig. 1. A model for examining interrelations of project tasks, roles, technical and soft skills

As observed in the researched literature, a project team is comprised of individuals with various soft skills and different personality traits. It can happen that the personality traits of team members clash and, in one or another way, impact the team performance. But if the personality traits are aligned, it can lead to creating an effective working team. Therefore, we propose a second concept model (Fig. 2) to investigate factors that play a role in development of soft skills in teams. The model acknowledges the significant work done by existing research on team formation, but our aim is to find a way to select and allocate team members to form balanced teams. Through considering the personality traits of the team members, we aim to formulate team competence profiles that can be used both in education and project staffing for combining team members with the right set of soft skills and for developing soft skills by working in such teams. As highlighted in [4], [7] and [8] soft skills can be trained trough doing projects in teams, and as claimed in [5], team capability refers to the utilisation of knowledge, which, we believe, can be fostered by trust developed over time.

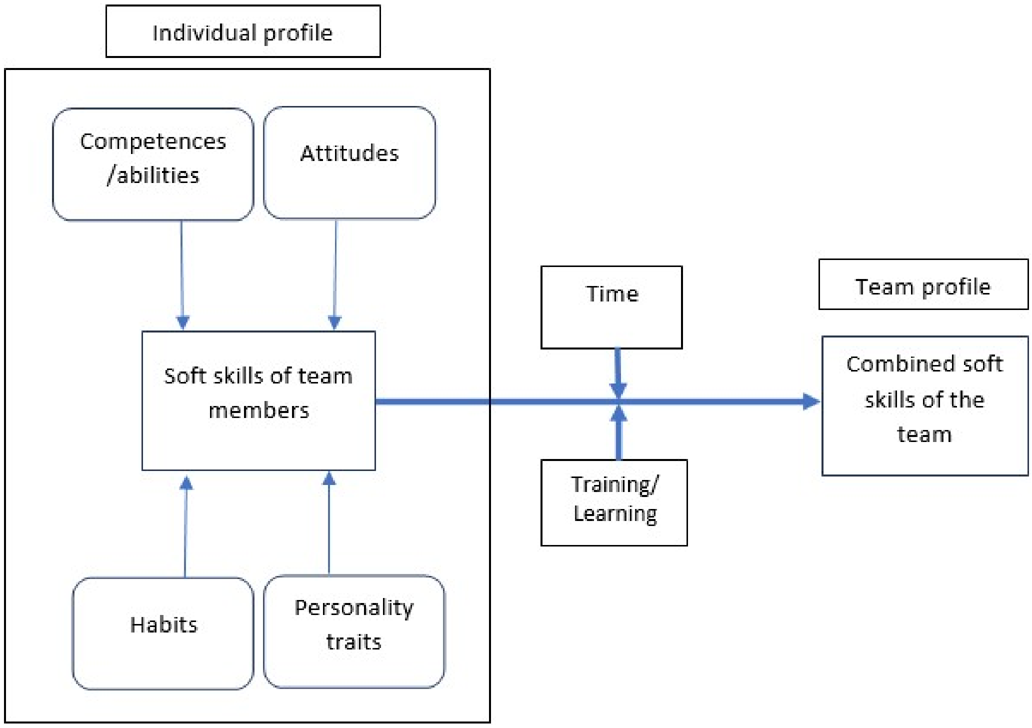

Fig. 2. A model for examining team competence profiles with focus on soft skills

Each team member has their own personality traits which can impact the way they associate with other team members, hence, impact the transfer of skills between them. This model proposes that the interrelation and transfer of soft skills between team members is influenced either negatively or positively by individual personality traits, thus, impact the overall soft skills of the team positively or negatively. In Table 1 we summarise meanings of personality traits and relevant scores to be considered when forming the team.

Our research is investigating methods and tools for composing “good” teams for a given project (set of tasks) as shown in Fig. 1 and for solving the problem of deriving the soft factors from individual soft skills by using more complex concepts like personality traits (see Fig. 2). After the elements and relations of these two conceptual models are properly investigated, we aim to incorporate the developed team formation approaches into engineering education. This can be enabled though project-based education and competence-based description of desired learning outcomes. Based on specific soft skills which are supposed to be trained, projects are constructed (or selected) which provide the learning settings and team situations needed to train the soft skills. The success depends on forming student teams with the right combination of individual competence profiles. In the next chapter, we will propose how such an approach could look like in an educational framework for project-based learning.

Table 1. Personality traits: meaning and measures (based on [5])

Dimension	Meaning	Score in the questionnaire
Extroversion	is the personality trait of seeking fulfillment from sources outside the self or in community	high scorers tend to be very social while low scorers prefer to work on their projects alone
Agreeableness	reflects many individuals adjust their behavior to suit others	high scorers are typically polite and like people, while low scorers tend to 'tell it like it is'
Conscientiousness	is the personality trait of being honest and hardworking	high scorers tend to follow rules and prefer clean homes, while low scorers may be messy and cheat others
Neuroticism	is the personality trait of being emotional	high scorers experience negative emotional state, sadness and anxiety, while low scorers emotionally more stable and even risk takers
Openness to Experience	is the personality trait of seeking new experience and intellectual pursuits	high scores may daydream a lot, while low scorers may be very down to earth.

5 PROPOSED APPROACH AND DISCUSSIONS

Rajala [1] provided a 3-D global engineer framework and described attributes of technical, professional and global competences required for future engineering graduates if they want to succeed. Our proposed approach aims to develop students' team projects which contain team situations – and respectively learning situations – which require a set of professional and global competences in connection with a technical tasks which requires technical competences. Engineering students conduct the technical tasks and inherently get into the team-related learning situations which train their soft skills. The project and learning design considers the connections between tasks, team roles, competence profiles, soft skills, and hard skills as described in Fig. 1.

Our research and the respective student projects are embedded into a cooperation (European Partnership for Project and Innovation Management – EuroPIM) between a number of European Master's programmes in IT, engineering and project management which gives us the chance to form international and interdisciplinary teams [9]. In this setting, we are developing a guideline on how to construct (or select) project cases and how to form student teams based on the intended learning outcome, specifically looking at the soft skills.

As an example, we refer to the development of an mobile app in teams of 4-5 students (mixed from two different countries) which was conducted in agile sprints, using the scrum method, in a 100% online setup [10]. This format was conducted and evaluated several times within the EuroPIM partnership.

The scrum project foresees individual work of the students and collaboration is happening only in specific team situations, the so-called scrum ceremonies. The scrum ceremonies are the relevant learning situations with respect to soft skills. In addition, this type of project foresees only 3 team roles: the scrum master who is a process-focussed facilitator and coach, the product owner who is a result-focussed driver and shaper, and the team members who are considered to be a group of equals. Therefore, the scrum ceremonies can be considered as tasks (see Fig. 1) which contain specific team situations (see description of the 5 ceremonies in Fig. 3) which are connected to specific soft skills (see [10]).

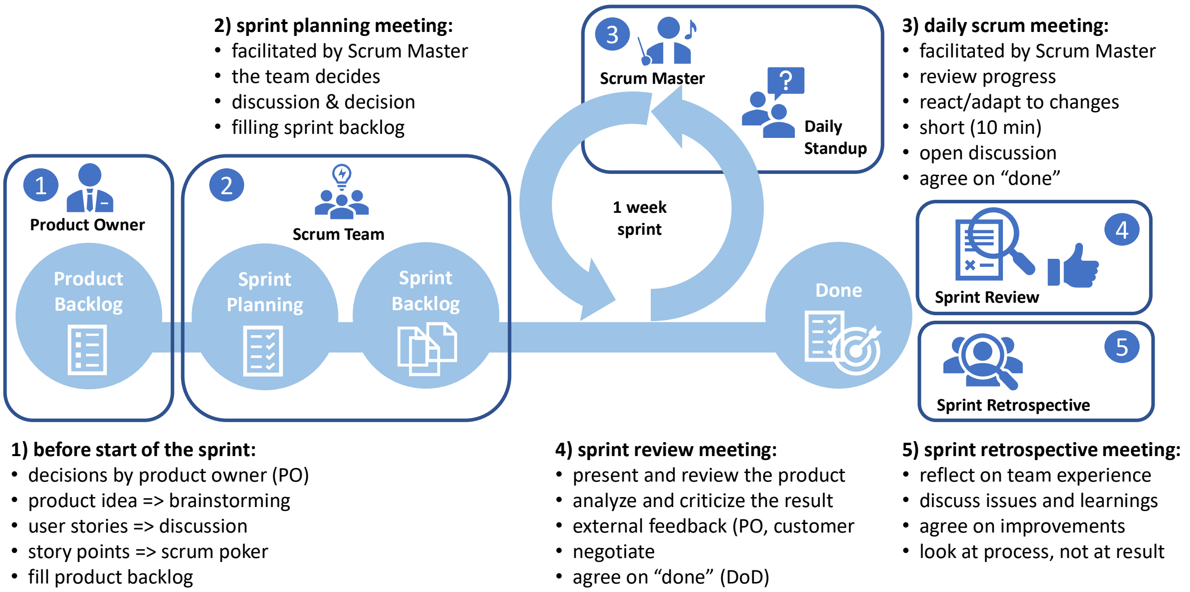

Fig. 3. Analysis of the 5 scrum ceremonies regarding team situations and team roles [10]

Based on the experience, we propose a 5-step approach for designing international and interdisciplinary cross-border projects where students from different back-grounds and cultures can train technical, professional and global competences.

1) Before the course:
   - Based on the planned learning of the course, define a possible case study to stimulate a relevant project scenario (preferably with industry involvement, e.g. the development of an mobile app as in [10])
   - Define the list of project tasks to be performed by the team within the course → Tasks will determine the roles of the team members → in case of the scrum project (Fig. 3) these are the 5 scrum ceremonies and the 3 scrum roles which are part of the project.
   - Design a self-evaluation questionnaire for the students to assess their soft skills before doing the course (e.g., as a catalogue of soft skills, the list provided by Matturro et al. [3] can be used; questions may be adapted from [7]) → initial profiles of students
   - Based on the required team roles, define which students will be assigned to a specific team and which role each student may perform in order to fulfil the project tasks → this is an initial assignment which will be refined at the beginning of the course

- Plan the intended learning outcomes based on the initial profiles of the students and the anticipated project (learning) situation during the project

2) At the beginning of the course:
    - Perform a team building exercise with each student team in order to define the set roles for the project → build a balanced team (based on personality traits assessment [5] or Belbin's role theory [8])
    - Invite company representative to provide the case → create a realistic project kick-off situation (e.g. in the discussion of user stories, see (1) in Fig. 3)
    - Reflect with students on the experience during team building and project kick-off and ask them to refine their self-assessment
3) During the course
    - Provide students with project management methodology → training of technical competence (e.g. a scrum training and test)
    - Provide students with tailored soft skills trainings and knowledge
    - Project work in cross-border (cross-cultural) teams → training of global and professional competences
    - If required, conduct team exercises, e.g. for conflict resolution
4) At the end of the course:
    - Organise reviews (e.g. pitches, feedback sessions) with company representative → training of professional competence
    - Assess the quality of the project results → evaluation of technical competence (e.g. in the sprint review in Fig. 3)
    - Conduct the self-evaluation survey on acquired soft skills → evaluation of the soft skills gap closed during the course (examples: see Fig. 4)

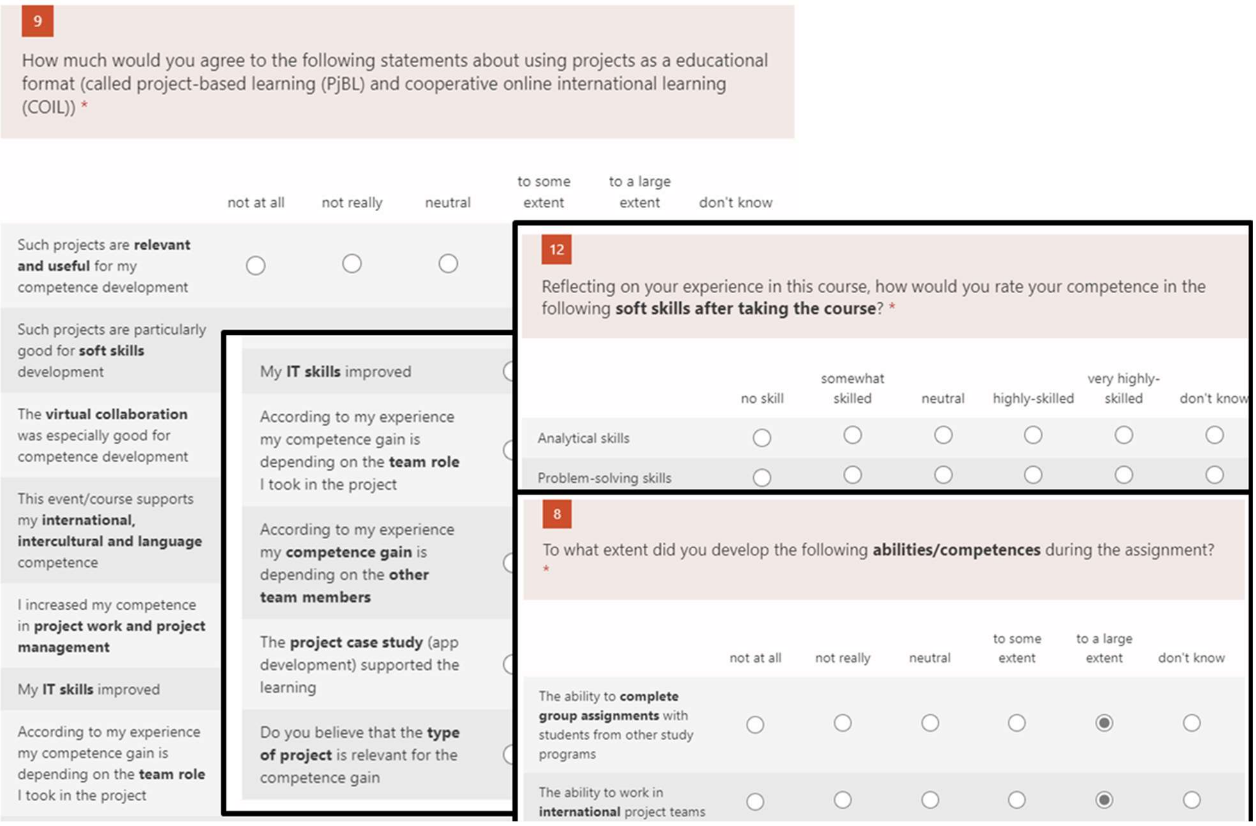

Fig. 4. Examples of survey questionnaires used in the agile cross-border projects

5) After the course:
    - Lessons learned workshop in order to reflect on the team situations and to raise the awareness of students for the soft factors

Our research is based on conducting student projects using above-mentioned 5-step approach. We conducted several trial runs with student teams from 2 countries (e.g. Germany-Kazakhstan [10], Germany-Spain) and participants numbers from 10-50. Evaluations showed positive feedback of students and teachers though some results were surprising (e.g. English language communication was a minor problem, while IT literacy was partly challenging). At the next step we aim at evaluating the impact on students' soft skills based on survey results and expert reviews. For this we intend to refine the methodology and to validate the concepts and quality of the methods based on conducting student projects within our European consortium.

6 SUMMARY

Designing student team projects with specific team situations in mind can support the development of soft skills of engineering students. Nevertheless, a straight-forward methodology for connecting project tasks, students' team roles, learning situations and soft skills in a meaningful learning design is a challenging task. The proposed 5-step approach is a first draft of a systematic framework which might finally support teachers and students in systematically increasing the learning outcomes in project-based learning, especially with respect to soft skills.

Making sense of interdisciplinarity in challenge-based learning:

A two-step co-creation approach towards educational redesign

ABSTRACT

Challenge-based learning gains popularity in engineering education for allowing students to transcend academic and disciplinary boundaries and to fully engage in real-world problems, but it is largely underexplored how to improve specific designs of such educational practices to promote interdisciplinary learning experiences and competencies. This paper describes two studies that together in two steps make up an evidence-based redesign of a challenged-based course featuring group-work projects in an undergraduate program combining engineering with liberal arts and sciences. A first study based on observation and interviews collects different and varying learning experiences throughout students' learning activities. The results showed that interdisciplinary experiences are constructed in complex dynamics between students' disciplinary identity formation and the interdisciplinary and collaborative course configuration. Such dynamics may result in positive learning

experiences (engagement and interdisciplinary enrichment) as well as negative ones (disengagement and frustration). Especially regarding the discrepancy between common experiences across the three phases of tackling the challenge (mapping, mitigating, integrating), representatives of parties important for the course were invited to a roundtable session in a second study to discuss and reflect on the first study's findings and what they can mean for the course design. Understandings achieved in the session are used as input for upcoming course redesign towards a more desirably organized challenge-based learning. The two-step approach towards redesign is an example of involving researchers and students in evidence-based educational redesign, exemplifying the value of naturalistic research and educational co-creation in understanding and optimizing students' learning experience to achieve fruitful challenge-based learning.

1 INTRODUCTION

Our rapidly changing world calls for experts who can transcend traditional disciplinary regimes. Academic programs increasingly try to incorporate interdisciplinary elements in their curricula and there is a growing number of programs with an overall interdisciplinary signature. Challenge-based learning is a dominant approach in weaving interdisciplinarity in academic education [1]. Still, little is known about the way challenged-based courses contribute to interdisciplinary learning experiences and competencies. Analyzing how students reflect on their interdisciplinary learning experiences in specific challenged-based courses may provide insights in the strengths and weaknesses of such forms of academic education and help to identify course design characteristics with positive or detrimental effects on the development of interdisciplinary competencies.

This paper presents a case of understanding the interdisciplinary experience in challenge-based learning and applying such understandings to improve challenge-related educational design. The study focuses on a specific project-based course in a Dutch Liberal Arts and Science (LAS) undergraduate program. The entire program emphasizes students' self-determination and interdisciplinarity, allowing students to tailor unique academic trajectories based on personal pursuits and bringing students with different academic interests and backgrounds together in collaborative project settings. One of its courses, called Real-World Challenges, aims to prepare students for working on grand and wicked problems on a scale similar to real-world contexts. This 19-week course gives students substantial freedom in contributing their own interests and expertise to addressing societal challenges. Students themselves choose the specific topics to work on and accordingly form groups. In one semester, the groups try to diagnose and ease the challenges by developing interventions through, citing the syllabus, 'multidisciplinary solutions and systems thinking.'

Besides the preparing week during which students determine project topics and groups, the course consists of three phases. In the first phase (Mapping and Modelling, 5 weeks), groups of around 14 students analyze the challenge as a complex spatial-temporal system from different angles, decomposing it into heterogenous constituents, and comprehensively mapping and modeling it by describing involved critical issues, stakeholders, and their interrelations. In the second phase (Mitigation, 9 weeks), the groups divide into smaller 'expert teams' of two to four students. Expert teams apply their specialized expertise to devise mitigation strategies for the identified critical issues towards solving the general problem. In the third phase (Integration, 4 weeks), students return in the large group to attune and synthesize separate mitigation strategies into a collective final report that addresses the challenge in line with the overarching model made in the first phase.

Since the start of this LAS program more than eight years ago, this challenge-based course highlighting student autonomy and interdisciplinary exchange has undergone little change in design. In 2020, it participated in a practice-based educational research project, STRIPES2021 (STructuring Interdisciplinary Projects for

Engineering Students), which is supported by COMENIUS Leadership Fellows and aims to help educators better structure interdisciplinary education.

2 METHODOLOGY

Studies regarding the interdisciplinary nature of course were conducted in two steps. The first step featured of an in-depth qualitative research on students' learning experiences and perceptions of interdisciplinarity. The study engaged in classroom practices and especially focused on how interdisciplinarity emerged as cognitive-social systems through the process of challenge-based learning and project work [2]. Building on 35.5-hour observation of class and group meetings and informal talks with students, further interviews (N= 25) were conducted with students from the 2020 cohort. The interviews focused on the design and process of the project work, students' disciplinary identities, and their learning experiences throughout the course. This step served to develop a detailed overview of the strengths and pitfalls of challenged-based interdisciplinary education in such a free, autonomous setting.

The second step involved a roundtable session meant to provoke insights for possible redesigns of the course. The session invited a course coordinator who developed and supervised the course and two students from different years who had followed the course in different years. By involving the two groups, this step emphasized a student-staff partnership and followed a co-creation approach which directly enables the exchange between different knowledge and experience in education and reinforces the values of equity and interaction [3], as the program itself highlights. In the session, the participants were gradually presented with findings of the first study and brought into discussion. Along the demonstration of research findings, students were encouraged to share and compare their learning experiences, which simultaneously validified the first-part research findings by recognition. Participants structurally discussed, brainstormed, and reflected upon the research findings and what they may mean for the educational design of SP4. Therefore, the research findings were communicated with the educational community of the program highly respecting its autonomy and culture. The roundtable session resulted in a report about possible ways towards improvement and challenges to further investigate and address mentioned in the discussion. This step served to bridge the gap between research findings and the educational practice as well as to deepen the insights about the stakeholders' perceptions of interdisciplinarity in academic education.

3 RESULTS

3.1 Naturalistic study: identifying problems

Researchers' engagement in the first study showed variations of students' learning experiences in the course, both in a vertical dimension through three phases and in a horizontal dimension across individuals, particularly in the second phase, Mitigation. Analyses focusing on the horizontal variation have resulted in a detailed account about how interdisciplinarity has been constructed and enacted in this specific educational context where individual disciplinary identities manifest, negotiate, and act upon each other in the interactive groupwork dynamics. One an individual level, students showed different identities in how their academic pursuits were configured regarding disciplinary constellation. Working in expert teams, different patterns of group-work experience regarding interdisciplinarity emerged following various circumstances. The interplay between individual levels and group levels illustrates dynamics of interdisciplinarity in the course, partly orchestrated by the project design and partly shaped in concrete interpersonal transactions.

While in another publication we addressed intersectional academic identities and their construction of interdisciplinarity in details, we are also interested in the practical implications of our explorative and descriptive research regarding learning experiences for the design of the challenge-based course. The implications firstly concern the horizontal variation in learning experiences: During the mitigation phase, not all students shared a fruitful interdisciplinary experience. Instead, some students missed meaningful connections with other disciplinary input and considered their experience as monodisciplinary: 'But then you had the mitigation strategy in the mitigation phase …[I] didn't experience it really like that [interdisciplinarity] because I was just working on my own expertise. So, I didn't really feel very interdisciplinary'. Other students expressed an experience of shallowness and not being able to apply their expertise: 'I have the feeling that, for example, I got to apply some of my expertise, but a lot of it I also just have to look up online… [the topic] was what we were interested in. But it wasn't necessarily that we applied the knowledge that we already had. We had to gain more knowledge before being able to apply it. In that sense, in my opinion, it isn't really about the interdisciplinarity at that point. It's just more about Googling.' This non-disciplinary experience as well compromised the engagement of students.

Furthermore, the vertical variation of perceiving interdisciplinarity also matters in how students experience their learning journeys. Unlike the various patterns identified in the Mitigation phase, students shared large commonalities in how they experienced SP4's first and third phases. When the beginning Mapping and Modelling phase is commonly described as brainstorm and discussions full of exchanges between different disciplinary backgrounds, the third, named and emphasized as 'Integration', is surprisingly characterized by a lack of engagement, interaction and interdisciplinarity in students' experiences.

External factors such as heavy end-semester study load and communicational constraints during the Covid-19 crisis partly explained this problem. However, interviews yet showed that practices during the Integration phase were fairly limited to repeating the maps and models from the first phase. Similarly restrained were freedom, creativity, and flexibility regarding project work from which student have expected much. Some students questioned whether different approached were brought together during the integration phase and accordingly distanced themselves from taking tasks. Many students, similarly, contributed solely by summarizing their Mitigation-phase achievements without an overview of the whole project. Students often commented the Integration phase as mainly revising and editing documents, a mechanical process without actual mental challenges or growth to understand or synthesize different perspectives.

3.2 An analysis of the problem and educational design

Reflecting upon the structure of the course, the three-phased project design in addressing challenges implies a sense of reductionism and linearity, which related to students' disengagement during the Integration phase. Primarily, the three phases are demarcated based on an assumption that complex problems are aggregations of affiliated issues that connect but can be dismantled, tackled separately, and later brought together. Groups, in Mapping and Modelling, were asked to sort out various nodes in models and reduce holistic problem maps into jigsaw pieces. Therefore, what the large group achieves in this first phase largely determines following activities. Integration, consequently, becomes the closing section in a ternary form that repeats the opening, mainly patching together the previously defined critical issues, focusing hardly on content but formation of the final assignment documents.

Second, projects' three phases demonstrate a sequential, linear structure: One follows the other in time. However, the linearity cannot capture the logic behind the phases. When mapping and modelling problems, students were already asked to envision specific critical issues and consider their interlinks. Concerning Integration, the syllabus also suggested 'reflect[ing] on how the mitigations of the smaller phase-2 groups can be integrated in the original models of the overarching problems', explicitly referring to the two earlier phases. Therefore, the three phases are actually interwoven and symbolize recurring moments and iterative processes facing complex, holistic systems. The inconsistency between the time-wise linearity and logic-wise non-linearity in SP4's educational design actively acts upon students' learning experiences.

This reductionist and linear assumption also renders the Mapping and Modelling phase dominant impacts on the group dynamics and interdisciplinary experiences throughout the project. Specifically, the composition of expert teams in Mitigation largely complied with the underlying logics of initial problem definition and critical-issue division. When critical issues are framed as disciplinary aspects, corresponding expert teams are likely to be homogeneous, with members sharing similar disciplinary focuses. Contrariwise, identifying a critical issue as a specific phase or facet of the larger problem stimulates groups to recognize problems' interdisciplinary nature and promote miscellaneous teams allying distinct disciplinary expertise. In homogeneous and miscellaneous groups, where respective critical issues are established and approached differently, work dynamics also take place differently, leading to different perception and experience of the application of disciplinary expertise, transactions across disciplines, and thus interdisciplinarity.

3.3 Roundtable session: creating input for change

Empirical findings about students' learning experience and theoretical reflection on the course's set-up were together brought into the roundtable session to create an environment for discussion, reflection and co-creation. In the session, the researcher acts both as a party in the co-creation that provide outsider insights and as coordinator to facilitate the communication and encourage others to come up with possible ways to improve the course. When sharing the research findings about learning experience, both the compromised interdisciplinary experience (non-disciplinary and monodisciplinary) and the disengagement in the Integration phase were recognized by students from experiences of themselves and peers. For example, one student described the Integration phase as 'more like mixing and matching the parts in a report rather than trying to understand [different perspectives].' The analysis of the reductionism and linearity implied in the design to address challenges was also endorsed by both educators and students as a critical problem in designing interdisciplinary and challenge-based education.

The roundtable session first identified the links between different expert teams as the key to overcoming the problem in educational design and to improvement of the course. Although students expressed that 'integration feels a bit rushed in the end' and believed if given more time they would be able to experience more meaningful learning in the Integration phase, prolonging the Integration phase does not mean the definite solution: Students need to read into mitigation strategies of other teams during the extra time, thus a better in-depth understanding of other teams' work is pivotal for meaningful integration.

Consequently, the discussion focused on possible ways to enable links between expert teams and resulted in several proposals for educational (re-)design.

First, activities during the small-team-based mitigation phase could be planned to allow students to learn about others' work in an earlier phase and make connections. One example is a mitigation strategy market, where all expert teams would present their work by far and students could then walk around to talk with peers, sharing ideas and comments, pinpointing possible links between different disciplinary perspectives, and helping each other shape further mitigation trajectories. Similarly, a mid-term evaluation halfway at the Mitigation phase can give students chance to present their work at the current stage. Guided by course coordinators or external experts, open conversations during such an evaluation moment can involve more peer teaching and explanation from different disciplinary perspectives, so that individual members in expert teams can understand work in other teams better and identify links with other teams more easily in a more structured way.

Second, it is recognized that the challenges identified at the preparation phase of the course are too broadly defined. The elements and expertise recognized in the initial mapping and modeling of the challenge are impossible to be reasonably covered by four to six expert teams. Therefore, the mitigation phase can only attend a few knots on a web-like model and a lot in the model will be omitted in the whole Mitigation phase. According to students, even one critical issue treated in an expert team now is complex enough and have many perspectives to be qualified as a topic of challenge for the whole large group. A watered-down approach is proposed to better decide on the topic of challenge: After identifying different critical issues of a general, broad grand challenge, the group would further focus on one critical issue and repeat the mapping-modelling process until the resulting model is manageable for the group with a limited number of members. By narrowing down the scale of the challenge, students could also further engage together in connections between and among different aspects and perspectives of a problem, thus have a firmer base to integrate different mitigation strategies.

Therefore, the integrative endeavor is less emphasized or concentrated as the last phase of the challenge-based project work but is present throughout the entire course. In other words, the whole project is actually focusing on integration, not only in the last phase. This shows that specialization and integration are two simultaneous aspects in addressing challenges, not to be separated in time or activities. To accomplish the proposed (re-)designs for the course, educators need to either transcend the reductionist, linear curriculum design or instruct and scaffold closely through the first phase, from defining the scale of the challenge to the forming of expert teams.

4 SUMMARY AND ACKNOWLEDGMENTS

This paper, based on a case, described a two-step approach that brings educators and students together to reflect on a challenge-based course and together create improvement for the course in the future. In this co-creation approach, researcher functions both as mediator and catalyst. On the one hand, the researcher collects learning experiences that are used as input to help represent a student perspective for educational improvement. On the other hand, the researcher brings individuals from different positions in education together and facilitate the intensive discussion and reflection. Therefore, this two-step approach shows how the sociological, naturalistic epistemology and methods of social studies can contribute to educational practices. Unlike the researcher-centered approach commonly found in educational design and improvement, the two-step approach presented here puts educators and students who are directly involved in the learning practice at the center. Therefore, this paper demonstrates an initiative to engage different stakeholders, especially students, in educational design. The highly emphasized engagement in the co-creation approach also respects and complies with the values about student-involvement, autonomy and community favored by this LAS program.

This study is part of the COMENIUS Leadership Fellows 2019 project: STRIPES2021. We thank the program and all involved educators and students for their help.

ABSTRACT

This concept paper presents the large-scale measures and results that the Faculty of Engineering of the Friedrich-Alexander Universität Erlangen-Nürnberg (FAU) has developed to shape the future of learning and teaching of propaedeutic skills in the field of mathematics as a central basis of engineering subjects and to inspire pupils and young people for engineering studies. Since 2020, the Faculty of Engineering has developed a three-tier, structured voluntary program that is attended by several thousand pupils and freshmen per year:

1. Summer review courses in mathematics for pupils after the 10th and 11th school year during the summer holidays in accordance with the Bavarian school curriculum

doi:10.5821/conference-9788412322262.1411

2. School leaving exam preparation courses in mathematics shortly before the university-entrance diploma acquired at a secondary school in Germany, the so-called "Abitur"

3. Math review courses for freshmen.

The methodological approach of the article lies in the presentation of the educational measures and in the analysis of the results of systematic student evaluations. This leads to generalizable, transferable recommendations for the future design of such large-scale measures for universities, derived from answering the proposed research questions and evaluation results.

1 INTRODUCTION: MATH ANXIETY - DIFFICULTIES FOR A SUCCESSFUL HIGH SCHOOL EXAM AND STUDY ENTRY IN ENGINEERING AND NATURAL SCIENCES

For years, the math skills of prospective high school graduates in Germany have been very "different" (many good, many just sufficient) with a large spread. There is a variety of literature available as mathematical support for pupils, such as "Taking Fear Out of Math: A Self-Help Guide for Parents and Students" [1] or – in German language – "Keine Angst vor Mathe" [2] or "Mathe ohne Angst" [3], and also scientific literature for teachers to overcome the "fear of mathematics" of their pupils and students such as "Math Anxiety: Strategies to Increase Confidence in Your Students Who Fear Math" [4], "I'm Just Not A Math Person! - Recognizing, Understanding, and Managing the Fear of Mathematics" [5] or "Mathematik-bezogene Angst" (in German language) [6]. On the other hand, the authors of this paper are not aware of any comparable books for other school subjects such as "Don't be afraid of English" or "History without fear". Due to the CoViD-19 pandemic, there are further gaps in skills due to the absence of contact teaching and initial difficulties with homeschooling during the lockdown phases, especially in 2020. All these topics discourage many high school graduates from taking up engineering and natural science study programs.

2 DESCRIPTION AND METHODOLOGY

2.1 Description and overview

For years, FAU has been offering its "Mathematics Review Course for Freshmen" ("Mathematik-Repetitorium") before the start of the winter semester. The mathematics topics from high school are repeated in the two weeks before the start of the lecture period. In this way, the heterogeneous degrees of knowledge of the first semester students can be evened out.

The integrated concept presented in this paper describes an approach that starts much earlier in the "student life cycle". For this purpose, the review course for freshmen was enhanced to a structured offer in three graded and coordinated courses offered online via Zoom (see Fig. 1):

1. Summer review courses in mathematics for pupils after the 10th and 11th school year during the summer holidays in accordance with the Bavarian school curriculum (tutorials in groups of around 15 participants each, duration 6 weeks during the summer holidays with 2 hours of tutorials per week). The educational ideas and objectives are to close gaps in education incurred in the previous 10th and 11th school year and to prepare the pupils for the coming school year.

2. School leaving exam preparation courses in mathematics in April shortly before the German high school leaving exams, the “Abitur” in May complemented by information events on the range of degree programs offered at FAU (tutorials in groups of approx. 15 participants each, duration 2 weeks during the Easter holidays with 3 hours of tutorials daily). The educational objectives are to transfer competencies to enable the pupils to pass the high school leaving exams in maths with good grades, especially for pupils that are not confident in their mathematics abilities, to attract them to engineering studies and – ideally – to FAU.

3. Math review courses for freshmen of FAU (lectures plus tutorials in groups of around 15 participants in the 2 weeks before the start of the regular lectures of the winter semester with daily 2 hours of lectures + 2 hours of tutorials; usually in attendance, in fall 2020 and 2021 online due to CoViD-19). The educational objectives are to refresh mathematical high school competencies for all students, especially for students that have passed their high school exam some years earlier due to a vocational education or a voluntary state service after the high school exam, and to prepare them for higher mathematics and mathematics oriented engineering courses in the first semesters.

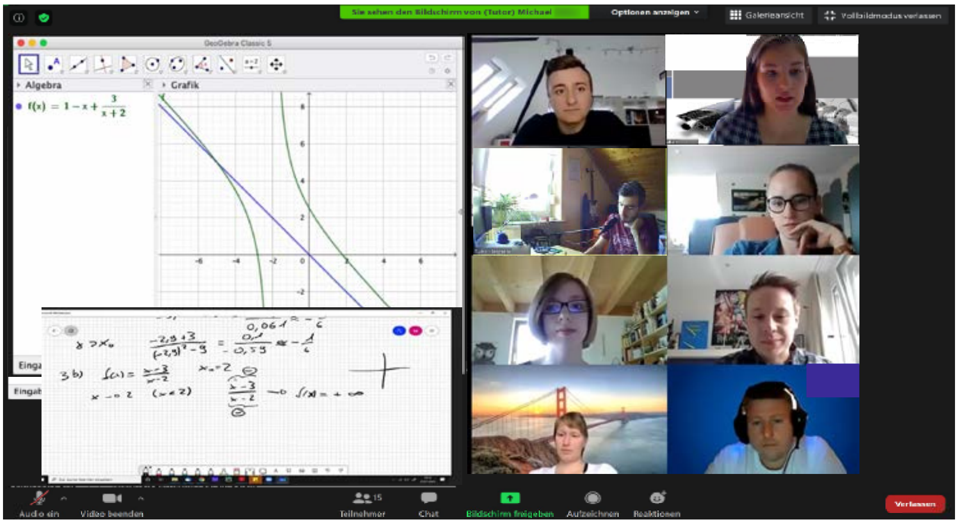

Fig. 1. Online tutorial mathematics

2.2 Key facts of the courses

Approximately 500 – 1 500 pupils registered for each course, which required the hiring of approximately 50 - 100 students per semester as tutors. The tutorials were mainly carried out by engineering students in order to ensure a high level of practical relevance. These were supplemented by students from the natural sciences faculty, mainly by students from the mathematics teacher training program. The costs for tutors also formed the largest part of the required material resources (approx. 25 000 – 50 000 € per course). The organization and scientific management was carried out by full-time staff from the Faculty of Engineering, here primarily from the Department of Mechanical Engineering.

Online research revealed that comparable courses are often offered at other universities for first semester students, but hardly any courses for pupils or courses to prepare for the high school leaving exam.

2.3 Pedagogical design: Engaging pupils' attention and motivating the pupils in the courses

Since the summer courses were announced as "first aid maths course" for 10th and 11th grade pupils and "math Abitur crash courses", mostly pupils with deficits in mathematics participated (in contrary to "tech summer courses for pupils", where mostly math and engineering interested pupils participate). Therefore, the pedagogical design aimed to help these pupils to close their competency gaps by active work and to lower their maths anxiety: "math can only be understood by self working on exercises, not by listening to a lecture or watching tutors solving mathematical problems". No "classical lectures" ("Vorlesungen") with mostly passive students were offered and also no "blackboard exercises", were a tutor writes solutions of math exercises on the board and the students write them down in their notebook, but only tutorials (see Fig. 1).

In online courses, it is often hard to motivate students to do active work. To engage the pupils' attention, the Zoom sessions were created in a very interactive manner: students were asked to edit exercises on their own, they were (repeatedly) asked to turn on their cameras and often they were distributed to breakout rooms with about 3 students each for about 10 minutes to edit and discuss exercises while the tutors "jump" between the breakout rooms and answer questions.

For the courses in the 10th and 11th grades, the Faculty of Engineering did not develop own exercises, but exercise books from the school book series "Lambacher Schweizer" [7], used by most high schools in Bavaria, were used, and for the Abitur courses, the collections of Stark publishing house of the official exams of the Bavarian State Ministry of Education of the last years were used [8]. This ensured that the taught topics fit well to the school teaching plan and Abitur exams.

The following list shows exemplarily the topics of the 11th grade summer course [7]:

- Graphs of proper rational functions
- Differential calculus of real-valued single variable functions
- Applications of the derivative
- Analytic geometry
- Advanced techniques of differentiation

- Natural exponential and logarithm functions
- Probability and stochastical independence
- Applications of differential calculus

In the Abitur courses, each day the complete Abitur maths-exam of one of the last years were worked, covering the topics analysis, stochastic and geometry.

2.4 Research questions and evaluation methodology

The following research questions were defined and were answered by analyzing student evaluations:

1. What is a good course design for universities to improve mathematical skills in the last high school years and for high school leaving exams "Abitur" regarding practical and organizational considerations?
2. Which pupils choose voluntary maths review and Abitur courses regarding their mathematical competencies (mostly good pupils who want to become very good – or mostly "bad pupils" in math who want to become average)?
3. Additional question: How can you attract prospective high school graduates for engineering degree programs and for your university?

To answer these questions, mid-term and final evaluations were conducted in all courses. The results of the summer courses lead to recommendations for action for the school leaving exam preparation courses and these led to recommendations for the freshmen review courses.

In the case of only a final evaluation, the course members are only moderately motivated to take part, since there can be no further improvement in the current course (response rates about 10 to 30%). In order to be able to implement improvement measures in the second half of the course, an additional mid-term evaluation was carried out halfway through each course as an anonymous survey on the e-learning platform StudOn (Ilias) with response rates of about 50%, what is very good for an online evaluation. As a 3rd evaluation stage, a short survey was carried out for the school leaving exam preparation courses about one month after the last high school exams took place to analyze retrospectively if these course were helpful to pass the maths exam.

3 STUDENT LEARNING GAINS

3.1 Evaluation outcomes and effectiveness of the program

The evaluation shows that the summer review courses after the 10th and 11th school year during the summer holidays had a clearly positive effect on the image of the university (Fig 2). Most of the pupils (approx. 80%) rated the courses "very good" or "good", the degree of difficulty was mostly rated "just right". Many participants also showed interest in studying at FAU (across all disciplines). A large number of pupils also would like to take part in a high school leaving exam preparation course based on this summer course. Due to these convincing evaluation results, the FAU offered this "Abitur" course for the first time in the Easter holidays 2021 and again in April 2022.

Here is a selection of typical quotes (translated from German) from the evaluation of the summer courses 2020 and 2021 [9]:

- "We think your offer is great, because maths teaching was almost completely absent for weeks - but everybody needs it as a compulsory subject in the 'Abitur'."
- "You never had the feeling of looking stupid, even if you had to ask more questions about an exercise before you understood it. I also thought it was pretty cool that we could always help each other and give tips."
- "The idea of a maths […] course was a really nice idea and I fully support it if this course would be offered again in the years to come."
- "I recommend the course to everyone and if preparatory courses are offered in the spring before the 'Abitur', I would definitely take part again and I would be very grateful to FAU :D"

Points for improvement were, among other things, the differing quality of the tutorial teaching, too many exercises dealt within a too short amount of time and the long duration of the tutorials.

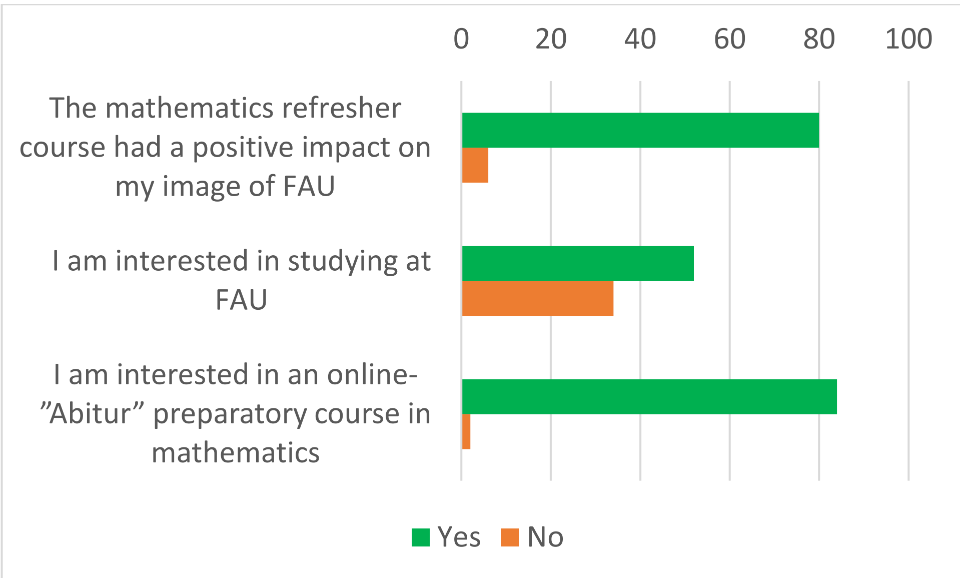

Fig. 2. Evaluation of the summer review course for 10th and 11th grades 2020

The final evaluation of the Abitur courses 2021 corresponds with the evaluation results from 2020 and was also very positive (Fig. 3). 85% of respondents rated the course as "very good" or "good" (n=582) and helpful, but they were still skeptical about their future success in their oncoming math high school leaving exams – only half of the respondents felt “very well prepared” or “well prepared” for their exams.

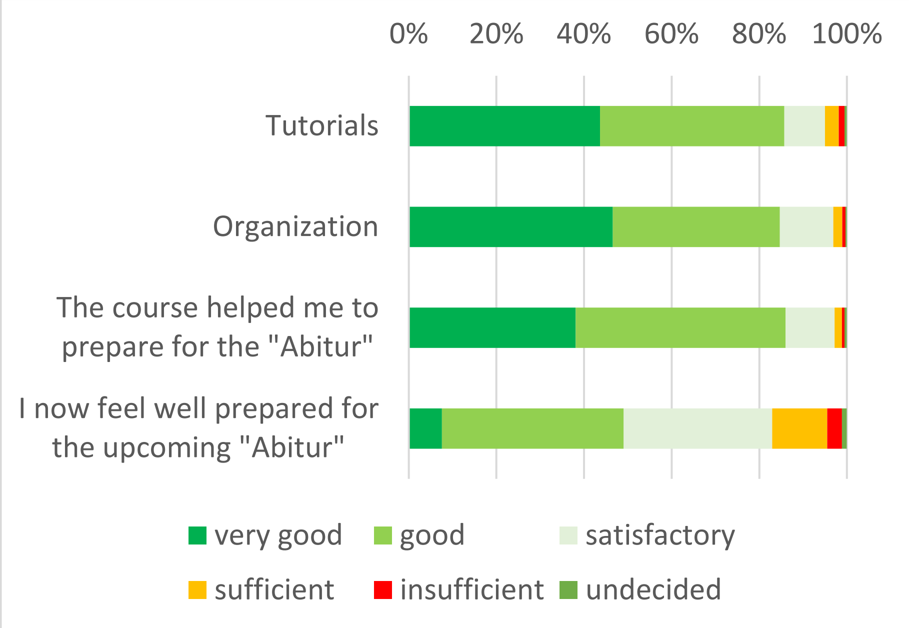

Fig. 3. Mid-term Evaluation of the Abitur course 2021, n=582

Due to the nationwide offer, many participants in the school leaving exam preparation course do not want to study at FAU, but rather at another university. Around 40% of high school graduates in the 2021 course did not yet know if they would like to study at FAU (see Fig. 4), which shows that there is great potential for the acquisition of future students at FAU. The evaluation also shows that fewer students who already have a strong affinity for technology and maths have taken the course, but rather those who have a lot of catching up to do in mathematics and who are a bit afraid of studying engineering. Only 15% were eager to study engineering (in 2022 this percentage was higher with 23%). Therefore, there is a great potential to attract future students for technical subjects who would otherwise hardly have sought out studying engineering.

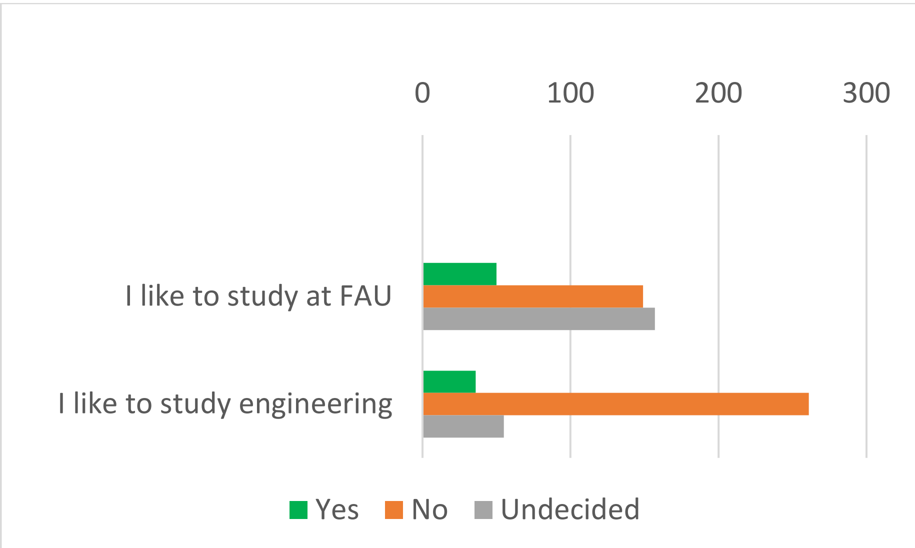

Fig. 4. Final evaluation of the Abitur course 2021

3.2 Answering the research questions

By analyzing the various evaluations, the following answers to the asked research questions were elaborated:

1. What is a good course design for universities to improve mathematical skills in the last high school years and for high school leaving exams "Abitur" regarding practical and organizational considerations?

    - It's too late to start maths review with freshmen – you should start much earlier - one or two years before the high school leaving exams.
    - Online courses (during school holidays) offered by universities are a great measure to improve mathematical skills. They transcend geographical borders and can make your own university/college known state-wide and even nation-wide.
    - Offering tutorials with pupils working on their own is better than offering "classical lectures" or blackboard exercises, since "math anxiety can only be lowered by calculating math exercises". The last survey of the pupils cohort after the completion of the "Abitur" exams in July 2021 via the platform strawpoll.de was particularly revealing and confirmed the effectiveness of the courses (Fig. 5):

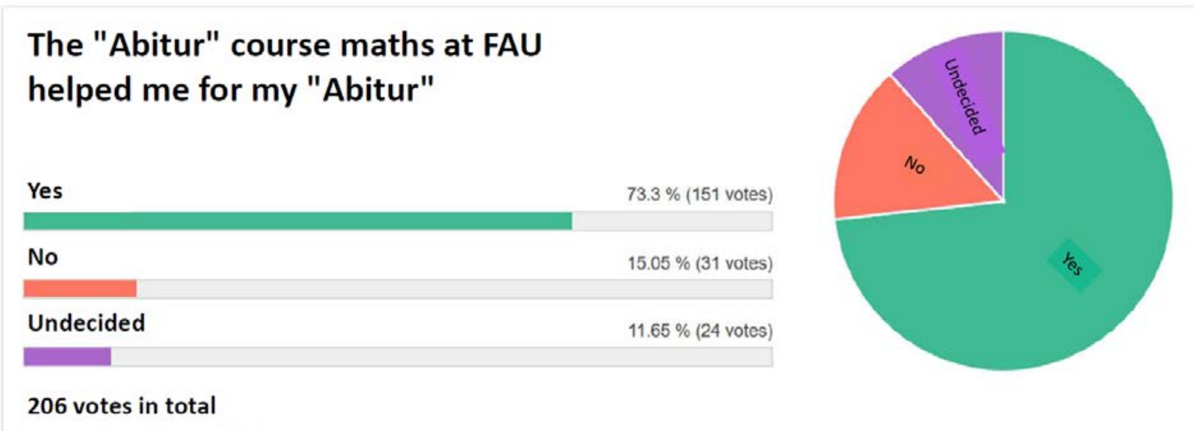

Fig. 5. "Post-evaluation" of the Abitur course 2021

Lessions learned - Recommendations for action

- Timely planning and information for schools (e.g. via e-mail to school mailing lists, parents' councils or publications [10])
- Provision of an efficient online registration system that pupils without a university account can use
- Timely licensing of the required teaching materials, publishers often offer cost effective bundled licences for teachers (so-called "Fachschaftslizenzen")

- Quality assurance of the tutors' teaching performance (partly criticism from the evaluation): conduct kick-off meeting with all tutors, implement tutor training with professional advisors (this was established from autumn 2021 on at FAU for all new tutors)
- Planning of sufficient administrative capacities for the student tutors
- Acquisition of financial resources if the courses are to be offered free of charge, or use of funding opportunities (e.g. federal programs like action programs to "catch up" after the Covid-19 pandemic)
- Pre-planning of evaluations, propagate feedback of the mid-term evaluation to the tutors

2. Which pupils choose voluntary maths review and Abitur courses regarding their mathematical competencies (mostly good pupils who want to become very good – or mostly "bad pupils" in math who want to become average?
   - As expected, the courses attracted mostly high school pupils and graduates which were less interested in mathematics and therefore had great difficulties in maths. Therefore, the course design focussed on tutorials to encourage the pupils to do math exercises on their own.

3. Additional question: How can you attract prospective high school graduates for engineering degree programs and for your university?
   - The course had a very positive impact on the image of FAU and especially its Faculty of Engineering.
   - Approximately 30-40% of high school graduates do not yet know whether or where to study. This shows great potential to attract these students for engineering study programs. Attractive accompanying study information events that are integrated in the maths review courses give the opportunity to strongly raise this percentage: "No fear of math" may lead to "engineering is cool".
   - Unfortunately, in the final evaluation of the Abitur courses, only 15% to 23% said that they want to study engineering. This shows that the "math anxiety" or disinterest in math and engineering could not be completely removed by these math courses, so further efforts must be made to inspire more students for engineering.

4 SUMMARY AND ACKNOWLEDGMENTS

Consecutive maths review courses offered by universities on different levels starting from 10th/11th graded over high school leaving exam courses up to freshmen courses strongly help pupils to overcome problems in maths and enable pupils and students to loose their fear of maths and to attract them for engineering degree programs. They can strongly improve the image of the offering university. Online courses transcend geographical borders and can make your own university/college known state-wide and nation-wide.The research questions of this concept paper will be further analysed and answered by ongoing examinations and evaluations of future courses.

Acknowledgements go to the Central University Administration of FAU and the Faculty of Engineering for financial support of the courses and especially to the many highly motivated student tutors and staff.

ABSTRACT

Through the project "Technology Education of the Future" (FTS), NTNU has developed a holistic, systemic framework for re-design of its educational programmes in technology and engineering. FTS delivered its final report in January 2022 – a roadmap focusing on 'how', i.e., the concrete steps NTNU should take in the upcoming years in order to implement FTS' previous recommendations on 'why' and 'what'. This concept paper provides an overview of this roadmap, which outlines 12 *Main Actions* (MAs) within five *quality areas*, plus an overarching 'umbrella action' to enable the MAs. For each MA, some *Prioritised Measures* (PMs) are described. Based on a risk analysis we also provide *procedural advice*, emphasising factors deemed critical for a successful FTS implementation.

1 INTRODUCTION AND BACKGROUND

In March 2017, NTNU's Rector decided that the project "Technology Education of the Future" (FTS) for renewal of the university's programme portfolio within engineering and technology (in all around 150 study programmes on bachelor, master and PhD level, involving five faculties) should be established, with an ambition to *"promote a new generation of engineering and technology education which is updated in all areas according to international development and society's needs."* For a number of reasons, the formal project start-up was delayed until August 2019. In 2019-2020 FTS reviewed international trends and global best

[1] *Corresponding Author: Geir Egil Dahle Øien, email geir.oien@ntnu.no.*

doi:10.5821/conference-9788412322262.1255

practices, aggregating a broad platform of knowledge - cf. [1] and the many references therein, which among other things sum up FTS' aggregated findings wrt. international trends and state-of-the-art. This knowledge platform served as a starting point for SWOT analysis of NTNU's current technology education [2] and subsequent quality development in the FTS programme portfolio [3]. By February 2021 – based on the above analyses and findings – the project had also created a holistic conceptual framework for the future FTS study programme portfolio, consisting of a *vision*, *principles* and *competence profiles*. The vision is:

NTNU's technology programmes educate creative world-class graduates – able and willing to contribute to a better world and a sustainable future.

The *FTS principles* were developed as systemic guidelines for further portfolio development to realise the vision, and adopted by NTNU's Rector in June 2021. At 'short heading' level, the FTS principles are summed up in Fig. 1:

Figure 1 The 10 FTS Principles.

The term *holistic competence* in Principle I refer to the FTS *competence profiles,* which consist of 12 *competence objectives* that students should have achieved upon graduation. FTS has developed such profiles for bachelor engineering programmes, 5-year integrated master programmes in technology, and PhD programmes. The 12 objectives are divided into five categories, with digital competence and sustainability competence *embedded into* the objectives across categories [2].

The remainder of this paper is organised as follows: Section 2 describes the methodology used when developing both the above framework and the subsequent roadmap for implementation. Section 3 summarises the roadmap for implementation, with Main Actions (MAs) and Prioritised Measures (PMs) supporting the vision, principles and competence profiles. Subsections 3.1 – 3.6 discuss the individual MAs and selected PMs under each MA, while Subsection 3.7 outlines procedural risks and recommendations related to implementation. Section 4 briefly summarises the contribution of FTS and some future challenges and possibilities to follow.

2 METHODOLOGY: KNOWLEDGE FOUNDATION AND THEORY OF CHANGE

The FTS results have been developed in dialogue with key stakeholders [4], the main development done by a core project team of faculty and students, co-led by the FTS project manager and coordinator. The initial phase consisted of an outside-world analysis focusing on future needs, technology trends, and recent and expected developments in the higher education (HE) sector [1]. Through literature studies (cf. reference list in [1)], interviews, workshops, stakeholder meetings, study trips, and participation in international meetings, we identified state-of-the-art and expected trends in engineering and technology education, expectations and feedback from employers and alumni, and governmental expectations. These insights were subsequently "triangulated" with faculty and student input, views from a Nordic university expert group, and official university statistics, strategies and policies. Results were used to propose future-fit graduate *competence profiles* [1] and to perform a *SWOT analysis* [2]. Subsequently, a holistic *framework for future development* was developed [3]: Following a *Theory of Change* (ToC) methodology [5] we formulated the above *project vision* (in ToC terminology, *ultimate outcome*), and eight *long-term outcomes* (LTOs) to support the vision. Furthermore, we identified the 10 *FTS principles* – in ToC terms, *preconditions* – most essential for realising the LTOs [1, 3]. Finally, drawing on experience from FTS pilots, additional surveys by cross-faculty working groups, and integration of FTS perspectives into regular NTNU processes, we assembled a list of *interventions* identified as potentially helpful in realising the FTS principles. Those interventions considered to potentially have most impact – from now on referred to as *prioritised measures (PMs)* – were then clustered under 12 MAs, to create a roadmap for implementation.

3 RESULTS: MAIN ACTIONS AND PRIORITISED MEASURES

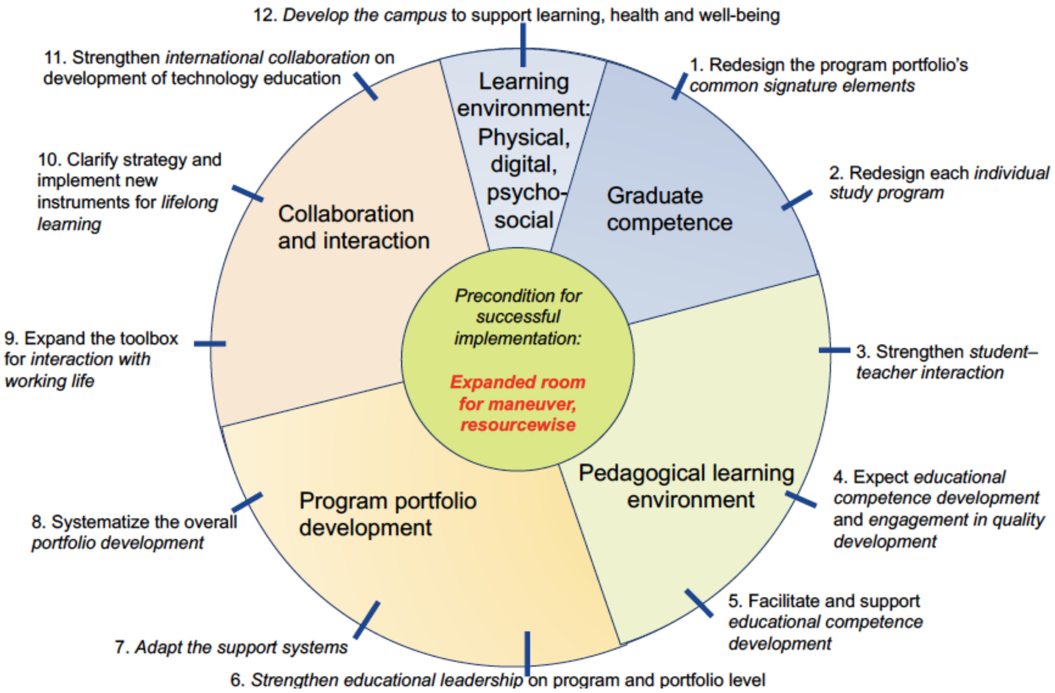

Figure 2 Overview of FTS' recommended Main Actions (MAs).

The core of the FTS roadmap for implementation are the 12 MAs, distributed across the five *quality areas* covered by the 10 FTS principles. In addition, we propose an ‘umbrella action’, *Expanded resource-related room for maneuver within the education area*, which spans all quality areas and is deemed necessary to enable implementation of the 12 MAs. At ‘heading’ level, the MAs, their distribution between quality areas, and the ‘umbrella’ action are illustrated in Fig. 2.

3.1 Main Actions for future graduate competence profiles

MA1: *Redesign the programme portfolio’s common elements and signature courses.* This MA supports FTS principles I and II. Elements and courses shared between many programmes in the FTS portfolio include: *Introduction to the Engineering Profession, Introductory Course in Philosophy, Technology Management, Experts-in-a-Team,* and common courses in mathematics, statistics and IT. *PMs* include:

- Review and revise the content and pedagogical approaches in all common elements and signature courses (using FTS principles III – V as guidelines)
- Establish dedicated introductory courses and sequential ‘ladders’ of core courses in all engineering and technology programmes
- Integrate team-based and project-based learning on authentic and ‘wicked’ problems in courses from the early phases of the programmes.

MA2: *Redesign each individual study programme.* This MA supports FTS principles I and II. MA2 does the same for the *programme-specific* elements as MA1 does for the common elements. Together they lead to a complete redesign of each programme - an operation at the very core of the FTS implementation. *PMs* include:

- During its next periodic review, gap-analyse each study programme against FTS principles I - VI and the FTS competence profiles
- From the general FTS competence profiles, derive a programme-specific competence profile and a Learning Outcome Description
- Using e.g. a programme-to-course mapping matrix, redesign each programme’s course plan, learning activities and assessment methods to align with the new profile and FTS principles, and create an *integrated programme description* [6].

3.2 Main Actions for pedagogical learning environment

MA 3: *Strengthen Student-Teacher Interaction.* This MA supports FTS principles III and IV. It is known to be important for students’ motivation, retention and learning that the *first years of their studies* promote learning, belonging, well-being and identity. Hence *PMs* include:

- Prioritise more teaching capacity to the first part of the study programmes
- Strengthen collaboration between programme core and discipline departments, to facilitate more contextual learning in e.g. mathematics and statistics courses
- Strengthen along-the-way assessment, student feedback and dialogue
- Focus on teaching as a *collective responsibility*, and *collaborative teacher teams*.

MA4: *Expect educational competence development and engagement in quality development.* This MA supports FTS principle V. NTNU’s current guidelines and personnel regulations clearly emphasise the importance of documented educational competence for appointments or promotion, but should be more clear wrt. *expectations on the actual use of such competence in development of educational quality after appointment.* The *PMs* are therefore:

- Revise guidelines for academic appointment and onboarding to emphasise educational development
- Discuss educational competence and quality work in annual appraisal interviews.

MA5: *Facilitate and support educational competence development.* This MA supports FTS principle V. Here, the following points have been identified as particularly important: That a relevant *offer of courses* and a good *support apparatus* are available, that teachers are given *time* to develop educationally, that *heads of departments* and *study programme managers* also develop educational competence, and that the institution recognises *the value* of educational competence development and quality work. The *PMs* therefore include:

- Further strengthening institutional support and course offerings for educational competence development – and freeing up teachers' time to use it
- Strengthening NTNU's *Centre for Science and Engineering Education Development* (SEED), and establishing didactic resources at individual faculties
- Creating FTS-specific development modules for study programme managers, and including basic educational competence modules in NTNU's development programme for Heads of Department
- Revision of NTNU's incentive structures related to educational development.

3.3 Main Actions for programme and portfolio development

MA6: *Strengthen educational leadership at programme and portfolio level.* This MA supports FTS principles VI and VII. *PMs* include:

- Revise mandates and clarify process descriptions in the education quality system
- Strengthen dialogue between study programme leaders, faculties and departments on programme development, and provide study programme leaders with dedicated programme development funds
- Create arenas promoting educational dialogue and culture building, and dissemination of educational practice, across study programmes and faculties.

MA7: *Update NTNU's support systems for learning, and for educational quality work.* This MA supports FTS principles VI and VII, and shall ensure that NTNU's educational support systems are appropriate, functional and suitable for services and quality processes which are important for FTS implementation. *PMs* include:

- Adapt administrative IT systems and learning support systems to actively facilitate programme and portfolio development in accordance with FTS principles
- Facilitate automated data capture to enable knowledge-based educational quality development. In particular, strengthen *the programme perspective*.
- Enhance NTNU's ability to analyse societal needs and technology trends, to strengthen the knowledge base for portfolio development and dimensioning.

MA8: *Enable more holistic programme portfolio development.* This MA supports FTS principle VI. *PMs* include:

- Assess and if necessary revise the structural constraints for NTNU's programme types, to ensure they are aligned with FTS principles and competence profiles
- Regularly revise the overall FTS portfolio's orientation, balance and scope with particular focus on academic-strategic *relevance*, academic and economic *sustainability*, good *communicability* and appropriate *agility.*

Note that MA6 and MA7 support MA8 - educational leadership and well-functioning support systems are both vital to programme portfolio development.

3.4 Main Actions for collaboration and interaction

MA9: *Expand NTNU's toolbox for collaboration with working life.* This MA supports FTS principle IX. *PMs* include:

- Introduce elective courses giving ECTS credits for *supervised professional practice* in all technology and engineering programmes.
- Strengthen strategic working life collaborations on *projects and student assignments*, at all levels from individual courses to master's and PhD theses.
- Expand *industry sabbaticals* as a collaboration instrument.
- Link *Business Networks* to all study programmes, focusing on programme recruitment, retention and relevance.
- Develop a scheme for *practice-oriented international student exchange*.

MA10: *Clarify the institutional strategy on lifelong learning and develop instruments for its implementation.* This MA supports FTS principle IX. Lifelong learning (LLL) has been high on the political agenda for several years, and the FTS mandate particularly emphasises this issue. *PMs* include:

- Develop a clear institutional strategy and associated new tools for LLL
- Facilitate open online access of learning resources in all ordinary courses
- Incentivise development of *small, digitally delivered course modules* – facilitating future micro-credentials, cross-disciplinary course design and integrated learning.

MA11: *Strengthen international collaboration on development of technology education.* This MA supports FTS principle VIII, and serve to heighten NTNU's international visibility, and enable sharing with and learning from international education networks. *PMs* include:

- Stimulate NTNU's teachers to participate in international education networks
- Prioritise participation in international education initiatives and consortia where NTNU can be inspired by internationally leading technical universities
- Link international student exchange agreements systematically to institutional collaboration on educational research and development

3.5 Main Action for physical, digital and psychosocial learning environment

MA12: *Develop campus solutions for learning, health and well-being.* This MA supports FTS principle X. NTNU's ongoing *Unified Campus* (UC) project [7] aims to gather NTNU's academic communities in Trondheim from scattered locations to one unified campus. The UC project's *Thematic User Groups (TUGs)* on *Learning Spaces* and *Campus Hubs* have recently developed principles for learning space and campus hub development which we view to be in line with FTS' principles. The *PMs* are thus:

- Develop new learning spaces and campus hubs according to the principles developed by the corresponding TUGs in NTNU's UC project.
- Establish a physical 'Learning Hub' centrally located at NTNU's campus, as a user-centered '*one stop shop'* support centre for teachers in their development of educational competence and new forms of teaching.

3.6 Enabling Main Actions by increasing resource-related room to manouver

It is not realistic to carry out the MAs and associated PMs without expanding – at least temporarily - the *resource-related room for maneuver* within NTNU's education area. There are significant cost drivers related to, e.g., capacity building, competence development, infrastructure development, and pedagogical renewal. FTS therefore proposes the enabling 'umbrella action' *Expanding the resource-related room for manouver within education,* with the following PMs:

- Establish *'NTNU Education Boost 2030'* – a temporary institutional initiative to increase strategic investment in education, to restructure the educational portfolio and improve its quality, and thus reduce drop-out rates, strengthen throughput and improve recruitment - and over time increase education-related income
- Critically review resource use on teaching and assessment in the FTS portfolio - to uncover activities and practices that should be deprioritised, changed, or terminated – so that resources can be reallocated to support FTS implementation
- Strategically re-dimension the FTS portfolio (programmes and courses) to ensure that long-term portfolio development can be carried out on the desired quality level within the resource frame expected to be available after 2030
- Actively seek to expand funding within the field of education by means of external sources, e.g., project funds from the Norwegian Directorate for Higher Education and Skills or Erasmus+, and industry co-funding e.g. for professorships, education infrastructure, continuing education, and internships.

3.7 Responsibilities, risks, and procedural advice

FTS' final report [2] includes a tabular overview of all MAs and PMs, with proposed timelines, qualitative assessment of resource needs, and assigned main implementation responsibles. To maximise clarity, it also contains six sub-tables focusing on one main responsible each: The Rector, NTNU's executive committees for engineering education, faculties, departments, programme leaders, and course coordinators. Table 1 shows the PMs where the *departments* are main responsibles.

Table 1. Prioritised measures for which the departments are to be primarily responsible.

Quality Area	MA	PMs for which the departments are primarily responsible
Pedagogical learning environment	*3: Strengthen student - teacher interaction*	3.a: Prioritise more teaching capacity to lower-year courses
		3.d: Facilitate collective teaching responsibility (for the dept's courses)
	4: Expect educational competence development and dedicated quality work	4.b: Discuss educational competence and quality assurance work in performance assessment interviews
	5: Facilitate educational competence development	5.a: Develop support and courses for teachers' educational competence development – and free up time for them to use the courses (department's responsibility is to free up time for its own teachers)
		5.b: Develop subject-specific didactic resources at departmental level
Collaboration and interaction	*11: Strengthen international collaboration on technology education development*	11.a: Stimulate teachers to participate in international education networks

In Oct. 2021, Dr. *Ruth Graham* did a snapshot FTS review [8], identifying implementation-related risks. Graham found that *"the single biggest risk facing the successful delivery of the FTS vision appears to be … the governance and ownership of the change effort post-January 2022."* In response, FTS has given NTNU the following *procedural advice* regarding the change process:

1. *The Rector, executive committees, deans, department heads, study programme leaders and course coordinators must first take ownership of the FTS proposals.*
2. *Subsequently, carry out a broad, thorough anchoring and motivation process*.
3. *Then make and communicate clear decisions on MAs and PMs to be prioritised.*
4. *All parties assigned as primarily responsible for adopted decisions must then be given a clear mandate and resources to follow up their responsibility*.
5. *The follow-up should be integrated in NTNU's regular, periodic quality processes.*
6. *Re-schedule resources to support prioritised follow-up at all organisation levels*.
7. *Link reasonable indicators to the follow-up - and ensure that they are monitored*.
8. *Along the line, gain experience by running pilot projects within selected areas.*
9. *For the first two years, implement a central support function for coordination, communication and various operational work related to the FTS follow-up.*

4 SUMMARY

The FTS roadmap has been designed to give NTNU's technology and engineering education a significant and systemic boost. The most important job – the implementation - is now underway; the final report is subject to organisational review in the spring of 2022, with actual implementation expected to start in the fall. This will require wise, visionary and inclusive leadership, prioritisation of fresh resources to education, and commitment, motivation and effort from the entire organisation. Several FTS proposals challenge established NTNU traditions, frameworks, cultures and practices. However, if successful, the change process should provide great opportunities and could potentially increase NTNU's international visibility.

ABSTRACT

The purpose of this study is to examine the effects of using a gamification tool as a new teaching strategy. Specifically, Kahoot! is evaluated as a tool for enhancing student learning. We test the tool empirically in a university class setting in an engineering degree, namely as part of the laboratory sessions of the subject Mechanism and Machine Theory during two consecutive academic years. The students were randomly divided into three different groups (control group, gamification group and writing group) and their results were evaluated depending on the learning method applied during the class. In terms of gamification, this project introduces real-time feedback to stimulate the interest of students and help them use the typical tools and methodologies of game-based learning. The analysis of their performance in the laboratory exam shows significant differences between the group that used gamification and the groups that did not. The study concludes that game-based elements and competitive activities enhanced student performance and recommend their use in educational environments to support the learning process.

1 INTRODUCTION

In recent years game design elements have started to be used for non-playful purposes [1]. Although the term is still being revised conceptually, gamification can be defined as using game-based mechanics, aesthetics and thinking to engage people, motivate action, promote learning, and solve problems [2]. In education, the idea is to motivate and stimulate students by using activities other than traditional ones, and facilitate – almost without them being aware – teaching-learning itself, especially in a social context in which student engagement needs to be increased [3].

Bearing in mind that the objective is to gamify the process not the outcome, it must be clear that gamification is not a panacea: it provides new tools but it is not the solution to all problems or applicable to all situations. Rigorous studies are required to fully examine the effects of gamification and determine how learning is best achieved.

In general, gamification techniques have positive effects on the involvement and motivation of students [3]. Gamified learning environments contribute to the learning and teaching process by raising levels of engagement, creating enjoyable learning environments and ensuring active participation [4–6]. However, some studies have not identified any significant effects on learning or have even detected worse academic results when students are forced to use game elements [7, 8]. The present study aims to provide new evidence on the effects of gamification in the classroom.

Personal response devices (PRDs) appeared at the beginning of the 21st century and they consist of an emitter and a receiver that, together with the corresponding software, enable teachers to ask their students a multiple-choice question (the question is projected on a screen) and students to send an answer using their individual control or *clicker*. Clickers provide a simple way to generate an atmosphere of student interaction that can enhance teacher-student communication. These systems increase attention levels, discussion, participation and engagement.

Kahoot! is a free virtual tool that has gained in popularity among teachers for its user-friendly nature and its ability to establish working dynamics in the classroom. It is highly appreciated by students. *Kahoot!* allows teachers to create surveys, questionnaires, puzzles and debates, and obtain students' answers in real time. Various studies on *Kahoot!* agree that this tool improves participation and the positive relationship between class members [9–11].

Mechanism and Machine Theory is a core subject taught in the fourth semester of the Degree in Industrial Engineering at Universitat Politècnica de Catalunya. It is one of the first times that the Industrial Engineering students have come into contact with the world of mechanical engineering. The evaluation of the laboratory sessions prior to this subject had not given expected results: the percentage of students who passed the practical exam was very low, and the teachers considered it a problem since it suggests that students were not able to put into practice the knowledge they had acquired in the theory classes. On average, the percentage of students passing the course is 70%, whereas the percentage passing the practical examinations is 40%, notably lower.

We hypothesize that the introduction of gamified feedback will help to highlight the most important concepts at the end of each laboratory session, and therefore, improve the learning process. The second hypothesis of this study is that the first of these two factors (gamification) is more important than the second (the feedback itself). In order to test this hypothesis, the questions that the students in the gamification group were asked were also presented to another experimental group in which students did a written test without using *Kahoot*!. The solutions of the test (feedback) were also provided after the practical session.

2 METHODOLOGY

The present study uses an empirical-analytical methodology to study gamification as a tool in laboratory sessions. The subject Mechanism and Machine Theory has a large number of students each semester (between 270 and 320) so the students were randomly distributed into 11 laboratory groups taught by 4 different lecturers. The aim of our intervention was to improve learning in the laboratory sessions.

A test questionnaire has been introduced as a feedback tool. Quick feedback helps students become aware, and they have greater perception of what has happened in the laboratory. This feedback has been introduced as a test questionnaire that has to be answered in the last 15-30 minutes of each session.

Two different feedbacks are analyzed. The first uses *Kahoot!* questionnaires. Since *Kahoot!* is a fast response system for the student, it is expected to be effective at improving knowledge retention and skill acquisition. The second uses a traditional questionnaire which, therefore, involves no competition or cooperative learning. To determine the effect of introducing not only a feedback tool but a feedback gamification tool, the laboratory groups were divided into three groups:

- An experimental group given feedback through the *Kahoot!* questionnaires– (Gamification group, GG). These learners use the mobile version of the app.
- An experimental group given a written test at the end of the session (with the same questions as in *Kahoot!*), acting as reinforcement and feedback, but without the other components that *Kahoot!* may have (Writing group, WG).
- A control group subject to no intervention (Control group, CG).

The students were divided up in this way to avoid teacher and timetable factors. Table 1 summarizes the number of students in each group. Note that some students do not participate in the laboratory sessions.

Table 1. Overall number of students for each group and academic year

Number of students	**2016-17**	**2017-18**
Gamification Group – GG	37	41
Writing Group – WG	115	86
Control Group – CG	113	100
Not attending	41	56
Total	306	283

Academic performance was assessed by comparing the marks of students in each of the pedagogical groups. The mean mark, standard deviation and number of students who passed the exam were calculated for each evaluation. In this work we focus on three laboratory sessions. Along the text, M_{lab1} is the mark for the first laboratory exam (assessing sessions 1, 2 and 3). A Student's T-Test was also used to find significant differences between the experimental (GG and WG) and the control (CG) groups.

Therefore, for the GG the relation between the *Kahoot!* test score and the grades in M_{lab1} was studied. Likewise, for the WG, the relation between the writing test score and the grades M_{lab1} was examined. To this end, linear correlations were calculated and Pearson, Spearman and Kendall coefficients determined.

Finally, whether or not there was a teacher effect was studied (that is to say, whether a particular student gets a better or a worse mark depending on the teacher who has taught the subject). Therefore, the students were grouped according to the lecturer who taught the sessions and a Student's T-Test was used to determine significant differences between the four groups.

3 RESULTS

Because feedback is now a part of laboratory sessions 1, 2 and 3, differences in the laboratory exam 1 marks (M_{lab1}) can be expected among the three groups. During the academic year 2016-17, 62.16% of the students who took part in the gamification passed the exam while only 54.87% of the control group and 58.26% of the writing group did the same. Similarly, during the academic year 2017-18, 87.80% of the students who took part in the gamification passed the exam while in the control group and the writing group the percentages were 74.74% and 77.91%, respectively.

Moreover, it can be seen that for laboratory exam 1 (M_{lab1}), the mean grade obtained by the students who took part in the gamification sessions (5.59±2.43, academic year 2016-17; and 6.90±1.68, academic year 2017-18) is more than one point higher than the control group (4.50±2.17, academic year 2016-17; and 5.75±2.30, academic year 2017-18). However, this difference is not so clear for the writing group (4.71±2.37, academic year 2016-17; and 5.57±2.24, academic year 2017-18). A Student's T-test between GG and CG demonstrated that there is a significant difference between these two groups (p-value < 0.05). The differences between the WG and the CG group are not statistically significant.

Figure 1 shows the boxplot obtained for M_{lab1} for both academic years and for each teaching methodology. The central block is delimited by the position of Q1 and Q3 quartiles and the line representing the median is drawn in the box. It can be seen that the median is also higher for the gamification group than for the writing and control groups.

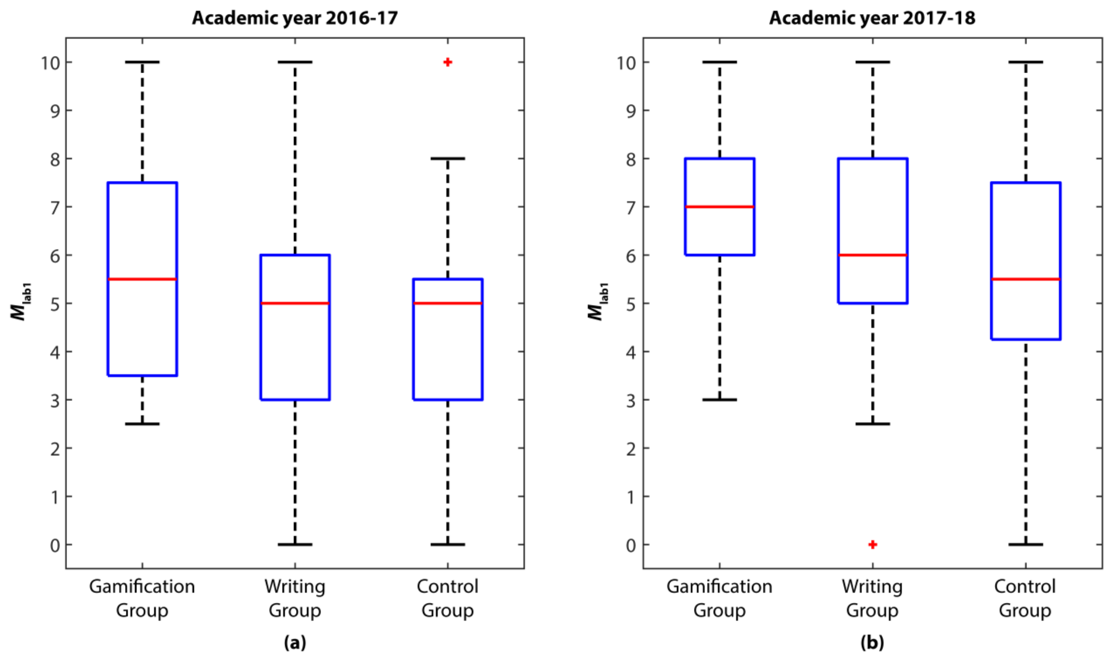

Fig. 1. Boxplot of laboratory exam 1 marks. (a) Academic year 2016-17 (b) Academic year 2017-18.

Differences between GG, CG and WG are not presented for other evaluation marks obtaining during the course. This could be a way to ensure that students are randomly distributed among groups. Differences only appear when a gamification methodology is applied.

The relation between the grades obtained in feedback tests and the laboratory 1 exam was studied. As well as the *Kahoot!* score (based on both correctness and speed of the answers), the grade the students would have be given in the final exam was calculated. Figure 2 shows, the relationship between the calculated *Kahoot!* grades ($M_{Kahoot!}$) and the grades obtained by students on the laboratory exam 1 (M_{lab1}) for the gamification group (GG). Similarly, Figure 3 shows the relationship between the writing test marks (M_{WT}) and the ones obtained in the laboratory exam 1 (M_{lab1}) for the writing group (WG). The graphs also show the polynomial regression line that adjusts these values and the corresponding R^2 parameter.

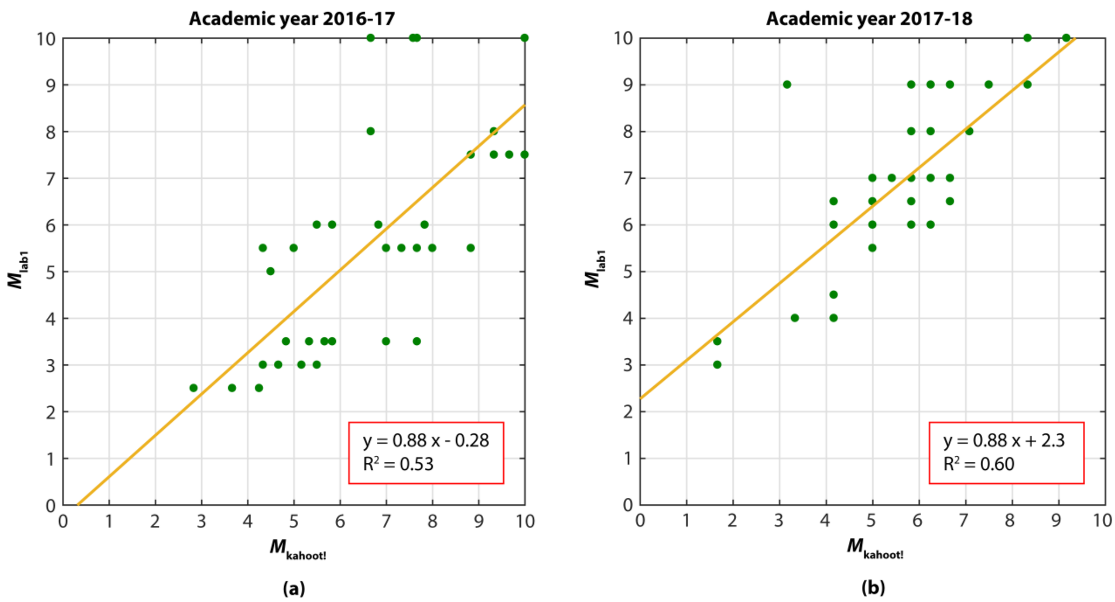

Fig. 2. Scatter graph of the lab exam 1 marks (M_{lab1}) versus the Kahoot! marks ($M_{Kahoot!}$). (a) Academic year 2016-17 (b) Academic year 2017-18.

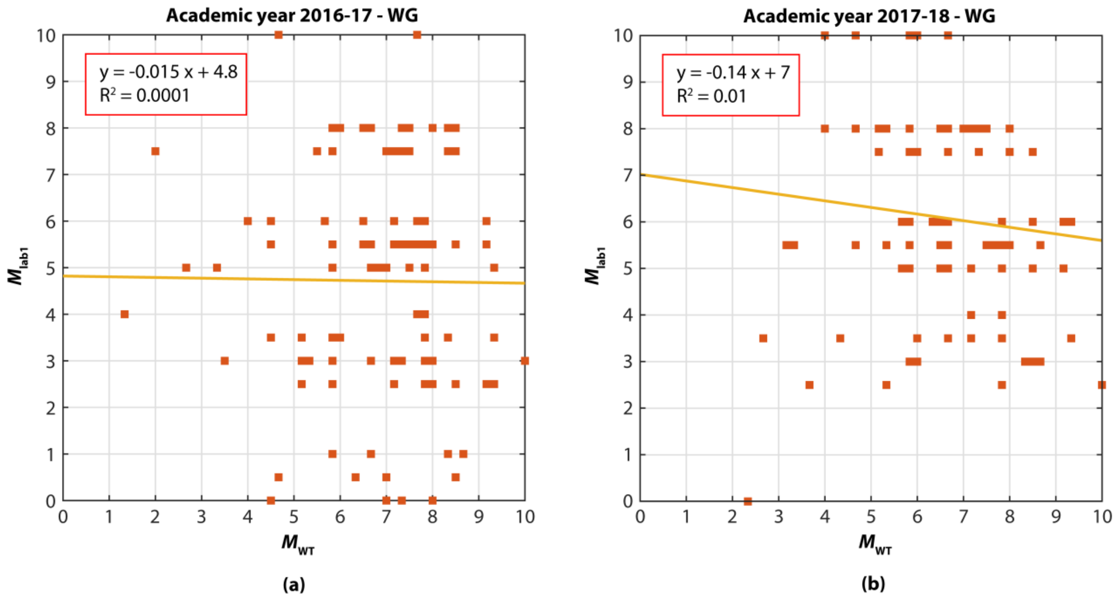

Fig. 3. Scatter graph of the lab exam 1 marks (M_{lab1}) versus the writing test marks (M_{WT}). (a) Academic year 2016-17 (b) Academic year 2017-18.

Three different correlation coefficients (Pearson, Spearman and Kendall) and the p-values of the statistical tests were calculated. For GG, the p-values were much lower than 0.05, so there is a significant positive correlation between the marks obtained in the *Kahoot!* test and the ones obtained in the laboratory 1 exam (correlations between 0.5 and 0.7 depending on the indicator used). However, the correlations for the writing group are not significant.

The teacher effect was also analysed. As explained above, the sessions are taught by four different lecturers. For this analysis, students were grouped according to the lecturer who taught their laboratory session. However, the Student's T-test does not detect any significant differences between the four groups studied (p-value > 0.05). Therefore, it cannot be affirmed that the teaching staff has an effect on the grades of the students.

4 SUMMARY AND ACKNOWLEDGMENTS

The main goal of this study was to analyse whether a gamification tool could improve learning in the laboratory sessions of the subject Mechanism and Machine Theory. For this purpose, during two consecutive academic years, we divided the students into three groups each of which was subject to a different methodological intervention. At the end of the first three sessions, the gamification group (GG) answered a *Kahoot!* questionnaire; the writing group (WG) answered the same questionnaire but on paper, and the control group (CG) was not given a test of any sort.

The results show that:

- The gamification group had a higher success rate in the laboratory exam (Laboratory exam 1) than the control group. Moreover, on this evaluation, the average grade of GG students was statistically greater than the average of

CG students. Furthermore, the grades of the other evaluations do not show these differences. It can be seen that gamification has a positive effect on grades.

- The writing group shows no significant improvement with respect to the control group. When the feedback is not gamified, it does not enhance academic results. These results suggest that gamification is the key to the improvement not the feedback itself.
- A statistically significant positive correlation was detected between students' Kahoot! scores and laboratory exam 1. This correlation fulfils one of the initial objectives of the study, which was to provide students with tools (questionnaires) for self-evaluation so that they could better manage their learning process.
- No significant differences were detected in the grades of the various groups who did laboratory exam 1. This reveals that it was not the lecturer of the laboratory session who marked the difference but the intervention itself.
- As has been mentioned, there was a need to elucidate whether *Kahoot!* is effective or not. The reasons why it seems to improve active student learning, participation and retention of concepts or why it is no guarantee of better learning need to be determined. In the light of the results presented, in general it seems that gamification has provided a (modest) increase in the teaching-learning process in the laboratory practicals of the subject Mechanism and Machine Theory.
- Finally, from a general perspective, further educational research is needed to evaluate whether enjoyment and, in this case, the use of game-based student response systems really help with teaching and learning or are simply more fashionable at present in the field of education.

The authors would like to thank the students who participated in the study.

ABSTRACT

Educators have experienced significant challenges managing assessment processes over the last two years, particularly when converting in-person interactive and group-based activities to an online format. This was of immediate concern during the initial stage of the Covid-19 pandemic, when interim measures for online assessment were introduced rapidly without the benefit of prior planning and design. As we emerge from the emergency phase of the pandemic, it appears there will be lasting changes to delivery and assessment in higher education, involving more hybrid and blended solutions. This paper discusses how an on-campus peer feedback assessment process for mathematics has been converted to a digital format to facilitate flexible modes of delivery either on-campus or online. A weekly paper-based peer-feedback process had been previously established in our large (150+) first-year engineering mathematics class. The new process involves weekly submission of work through the university Learning Management System (LMS), Canvas, which is peer marked by students using model video solutions for selected questions. Students complete a rubric and provide comments. After each session, students complete a reflective journal, considering their work over the week and the comments they have received. Engagement with the new flexible process has been shown to be comparable to the old system, while the quality of feedback given to peers in the online process is superior to those provided in the paper-based system. The system has been shown to be robust when rapid changes in delivery modes occur.

1 INTRODUCTION

1.1 Peer assessment and reflection

Peer assessment has been used as a tool across a number of disciplines to encourage students to think about how assessments are evaluated and make critical judgements about quality of work [1], and has been considered to be a fundamental

[1] *Corresponding Author*

L T Pick

l.pick@qub.ac.uk

doi:10.5821/conference-9788412322262.1117

skill that graduates will need in their future careers [2]. A number of studies over the years have highlighted the benefits for students in engaging in peer review and assessment processes in mathematics. These include developing critical thinking skills, increasing agency over their own learning and improving outcomes [3-5].

1.2 Context of module and the assessment process

The stage 1 mathematics module in the School of Mechanical and Aerospace Engineering is a large core module, typically with 150+ students, taken by all year 1 students from the mechanical, aerospace and product design engineering pathways. Prior to the onset of the Covid-19 pandemic, the module was delivered by means of a traditional two-hour lecture, followed by a one-hour “feedback session”. The feedback session format was developed and introduced in the 2016-17 academic year [6] and involved students completing weekly worksheets in a logbook, then attending a session where they worked in a small group. At the feedback session some model answers were demonstrated on the board, and students marked their peers’ work, making some comments. After the session, students wrote a short weekly reflection, and at the end of the year submitted their entire logbook along with a longer reflection piece. This process worked well for several years as an in-person activity that encouraged weekly participation, interaction with peers and active learning. This continuous assessment element contributed 40% of the module mark, with the other 60% from a final examination. The continuous assessment element was intended to evaluate the ability of the students to reflect on their own work and make improvements, and develop their transferable skills over the year such as technical communication and groupwork, while the examination tested their mathematical ability (Table 1). For this reason, it was compulsory for students to pass both elements in order to pass the module.

Table 1: Assessment weighting and major learning outcomes

Continuous Assessment	**Written Exam**
Based on submission of worksheets, reflections and contribution to peer feedback	End of year
worth 40%	worth 60%
Tests Learning Outcome: evaluate and reflect on the quality of your work and learning.	Tests Learning Outcome: identify and apply appropriate mathematical techniques for solving engineering problems
Formative and summative	Summative

After the rapid switch to online learning due to the Covid-19 pandemic, an interim solution was developed to allow the students to carry out the peer review process online using groups on MS Teams during the 2020-21 academic year. Several key issues were identified during the year, including the fact that the process was cumbersome for students, not all students engaged well and monitoring of this was very difficult for academic staff, and marking at the end of the year was extremely challenging as there were a large number of documents to look at for each student. However, a clear benefit of the process was that the quality of the feedback left by students for their peers was very high, with many leaving detailed and helpful comments every week. This constrasted with the short handwritten points that students had previously tended to make in the paper-based logbooks.

2 METHODOLOGY

2.1 Development of a new flexible process

In September 2021, the university returned to full in-person teaching for the first time since the pandemic. While issues had been found with the online peer-review process, it was not possible to return to using the old paper-based method for three reasons:

1. There were clear health and safety concerns with students sitting in close groups and passing physical logbooks around the group.
2. There was a high probability that some students would be self-isolating at different times throughout the year and so would be unable to meet their groups in person.
3. There was a possibility that teaching staff would contract Covid-19 and so would need to teach from home, or that the campus would close for a period of time and teaching would revert online.

It was also recognised that students generally spent more time writing longer and more detailed feedback comments when working digitally than they would have previously handwritten in books, and so it was felt it was desirable to retain this.

The first consideration was how to structure the assessment and determine what systems needed to be put in place for the 2021-22 academic year. In order to address the issues found with the interim online system, and the three concerns listed above, the decision was taken to manage all submission of worksheets and peer marking online, but to use the university Learning Management System (LMS), Canvas, to manage this. Students were required to submit their scanned worksheets to Canvas each week by 9am on the day of the feedback session, and were then randomly assigned three anonymous peer worksheets to review. Students could attend a computer suite, or an assigned groupwork room if they prefered to use their own devices. Students who were unable to attend in person due to self-isolation or for other reasons could access their assigned peer reviews from home. As students were working across different locations, pre-recorded video worked examples were provided, which were only made available for the duration of the feedback session via the LMS. Using the video exemplars, and through conversation with their peers and the session facilitators, students were required to give feedback by completing a rubric (Table 2) and by writing comments about the work. The set of peer scores received by each student each week was reviewed by the lecturer, any outliers in scoring were moderated, and an average value returned. This provided ongoing weekly feedback to students. Guidance was provided to students to ensure they understood that the aims of giving feedback were to be constructive and to provide opportunities for improvement, and that the benefits to themselves included: receiving regular feedback on their own work, learning from looking at others' work, developing independent learning, recognising their own strengths and weaknesses, gaining opportunities for active learning and improving reflection and communication skills.

Table 2: Rubric for peer scoring

	3	2	1	0
Effort	Clear evidence of effort in answering (even if not correct)	Good effort in answering but room for improvement	Some effort, but not satisfactory	no effort
Correctness	All correct	Mostly correct with some small errors	Mostly incorrect	no effort
Coherence	Method can be followed very clearly (even if answer not correct). Excellent annotation, notation and clear steps	Method can mostly be followed, a few steps missing or would benefit from better annotation or notation	Difficult to follow method, unclear working (even if correct)	No effort
Conciseness	Method used is appropriate and very efficient	Method is appropriate but could be simplified	Method is overly complicated or long	No effort

After the session, students transferred the reviews they gave and received into a "reflection journal", a template for which was provided, and wrote a weekly reflection consisting of around five bullet points. There was an optional opportunity for students to submit their "work-in-progress" to the lecturer for formative feedback in the middle of semester 1, to ensure that their work was at an appropriate level. At the end of each semester students were required to write a 500-word summary reflection and submit the whole journal for review by the lecturer. The breakdown of the final mark allocation for the continuous assessment piece is shown in figure 1, and includes marks for the quality of the student weekly and end of semester reflections (20 marks assessed by lecturer), the quality of feedback left by the student for others (5 marks assessed by lecturer), and the moderated peer scores discussed above (15 marks obtained from scaling the sum of each student's moderated and averaged peer reviews).

In the original paper-based system there was a requirement for students to attend a minimum of 75% of the peer review sessions to ensure engagement. To allow for more flexibility in the 2021-22 year, and to take into account that students could be working remotely, this requirement was modified to require students to complete at least 75% of the work, i.e. submitting 15 out of the 20 assessed worksheets, and providing peer reviews on at least 15 out of the 20 sets assigned to them.

2.2 Data reviewed

Data was extracted from Canvas to show the number of submissions over the year and the number of peer reviews completed. The grades across the academic year 2021-22 for the continuous assessment element are compared with the final grades for the continuous assessment from the year prior to the pandemic.

Reflection journal							
Criteria	Ratings						**Pts**
Quality of weekly reflections on own work over the week	5 Pts	4 Pts	3 Pts	2 Pts	1 Pts	0 Pts	**5 pts**
- Commentary on how difficult or easy the work was	Excellent	Very good	Good	Satisfactory	Poor	No merit	
- Commentary on particular areas of focus							
- Indication of time management							
- Indication of resources used							
Quality of weekly reflections on comments received from peers	5 Pts	4 Pts	3 Pts	2 Pts	1 Pts	0 Pts	**5 pts**
- Evidence that comments from peers are being read and reflected on	Excellent	Very good	Good	Satisfactory	Poor	No merit	
- Commentary on whether you are learning from others' work or not							
- Evidence that you are identifying areas of improvement or areas of your own good practice as appropriate from the peer feedback							
Quality of end of semester reflection	10 Pts	8 Pts	6 Pts	4 Pts	2 Pts	0 Pts	**10 pts**
- Commentary on what problems have you encountered and how have you dealt with them?	Excellent	Very good	Good	Satisfactory	Poor	No merit	
- What was especially satisfying to you about either the process or the finished piece of work?							
-What does your work this year reveal about you as a learner?							
-Have your goals changed as you have progressed through the module?							
-How have you used the feedback received to improve your work?							
-What have you seen in other students' work or learning that you would like to try in your next module?							
-How have you contributed to the group in the feedback sessions?							
-Looking back at this module, what would you like to try to improve?							
-How confident are you that you will pass this module?							
Quality of the peer feedback you left for others	5 Pts	4 Pts	3 Pts	2 Pts	1 Pts	0 Pts	**5 pts**
Is your feedback:	Excellent	Very good	Good	Satisfactory	Poor	No merit	
- Constructive?							
- Specific?							
Does your feedback:							
- Offer opportunities for improved performance?							
- Show that you are reviewing the work carefully?							
Worksheets (from peer reviews)	15 to >11.0 Pts	11 to >9.0 Pts	9 to >7.0 Pts	7 to >6.0 Pts	6 to >0 Pts		**15 pts**
	Excellent	Very good	Good	Satisfactory	Unsatisfactory		

Fig 1: End of semester rubric (marked by lecturer)

3 RESULTS

3.1 Engagement with the process

The engagement of students with the process was evaluated by comparing data from 2019-20, when the on-campus paper-based system was used, and from 2021-22 when the digital method was used. In 2019-20 there were 158 students in the class compared with 167 in 2021-22. Figure 2 shows the percentage of students who submitted each worksheet and the percentage who submitted the worksheet *and* completed their peer reviews. This is compared with the percentage of students who attended the sessions in 2019-20. Comparing the students who completed both tasks in 2021-22 (submitting worksheet and completing peer reviews) with the student attendance in 2019-20, it can be seen that the data is remarkably similar during the majority of first semester, up to worksheet 10. In the second semester some divergence is seen with the 2021-22 cohort having higher engagement in the early part of the semester, and lower engagement later. Overall, the average engagement per session was 89% with the paper-based, on-campus only system, and 88% with the digital system used in 2021-22, with students flexibly completing the work on campus or at home. It can be seen that the engagement was high for both years, with a minimum of 83% in both years, and a maximum of 96% in 2019-20 and 94% in 2021-22. It is worth noting that the module was taught by different lecturers in the two years, but engagement remained similar. This shows that using an online or blended system for carrying out peer review can work very well, and agrees with work carried out in other disciplines [7-8].

Figure 3 shows the number of students who completed different numbers of worksheets in 2021-22, and is compared with the number of students who attended a certain number of sessions in 2019-20. It should be noted that only 19 worksheets were provided in 2019-20, so the numbers have been scaled for comparison. It can be seen that almost half of all students completed all worksheets in 2021-22, while nine students (5%) failed to complete the minimum of 15/20 worksheets. It was also found that a further five students did not complete the required number of peer reviews despite submitting their own worksheets, resulting in 14 students (8%) overall failing the continuous assessment element. In 2019-20, eight students (5%) failed to attend the minimum number of sessions.

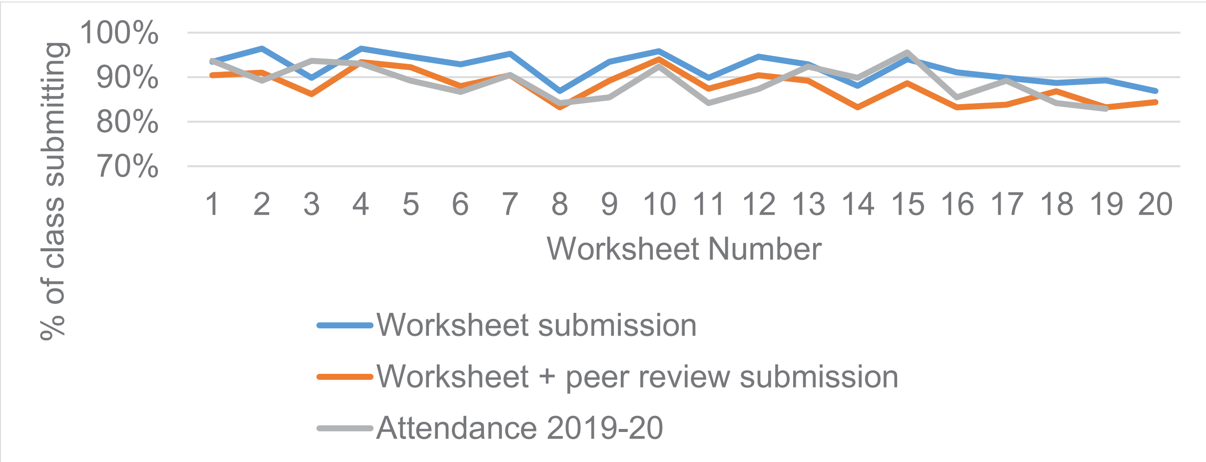

Fig. 2: Engagement with each feedback session

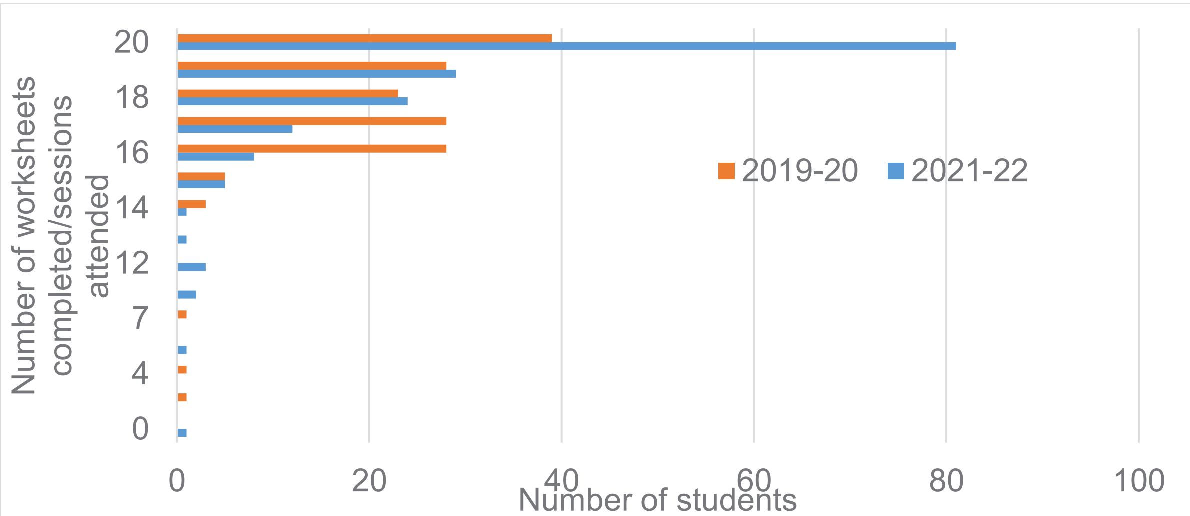

Fig. 3 : Number of students completing a given number of sessions

3.2 Grades across the year

115 students (68%) took the opportunity to submit their work-in-progress reflection journal for feedback in the middle of semester 1. The average formative grade awarded was 76%, with a standard deviation of 15%. Students were provided with rubric scores and feedback. The end of semester 1 summative submission had an average grade of 74%, with a standard deviation of 18%. The second semester submission showed an average grade of 66% with a standard deviation of 18.5%.

This drop was anticipated as semester 1 contains content that should mainly be revision to the students from their previous studies, whereas semester 2 content is likely to be new and therefore more challenging Overall the final average for the continuous assessment was 69%, compared to a 58% average in 2019-20

3.3 Student peer reviews

The average peer review scores given to each worksheet varied between 9.3 and 11.3 out of 12, with a standard deviation between 1.5 and 2.7 across the year. It was noted that there was good consistency across the worksheets, however, the scores are on the high side and may indicate leinent marking by the students, or an issue with poor differentiation by the rubric that was provided. This may need to be addressed next year to provide a better spread of marks. However, the peer scores contribute only 15 out of 40 marks and if they are extracted from the final marks for the continuous assessment, the overall average would drop to to 64%.

3.4 Student comments for their peers

As found in 2020-21 when the peer review process was carried out online, it was clear that the students provided good quality feedback for others when working digitally in 2021-22. Some examples of student feedback are shown in figure 4.

9) correct answer found using appropriate method, well done. Be careful as when you wrote inverse= (matrix), you put a value of -5/15 for the element a12. Whereas the correct value is -5/18. However, your working was clear so I was able to identify that you had found the value to be -5/18 previously and had simply made an error when writing, hence I haven't removed any marks.

Question 3 c is a very concise solution to the question with the correct answer. Well done. Question 5 e would have benefitted from a single additional step just before the final answer however it is all correct. Question 6 e gives the correct answer and an easy to follow solution. One change I would have made would be to explicitly reference the standard integral that you used. In question 8 d you have made a mistake regarding your partial fractions in obtaining -1 2 and 3 and values for the numerators. The correct answers were 2 2 and 1. Please try this question again as your integration was not what led to the wrong answer.

Figure 4: Examples of student peer comments

3.5 Adaptability and accessibility online and in person

As anticipated at the beginning of the academic year, there were times when students were unable to attend in person for various reasons including the fact that a substantial number of students tested positive for Covid-19 at various times across the year, the semester 1 lecturer tested positive for Covid-19 and delivered teaching online during the weeks corresponding to worksheets 7 and 8, and the university switched to a short period of online teaching during the weeks corresponding to worksheets 12, 13 and 14. It can be seen that during these periods the system continued to function as before with no discernable difference in engagement, suggesting that the process is robust and adaptable to rapid change. In addition, improvements in technology have made the process relatively straightforward to implement, compared to findings in earlier studies which found adapting peer review processes to online courses to be more complex and difficult [9].

3.6 Student feedback on process

Module evaluation surveys are issued to students electronically at the end of each module in the school. For this module, 57 responses were received (33.5%). Some freeform comments boxes were provided to ask students open-ended questions about what they found valuable in the module and what they would like to be improved. There were 35 comments about what students found valuable, 17 of these related directly to the peer feedback process, with students indicating it helped them to develop skills and to identify their strengths and weaknesses:

“The worksheets, along with the associated peer reviews, were very useful in developing my skills”

“The worksheets … showed me not only what I knew but what I didn’t know”

“I enjoyed the fact the assessment on the course was peer assessed as it allowed me to see how well my peers were coping with the module. It also allowed me to compare how well I was doing with the module”

There were 22 comments about areas that the students would like to see improved, with only four of these about the peer feedback process, mainly indicating that the quality of the feedback left by some students was not always helpful or accurate:

“Student feedback was mostly unhelpful. Students aren't well equipped to give valuable feedback. I found filling in my reflection journal very challenging, since the feedback I received was mostly bad.”

“I don’t like the peer review / reflection journal. Sometimes, people marking my work understood the topic less than me and tried to correct things that did not need corrected. In my opinion maths should just be an exam, like in school.”

4 SUMMARY

Converting an in-person paper-based peer review process to a digital flexible format for a year 1 engineering mathematics module has shown that engagement with the process remained high, with at least 83% participation in each session in both formats. Similar percentages of students met the minimum attendance/participation requirements. Continuous assessment marks with the new system appear to be higher than with the previous system, some of which may be attributed to the fact that peer review marks may be overly high, and this will be looked at next year, however they contribute only a minor fraction of the overall mark. Quality of the comments left for students by their peers is higher in the new system, and student opinions of the process are generally positive. This type of process could be adapted across other mathematics modules, but also many other types of engineering module to provide flexible means of students accessing and participating in continuous assessment and peer review. As this is based on only one year of data, the process will continue to be monitored and adapted as appropriate.

ABSTRACT

This article presents a set of experiences related to the setup and exploration of potential educational uses of a collaborative robot (cobot).

The basic principles that have guided the work carried out have been three. First and foremost, study of all the functionalities offered by the robot and exploration of its potential academic uses both in subjects focused on industrial robotics and in subjects of related disciplines (automation, communications, computer vision). Second, achieve the total integration of the cobot at the laboratory, seeking not only independent uses of it but also seeking for applications (laboratory practices) in which the cobot interacts with some of the other devices already existing at the laboratory (other industrial robots and a flexible manufacturing system). Third, reuse of some

doi:10.5821/conference-9788412322262.1284

available components and minimization of the number and associated cost of required new components.

The experiences, carried out following a project-based learning methodology under the framework of bachelor and master subjects and thesis, have focused on the integration of mechanical, electronic and programming aspects in new design solutions (end effector, cooperative workspace, artificial vision system integration) and case studies (advanced task programming, cybersecure communication, remote access).

These experiences have consolidated the students' acquisition of skills in the transition to professional life by having the close collaboration of the university faculty with the experts of the robotics company.

1 INTRODUCTION

A collaborative robot (cobot) is an example of an industrial robot in which, basically, the measurement of force in the end effector and mechanical joints has been added to the traditional way of controlling the position and speed of the end effector in order to sometimes allow the physical contact with the human operator. A second characteristic is the elimination of the physical barrier between the cobot and the operator: through sensors and programming, the approach of the operator to the cobot translates into a reduction in the speed of the cobot and even its stoppage [1]. A third characteristic is the flexibility of the cobot's tasks, in the context of cooperation between the cobot and the operator, which allows a cobot to be started up accompanying the operator in jobs in small and medium-sized companies in tasks that were initially carried out manually (assembly).

As can be seen in the previous paragraph, one of the challenges in the implementation of tasks and processes in which the cobot and the human combine their skills to improve performance. The cobot can be useful both at the organizational level of the company and at the level of interaction with the operator [2]. In this last aspect, a cobot oriented to access and use by a human operator must allow various operators with different training to develop skills, or perfect existing ones for an effective teamwork.

It is necessary to address the practical use of cobots in higher education for various reasons, including:

a) current manufacturing processes are in transition towards a connected industry (industry 4.0) in which collaborative robotics is included as an emerging technology [3]
b) the improvement of the functionality of the cobot through programming algorithms (basic task programming, recursive programming, programming using artificial intelligence algorithms) can transform the cobot in the direction of a cognitive robot in a few years [4]

Higher education must accompany the engineering student in this adaptation. This requires changes in the engineering curriculum [5], specifically the inclusion of collaborative robotics concepts in industrial robotics subjects, the creation of laboratory practices with cobots, and the development of final degree projects.

The Section two explains the methodoly developed, paying attention to the relationship between different users. The section three explain in more detail the effectiveness of this approach in the development of three case studies. Finally, conclusions are future steps are presented.

2 METHODOLOGY

The methodology used in this work is project-based learning. The methodology has been adapted to three scenarios:

a) Subject within an engineering degree
b) Final degree project
c) Life-long learning

The agents involved in this methodology are:

a) Teachers of various subjects
b) Teachers and experts from robotics companies
c) Teachers, laboratory maintenance staff, final degree students

2.1 Subject

There are two subjects, Industrial Robotics and Computer Vision (RIVC) and Integration of Automatic Systems (ISA) that use the same laboratory resources. The first one divided in two parts show industrial robotics and the relationship with computer vision (2 h in laboratory each week, 14 th weeks). The second subject is a project oriented subject (3h in laboratory each week, 14 th weeks), with the aim to encourage students to the development of final projects in automation. Both subjects share in the experimental part the need to consolidate teamwork skills.

2.2 Final degree project

Some final degree projects have been proposed and developed [6], [7], [8], [9], [10], all of them oriented towards the integration of a collaborative robot UR3e [11] in the laboratory: development of electronic prototypes, design and programming of robotic applications. The main aim is to reduce the gap between undergraduate engineering students and professionals in electronics and automation companies. The first final degree project related to the start up of the cobot in the laboratory (two months) allowed the robot station to be shown at an open session for future engineering students (february 2020) at the hall of our school. Finally, the student published an article into an Spanish Journal as a first author [12].

2.3 Life-long learning

In this aspect, collaboration between the University and robotics companies is being promoted. Some students carry out internships and final degree projects in companies with the advice of the teaching staff.

The teaching staff provides students with the possibility of attending an annual fair (Advanced Factories) with the latest developments in industry 4.0. Students are asked to attend, meet with business experts and prepare a small document with a list of companies and future job opportunities.

3 RESULTS

3.1 Electrical gripper

The end effector is the device that, mounted on the end of the robot (or cobot) arm, allows it to perform a certain task. There are two main categories of end effectors, grippers that allow the manipulation of objects, and specific tools that allow implementing tasks such as welding, painting, etc. In academic environments, it is common to illustrate the use of robots and cobots mainly in tasks that involve the manipulation of small objects. According to this, the most commonly used type of gripper are electrical grippers.

When thinking about equipping the collaborative robot with a gripper, multiple commercial models available on the market could have been compared and one of them could have been purchased and installed on the cobot. This would have been a quick and easy solution, but it would also have been expensive. And, perhaps more important, very little would have been learned from the process. That is why, instead of acquiring a commercial gripper, the design and prototyping of it from scratch was considered as an alternative and a final degree project with this goal was proposed [10]. This option is viable, since the challenge is within the reach of students who are finishing the degree in Industrial Electronics and Automation and since the necessary means are available at the school. In addition, it is an option that has its advantages, the main ones being that both the student and the supervisor (teacher) acquire new knowledge and that the obtained product has a much lower cost than its commercial equivalent.

Taking previous considerations into account, and using as reference the basic models of adaptive electric grippers commercialized by some of the most important manufacturers (Schunk, Robotiq and OnRobot), a 2-finger parallel gripper with electrical actuation has been designed. The mechanical design is simple and it can be easily implemented with conventional 3D printing equipment. The actuation and control are based on the use and programming of a Dynamixel AX-12A servo motor and an Arduino Nano board. The result is a gripper with a maximum opening of 80mm, which allows handling objects of up to 1kg and with an opening/closing time of less than 1 second. These characteristics are comparable to those of simple commercial pliers, but obtained at a much lower economic cost: the total cost of the prototype remains around 100 euros, while a comparable commercial model can be around 1,000 euros. All the details about the mechanical, electrical and electronic design of this gripper can be found in [10].

Figure 1 shows the first prototype of the gripper. This prototype has already been installed in the cobot. It works correctly and it is going to be used extensively. Additionally, according to available economic resources and opportunities, more collaborative robots will be acquired and new copies of the gripper will be manufactured and installed with reduced effort and cost.

Fig. 1. First prototype of the 2-finger parallel gripper.

3.2 Workpiece classification using computer vision

Another relevant result of the work carried out so far has been the implementation of a complete example that combines the use of collaborative robotics with computer vision [8].

In this example, the objective is to classify objects of different types and colours that at the beginning are randomly distributed in a given area close to the robot. To do this, an artificial vision system must identify the type and location of the different objects and provide this information to the cobot. At the left side of Figure 2, a photo of the whole system is presented, where the initial zone and the destination zones and containers can be observed.

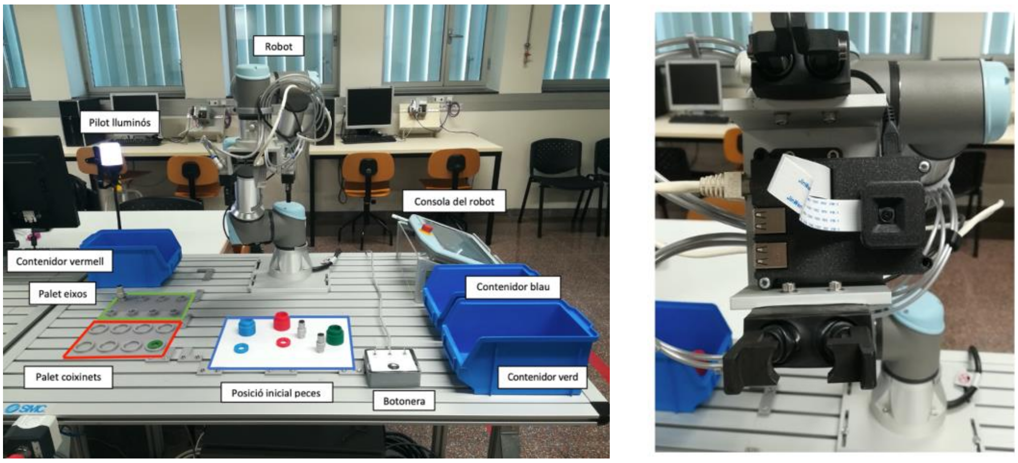

Fig. 2. Workpiece classification system: (left) whole system; (right) detail of the integrated vision system.

For the development of this example, and again following the principle that designing from scratch is much more educational and cheaper than acquiring commercial devices (the cost of an industrial vision system is also in the range of a few thousand euros), a vision system based on a Raspberry Pi and a Pi camera has been designed and integrated into the robot. The choice of the Raspberry is motivated by its small size, its low cost (not only for the Raspberry but also for the camera) and for the possibility of using a standard environment for the development of computer vision applications: Python (programming language) + Open CV (Computer Vision library). The system has been mounted on an end effector with two pneumatic grippers (which was acquired just after the cobot and before designing and prototyping the electric gripper presented in the previous section), using a custom case with a fixation system that has been manufactured using 3D printing. Communication between the Raspberry Pi and the UR3e controller is established using the Ethernet ports available on both devices. In Figure 2, at rhe right, a photo of the vision system after installation is shown.

The scope and complexity of this example makes it suitable to be used, under a PBL (Project Based Learning) methodology, as a project to be solved in the Industrial Robotics and Computer Vision subject, an idea that will be put into practice starting the next academic course.

The resolution of the project will be planned according to the four fundamental problems to be solved: recognition and location of objects; transformation of image coordinates to robot coordinates; Raspberry-UR3e communication; manipulation by the robot. The solution of these four problems will go through the programming of both the Raspberry and the UR3e. In principle, all the work groups established in class will have to solve the same project (which accepts different types of solutions), but if considered pertinent, different variants may be established, such as those that may result from considering different sets of object types.

3.3 RoboDK tutorials and exercises

Both in industry and in academic environments, off-line programming and robot simulation environments are useful. In an industrial context, this type of software tools allow programs to be developed and simulated before testing them on real robots that must finally execute them. In addition, in an academic context, the availability of simulators makes it possible to have more working groups (pairs of students) in the laboratory than the number of real robots available (in the Industrial Automation and Robotics laboratory there are eight working places equipped with PCs + programming and simulation software, while there are only three robots, two conventional industrial robots plus the new collaborative robot; each group of students spends a good part of the time at their working place and they only use one of the robots to do the final tests).

RoboDK is an off-line programming and simulation software [13]. As a programming environment, it allows robots to program robots of different manufacturers by using a same high-level graphical language (this is a double advantage since the graphic language is easier to use and it is also universal and independent of proprietary language of each manufacturer). As a simulation environment, it allows programs to be tested independently of the fact that they can later also be tested on the real robot. As a whole, it can be useful both in laboratory sessions and in theory sessions to be able to illustrate many concepts.

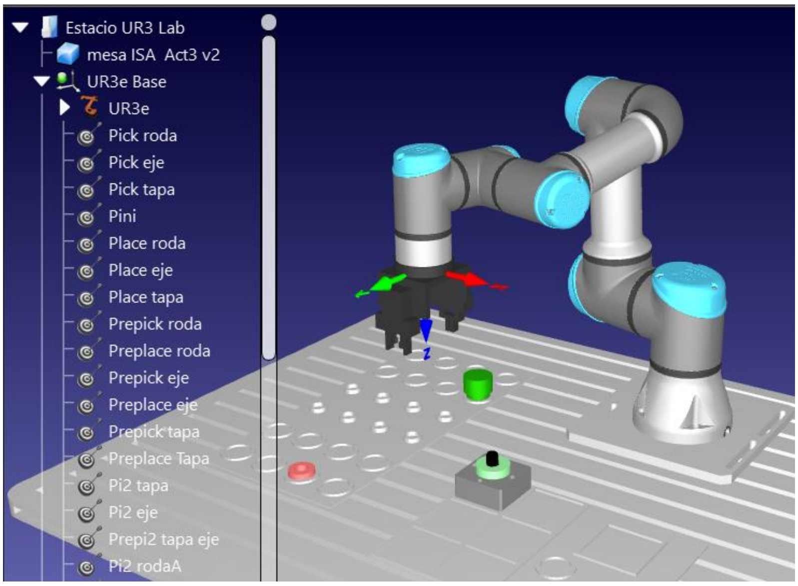

Fig. 3. Assembly example in RoboDK.

Given the potential educational utility of RoboDK, its study was proposed as part of a final degree project [9]. The result of this work was a set of basic tutorials and a set of programming and simulation exercises with different levels of difficulty (all of them documented and resolved). Figure 3 shows a screenshot of the solution of an exercise in which it is requested to program and simulate an assembly task.

Unlike the electric gripper and the parts classification system, which have not yet been used within the framework of laboratory practices of any subject, RoboDK tutorials and practices have already been used during the academic year 2021- 2022 in the subject Integration of Automatic Systems.

Thus, in the recent edition of this subject, the students enrolled (12) have carried out two 3-hour laboratory sessions about the use of the simulator and a third 3-hour laboratory session about the use of the real cobot. After these sessions, the students answered a System Usability Scale (SUS) satisfaction questionnaire with scale 0-100, obtaining a mean value of 61.2 and a standard deviation of 19.4 [14]. Figure 4 shows the response to question 5 “I found the various features of the tutorial to be fairly well integrated”, Likert scale 4 strongly agree, 0 strongly disagree.

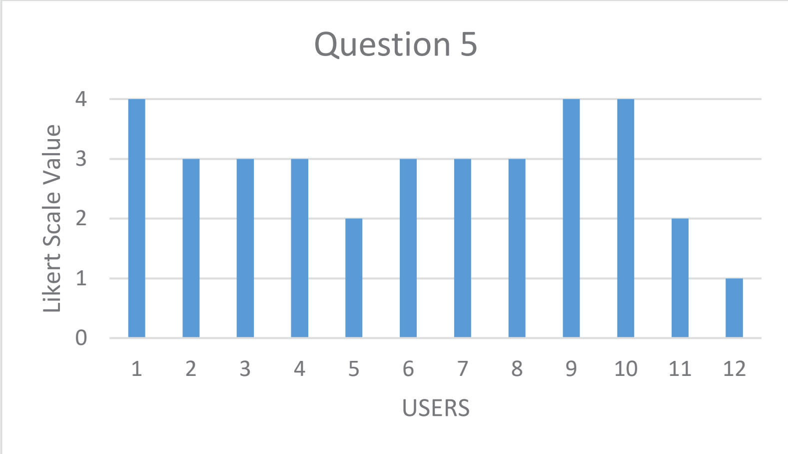

Fig. 4. Answers to question 5 of the SUS questionaire.

In this questionnaire, the students emphasize that the 3D simulator is easy to learn and use, although the quality of the tutorials must continue to be improved, since the 3D simulator interface is apparently in graphic format, while the advanced functionalities are in text format and it uses Python programming, so learning the simulator is not so easy.

4 SUMMARY AND ACKNOWLEDGEMENTS

This article shows how to promote the development of projects in industrial robotics in the teaching laboratory, achieving integration with the rest of the equipment and facilitating the learning and skills of undergraduate engineering students.

Taking into account the projects already developed, the next steps are in the direction of add a second robot and develop collaborative task between students and robots, measuring in more detail the satisfaction of the students with this approach and promoting innovation projects (design of a sensitive gripper, use of OPC UA communications in collaborative robotrics).

This work has been partially funded by EXPLAINING project (EXPLainable Artificial Intelligence systems for health and well-beING) (Ref. PID2019-104829RA-I00 / MCIN/ AEI / 10.13039/501100011033) from the Spanish Ministry of Science and Innovation.

ABSTRACT

Most instructors of engineering students will be familiar with students who – instead of engaging actively with a given field of knowledge – merely reproduce the curriculum at the exam. This study hypothesizes that students will achieve a higher taxonomic level of learning outcome by using a didactic tool – with a higher degree of understanding, application, and reflection as a result. We have developed such a didactic tool, Quizry, to create engaging teaching sessions through a special learning process: students producing quizzes for one another.

We applied the French researcher Guy Brousseau's theory of didactical situations in teaching and his five phases as a theoretical basis for our study. In the first phase, the didactic contract is established between the students and the instructor, i.e. the assignment of producing quizzes is handed over. During phases 2-4, the students work with the concrete quizzes (a-didactic parts), and lastly in phase 5, recap, cohesion of learning and transfer is established.

We examined the relationship between producing quizzes and student learning outcomes through the lens of the American professor Vincent Tinto's influential three-fold model of motivation: self-efficacy, sense of belonging and perception of curriculum. The students' self-efficacy and perception of curriculum are strengthened by working with the topic several times.

Among other things, the study showed that 79% of the respondents reported that preparing quizzes for other students improved their learning outcome compared to traditional learning.

1 INTRODUCTION

1.1 Background

Most instructors of engineering students will be familiar with students who – instead of engaging actively with a given field of knowledge in class and as preparation for class – merely reproduce the curriculum at the exam [1]. This often leads to low learning outcomes and subsequently to poor grades. Furthermore, research has shown that students tend to quite rapidly forget knowledge acquired in this way: a dissatisfactory learning result for students, instructors and institutions of higher education alike. This study hypothesizes that students will achieve a higher taxonomic level of learning outcome by using a didactic tool, hereafter known as Quizry – with a higher degree of understanding, application, and reflection as a result [2]. We have developed Quizry to create engaging teaching sessions through a special learning process, i.e. students producing quizzes for one another.

We applied the French mathematics didactician Guy Brousseau's theory of didactical situations in mathematics [3], according to which teaching situations may be divided into five phases. In the first phase, devolution, the didactic contract is established between the students and the instructor, the academic problem is handed over, and the students accept the responsibility.

Phases 2-4 are generally about the students being engaged in activities. In our study, the students are preparing multiple choice quizzes, both individually and in groups, and they answer the quiz questions individually. In phase 5, institutionalization, the results from phases 2-4 are collected. This activity took the form of a joint recap of the students' answers to the quiz questions.

In our study, we examined the relationship between Quizry and student learning outcomes through the lens of Vincent Tinto's influential three-fold model of motivation: self-efficacy, sense of belonging and perception of curriculum [4]. Furthermore, we examined the relationship between Quizry and student learning.

The students' self-efficacy is strengthened by working with the topic several times [4]. The group work with the preparation of the quizzes can help to strengthen the students' sense of belonging. In addition, if students experience the work with the quizzes as meaningful, it can strengthen their perception of curriculum.

The washback effect, which has been described by several theorists, e.g. [5], says that the purpose of participating in a course, for many students, is to a large extent to be able to pass the exam with a satisfying result. By having the students prepare quiz questions for each topic, the students are forced to reflect on what they have learned, which can contribute to avoid simple reproduction.

1.2 The didactical tool Quizry

Initially we contemplated methods for engaging students more inside and outside class, enhancing their learning outcomes. Thus being able to apply and transfer that knowledge and these competencies much more easily and qualified later in their study programmes as well as eventually in their professional lives as engineers. Based on our reflections, the idea of students producing quizzes emerged. We decided on developing and implementing a study process involving quiz work as part of preparation for class and as a didactical tool in class. In addition to implementing Quizry in different study programmes, we also had the opportunity to simultaneously conduct a systematic study of how to strengthen students' learning outcomes by using Quizry.

The basic idea is, as mentioned, to engage students through quiz work and to make the students do the work, as this often results in better learning processes and outcomes [6]. For this purpose, all students are part of a quiz-group, and the quiz-groups have different tasks at each teaching session.

At the end of each teaching topic the students worked on Quizry:

Before teaching sessions all students prepare for class as usual; however, in addition we ask them individually to bring to class one quiz question with at least three plausible, valid answers and one possible answer should be the better answer.

During the teaching sessions, the students first discuss the quality of their individual questions/answers in their quiz-groups; second agree on one quiz question/answers; and third send that question to a so-called quiz-responsible group. The task of the quiz-responsible group is to produce the quiz for the teaching session, and in doing so they decide which questions/anwers to use, modify and add. All quiz-groups are at one point during the semester responsible for producing a quiz. Quizzes consist of 10 questions/answers, and the quiz-responsible group makes sure that there are sufficient questions/answers.

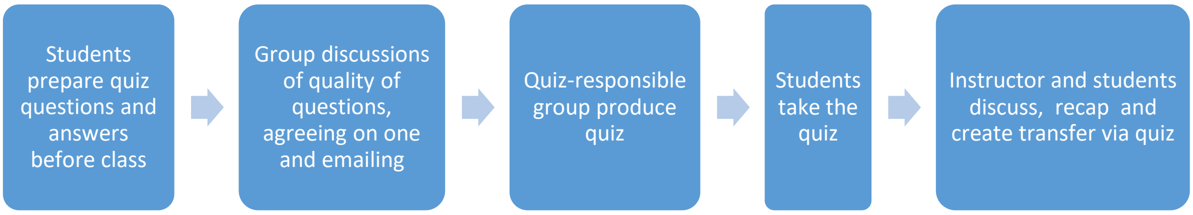

Figure 1: Overview of the Quizry learning process

The study was conducted in the autumn semester 2020 at Technical University of Denmark in three different BEng courses across two study programmes. Quizry was used in two subject areas: managerial economics and cultural understanding in the 2nd and 4th semester. A total of 76 students participated in the courses. Due to the pandemic, we partly experienced lockdown, students being tested positive for COVID-19, online teaching and online exams, which complicated the data collection.

1.3 Hypothesis

The study hypothesis is that students who work with quizzes will strengthen their competencies of understanding, applying and analyzing within selected topics in different disciplines.

We expect that the teamwork will result in a positive impact on students' perception of curriculum, self-efficacy and sense of belonging alike. In addition, we anticipate that the students' learning outcome will reach the highest level in connection with their teamwork on their own concrete, specific quiz.

2 METHODOLOGY

2.1 Methodology

During the study, we have collected various qualitative data through questionnaires answered by the involved students and undertaken indirect partipant observations by instructors.

We have chosen the questionnaire format as it gave an opportunity to receive anonymous answers, so that students did not have to worry about giving very honest answers/opinions of the learning process or other concerns. The questionnaire consisted of five open-ended questions and one closed question regarding quality of learning with the categories "Yes, better", "Yes, however, almost the same" or "No". At the end of each Quizry, each student in the quiz-responsible group individually answered a questionnaire; furthermore time was set aside for all students to answer a questionnaire of self-reflection on their learning outcome.

Besides the questionnaires, we decided to use covert indirect participant observations during the Quizry process. We chose covert observations in order not to influence the learning process itself and not to affect the answers of the questionnaires. As for indirect observations, we observed the students' behaviour during the Quizry process in class. As a result of our positions as instructors, we became participants in the Quizry process.

3 RESULTS

3.1 Quantative and qualitative results

We have systematically researched and evaluated the students' perception of their own learning in connection with the use of the Quizry. Each student from the 10 quiz-responsible groups was asked to answer a survey regarding their learning. The overall results are shown in Table 1:

Table 1. Overall results from surveys.

		Enhanced learning through quiz work		
Group	Answers	Yes, improved substantially	Yes, slightly	No improvement
1	2	1		1
2	5	2	3	
3	5	3	2	
4	3			3
5	4	3	1	
6	4	2	1	1
7	3	2		1
8	4	2		2
9	3	1	2	
10	4	2	2	
	37	18	11	8
In %		49%	30%	22%

We received a total of 37 answers in the three different courses. 79% of the respondents answered that preparing quizzes for the other students improved their learning outcome compared to traditional learning. As the table shows, 49% state that their improvement was substantial, whereas 30% state that their learning outcome improved slightly.

The respondents were asked to qualify their work with the quizzes in general, and the students gave us statements such as:

- "Very educative and interesting to see the groups quizzes"
- "The idea with quizzes is very good. Should be extended to all lectures"
- "A good way to recap a topic"
- "You remember the questions you prepare"

- “Funny and different way to learn”
- “Educative to prepare quizzes, less rewarding to answer the other groups quizzes”

As is evident from table 1 and the statements above, the students found the learning activities very educational, i.e. Quizry underpins Tinto’s self-efficacy and perception of curriculum.

Through our observations during teaching sessions, the following came to surface:

- All Quizry groups were inclusive during the teamwork
- In the process of making Quizry, students started revisiting teaching materials such as books and assignments
- Some students started out by resisting the learning process, Quizry, with comments such as “why do we have to make a quiz, we are used to instructors making quizzes?”
- Students found it difficult to phrase valid questions and plausible answers
- The quality of the various Quizries was to a large extent dependent on the time students spent both preparing at home and in class
- Tendency to cut corners and preference for easier parts of the topic
- The teamwork was at times challenged by the fact that some students were not well-prepared or did not attend class that day
- By the end of the semester, students increasingly focused on exams and and less on working on Quizry
- As instructors we experienced the need to continously frame Quizry in order to maintain students’ focus and motivation on the process

The Learning Management System used is DTU Learn/Brigthspace, which has multiple possibilities to set up quizzes, but also lacks some features which would have been beneficial for our use. When the students had answered a quiz question, the students were taken to the next question without being told whether their answer was right or wrong. The same was the case when finalizing the quiz. This resulted in some students working around the system; they answered the quiz as intended but without delivering it in order to keep it open, so they could still see what they had answered.

It seems like the quiz module was originally designed for testing purposes and not as a didactical tool in itself. Answering the quiz is quite an independent and individual task for the student, and not until everybody had finished the quiz were we able to discuss answers and results in class. A didactical software tool such as Kahoot might have suited our purpose even better. The gamification and the possibility to take discussions after each question might have improved the process further, which actually was our initial idea.

4 DISCUSSION AND CONCLUSION

4.1 Discussion and suggestions for future research

During the project we have obtained some insights:

Formulating good MC questions is not easy and can be quite challenging. Lotte D. O'Neill [7] mentions several design errors, which should be avoided. For a student, who may only design MC questions once, and under strict time limitations as well, it is a difficult task. As part of the quality control, we had to go in and modify some of the questions and anwers.

- The framing of the quiz work to the students at the beginning of the project could be repeated advantageously more in depth during the course. We observed that it was more difficult to maintain a few students' focus regarding the quiz work later in the process.
- Some students did not use sufficient time at home preparing the quiz questions, which resulted in some of the input to the quiz-responsible group was not of sufficient quality. As a consequence, instructors used more time than planned during and in between classes. The lack of engamement from some of the students due to not preparing the quiz questions at home influenced these students' learning.

We would like to research further the impact of engaging students on self-efficacy and sense of belonging. Moreover, we are very interested in examining to which extent students' course expectations influence their quiz work, e.g. students' resistance to learner-centered-teaching (LCT) and lastly reasons, including socio-economic, why students fail to prepare. We would like to conduct such research with a higher qualitative focus, e.g. semi-structured interviews and various observation methods to an even greater extent.

4.2. Conclusion

Our study results show that an extensive part of students experienced improved learning outcomes compared to traditional teaching.

It is evident from our study that students who work with Quizry will strengthen their knowledge and compentencies; however, it is also clear that the students putting most effort into Quizry are the ones who obtain the highest learning outcomes. Furthermore, the students appreciate the opportunity of various didactical tools. The study shows that Quizry enhanced the students perception of curriculum, self-efficacy and sense of belonging.

Ingolstadt, Germany

Conference Key Areas: *Industry and Companies liaison. Regional Involvement and Innovation, Digitalisation & Hybrid models*
Keywords: *entry-level employee training, individualization, digitalization, aerospace software development*

ABSTRACT

This research follows a previously published paper presented by Pourtoulidou and Frey which describes the conversion of a classroom-based to blended training for new employees entering aerospace companies [1]. This paper presents the lessons learned that derived from the analysis of the results after evaluating the blended training according to the participants', subject matter experts', and trainer's perspectives.

Prior to the training, Pourtoulidou and Frey analyzed the demands of aerospace companies and the labor market in order to develop this introductory training [1]. The classroom-based training was developed, implemented and evaluated in 2018/2019. Utilizing this evaluation, the blended training consisted of an online phase, which

[1] *Corresponding Author*

D. Pourtoulidou

dpourtoulidou@gmail.com

doi:10.5821/conference-9788412322262.1257

lasted six months and provided access to lecture videos, literature material, quizzes, forums and virtual meetings over the Moodle platform. In the middle of the online phase, a face-to-face session took place in October 2021 in which the participants worked with practical applications and associated with subject matter experts operating directly in industrial projects.

The lessons learned focus on the training development for employees' blended courses and on the specific limitations resulting from developing a joint training for entry-level aerospace engineers. The flexibility and further benefits of the training's online phase were well received from the participants, while the opportunity to meet, work and exchange experiences in person during the training was highly appreciated. The impact of COVID-19 on participants' experience and feedback was also visible and commented on.

1 INTRODUCTION

In 2017 a network of eight German companies formed under the publicly funded research project "Avionic System Software Embedded Technologie 2" (ASSET-2) formulated the demand for an introductory training course for new employees entering the aerospace industry [1 - 9]. This demand derives from the recruitment process in the aerospace industry that draws employees from pertinent fields, e.g. automotive engineering and STEM. Aerospace companies need to reach out to software engineers or software architects with a wide variety of academic and professional backgrounds. Afterwards, the challenge remains for each company to train the new software engineers or software architects through training courses, which cover the basics for their introduction to aerospace software development depending on their role.

2 PROJECT BACKGROUND

2.1 ASSET-2

Ingolstadt University of Applied Sciences developed an introductory training course as a classroom-based training for the "knowledge transfer" subproject of ASSET-2 to cover the companies' demand [2 - 9]. This training contained theoretical knowledge, practical applications and contact with subject matter experts in order to offer to companies' new employees a common elementary introduction to aerospace software development. The development of the classroom-based training started with the needs analysis; followed by the implementation and the evaluation of the training [2 - 9]. The feedback from the participants and the companies confirmed the initial consideration for the training and revealed the need for individualization of the training, as the individual background of the participants shows a wide spread. The participants expressed their individual learning needs and stated that they were in favor of the opportunity to self-regulate which parts of the training they will attend.

2.2 IDEA

Based on the ASSET-2 feedback, the further development of the training started in 2020 under the publicly funded research project “Integrierte Design- und Entwicklungsumgebung für Aerospace” (IDEA) by the Federal Ministry for Economic Affairs and Energy[2]. The subproject “knowledge transfer” within IDEA aimed at minimizing the restrictions and disadvantages of the aforementioned classroom-based training by offering flexible training units that fit into the employees’ working schedules and make the training adjustable to participants’ needs. The ASSET-2 main goal of introducing the new employees to aerospace software development and promoting the knowledge transfer among the participants remains a primary goal for the extended network of twelve German aerospace companies and academic institutions. However the IDEA blended training, which is the result of the conversion of the ASSET-2 typical classroom-based training, foregrounded the learning needs of the individuals. The criteria for the conversion of the ASSET-2 classroom-based to IDEA blended training are described in a prior publication of the authors [1].

3 LITERATURE REVIEW

The development of blended or hybrid trainings started before the 2000s and therefore is a rather old trend. The sudden obligatory shift in online learning that resulted from the mandatory reduction of the face-to-face training sessions since the beginning of 2020 is obvious and lies in the COVID-19 restrictions. The explosion of the amount of online trainings and online digital learning resources is evident.

Since the early 2000s, researchers have studied the use of blended learning in training development [10]. Training courses containing a mix of online and face-to-face learning modules are called blended or hybrid courses [11]. The positive influence of blended approaches on learning outcomes has been shown through studies in university settings or in vocational education [12, 13, 14]. Vitally relevant for this research are studies about professional trainings, which were developed for employees and take place within employees’ current job position aiming at their professional development. The advantages of professional trainings concern both the employees and the employers. Employees benefit from blended learning methods due to the flexibility and the accessibility of participating in blended courses [11]. Employees’ learning success results in increasing employers’ benefits while reducing the costs of training development [11, 15]. An explorative study in a Belgian-Dutch context confirmed these benefits of blended learning [16]. Other studies highlight the ability to enrich the learning process in a blended course with the use of online material beyond one institution, and to allow the participants to engage with it at their own pace [17, 18]. Research evidence shows the improvement of the effectiveness in industrial trainings when comparing the different

[2] It was renamed to Federal Ministry for Economic Affairs and Climate Action in January 2022.

learning approaches using experimental design [19]. The dropout rate is, also, positively influenced by blended learning but is highly dependent on the setting of the blended course and is not relevant for this research [20].

4 METHODOLOGY

This chapter describes the research methods, the implementation and analyses the feedback of the blended training after its evaluation from the subject matter experts', the trainer's and the participants' perspective.

A challenge for evaluating these trainings is that the companies demand data protection and absolute confidentiality regarding the employees and the training material. The mandatory data protection issued for the companies and their employees forbid any external evaluation. This influenced the methodology of evaluating the ASSET-2 classroom-based and the IDEA blended training, which is described as follows. The evaluation was executed by interviewing all contributors in semi-structured interviews. Due to the geographical distance the researcher conducted telephone interviews with the 22 participants and the 3 subject matter experts and a face-to-face interview with the trainer. The collected data were recorded via a voice recorder, anonymously transcribed and analyzed using content analysis.

4.1 ASSET-2

The ASSET-2 classroom-based training was implemented in October 2019 in which 11 employees participated [2 - 9]. At that time, they were starting their careers within the network in the field of aerospace software development in Germany. This training lasted two days and took place in Ingolstadt. The participants of this training belonged to 6 different companies and had various educational backgrounds from STEM fields. Before the training, the participants answered a prior-training questionnaire about their knowledge and their educational and professional background. Directly after the training they were asked to fill out a post-training evaluation questionnaire with close-ended and Likert Scale questions. Approximately three months afterwards, telephone interviews took place to get feedback after the new employees had actively been participating in work projects and had settled in their new position.

4.2 IDEA

The implementation of the blended training got caught up by the COVID-19 restrictions. During the COVID-19 restrictions in 2020 and 2021, the availability of the participants for the face-to-face session was difficult to foresee.

The duration of the online phase was planned to last 7 months during which the face-to-face session would take place. During the online phase the participants had access to lecture videos, literature material, quizzes, forums and virtual meetings over the Moodle platform. After the conversion of the ASSET-2 classroom-based training, the proportion allocated to the online phase was planned to cover approximately 78% of the training's material, which resulted in approximately 22% for the face-to-face session [1]. The average commitment for the online phase was estimated to be 10 hours. The online modules were staggered in chapters not dependent on each other. A participant could either skip a chapter or a video. Skipping an online module or part of it was up to each participant according to their educational and professional background. All online material was from the beginning of the online phase available with no restriction other than not being able to download the videos due to license restrictions. Rewatching a video at any time was possible with a working internet connection.

The duration for the face-to-face session was originally planned to last 5 work hours but was extended to one day (approximately 8 work hours) due to adding extra time for discussion and break time. The desired date for the face-to-face session was planned so that the participants could access the online material before and after the face-to-face session simultaneously while working in their business projects. The face-to-face session consisted of multiple parts. It started with a team event to get to know each other that took place the day before the main session. The participants were welcomed and met each other face-to-face with the trainer and the experts in an informal environment. The team event reached all participants, where 70% would need to travel a day in advance to arrive in Ingolstadt and 30% were locally based. As part of the actual face-to-face session subject matter experts were invited to offer insights about common problems in the field and advice according to their past experience. Also the participants engaged in group activities with practical applications.

The actual implementation of the IDEA blended training "Fundamentals in Avionics Software Development: Verification" took place in 2021/22. After consultation with the companies in order to ensure the maximum availability of the participants, the online phase started in August 2021 and ended in February 2022, the face-to-face session took place in October 2021. 11 employees from 5 different companies participated in the blended training.

The methodology of evaluating this training consisted of three steps. At first, before engaging with the training, the participants completed an online questionnaire about their educational and professional background. The online questionnaire prior to the training investigated the learning needs of the participants while they were starting their new job position. At the end of the face-to-face session, directly after participating in the training the participants answered a second questionnaire to assess in which level the materials and the teaching methods of the online and face-to-face sessions correspond to their needs and learning preferences. Both questionnaires contained multiple choice, Likert scale and open-ended questions. Step three included interviewing the participants, the trainer and the subject matter experts, who contributed in developing and implementing this training. Approximately three months after the face-to-face session the participants assessed the training's effects on their current professional role and their everyday working challenges in interviews. The interviews with the participants were conducted three months after the training in order to evaluate the training after gaining relevant experience in their new position. In addition to the participants' interviews, interviews with the trainer and the subject matter experts took place, which assessed the training from their perspective.

5 RESULTS

The results after evaluating the two trainings are presented here without referring to any personal information on the participants and every person that contributed to the trainings' development and implementation. In every research study the participants' personal data are highly protected. An additional requirement for the ASSET-2 and IDEA research projects was the confidentiality regarding job projects in which the participants are currently or were formerly working. The network's companies cooperate within the projects but are also competitors in similar and/or the same fields. Due to companies' privacy policies the employees participating did not take an exam or a test that would evaluate their knowledge. The participants could at any step of the evaluation withdraw their consent to participate in this study or skip a question. Their feedback on these trainings relied on their self-assessment according to their personal experience and opinion.

5.1 ASSET-2

The evaluation of the ASSET-2 classroom-based training outlined two main points; the demand for an introductory training in aerospace software development and the accessibility of the classroom-based method for this training [2 - 9]. The new employees that attended this training entering the aerospace industry with relevant or non-relevant educational and professional background confirmed the demand for such an introductory training. The appropriate time of participating in this was concluded to be directly after entering and up to one year working within the aerospace industry. The training method satisfied 80% of the participants and contributed to gaining knowledge. Nevertheless, they expressed further needs such as individualizing the training due to its long duration and large input, which was for some participants maybe already known or not absolutely related to their current position. 80% of the participants were in favor of the opportunity to self-regulate which parts of the training they would attend. 70% stated that they are willing to attend a training with online sessions that will cover a part of the training. Only 10% answered positively to participating in a strictly online training. All participants assessed as most important the practical activities and the interaction with the other employees from different companies and projects, with the trainer and the subject matter experts. The feedback from ASSET-2 was extensively analyzed in [1].

5.2 IDEA

The evaluation of IDEA blended training offered the following results, which will be presented from three different perspectives: the participants', the subject matter experts' and the trainer's perspective.

Participants' perspective

The IDEA blended training was well received from the participants. All participants mentioned as main benefits of this blended training the accessibility and the flexibility. Everybody appreciated participating asynchronously during the online phase without being limited in place and time when accessing the material and completing any tasks. 60% of the participants accessed the whole material before the face-to-face session, 20% of them only parts of it before the face-to-face session and 20% after the face-to-face session due to lack of time. The 20% of the participants, which did not access the material before the face-to-face session, stated during the interview that they intend to engage with it in the future depending on their workload.

All participants of the IDEA blended training commented very positively on the opportunity to meet and discuss with other employees from different departments and companies, who are experienced approximately in the same level as themselves. 90% of the participants stated they experienced a trustworthy environment and were encouraged to express their problems and questions during the face-to-face session. The participation in the team event was highly regarded by all. In particular, 70% explained that the team event contributed to "*breaking the ice*" and to feeling assured that neither comparisons nor (informal) assessments take place during the session. Also the participants living near the place of the training, stated that they were glad that they had joined the team event.

According to 70% of the participants, the contribution of the subject matter experts and the trainer played an important role in the atmosphere of the training because they were open and shared their experience from real-life work projects transmitting a feeling of "*everybody faces problems*". This was highlighted by 30% of the participants as "*cool, friendly and approachable experts*" which encouraged their self-confidence. In general, all participants liked the use of the blended learning method and emphasized the importance of the face-to-face session for collaborating.

For 60% of the IDEA blended training's participants this was the first training and business trip within their new position in their new company and in this industry. 40% mentioned that they were likely more excited to participate in a face-to-face training in October 2021 because of the long absence of face-to-face trainings and generally face-to-face sessions due to the past two years of COVID-19 restrictions.

Subject matter experts' perspective
This interest for face-to-face interaction was also reported from the subject matter experts, which participated in the face-to-face session. The subject matter experts presented the daily problems and experience gathered, while working in this field. 40% of the participants gave feedback personally to the experts directly after the expert discussion during coffee and lunch break. The experts perceived that the participants were feeling able to discuss openly and showed interest about their experience.

Attending the face-to-face session remains time-consuming for the subject matter experts but according to their opinion, this contributes to everybody's openness, and feeling of safety on a professional level. So, as one subject matter expert stated, "*can the participants express themselves without being afraid of being judged, what enriches the training outcomes*".

Trainer's perspective
The trainer received positive feedback from 40% of the participants directly after the face-to-face session. The trainer's feedback on the blended training highlights the difficulties of implementing a blended training. The flexibility during the online phase resulted in a lack of information about the participants' learning process during this phase. How the participants were engaging with the online materials was visible for the trainer only through their participation in the quizzes. This allowed some assumptions but the extent of the engagement remains unknown, since a participant may have taken a quiz without having watched the relevant video. Therefore, the trainer is required to be prepared for participants that are not at all introduced to the trainings' subjects. This issue did not negatively influence the implementation of the face-to-face session because of the session's topics. In other technically more challenging trainings and in particular exercises, which would require specific technical knowledge, this could cause problems for the training's implementation.

6 LESSONS LEARNED

The above results confirm the importance of the blended learning's benefits for employees entering a new role at a company and led us to following valuable lessons learned for the blended training.

- Offering a blended introductory training helps to quickly cover any theoretical deficits of new employees in the first stages of their new role. Not having to wait until a specific amount of participants is available for a training to be carried out results in a significant gain for companies [16, 18].
- Clearly structured material in the online phase containing all information regarding the training and its implementation are necessary. This determines the level of flexibility that can be offered.

- Self-assessment tools and/or a final exam aiming at a certificate for the successful participation enhance the gain the training has for the participants. The opportunity to choose themselves if they take an exam or not remains important.
- Employees working in tech-related industries possess a professional tech affinity and welcome the use of technologically advanced tools. This assured that the target group of this training would be able to engage easily with the online material. Nevertheless, offering tech support during the online phase is considered an inevitable requirement to ensure the desired level of flexibility regarding user experience.
- The value of human interaction is proven to positively influence the effectiveness of blended learning trainings [21]. The time allocated to the face-to-face session is highly valued by the participants and ought to be filled with activities which reinforce interaction and promote developing practical skills. Even small coffee breaks as the ones that were planned directly after the expert discussion with the subject matter experts are valuable, as participants expressed their appreciation for presenting examples and problems, which the experts faced in past and present projects. The participants in conjunction with this stated that the trustworthy atmosphere eliminated their hesitation of expressing and comparing themselves with other new employees. This confirmed their confidence and self-esteem in their professional expertise.
- Our experience confirmed the need for at least 22% of face-to-face session, but the blend between face-to-face and online modules depends on the training material and the availability of the participants [1]. The time allocated to the face-to-face session can differ according to the availability of the participants. One work day devoted to the face-to-face session was evaluated as adequate for this training but a second day devoted to extra practical exercises would be welcomed.
- The subject matter experts enhance the training’s outcome but have to align with the training’s goals. The communication between the subject matter experts and the trainer influences the atmosphere during the face-to-face session.
- According to the experience gained during the IDEA training’s implementation if the same level of knowledge is needed for a practical application, it is important to either require specific preparation from the participants prior to the face-to-face session or plan more time for introducing the learners to the subjects of the exercises. Problems deriving from the flexible conditions during the online phase depend on the content of the training and the target group. Answering a short questionnaire before attending the face-to-face session and stating the level of engagement with the online modules may offer insights to the trainer about the knowledge level of the participants taking part in the face-to-face session and if they have questions up to this point. The absence of such requirements for this training was purposely decided in

order to offer the maximum level of flexibility in engaging with the online modules.

- 40% of the participants explicitly stated that they preferred gathering their questions during the online phase and asking those in the face-to-face session rather than contacting the trainer during the online phase. Although different options of contacting the trainer and posting a question in the online platform of the training were available, they mentioned that they wanted to discuss their question(s) with the trainer in person during the face-to-face session. Planning a time slot during the face-to-face session for answering these questions is needed in any case. The trainer and/or the subject matter experts should expect questions during the face-to-face session that were gathered during the online phase or the practical applications. Although there could be a time slot for clarifying questions in the beginning of the face-to-face session, we suggest to plan, also, a closing open discussion, where participants can express any unsolved issue.

7 SUMMARY

This paper presented the lessons learned that derived evaluating the blended training according to the participants', subject matter experts', and trainer's perspectives. It outlined the gain for new employees entering the aerospace industry after participating in a joint training within the network. The benefits of the flexibility a blended training offers were confirmed while highlighting the necessary existing conditions during the online phase: clear structure, guidelines, self-assessment tools and tech support were mentioned as the most important. The face-to-face session has proven to be an absolutely essential part of a blended training due to the interactions among all associates. Successful interactions require communication between the trainer and the subject matter experts prior to the training and additional time for open discussion during the face-to-face session. The participants emphasized the positive effect of interacting with the subject matter experts and the trainer on their confidence and self-esteem. The ideal blend between online and face-to-face modules is not a universal fixed percentage because it highly depends on the training material and objectives. Conducting further research in professional blended trainings of different industries may enlighten the influence of such trainings on the employees' later performance.

ACKNOWLEDGEMENTS

The authors thank the participants of ASSET-2 and IDEA trainings and the subject matter experts that participated in the development of these trainings. This research was funded by the German Federal Ministry for Economic Affairs and Climate Action through the project IDEA.

ABSTRACT

Fonaments matemàtics is a required 1st year subject in engineering career at the university EPSEVG (*Universitat Politècnica de Catalunya*) with approximately 270 students enrolled each semestre that traditionally it had a medium pass rate.
Over the last 6 years we have introduced gradual changes in the teaching planning of it with the idea of achieving: 1) that students work throughout the course, 2) leveling knowledge and 3) reduce the number of students not presented to any exam. The changes have been implemented and corrected based on our feedback from students (engagement, grades, acceptance and survey assessments). The introduction of the calculator, laptops and tablets in everyday life and the use of the tools of the UPC virtual platform have been key.
In this contribution, we present the strategies used and the good results obtained.

1 INTRODUCTION

1.1 Background

The Universitat Politècnica de Catalunya (UPC) is a federated university that brings together 16 school centres, such as the *Escola Politècnica Superior d'Enginyeria de Vilanova i la Geltrú* (EPSVG) [1]. EPSEVG is a School Engineering centre since 1901, currently with 6 Bachelor's degrees in industrial and ICT engineering and about 1400 students. The paper focus on the analysis of a required subject of 1st semester (1st year) at the EPSEVG, called *Fonaments matemàtics* (hereafter FOMA) with about 260 students enrolled each year (in Setember). Specifically the study is done with the students of Bachelor's degree in: Industrial Design and Product Development Engineering, Mechanical Engineering, Industrial Electronics and Automatic Control Engineering, Electrical Engineering and Marine Sciences and Technologies. All students of different degrees are mixed and divided into 5 groups of about 52 students each group and the teaching involves between 3 and 5 teachers.
The type of student enrolled in this subject is heterogeneous in terms of knowledge of mathematics and in general with low cut-off marks. For example, in the academic year 2020-21, 1st semester of which the school already has a published report (see Table 1), 246 students were enrolled, the cut-off mark for entering university (moving in the interval [5,14]) was 5.4, ie the student's grade with the worst grade), of which 58% have a low grade, in the range [5,8) with respect to previous studies before university. In addition, the type of student is heterogeneous with respect to the knowledge of mathematics acquired: 17% of students come from 'higher degree training courses' (CFGS) and therefore have a very low level of mathematics while the remaining 83% have entered through the PAU tests. The university entrance exam (PAU) is a requirement for students with a high school diploma or equivalent to enter college.
In summary, traditionally FOMA had a low-medium pass rate (see Table 1).

Table 1. Enrolled students at FOMA subject (EPSEVG) each semester since 6 years ago and cut-off mark for entering EPSEVG.

Semester	Enrolled	Cut-off mark
	#	[5-14]
2016-17Q1	277	5,34
2017-18Q1	247	5
2018-19Q1	259	5,25
2019-20Q1	273	5,3
2020-21Q1	246	5,4
2021-22Q1	276	5,94

1.2 Contents and teaching planning

FOMA gives the student the first mathematical contents at the university: 1) calculus of one variable like differencial and basic integral calculus, 2) linear algebra with linear systems, vectorial spaces and basic linear aplications (with only diagonal matrix associated).

The distribution of classes throughout the course is: 2 sessions of 2 hours per week during the 15 weeks of the course. Although the Bologna plans are being implemented, and all subjects should be assessed continuously throughout the course, in practice it is very common for subjects to be assessed with only two exams: a mid-term partial examination and a final exam at the end of the course, proof of this is that EPSEVG has reserved two weeks exclusively for the partial and final exams, respectively.
In this article, when we refer to continuous assessment, we mean all the acts we do throughout the course, in addition to the partial and final exams.

The coordinator of FOMA for 6 years, since 2016-17 academic year, in its beginning focused on placing teaching in the context of engineering adding to the traditional CV the learning of errors and numerical methods, as well as the use of calculators and the computer in the day to day - with the use of Matlab / Octave or Geogebra software - as complementary work tools.
Over the years, there have been several mathematics teachers who have helped at some point in this process of change - all of them highly qualified with a teaching career of no less than 20 years.
During the covid-19 period the teaching was completely online and we designed Moodle activities for the students. In the last two years, we have taken advantage of it and increased the online activities of the continuous assessment.
In this paper we show the academic planning of FOMA and the academic results.

2 METHODOLOGY

To compensate for the lack of homogeneity in mathematical knowledge and in general the low rate of the students (see section 1.2), the teachers involved continosly try different strategies. In general teachers try
- to avoid bad academic results,
- to reduce the number of students not presented to any exam,
- to promote that students work throughout the course,
- to level mathematical knowledge.

Specifically over the last 6 years we have introduced gradual changes in the teaching planning of it with the idea of achieving it.
The changes have been implemented and corrected based on our feedback from students (engagement, grades, acceptance and survey assessments). The introduction of the calculator, laptops and tablets in everyday life and the use of the (Moodle) tools of the UPC virtual platform have been key.

2.1 Continuous evaluable activity

Table 2 shows, across the years, the evolution of the design of the continuous evaluable activity, number of activities and weight.
The table does not show the self-learning activities in the virtual classroom that were prepared from the beginning so that they would be leveled in Derivatives and Integrals, these activities were very well received and are introduced in all courses somehow. These are Moodle quizzes with Wiris [4] which can be done as many times as you want, and the solution always comes out. Wiris math calculator is integrated in the UPC Moodle platform and allows you to define quizzes with random parameters / constants, and mathematical tools. This is the strategy we propose to level knowledge.

Table 2. Design of the continuous evaluable activity at FOMA subject (EPSEVG) each semester during 6 years.

Semester	**Weight**	**Hand exercises per student**		**Moodle activity per student**		**PC activities per student**	
	%	%	#	%	#	%	#
2016-17Q1	25	-	-	-	-	25	2
2017-18Q1	40	-	-	-	-	40	2
2018-19Q1	40	-	-	-	-	40	2
2019-20Q1	40	-	-	5	1	35	2
2020-21Q1	50	-	-	10	2	30	2
2021-22Q1	40	5	2	20	10	15	1

Table Moodle activities are Wiris-type quizzes where questions are taken at random from a question bag. The questionnaires are individual, lasting 1h, distributed throughout the course to do at home, from Friday to Monday, with between 3 and 5 attempts, each time a quizze of the same type but different qüestions. The grade obtained is the maximum of the attempts grades. We propose this strategy to make the student work continuously and do not leave the subject.
The PC activities consists of doing an individualized project at home during 5 days, in pairs or individually, with the computer and the use of Matlab / Octave and Geogebra. This is performed in order to develop the students skills in applied mathematics and allow the mobile / tablets, calculators or laptop to form part of the learning process of the subject and not just tools for personal use. The hand exercises are individual, performed in class, previously notified, with notes and calculator and under the supervision of the teacher. The aim is to prepare for specific problems of interest to the subject that may arise in the exams. Finally, all these strategies were implemented together in the continuated activity of last semester 2021-22.

3 RESULTS

3.1 Continuated academic results

We find the relevant academic results during last semester 2021-22, and that can be compared somehow to 2019-20 one, when begun the use of the Moodle tools of the Virtual Platform, in form of quizzes (see Table 3). The more deliverables you order, the more they make. Especially important is that when we increase the number of quizzes, and therefore make them follow in time, the percentage of students who do not do any activity drops from 9 to 3. And total deliveries move to 668 to 6657. Also relevant that deliveries per enrolled student increase from 2.6 to 25. Last setember, an student that followed the course sent an average of 29 activities.

Table 3. Continuated academic results and survey satisfaction at FOMA subject (EPSEVG) each semester during last 2 years, except the covid-19 semester.

Semester	**Total deliveries**	**Deriveries per student rated**	**Deliveries per student**	**Students without any delivery**
	#	#	#	%
2019-20Q1	698	2,81	2,56	9,2
2021-22Q1	6657	28,8	25,0	2,9

3.2 Continuated academic results of 2021-22Q1 semester

The engagement of 276 students is shown in figures 1 where for each activity (quizzes) it is plotted: the number of deliveries (between 3 to 5 attempts of each quiz), the averaged grade (the grade is the maximum of all attempst) and the percentage of students that deliver it. Last deliver (no 10) was two days before Christmas.

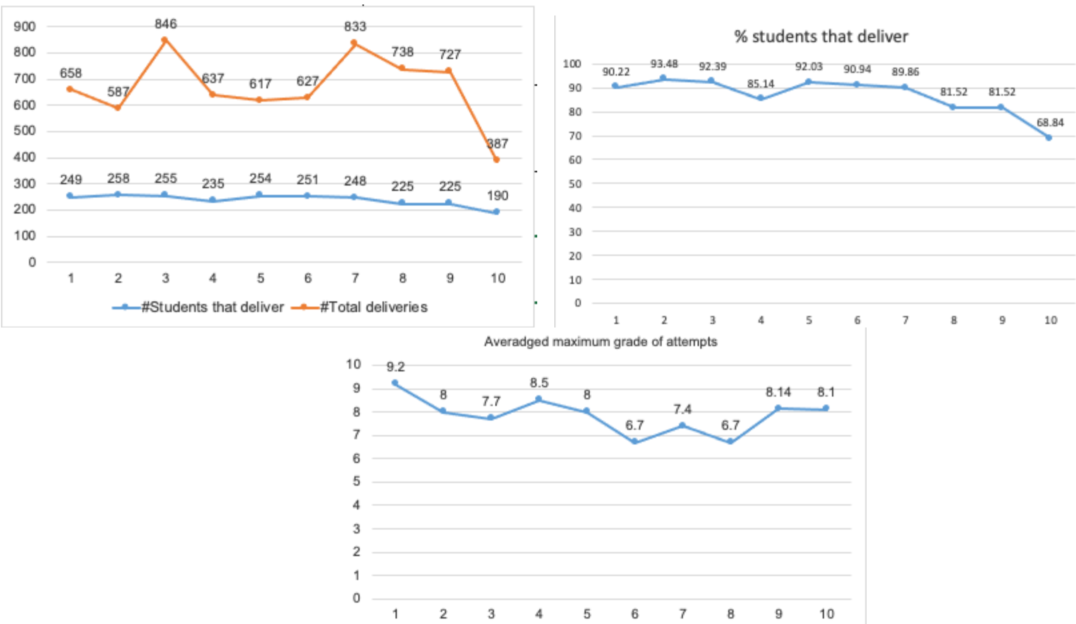

Figure 1. Continuated assessment results in 2021-22Q1 semester for each (approximately) weekly deliver at the x axis (time line).

3.3 Academic results

The objective data for measuring the results can be found in Table 4. Table shows information of final grades of students every semester since 6 years ago,:
-the average final grade (measured from 0 to 10), calculated with respect all enrolled students,
- the percentage of not presented students to any evaluative act, the approved students with a grade greater or equal 5 and finally the excellent grades.

Table 4. Global academic results and survey satisfaction at FOMA subject (EPSEVG) each semester during 6 years. NP=not presented, A=Aproved (≥5), E=Excellent (≥9)

Semester	Average grade	NP	A	E	Student survey	Rating survey
	(0-10)	%	%	%	%	(1-5)
2016-17Q1	4.6	10,11	54,2	6,86	27	3,8
2017-18Q1	3.8	7,69	44,9	1,62	37	3,1
2018-19Q1	4,6	9,30	55,2	1,50	27	3,2
2019-20Q1	4,6	6,96	61,17	0,73	24	3.1
2020-21Q1	-	5,28	82,93	13,82	-	-
2021-22Q1	5	4,70	59,00	2,50	11	4.2

Firstly observe that the grades of covid-19 period (2020-21Q1) are out of context, as the teaching was completely online and all the evaluative acts were performed at home, with quizzes and without any physical control of teachers. Eventhough the

grades are overdimensioned, a value to keep in mind is the small value of 5.3% of not presented students, compared with the 10% we had at 2016-17. At that time the students were confined at home every day; that value probably approaches the minimum possible of non presented. It is gratifying to see that we have even improved this value in the last semester to a 4.7% of non presented.
We also observe that the total average grade increases to 5 at last semester, and we reach a 59% of approved with 2.5% of excellent results. Although it has been passed with higher average grade, in return it has been more difficult for students to obtain maximum marks, above 9.5.

Table 4 also shows the survey results from students:
- Percentage student that perform the survey.
- Rating survey, from 1 to 5, agreement to the question: 'Overall I am satisfied with this subject'. In the context of the EPSEVG school, the answer of this question is 3.6 in mean value of all subjects.

Again last semester, FOMA has the best ratings, compared with other semesters, improving the average school result. It is right that there is a low percentage of students who take the survey, but experience tells us that when there are few students who take the survey, they are the ones who are dissatisfied with the subject.
The personal perception and the feedback received from the students and comments to the surveys tell us that they don't like, or find it difficult, to run the Matlab / Octave programs, anyway they still gain skills in their applied use, as we have seen when students have to use it in other subjects of higher semesters.
The other perception of all the teachers of the subject is regarding the last semester, taken from the comments of the students in class, in all the groups, it is that: it has gone very well and the students liked to have the questionnaires every weekend for practice, even stated this in the survey comments.
Finally, the downside is that it has taken a lot of work for the teachers involved to prepare the material and follow up, that includes preparing and activating quizzes, correcting problems, projects and exams.

ABSTRACT

Global competence is an essential attribute for engineering graduates working in an interconnected and culturally diverse world, and higher engineering education needs to adapt to ensure that their students will acquire it before entering the labor market. For universities, the only way to ensure comprehensive global competence learning for all students is the holistic integration of related learning outcomes throughout curricula – which requires engineering educators to be able to (re)design their courses and programs accordingly. Considering that most engineering educators are subject experts of their discipline – but lay people when it comes to such competencies – we set out to compile a practical guideline for those wanting to integrate global competence learning within their disciplinary courses.

Following a participatory action research approach, we connected our own insights as global competence educators at a technical university with those of several cohorts of engineering educators and students enrolled in global competence courses. Synthesizing these insights, we could identify four essential lessons for integrated global competence learning: 1) learning opportunities can be found (nearly) everywhere, 2) relevance and authenticity must be emphasized, 3) theory and practice need to be integrated and 4) global competence cannot be taught, but it can be learnt. These lessons are illustrated with practical examples for fostering global competence learning in regular engineering courses.

1 INTRODUCTION

Professional demands on engineers are evolving, and global competence has recently emerged as a key factor for ensuring that graduates can succeed in our interconnected and culturally diverse world. Following calls from industry to instill global competence – described typically as the knowledge, skills, and attitudes needed to collaborate with diverse others appropriately and effectively (e.g., [1]) – numerous institutions have begun efforts to introduce such learning into their curricula. While the exact competencies constituting global competence are still under debate, several authors have attempted to identify those relevant to engineering contexts. Some of the most frequently quoted and used conceptualizations are those developed by Downey and colleagues [2], Lohmann and colleagues [3], and Ball and colleagues [4]. While their ideas of competencies differ slightly, e.g., in how individual aspects are named, they all appear to revolve around the same dimensions: intercultural communication skills, openness and appreciation for others' perspectives, teamwork and leadership skills, adaptability to living and working in different contexts, as well as global awareness, and an understanding of how culture may affect engineering work.

Despite an increased attention to global competence learning in technical curricula, scholars still emphasize that engineering education needs to catch up to equip graduates with those practical competencies so demanded in industry [5, 6]. There is no denying that technical expertise constitutes the basis for engineering students' future employment, but for the time being, global competence is what will make graduates stand out among their highly-trained competitors on the global labor market [7]. For universities, well-known approaches thought to enable such learning are international mobility experiences such as studies, internships, service learning, or research abroad, or in some cases specific courses or modules on the issue. However, as typically only a small minority of students take advantage of such offers, and considering the need to foster global competence in *all* students, calls for more comprehensive global competence strategies have been made [8-10]. Key agents to achieve this goal are engineering educators who sensibly design their courses for integrated disciplinary and global competence learning.

This is, however, easier said than done; global competence learning is different from much other engineering learning, and any attempt to comprehensively integrate it with disciplinary technical contents requires careful consideration. A recent study by Passow and Passow [11] identified three principles for such curriculum design in engineering: 1) engineering practice extends beyond science-based tasks to both technical and social tasks critical to project success, 2) non-technical skills should be taught in context rather than in isolation, and 3) engineering education should display a greater connection to practice including authentic problem-solving, iteration, working towards a bigger picture, and realistic social dimensions (p. 501). Their work clearly shows how the traditional differentiation between hard and soft skills is outdated and an integrative approach to teaching competencies in context is needed. Considering that those aspects are interconnected in the professional world, such an approach should certainly be of interest for engineering teachers, as they are responsible to prepare their students for their future life as professionals.

However, with engineering educators themselves often being educated in a hard-science teacher-focused tradition, rather than an integrative student-focused pedagogy, these ideas of global competence learning may appear foreign, and can be perceived of as potentially troublesome ad-ons rather than as easily integrated aspects that ought to be part of their discipline. Additionally, considering the vagueness of the concept, its complex and multifaceted nature, and the fact that global competence goes beyond knowledge and also comprises attitudes and skills [12] educators wanting to practically work with it are faced with a daunting task.

Looking more closely at specific classroom environments that could support global competence learning, Mullins and Wood [13] suggested that lessons should be student-centered, authentic, contain continuous feedback, and provide students with clear expectations and opportunities to be in charge of their learning. Other important factors were pointed out by Atadero and colleagues [14], who proposed that academic activities fostering appreciation of diversity in engineering should be explicit in their intent while relevant to engineering, have a longer-term focus for sustained engagement with such issues, and measure the students' perceived links between engineering and diversity. While these suggestions provide useful contributions for global competence learning in engineering classrooms, they may still be too vague for non-experts, such as engineering educators, to practically implement

This paper aims to illustrate practically applicable guidelines for global competence education including crucial questions that educators need to reflect on when wanting to integrate global competence learning. Based on our own background as global competence educators and the practical insights and experiences from engineering educators and students at our home institution, this paper synthesizes insights from theory and practice and presents key lessons for the successful introduction of global competence learning within disciplinary engineering courses.

2 METHODOLOGY

We followed a participatory action-based research approach, which is characterized by the collaborative co-creation of knowledge with stakeholders to solve practical problems [15].This approach connects theory with practice and reflection, and, in our specific case, combined our own insights and experiences as global competence educators with those from engineering educators and students as stakeholders and experts of their discipline and classroom settings. Accordingly, we collected and synthesized both insights and best practices from literature with discussions and reflections of several cohorts of engineering educators and students enrolled in elective global competence courses at a large Swedish engineering university. This helped us in connecting the rather general insights from internationalization literature with the real-life contexts of engineering education. The result of our efforts is a practical and broadly applicable set of guidelines for integrative global competence learning in regular disciplinary engineering classes.

3 RESULTS AND DISCUSSION

Finding ways to instill global competence in students is already a challenging endeavor, but finding ways to ensure that engineering educators – whose teaching expertise lies in the technical rather than the social realms – can do that is on a whole different level. To support this process, we have connected theoretical and practical insights to create the four most essential lessons learnt for those wanting to foster global competence learning in their students: 1) learning opportunities can be found (nearly) everywhere, 2) relevance and authenticity must be emphasized, 3) theory and practice need to be integrated, and 4) global competence cannot be taught, but it can be learnt. In the following, we will elaborate on those four lessons and provide examples of how they can support the practical implementation of global competence learning within a wide range of disciplinary engineering classes.

3.1 Learning opportunities can be found (nearly) everywhere

The first lesson to be learnt – something that may otherwise be a perceived obstacle for engineering educators – is the fact that global competence learning might happen nearly everywhere. When thinking of global competence learning opportunities, many might first think of the classics: studies, internships, or field trips abroad or potentially even specific courses for students. While those certainly are great learning opportunities, they are not the only ones, and may in many cases only reach a small subset of students. A common misconception of many engineering educators and students is the idea that global competence just does not fit to, or into, specific engineering courses, particularly when it comes to highly logic- or science-based courses. However, we would like to introduce Kahn and Agnew's [16] poignant conclusion that "[n]ot all coursework needs to include global learning outcomes, but it is increasingly understood that all courses can be internationalized, including the hard sciences" (p. 58). When looking more closely at certain typical global competence learning outcomes, it becomes clear that even highly logic-based or technical courses provide opportunities for developing at least some competencies. To illustrate this better, we will take a deeper look at popular global competence learning outcomes, such as intercultural communications skills, openness and appreciation for others' perspectives, team-working and leadership skills, adaptability for living and working in different contexts, as well as global awareness and an understanding of how culture may affect engineering work.

Most of these competencies can be directly practiced through collaborations with diverse others, prime examples for such would be intercultural collaborations with other student groups (in person or virtually), as well as collaborations with industry partners or other stakeholders of engineering work, which is the focus of several service learning courses. Such learning opportunities bring students together with others from diverse backgrounds (e.g., national/regional, university, discipline) and introduce them to different perspectives, and in some cases even allow glimpses into different professional context, with their own rules and standards. For all these reasons, it is no surprise that such activities are often first thought of when it comes to integrative global competence learning. While invaluable chances for competence development, it must be considered that setting up courses including such activities involves much planning and resources, and the majority of these examples is only feasible for some courses and not others. The Covid-19 pandemic has proven that many courses could move to the virtual sphere, which in some cases attracted more external course participation – which would be very advantageous for especially those courses that otherwise would not allow much interaction with external actors.

Relatedly, another obvious learning opportunity potentially touching several of the social or interaction-focused competencies are cooperative learning, or group exercises, where diverse students will have to collaborate on problems together. Here it is important to note that in their everyday usage at engineering universities, some of the concepts we talk about are easily misunderstood or overgeneralized: *culture* may be interpreted as "people from different countries," and *diversity* may be equated with "people of different genders" or in some cases "people of different abilities." It should be clear that such isolated factors are not the sole defining aspects making up a person's perspective, and when global competence scholars talk about culture or diversity, they typically refer to a wide variety of factors potentially affecting one's viewpoint, including the aforementioned aspects, but also ethnicity, religion, education, discipline, professional background, and many others. Following this line of thought, it is easy to see that all classrooms – even those consisting of students having similar nationality, gender, or abilities, can be inherently diverse.

During discussions and the exercises themselves, students will have the chance to practice communication, teamwork skills, and conflict management, and they are likely introduced to diverse perspectives. By mixing student teams, and ensuring they interact with diverse others, a first step for global competence learning can be laid. Considering that the majority of engineering subjects allow for group exercises of some type, they are an easily implemented and non-disruptive addition to many courses. The engineering educators we talked with had at minimum small in-class group assignments or discussions, and several had students collaborate in labs or longer projects. They generally acknowledged the value of bringing students with different values, backgrounds and skills together to work on common problems, both for the potential for new perspectives and more creativity, and believing that working with others will prepare the students better for their professional life. This was, however, not always unproblematic, and conflict within groups was something both the educators and students were familiar with. A particular issue repeatedly highlighted was certain team members' lack of contributions, which the students found particularly frustrating when such behavior affected grades. Educators, aware of such conflicts, had different approaches to deal with this: some allowed students to choose their own groups in order to reduce conflict potential, others implemented group work reflection exercises to find out whether they should intervene, and others believed that students should learn to navigate such situations by themselves since they will have to do that later in their jobs.

For especially the knowledge-based competencies, a fruitful way to introduce new perspectives and widen students' horizons is by careful selection of course materials – for one, course readings or case studies could be chosen to represent the perspectives from authors from around the world. Additional discussions on how engineering is done differently around the world, examples could be the introduction of different engineering cultures and, if applicable, professional standards and regulations. The mutual interaction between historic, socio-cultural, or economic aspects and developments of the field may also be easily integrated in a variety of different subjects. For almost all disciplines, the history of how the field developed – and where it may be headed – may also comprise relevant knowledge and support a deeper understanding of the subject. If planned carefully, also insights into historical or societal contexts affecting the field could be incorporated in this regard. Another very contemporary approach could be in illustrating the potential connections of the basic science concepts of the field and local, international, or global challenges [16].

3.2 Relevance and authenticity must be emphasized

The second lesson for integrative global competence learning revolves around its perceived relevance and authenticity. The importance of global competence for professional practice has been acknowledged by universities, but the longstanding approach to solving that – the classic distinction between hard and soft skills – is now recognized as outdated, as it both differentiates between aspects that are connected in practice, and wrongly implies little diligence or depth to the "soft" aspects of the profession [7]. From a linguistic perspective, competence notions on the other hand may appear more pertinent to engineering education, but that should not distract from the fact that students, who may have a certain image of engineers as pure technologists in mind, may not immediately recognize their importance.

To ensure students recognize the value of such learning and develop the necessary motivation to hone their competencies, it is imperative that their disciplinary of professional relevance is *explicitly* clarified by the educator [10]. Many of the educators we spoke to had clear ideas and motivations behind the assignments they gave to students, particularly in terms of communication and collaboration, but did often assume the students' understanding of these benefits rather than being explicit about these goals. Moreover, if global competence learning is to be integrated with regular disciplinary learning, an additional factor to consider is authenticity. An effortless way to achieve authenticity is to let students work with real-world cases or issues, or let them relate what they are learning with potential areas of application. Showing students the potential and importance of course contents for real life contexts is not only great for motivation, but also enables them to look at the bigger picture and work on their systematic thinking skills. Regardless of whether students have to analyze or work themselves on case studies, they can provide wonderful examples for good – or problematic – implementations. By actively reflecting on the processes or decisions leading to final outcomes, they are a great opportunity for working on critical reasoning skills. Similar to case studies are also critical incidents, potential real life situations characterized by misunderstandings or conflicts, which can be used for reflections and discussions on how such situations could be handled appropriately.

Another simple way to convey relevance and create authenticity, while simultaneously offering the students another perspective, is the invitation of guest speakers. Depending on what makes sense regarding course contents, these may be researchers or experts from industry or other institutions for rather theoretical subjects, or industry partners, stakeholders, or alumni for the more practical subjects. The topics these guest speakers address may even be subject for later follow-up assignments or exercises. The educators we spoke to that did incorporate some kind of industry partners did typically have guest speakers, primarily for motivational purposes, or used their connections to provide case studies for the students to work on, the output of which would later be presented to the industry partners. In some cases, industry partners also took up supervisory or mentor roles. However, it was also pointed out that forming and maintaining relationships with such external partners was very time-consuming for the educators.

An approach we took in our own global competence course for students was to have themselves identify, approach, and then interview a person that could function as a mentor for them. While something like this might not be a common assignment within engineering subjects, it gave students a chance to reflect on their future professions and what type of person could function as mentor, to get out of their comfort zone, gain relevant insights into questions they had about professional life, and at the same time network and form connections for their future.

3.3 Theory and practice need to be integrated

The third lesson is that theory is a good starting point for much learning, but students should also have the opportunity to practice what they are learning. While hearing that certain competencies are invaluable in professional settings can be useful, experiencing their merit firsthand is even better. Related to this is experiential learning theory, originally proposed by Kolb [17], which rests on the idea that “learning is a continuous process grounded in experience” (p. 27). With the undeniable advantages of integrative learning through experiences, it is not surprising that also the CDIO guidelines for engineering education [18] are strongly informed by such an approach. By actively applying their knowledge, small issues that may otherwise be undetected come to the forefront, and the students are eased into using a holistic perspective to make theory work. The approach of having students apply their theoretical knowledge to projects was very common amongst the educators we spoke to. Only one of them, teaching a very fundamental theoretical science course, emphasized difficulty doing this due to their course contents being based on theoretical models with “little direct connection to application.” After reflecting on the issue and the feedback of other educators taking the global competence course with them, this educator did however propose emphasizing links to sustainability, i.e., how concepts could be used to solve problems, in order to show students potential areas for practical application.

A special tip related to competence learning is to also balance discomfort with support – students should have a chance to break out of their comfort zone, but at the same time do so in a safe environment where they can try, fail, and learn from failure. In the real world, mistakes can have costly consequences, but the engineering classroom can be a safe space to learn from trial and error. As a matter of fact, it has been pointed out that mistakes may be very valuable for learning [19] – assuming that they are properly introduced as a learning experience rather than a failure. This experiential approach does not necessarily mean students really have to go out of the classroom and practice engineering – several of the examples mentioned before, such as case studies, roleplays, or critical incidents – may function well for gaining such experience. They even have the advantage that they can be specifically targeted at common or extremely challenging situations that can be used as learning experiences. As soon as practice is involved, peer or teacher feedback or self-reflections can be used to revisit the learning experience and potentially gain an even deeper understanding of the subject. However, as stated earlier, it is crucial for the students to understand this reasoning in order for the exercises to fulfill their full potential. Many of the students we talked to saw their grades as important for getting a good job, hence the frustration with team colleagues potentially dragging their grades down. In an attempt at self-serving comradery, they might also for this reason be tempted to be overly positive when giving each other feedback in front of the teacher, which both runs counter to the idea behind the exercises and can easily be interpreted by the teacher as a lack of critical thinking.

3.4 Global competence cannot be taught, but it can be learnt

Our final lesson is that global competence cannot be taught, but that it can be learnt. Becoming globally competent is a lifelong, continuous process, which requires the learner to actively hone their competencies. A simple course, yet alone one only seeing competency development as additional informal learning outcome, will hardly be able to lead to globally competent students. It can, however, create the basic knowledge, skills, and attitudes – and the motivation – needed for students to continue the path to become globally competent individuals. The prior points have already hinted at the fact that the student – and not the teacher – should be the focus of such activities. Indeed, in creating globally competent students, educators should act as facilitators supporting their students – they can show them the basics, but the students have to do the work themselves. In a similar regard it is also important to view the educators as learners themselves. Every engagement with diverse perspectives can support them in becoming more globally competent educators, which in turn allows them to create more globally competent students.

4 SUMMARY

Addressing the great industry demand for globally competent engineers, universities have begun to look for ways to foster those competencies in their students, and the engineering educator is an essential key player in those efforts. With global competencies appearing foreign to traditional hard science teaching, there is always a risk of institutional efforts meeting hesitation or resistance from educators feeling top-down pressures to having to redesign their well-tried courses without seeing additional value in doing so. Connecting the insights from our own background as global competence educators with those of engineering educators and students, we have shown that technical and global competence can easily be integrated in a way that also mirrors professional practice without putting much additional strain on educators. We identified four key lessons for the integration of global competence in engineering courses; these related to the identification of vast opportunities for global competence development, the importance of emphasizing relevance and authenticity, the integration of theory and practice, and the fact that any approaches to global competence learning need to be centered around the learner. The latter lessons show obvious overlaps with what can be seen as good pedagogical practice in general, which also highlights how a good educator should – given the right training and support – be able to effortlessly tweak their course contents to increase the potential for global competence development. While our lessons are a first starting point for those educators wanting to do so, the institutional support given them for such endeavors – both in the provision of relevant training opportunities as well as encouragement and other incentives for redesigning their courses for additional global competence learning – will be the deciding factor to whether a *comprehensive* institutional approach to global competence development can have the desired effects.

5 ACKNOWLEDGMENTS

We would like to thank our colleagues and students who contributed their ideas and insights to this study.

ABSTRACT

The importance of integrating the Sustainable Development Goals (SDG) in the curriculum of all the bachelor and master degrees at UPC has been legally and institutionally recognised. At the Barcelona School of Civil Engineering, issues such as professional ethics, environmental impacts of infrastructures, respect for cultural diversity and gender perspective are currently cross-cutting competences highlighted and stated in the study plans as a transversal competence on Sustainability and Social Commitment (S&SC). However, its effective implementation requires significant teaching efforts in order to adapt academic curricula, so far limited to individual non-coordinated initiatives.

The launch of the “ODS-Camins Toolkit” project (Toolkit for the Promotion of SDG in the Civil and Environmental Engineering Fields) seeks to encourage the implementation of teaching innovation practices that contribute to the deployment and assessment of S&CS competences. The aim of the project is to exchange experiences, develop new practices, and draft a common pathway for the promotion and implementation of the SDGs in the field of civil and environmental engineering studies.
The paper will explain the experience of this one-year project, highlighting barriers, challenges, and sharing the lessons learned with the final purpose of involving all the community in the years to come. It will also present the Toolkit for the Promotion of SDGs in the Civil and Environmental Engineering Fields

1 INTRODUCTION

Education for Sustainable Development (ESD) facilitates the acquisition of knowledge, skills, attitudes and values needed to forge a sustainable future. It seeks to provide students with professional and personal abilities necessary to work and live in a way that protects environmental, social and economic well-being, for present and future generations. Applying ESD principles to engineering education involves working under an integrated approach, incorporating social and humanities disciplines, encouraging work in multidisciplinary teams, stimulating creativity and critical thinking, and promoting self-learning.

In Higher Education, the pathway to integrate the Sustainable Development Goals (SDGs) in the curriculum has started through a legal recognition that pushes towards this direction. Specifically, in the fields of civil and environmental engineering, issues such as professional ethics, environmental impacts of infrastructures, respect for cultural diversity and gender perspective are currently cross-cutting competencies included in the study plans as a transversal competence on Sustainability and Social Commitment (S&SC). However, its effective implementation requires significant teaching efforts in order to adapt academic curricula. This is not always easy, due to a lack of recognition by academic institutions.

At the Barcelona School of Civil Engineering (BSCE), several projects have recently been carried out on this topic. So far, these were individual initiatives with a certain degree of internal coordination but with low institutional leadership. These previous experiences, the recent legal enforcement and new institutional priorities have led to a change, and facilitated the launch of several initiatives promoted at different UPC levels. On the one hand, a bottom-up initiative called ODS-Camins Toolkit led by the Barcelona School of Civil Engineering, which aims at producing accessible educational resources to help lecturers integrate sustainability in their courses. On the other hand, UPC at higher institutional levels is leading a pilot initiative to guide and give support to different UPC schools on this endeavour. These coordinated actions aim at assessing the current situation and foster a planned deployment of the integration of S&CS competences in the context of the civil and environmental engineering studies.

Conceptually, this experience feeds from the on-going research projects Edinsost I & II [1,2,3] which have created the Engineering Sustainability Map (ESM), a tool that contains the ESD-related learning outcomes that any engineering graduate should have acquired upon completion of the studies.

There are previous academic research works [4] and institutional contributions [5] that identify and describes competences that engineers should acquire to deal with SDG challenges. However, in this paper the classification used is that recommended by the Working Group of the Sectorial Commission CRUE-Sustainability (Conference of Rectors of Spanish Universities) which should be integrated in the curricula of all Spanish university degrees. It stablishes four sustainability competencies units:

- CU1: Critical contextualization of knowledge establishing interrelationships with social, economic and environmental issues, local and/or global."
- C2- Ho: Holistic. Identification and analysis the environmental, social and economic impact of their professional activity and to propose, design, organize and carry out sustainable actions.
- C2-En: Environmental: Identification and analysis the environmental impact of their professional activity and to propose sustainable solutions."
- CU2- So: Social. Identification and analysis the social impact of their professional activity and to propose sustainable solutions."
- CU2- Ec: Economic. Ability to manage material, economic and human resources of projects in their professional field, in order to ensure the economic viability while taking into account the sustainability.
- CU3: Participation in community processes that promote sustainability.
- CU4: Application of ethical principles related to the values of sustainability to personal and professional behaviours.

The objective of this paper is to assess to what extent the ESM is fulfilled in the curriculum of Bachelor Degrees at the Barcelona School of Civil Engineering and discuss strategies to improve the level of integration of S&SC competences. This is embedded in a wider project called Toolkit-ODS Camins with the goal of creating an engaged "Civil and Environmental Engineering community" with a high commitment with SDGs.

2 METHODOLOGY

The following coordinated tools and activities have been implemented in order to achieve our objectives. Firstly, the ESM was shared among a group of lecturers to identify and assess their learning outcomes, competencies and SDGs integrated in a representative set of courses.

Then, based on this previous experience, an on-line survey adapted from [1] was addressed to all teaching staff to gather information on the SDGs addressed, methodologies used and learning outcomes and competences present in each of the Bachelor Degree in Civil Engineering courses. The survey included a table with the learning outcomes and competences and the teachers addressed were asked to recognise which were the 5 top ones addressed in their course. A total amount of 40 responses were collected, representing almost 50% of the courses. Based on this initial assessment and together with all involved parties (coordinators, lecturers, students) learning strategies will be suggested and planned to embed all the SDGs in the curriculum

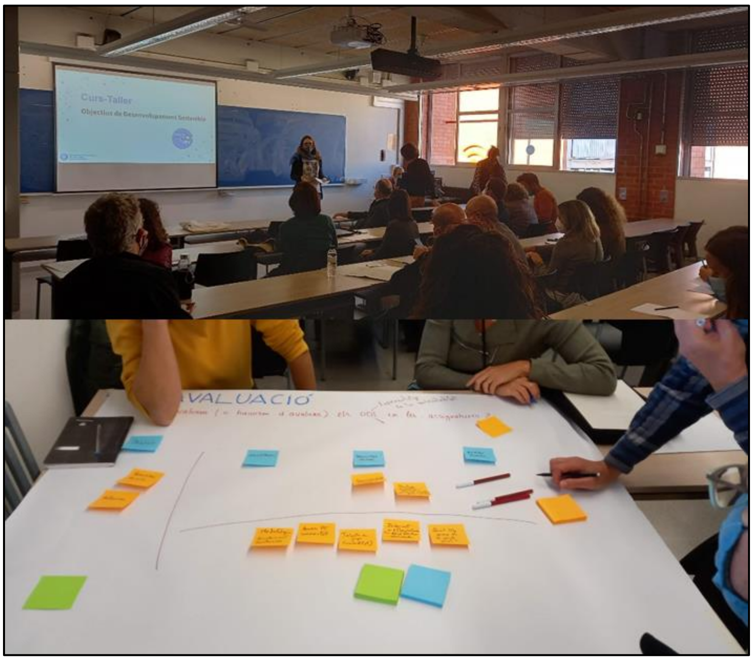

Fig. 1 Images of the workshop held in November 2021.

Finally, parallel activities to promote community involvement were undertaken such as workshops, meetings and a video recording. For instance, the workshop “Team building for SDGs engagement in the Civil and Environmental Engineering Field” was held in November 2021 (Fig. 1). More than 40 participants were informed on the institutional strategies and projects to embed SDGs in the curricula, and invited to discuss teaching and learning activities, their main barriers, challenges and needs. Moreover, a course on “Inclusive non-sexist language in teaching and research” was organized in March 2022, to address the SDG 5 on Gender Equality

3 RESULTS

Data from the surveys helped assessing to which extent the SDGs and sustainability competences are addressed in different courses of the Bachelor Degree in Civil Engineering.

Figure 2 shows how this Bachelor currently involves more than half of the SDGs. This is in line with the institutional goal of getting students to know the SDGs and their importance for society. It can be observed how the SDGs related to infrastructures, water, cities, climate and production, are among the most studied, while those related to education, inequalities, peace, hunger and poverty are barely introduced. The reason for this is the curriculum of the very same Bachelor, where socio-political competencies are barely included as learning outcomes.

The analysis has also shown that lecturers have been introducing the SDGs by their own, as individual actions lacking institutional support and funding. However, an institutional change is currently taking place both at the Barcelona School of Civil Engineering and UPC, who have fostered a coordinated strategy to integrate sustainability competences in the curricula.

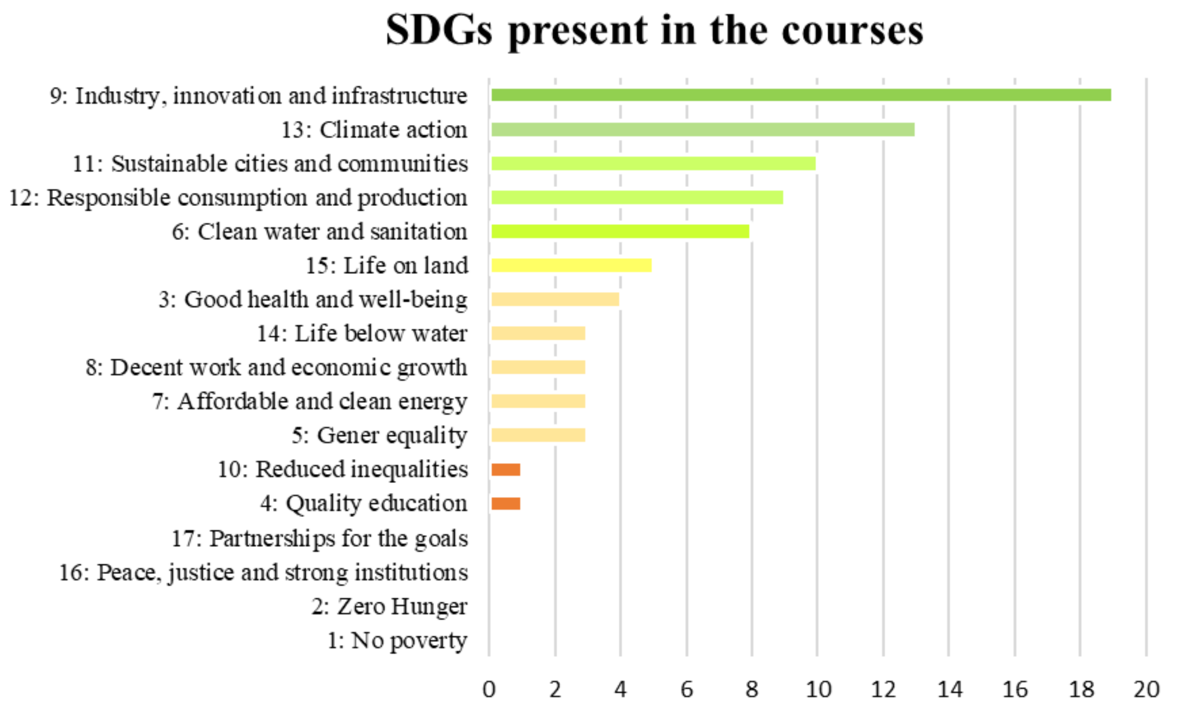

Fig 2. Number of courses that deals with each SDG in the Bachelor Degree in Civil Engineering.

A more detailed analysis on the four sustainability competence units (Figure 3) shows how they are deployed to a different extent. The graph divides the holistic unit (C2), in which the student achieves the capacity to prevent negative impacts, into four dimensions: holistic, environmental, social and economic. Competences related to the sustainable use of natural resources (C2) and critical contextualization (C1), which are the most closely related to technical aspects of civil engineering, are developed to a higher extent in the courses. Among them, social and economic aspects seem to be beyond the scope of many courses, as they are less present. However, civil engineers are responsible for planning, constructing and managing infrastructures that should be aimed at improving human well-being.

Competences dealing with C3 are placed in a medium position, meaning that the participation in community processes that promote sustainability seems to be reasonably accounted for. However, effort should be made to encourage transforming teaching-learning processes and include active methodologies and service-learning. The students will be better prepared to face complex problems if they learn how to collaborate and understand the local context and society.

Finally, the Bachelor Degree in Civil Engineering appears to invest more time at teaching negative impact assessment than addressing ethical aspects, as shown by the poor presence of C4 competence. Lecturers should discuss the risks, uncertainties and ethical implications that their future projects or professional activities will eventually have.

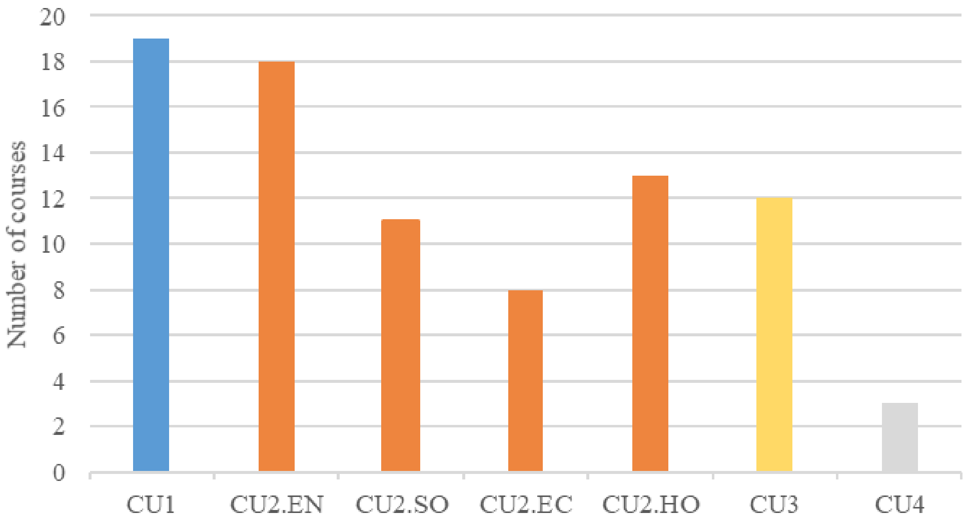

Fig 3. Presence of each competence unit at the Bachelor Degree in Civil Engineering.

Once the SME was completed, lecturers participating in the innovation project Toolkit-ODS Camins were encouraged to prepare a teaching activity to introduce the SDSGs in the curriculum. To this end, they were provided with a template and asked to fill in information on their activity, such as the SDG addressed and sustainability competences level acquired by the students.

These activities were included in the web site “Toolkit-ODS Camins”, which proposes a pathway to implement the SDGs in 4 steps:

1) Get familiar
2) Evaluate yourself
3) Prepare your own activity
4) More info

It shows a simple, straightforward way to learn and implement the SDGs in our courses. The web site will be launched soon, along with a promotional video.

4 CONCLUSIONS

The aim of this paper is to explain to which extent sustainability is present at the Bachelor Degree in Civil Engineering of the Barcelona School of Civil Engineering (UPC). It has been shown how competences dealing with C1 and C2 are present to a higher extent than C3 and particularly C4, which is still missing. These results are consistent with previous analyses of other Bachelor Degrees in Engineering at UPC.

However, some limitations should be considered. The assessment of the sustainability "presence" is based on the information provided by the lecturers' self-assessment. Considering the qualitative dimension and open-to-interpretation nature of some concepts, an external validation would be required. Thus, a more in-depth analysis should be done, and feedback from students ought to be included to increase the robustness of the results.

This initiative also seeks to encourage the implementation of teaching innovation practices that contribute to the deployment and assessment of S&CS competences and evaluate their learning outcomes. The aim of the project was to exchange experiences, develop new practices, share and disseminate them, learn and draw a common pathway for the promotion of the SDGs in the field of Civil and Environmental Engineering. For this reason, the results of the project will be disseminated in a video and web called Toolkit-ODS Camins, that will be used as guideline to integrate S&CS in other courses.

5 ACKNOWLEDGMENTS

The Toolkit-ODS Camins project has been funded by the UPC Call for Teaching Innovation Projects 2021.

ABSTRACT

We have implemented a methodology for using short videos as a part of a flipped classroom design in an introductory, multi-campus physics course for engineering students. These pre-recorded videos introduced theory and concepts to students ahead of in-class sessions, which enabled a reduction in the time used for traditional lectures. The time spent in classes puts emphasis on student activities, such as quizzes, Q&A sessions with the lecturer answering student-submitted questions, and problem solving.

The physics course has a modular design for customized delivery to a multitude of study programmes and is coordinated by a team of teachers who provide localized classes at several campuses. Although teachers manage individual classes, the course uses an open learning environment which allows enrolled students access to all study materials published by any teacher.

We present results from a questionnaire investigating student experiences with the use of short videos, by measuring the overall level of satisfaction with the videos, as well as collecting students' comments to the videos. We investigate correlations between student satisfaction with the videos and the comments they make, and whether students whose teacher is featured in the video are more satisfied than students without a personal relationship with the featured teacher.

Students report overall satisfaction with video length and level of precision, while requesting more worked examples and detailed calculations. We identify a set of good practices for flipped classroom designs, based on the students' feedback.

1 INTRODUCTION

Active learning is found to promote students' performance in science, engineering, and mathematics compared to traditional lecturing [1]. A controlled study comparing students' self-reported perception of learning in an active learning environment with a traditional one showed that the students attending the active learning classroom learn more, but feel they learn less [2]. One way to implement active learning is through a flipped classroom design where students watch videos introducing new content before class and in class students are engaged in activities such as quizzes, Q&A sessions with the lecturer answering student-submitted questions, and problem solving. A recent study of students' perception of videos in introductory physics courses for engineering study programs showed that including videos in physics increases the probability of passing the course [3].

The focus of this paper is students' self-reported experiences with "low-budget", short videos used for introducing theory and concepts in an introductory physics course for engineering students, using a flipped classroom approach. The videos were "low-budget" in the sense of using a basic setup of recording a teacher writing notes on an interactive display. Furthermore, preparation time could be minimized because the teacher was intimately familiar with the course curriculum, being a member of the team of teachers delivering the course, and having taught the course earlier.

In our investigation we posed the following research questions:

How do students perceive the videos and what is the correlation between students' reported satisfaction with the videos, and the comments they give as feedback?

What is the effect of having your own teacher producing the videos, as opposed to a video produced by someone else?

2 BACKGROUND

The focus of this paper is a compulsory introductory physics course for engineering students, which is taught in parallel across three campuses by a team of six teachers (subsequently anonymized as teacher A-F) for a total of approx. 1000 students. The inaugural run of the course coincided with the outbreak of the COVID-19 pandemic in 2020, which enforced a digital transition of the course delivery. Building on experiences gained during the “emergency remote teaching” phase [4], a flipped classroom design was implemented in 2022. In this design, students watched short videos ahead of sessions, which introduced physics theory and concepts. The in-class/synchronous sessions (i.e., digital, physical or hybrid) briefly recapitulated key points from the videos, before proceeding to active learning activities like quizzes and problem solving.

The videos were 5-10 minutes in length and were produced by one member of the teacher team. The videos used a simple, inexpensive format which enabled rapid production: The teacher filled in partially pre-written notes on a table-mounted interactive display, with audio narration - only a small number of videos showed the teacher. A screenshot of one of the videos is shown in Fig. 1 below:

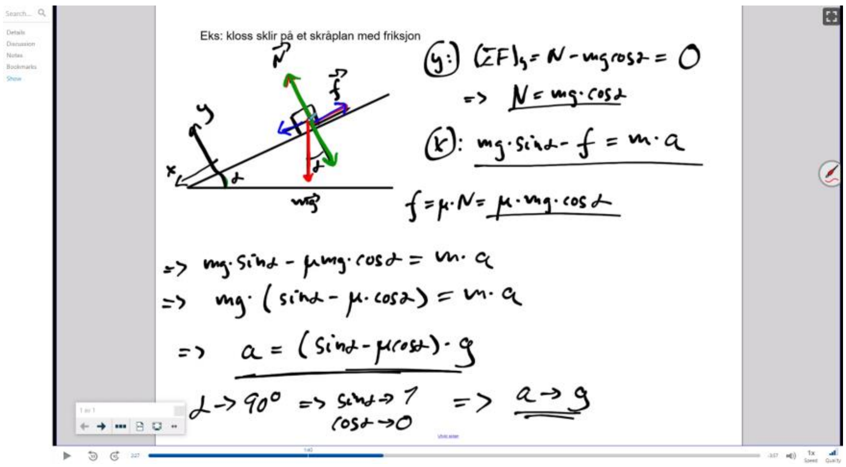

Fig. 1. Screenshot of one of the videos

Although all the involved teachers covered the same curriculum using the same set of videos, there was some variation in how in-class sessions were conducted: Some classes were given digitally; some in medium-sized classrooms; some in large lecture theatres. Furthermore, individual teachers had considerable autonomy in choosing how to present or approach any given subject during in-class sessions.

3 METHODOLOGY

3.1 Data collection

Data was collected by means of an anonymous online questionnaire, as part of a course evaluation from which only the subset of the questions regarding the videos is addressed in this paper. The questions, none of which were mandatory, were formulated as follows:

- What was your level of satisfaction with the videos? (Likert scale 1-5)

- How have you used the videos? Options: Preparation ahead of sessions/ Repetition or recap between sessions/ Aid for doing assignments and exercises/ Not used videos/ Have you used the videos in other ways than listed above? (Text answer)
- Satisfaction with teacher instruction in synchronous sessions (Likert scale 1-5)
- What worked well/less well with the videos? Suggestions for improvement? (Text answer)

3.2 Analysis

Likert-scale questions were analysed to check whether means between different student populations differed significantly, using an Aspin-Welch t-test [5]. The qualitative answers to how the videos had worked were coded inductively [6]. Codes were derived from the data and afterwards gathered into the three categories: *Appreciating short and precise videos*, *Wishing for more structure and better legibility*, and *Wishing for more examples.* To make a systematic overview, these three categories were correlated to the students' Likert scale answers of their overall satisfaction with the videos.

4 RESULTS

4.1 Student satisfaction with the videos

This section details the students' answers to the questionnaire. A total of n=259 students completed the survey, corresponding to a response rate of approx. 26 %.

The distribution of scores awarded to the videos by the students, on a 1-5 Likert scale, is shown in Fig. 2 (n = 246):

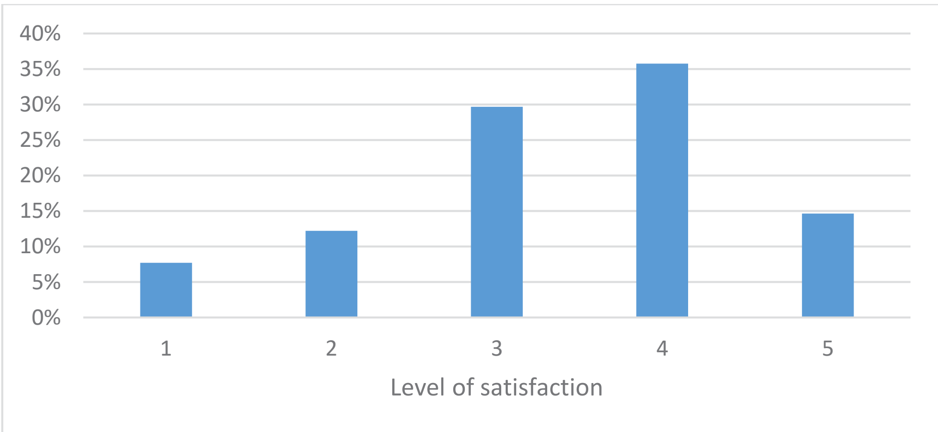

Fig. 2. Student answers to the question "What was your level of satisfaction with the videos?" (1-5 Likert scale; 1 = very dissatisfied, 5 = very satisfied)

The questionnaire did not specify which criteria the students should use to indicate the level of "satisfaction" with the videos, so implicitly Fig. 2 is a measure of "general student satisfaction", incorporating aspects like video and audio quality, clarity of the presentation, and the perceived learning effect. With an average score of 3,4 and a standard deviation of 1,1, students were generally satisfied with the videos.

4.2 Students' usage of the videos

The flipped classroom approach was presented to the students at the beginning of the term, with particular emphasis on how the students were expected to use the videos to prepare for sessions.

The various usage scenarios for the videos are summarized in Fig. 3 below:

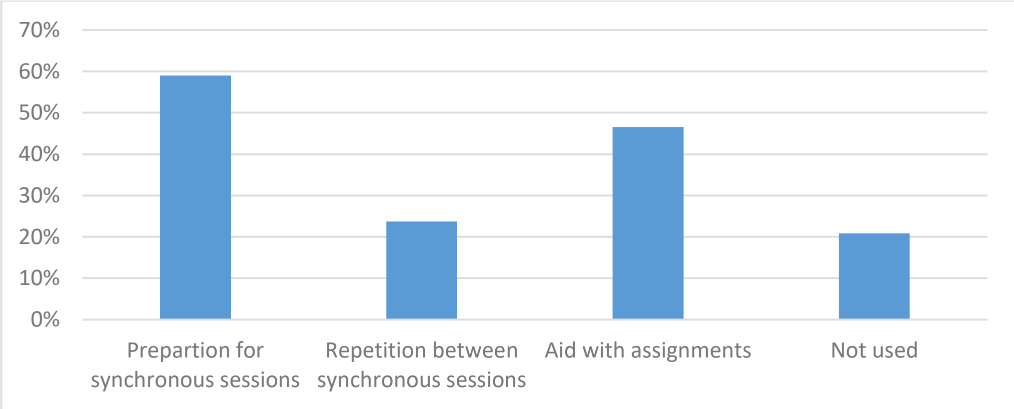

Fig. 3. Student answers to the question "How have you used the videos?"

In this respect, Fig. 3 above shows that some 60 % of the students used the videos "as intended".

Additionally, a significant proportion of students used the videos for repetition between synchronous sessions, and as an aid with assignments. No additional use cases were identified by the open question.

4.3 The effect of having your own teacher producing the videos

Of the six teachers in the teaching team, only teacher A was featured in the videos. Teacher A also gave synchronous sessions like the rest of the team, and was thus a "familiar face" for a subset of the students. The respective levels of satisfaction with the videos of teacher A's students vs. students taught by teachers B-F are shown in Table 1 below:

Table 1. Student level of satisfaction with videos: featured teacher (A)'s students vs. students taught by other teachers (B-F), as well as teachers B-F combined

Teacher	A	B	C	D	E	F	B-F
Student's level of satisfaction with the videos (1-5 Likert scale)	4,1	3,0	3,0	3,4	3,1	3,3	3,2
Standard deviation	0,9	1,2	1,2	1,1	1,2	0,9	1,1
No. of students	48	36	14	30	42	76	196

As shown in Table 1, teacher A's students and B-F's students have average levels of satisfaction of 4,1 and 3,2, respectively. Employing the Alpin-Welch test to compare averages, assuming independent populations with unequal population standard deviations, the observed difference is indeed statistically significant (p-value = $1{,}3 \cdot 10^{-7}$).

To investigate possible origins of the observed difference in level of satisfaction with the videos, data for the reported levels of satisfaction with teacher instruction in the synchronous sessions were compiled into Table 2 below:

Table 2. Students' level of satisfaction with teacher instruction for teachers A-F, and B-F combined

Teacher	A	B	C	D	E	F	B-F
Student's level of satisfaction with teacher instruction (1-5 Likert scale)	4,1	2,9	2,6	4,0	3,6	4,2	3,7
Standard deviation	1,0	1,2	1,1	0,8	1,0	0,9	1,1
No. of students	50	39	16	30	44	80	209

While teacher A was indeed highly rated, teachers D and F were given similar high ratings by their students – and so perceived teaching ability does not explain the difference in student satisfaction with the videos in Table 1.

The physics class consisted of both 1st-year and 2nd-year students, the latter of whom were familiar with a flipped classroom approach in an earlier course. The Alpin-Welch t-test found no statistically significant differences in the level of satisfaction between 1st- and 2nd-year students (p-value = 0,66).

4.4 Students' comments to the videos

The students' comments to the question, What worked well/less well with the videos were categorised into the three categories, *Appreciating short and precise videos, Wishing for more structure and better legibility*, *Wishing for more examples.* These categories are described in the following.

Most students who write comments appreciated the fact that the videos are short and precise: "*The videos are concrete and give an overview of the most important things, I like that very much", "Nice introduction to the topics",* or *"I like that the videos are short".* Students considered the videos "information-dense" and would sometimes pause the videos: *"A lot of learning in a short time".* The students also appreciated that the videos *"Are right to the point and explain the content in a good way".* The students favourably compared the short videos with much longer videos used in other courses, in which the length (from 25 minutes up to 2 hours) would make students lose focus and induce boredom.

Students were ambivalent about the teacher narrating and writing over pre-written notes: It was appreciated that this helped keep the videos short, but negative student comments to this approach were gathered into the second category: *Wishing for more structure and better legibility.* Students in this category commented on a lack of structure in the videos, and the use of handwritten notes: *"It is very nice that the* *videos are so short, but it is difficult to follow when the text is already written, and the teacher only explains what is written".* The handwriting itself was criticized by some: "*The handwriting is messy".* Other criticized the structure of the video: *"I do like the concept of flipped classroom, …, I find the videos chaotic, and they are overwhelming when you do not know the content. I feel the videos are more suited for repetition after the live sessions, not as preparation"*. Students who were focused on applications rather than understanding of physics commented e.g., *"It is difficult to follow the short videos, and it is unclear which of the formulas that are useful"*.

Comments in the last category, *Wishing for more examples,* opined that videos should contain more worked problems and examples: *"I think the videos should contain calculation exercises as well as more thorough explanations",* and *"It would have helped with more practical examples"*. These comments indicate that students would have liked to see worked problems and calculations in the videos, contrary to our intentions of using the videos to introduce the theory, while using the synchronous sessions to work on problem sets.

Correlating student comments within the three categories with the level of satisfaction with the videos, gives the distribution shown in Fig. 4:

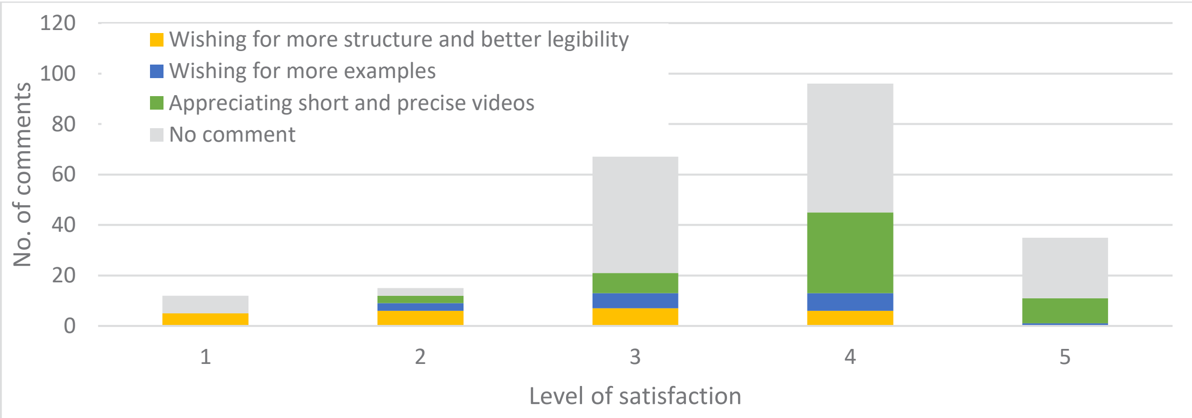

Fig. 4. Students' comments categories grouped by answer to the question "What was your level of satisfaction with the videos?" (1-5 Likert scale)

Dissatisfied students (score = 1) all belong in the category Wishing for more structure and better legibility, whereas "reasonably satisfied" students (score 2-4) are present in all three categories. Higher levels of satisfaction correlate with greater appreciation for short and precise videos. Note: A single student's comment can contribute to more than one category.

4.5 Students' suggestions for improvements

Students felt that structure could be improved by *"Handwriting text and calculations live instead of using pre-written text"*, and that the tradeoff in terms of *"It takes a little more time"* would be worthwhile.

Some students suggested that videos contain a list of recommended textbook exercises, relevant to the theory presented in the video, at the end.

A few students reported a dislike for the flipped classroom approach altogether, in favour of traditional lectures – in line with findings in [6], where flipped classroom is found to be less advantageous for certain groups of students.

5 DISCUSSION

5.1 General analysis

Overall, the students were satisfied with the videos, highlighting their short duration and precise, to-the-point presentation. Except for the students most satisfied with the videos, students across all satisfaction levels suggested improving the video structure, to make it easier to understand the logic of the learning material.

Comparing Tables 1 and 2, we conclude that familiarity with the teacher featured in the video, rather than exceptional instructional skills, is key to student satisfaction.

5.2 Suggestions for good practice in video-led flipped classroom designs

Based on Fig. 4 and the students' comments on the videos, we can suggest certain good practices for flipped classroom designs:

- A simple, low-cost setup with a digital writing surface (e.g. interactive display or tablet) is enough to produce videos of adequate quality.
- Video length vs. legibility: Keep videos short, but avoid static slides. Spending some extra time to write live text will increases legibility and makes it easier for students to follow the logic of the presentation.
- Video structure: Give a very brief overview of the video at the beginning, and point the students towards further study material (e.g. exercises) at the end.
- If the students are unfamiliar with the methodology, the teacher should demonstrate how to work with the videos by showing the first few of them in the classroom. Additionally, students need to be repeatedly reminded how they are expected to work outside the synchronous sessions, and the rationale behind the chosen approach.

5.3 Study limitations

The authors are aware of several methodological limitations to this study:

- The 26 % response rate is low.
- 20 % of the students participating in the survey, reported not using the videos.
- Even though the research questions focused on the videos and pedagogical approach in which they were used, it's difficult to decouple the significance of individual teacher performance during the synchronous sessions.

6 ACKNOWLEDGMENTS

The authors are grateful to all students who participated in the survey, and they also wish to thank all the members of the teacher team for their cooperation. We also thank reviewer 2 for providing constructive feedback that helped us clarify the last point in section 5.2.

ABSTRACT

Engineers are important participants in solving societal, environmental and technical problems. However, due to an increasing complexity in relation to these problems new interdisciplinary competences are needed in engineering. Instead of students working with monodisciplinary problems, a situation where students work with authentic complex problems in interdisciplinary teams together with a company may scaffold development of new competences. The question is: What are the challenges for students structuring the work on authentic interdisciplinary problems? This study explores a three-day event where 7 students from Aalborg University (AAU) from four different faculties and one student from University College North Denmark (UCN), (6^{th}-10^{th} semester), worked in two groups at a large Danish company, solving authentic complex problems. The event was structured as a Hackathon where the students for three days worked with problem identification, problem analysis and finalizing with a pitch competition presenting their findings. During the event the students had workshops to support the work and they had the opportunity to use employees from the company as facilitators. It was an extracurricular activity during the summer holiday season. The methodology used for data collection was qualitative both in terms of observations and participants' reflection reports. The students were observed during the whole event. Findings from this part of a larger study indicated, that students experience inability to transfer and transform project competences from their previous disciplinary experiences to an interdisciplinary setting.

1 INTRODUCTION

1.1 Section 1

Engineers are expected to be important participants in solving the grand societal challenges [1]. These aspects create new demands for engineering education in the future [1,2] and new ways of students' collaboration in more interdisciplinary situations across disciplines and faculties [3]. This paper describes the experience from a 3-days Hackathon event that took place at a large Danish company where 7 students from AAU (Aalborg University) and one student from UCN (University College North Jutland) worked in two project groups solving authentic complex problems. Students from AAU are used to project work on problems in teams with participants from their own discipline. At the Hackathon event students work with complex problems in an interdisciplinary group. Research shows that students have difficulties with collaboration on complex interdisciplinary problems [4,5]. The aim of this research is to answer the question: What are the challenges for students structuring the work on authentic interdisciplinary problems? Initially the paper introduces the theoretical framework used to interpret the data collected, then presents the methodology and finally describe and discuss the results.

1.2 Theoretical framework

There are different interpretations of the concept interdisciplinarity. However, this study uses the definition by Keestra & Menken [6] where interdisciplinarity is defined as a range of degrees from multidisciplinarity to transdisciplinarity. Multidisciplinarity is defined as a situation where disciplines work together in parallel. Interdisciplinarity is a situation where disciplines are integrated and finally transdisciplinarity is a situation where interdisciplinarity is integrated with non-academic domains. To extend the definition of interdisciplinarity the typologies described by Klein [7] are used. Klein [7] distinguishes between narrow and broad interdisciplinarity. Broad interdisciplinary collaboration teams are teams working together with very different understandings of ontologies, epistemologies and methodological approaches, whereas narrow interdisciplinary teams are teams that are closer aligned in relation to ontology, epistemology, methods and understandings. In relation to interdisciplinarity, boundaries and boundary crossings are very important. Carlile [8] defines three levels of managing knowledge across boundaries in relation to the differences, dependencies and novelty, see figure 1.

The first level – Syntactic transfer: When novelty is minor the knowledge between Actor A and Actor B can be transferred without problems and the category of the boundary object can be represented by a repository [9]. **The second level – Semantic translation**: With increasing novelty, the differences and dependencies can become unclear or there can be different interpretations of meanings. At this level, transformation of knowledge is not enough but translation of meanings or negotiations may be needed and the boundary objects can be categorized as

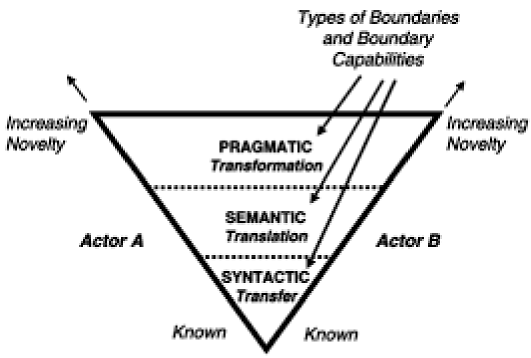

Fig. 1. An integrated framework for managing knowledge across boundaries [8, p.558]. Actor A and Actor B represent actors from different disciplines with differences and mutual dependencies. Increasing novelty entails increasing effort to manage the boundary.

standardized forms and methods. **The third level – Pragmatic transformation**: When novelty increases to a level where it affects the interests of the actors a transition to the pragmatic level occurs. The pragmatic level needs knowledge to be transformed from domain specific knowledge to a mixture of knowledge domains and the boundary object can be categorized as objects, models or maps [9].

2 METHODOLOGY

2.1 Research context

This study, which is part of a larger study, is based on a 3-days extracurricular event arranged by AAU in cooperation with a large Danish company. 7 students from four different faculties at AAU and one student from UCN participated in the event that was structured like a Hackathon. The students came from four different countries. The event took place at the premises of the Danish company, where the students stayed during the whole event together with three employees from the company and three researchers from AAU. The content of the Hackathon was a combination of round tours at the company, supporting workshops and group work. The group work was divided in four sprints with inspiration from a guide concerning PBL and Entrepreneurship [10]. Each sprint finalized with a pitch from the two groups. The overview of the Hackathon is shown in figure 2.

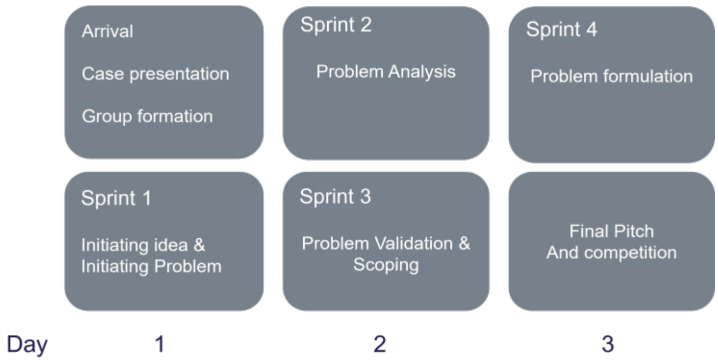

Fig. 2. Overview of the Hackathon event divided in four sprints finalizing with a pitch.

After students' arrival and accommodation at the company, employees from the company presented two different cases for the students. The first case - Case #1 belonged to a problem area familiar for the company whereas Case #2 was regarded as a new problem area. After lunch two groups were formed based on student competences and interest in the two cases. After group formation the students worked in four sprints finalizing with a pitch competition on day 3. The jury for the competition consisted of one jury member from the company and two jury members from AAU. The winning group was awarded with a cash prize.

2.2 Empirical data

The methodology used for data collection was a qualitative research design. Three researchers from AAU participated in the event. Two of the researchers conducted the workshops and structured the event. The third researcher was assigned the role as an observer during the whole event, without participation in the workshops. This researcher used an observation protocol [11, p.190] for recording the observations during the whole event. The observation protocol was divided in a descriptive part, supplemented with columns for details concerning participants, objectives, means and tools, messages and findings and a reflexive part with room for observers own thoughts and comments. The header of the observation protocol contained information about the current project phase. At the registration to the Hackathon event, the students were asked to give a short-written justification for participation and at the beginning of the event the students were asked to make a competence profile. The competences were parted in two: the professional competences and the PBL competences which worked as baseline for the final reflections and edition of competences gained at this event. After the Hackathon the students were asked to reflect about their experiences with the Hackathon event and give inputs to improvements for the future.

3 RESULTS

3.1 Students justifications for participate

From the students' justifications for participation, it is clear that it is very motivating for the students to participate in an event like this, especially when it is possible to relate the themes to their own studies and backgrounds. *"I would like to join this event because I think that the challenges sound really exciting and the themes fit very well together with my studies".*

Two of the students directly mentioned one of the themes as very important for their participation. The students also mentioned their own backgrounds as important and the experience of how they could contribute*: "With excitement I look forward to see what I can contribute in the context of Your enlightened themes and in the collaboration with other professional groups during the teamwork sessions…..".*

"Additionally, with my knowledge of [……..] together with a background in [……..] and experience in problem solving in a group, I feel I would be able to really make a difference and contribute to the workshop".

Collaboration and problem solving in groups was mentioned too. *"I want to participate because I see it as a great opportunity to work creative and innovative with other students on solving problems"*.

Moreover, reflections about the future about own career and their own role was mentioned: *"Events like this allow me to establish my professional qualities as I have to be a specialist in my area, aware of the fact that my input really matters".* And: *"The possibility to broaden my horizons and challenge my creativity is the reason for my participation"*. At a more meta level a student wrote: *"Furthermore, I am interes-ted in design processes, innovation and the human consequences from implement-ting smart technologies"*. Finally making new relations also mattered: *"And most importantly, challenging events are the place where amazing friendships start :)".*

3.2 Interdisciplinary team formation

After the presentation of the two cases the students were asked to write down their professional and PBL competences on post-it notes. Subsequently the students shared all the post-it notes on a large white board and presented their personal competences to the other students. With support from the researchers the students formed two groups, based on individual interests in the cases and based on the knowledge from the competence clarification. Group #1 working on Case #1 consisted of four students from four different faculties at AAU (Technical Faculty of

IT and Design (TECH), Faculty of Engineering and Science (ENG), Faculty of Social Sciences and Faculty of Humanities). This case was familiar to the company and the students were able to get information from employees from the company. Group #2 working on Case #2 consisted of three students from AAU (two from ENG, one from TECH) and one from UCN – (Energy management). Case #2 was a case the company had no experience with.

3.3 Working process

The analysis of the working processes for the two groups is based on the information from the observation protocol.

Group #1: The group used written material from the company as basis for communication and for developing the idea together. Trying to decide an idea – discussing pros and cons. They also were inspired by the round tour at the company. They had difficulties with a common platform for communication, but after some time they began to use a white board. The first pitch was not well organized – they had no plan for speaker and content and no agreement on idea and no project management. After the pitch, the group began to work individually to find a problem. They chose an idea and discovered it was already realized. Then changed the idea and discussed who the customer is. In the first sprint retrospective they agreed that they lost their focus and talked past each other. However, they have developed a concept that help them communicate. An employee from the company gave input to the group concerning the problem context, which made it easier for the group to clarify the problem. During the problem analysis the group was still unsure about the problem. This situation changed in the problem validation sprint, where the group used the Business Model Canvas (BMC), they were introduced to in a workshop. The BMC created a structure for the work and became a steering tool for the group. The group created a good understanding of the customer. Still there were no project manager in the group. The group used the white board to define the hypothesis and used a drawing as focal point, however they had problems concerning consensus for the work. In the preparation for the final sprint one student took the lead. The time pressure was evident, however, there was a consensus concerning the result. The final pitch presentation showed good understanding of the customer, the problem, market potential and the opportunities for the company.

Group #2: They started with expectation clarification and worked individual on own ideas. They used the white board to present many ideas to each other and discussed limitations. They had no specific project manager. The time pressure was very clear. They were ready for the pitch, but the problem was still open – they needed to narrow it down. After the first pitch the group used the white board, writing down what they agreed on. Despite disagreements they acknowledged their differences. In the sprint retrospective they agreed that they often end in circular discussions, that they need to be better to ask for help and to realize when they are agreeing. In the problem analysis sprint, it was clear for the group what the essential problem was. However, the group had difficulties delimiting and clarify the problem.

They struggled with identifying the customer. In the problem validation sprint, they started out with individual drawings, but joined using the drawings as focal points. One member of the group stood out as leader. The group rejected to use BMC, instead they used many different methods mixed together. Language was observed as a barrier sometimes. The group worked individual within own discipline, calculating system performance or sketching the solution, resulting in many drawings and calculations. Working systematically, two by two or individually. The time pressure was evident, however, there seemed to be a consensus concerning the result. The final pitch presentation showed a well-structured and well-designed presentation with technical details and a systemic approach. However, there was less determination concerning the customer and hence the problem understanding and possible opportunities for the company.

3.4 PBL competences

Before the group formation the students were asked to reflect on their professional competences and PBL competences. Some of the PBL competences mentioned before the group formation were: *Team collaboration, planning of the process, task delegation, project management, time management, work structuration, conflict management, problem identification and problem analysis.*

After the final pitch, the students were asked to reflect on their new competences acquired during the event: “Shorter time for handling selection [decisions]”, “Awareness of incorporation of “in-house” knowledge that is outside the group”, “Not being blind to externals”. “Acceptance of concepts from all of us”. “See the value in my collaboration skills in ‘the real world’ not tacit”. “Agreements in the group”, “Good team player”, “Value oriented”, “managing time”, “reflective”, “focus on finishing task”, “solution oriented”, “make room for every one to be heard”, “change management”, “giving presentation”, “take responsibility for initiating tasks”.

3.5 Students’ reflections

The students were asked to reflect on the Hackathon event. Some of the observations are described for the two groups below.

Group #1 reflections: Were not used to use all the technical resources present at the company. There is a lot of new tacit knowledge, which mean they need to be more explicit. The communication was a barrier, they used a lot of time because they talked past each other and needed to repeat the information to identify and set a common scene. Commented that it is important to identify the main problem and know the core problem to solve.

Group #2 reflections: Need to be more critical and to say “No”, especially when narrowing down the problem. Identify more soft skills and be able to reflect and identify on the process. The setting was familiar for one of the group members, however, the domain specific competences came only to a little extent into play. Learned new business skills and how to apply it in a company.

Besides the students own reflections, they were asked a question about their expectation to the event. One student answered: "*Learning the new form "Hackathon", "Getting to know [company name] better", and "Getting experience in the processes and in presenting new stuff".* Another student answered, "*Challenge myself with innovation and new concepts"* and a student answered, "*To use my competences, to work interdisciplinary and to hopefully find a solution to the problem".* Furthermore, the students were asked to elaborate on the experience from the Hackathon. One student answered: *"The Hackathon was a great event. The 'lectures' facilitated the development of the project, however I felt the introduction of the topics was not specific enough and left me wondering what we are actually supposed to do. The teamwork was very easy due to everyone being so open to forming new work relationships."* Another student answered *"The social aspect only benefited the teamwork, and I felt that it was very important"* and a student answered *"I think it was great, everything happened at [company name], and we were able to ask them questions. I think it was an experience both socially and professional. And I think it was good motivation".*

Concerning outcome of the event some of the student answers were: *"Knowing new things about myself, found my good presentation skills. getting better at listening".*

"It showed me how I work in interdisciplinary teams, where none actually knows each other beforehand. I also learned the importance of questioning my choices and not agreeing to everything that is brought up in the discussion."

"I experienced a new environment, where I found a new professional part of me. I have learned a lot about myself, and working together with people I don't know".

Students' ideas to improve the Hackathon were: *"Less time in pitching. Let people know a little time earlier that you had to present your own skills, I missed a lot."*

"A more thorough presentation of what the topics are and what is expected would be beneficial. Specifying whether the end result should be a business concept, a product or what would guide the groups in a good direction. Overall, loved it, so thank you for organizing it :) hope to take part in it again"

"Shorter pitches. Maybe we from the beginning could limit our pitches to 10 min. And maybe present, what it a good pitch?". "It was a great experience, and something I will recommend to others"

3.6 Discussion

The two groups performed differently. Group #1 was a broad interdisciplinary group working on a case the company had worked with before and where an expert was available for further in-dept knowledge. The group had a solution early in the process. The group had troubles with finding an agreement, structuring, managing, communicating and understanding each other. However, when they were introduced to Business Model Canvas, they used this model as a boundary object to structure the process and the project. They created a good understanding of the customer in relation to the case and used the guided company round tour to get inspiration for their solution. Group #2 was a narrow interdisciplinary group working on a case unfamiliar to the company, therefore they could not get any expert knowledge. They were all used to work with technical problems and they had many ideas to solve the technical challenges. Each group member worked in a structured way and they used the white board intensively in the whole process. Communication was difficult and they disagreed about scope. They had troubles identifying the customer and the real problem, but very early focused on the technical part, from different angles, making calculations and drawings. The drawings were this groups boundary objects, as they did not want to use the Business Model Canvas. Referring to Carlile [8] the novelty for both groups were high. The problem areas were new for the students, the time frame very short and the team composition different from what they are used to. Both groups had difficulties with transferring their previous experience and knowledge concerning project work to the new situation. The participants forgot about their experience of how they used to do and needed more support and steering from the facilitators. The general lack of management affected their process and management of time. It was difficult to use knowledge developed in a monodisciplinary setup in the interdisciplinary setup and decide how to work together in the new situation. More time to strengthen their relations could help the process. It was difficult to keep the time in the pitch presentations, more training could help. Moreover, it is difficult for students to express their competences without preparation. They may need more time for that and for creating the necessary relations in the groups. The winning group of the Hackathon event was Group #1, basically because this group had the best understanding of the problem and the customer. Group #2 was more focused on the technical aspects and on a technical solution. At this event the two groups worked with two different cases – the broad interdisciplinary group with the most familiar problem area and the narrow interdisciplinary group with the less familiar problem area. In future Hackathons it will be preferred to present only one case for the students in order to create more even criteria for the competition.

This Hackathon, which is part of a larger study, shows difficulties for students to transfer their monodisciplinary knowledge and experience to an interdisciplinary situation, without guidance and preparation. However, the students' reflections and comments after the Hackathon show that the step from monodisciplinary project work to interdisciplinary project work is difficult, but events like this Hackathon in Engineering Education can help students to experience the challenge of interdisciplinary boundary work and experiment with coping strategies. One step may not be enough but events like this used in different contexts can scaffold the students' interdisciplinary competence development.

4 ACKNOWLEDGMENTS

This work is part of the research project *InterPBL*, a research project aimed at developing innovative educational models to educate engineers to work proactively and interactively in an interdisciplinary work environment. It has been funded by The Poul Due Jensen Foundation.

Abstract
Listening to scientific presentations and reading scientific literature are core activities of any scientist, and frequent components of students' curricula. When employing these activities in teaching, finding the right balance between student instruction and autonomous learning is important for best learning outcomes and teachers' workload. We here present our course design for a coordinated lecture series and journal club, that finds this balance by leveraging modern learning concepts in a digital environment. Participating students were tasked to read a landmark scientific paper every week ahead of a lecture by a scientist with practical experience on the topic of that paper, often an author of that week's paper. Students then had to hand in written answers to three questions probing their understanding of the topic and the paper. In a subsequent seminar, activating questions were discussed by the students in break-out rooms and then answered by randomly chosen students in class, followed by a broad discussion that included the homework questions. Students gave weekly feedback on their learning progress and experience, and the course was then dynamically adapted accordingly. This yielded a course with largely increased course capacity, reduced teachers' workload, and substantially enhanced learning outcomes, qualitatively and quantitatively compared to previous implementations of the course.

1 Introduction
Scientific core activities include listening to presentations, discussions, literature research and writing, and critical appraisal of each of these [1]. While University level teaching generally considers these skills to be important, they are not taught comprehensively, with only few courses focussing on these skills specifically [2,3].
A contributing factor might be the high time consumption of scientific reading formats for both students and teachers. First contact with scientific communication needs a high degree of instruction and supervision. This is contrasted by tight teaching

doi:10.5821/conference-9788412322262.1332

resources [4] and increasing numbers of student enrolments [5] that make it difficult to realise small scale formats like journal clubs or expert discussions.

Progressive teaching concepts like active learning and peer-teaching could overcome such limitations. Solutions could include topic rather than paper-specific journal clubs [6] or active teaching [7], peer-mentored learning [8], which proved to increase student engagement and learning outcomes; this could potentially be further enhanced by restructuring a course into problem-solving and instruction phases [9].

Furthermore, science-related classes feature a huge variety of topics, which creates challenges and chances alike. Being confronted with expert-level knowledge from different fields can be overwhelming and discouraging, however it can also be utilised to make students profit even more. Studies showed that interleaving different topics enhanced memory and problem-solving ability [10] and that translation between different research fields greatly improved metacognition, which consequently increased active learning success [11]. Another point to consider when covering different topics in an iterative manner is the frequency of testing or feedback on learning status. Meta-analysis showed no significant correlation between test frequency and academic achievement but also suggested that topic associated, frequent assessment outperforms centralised assessments (e.g. midterm or final exams) regarding learning outcomes [12,13].

Our previous “student peer teaching” concept [14] for the presented course included many of these considerations already. Each week, a student presented a scientific paper and its associated topic to the class in a full lecture, supported by us in the preparation and during Q&As. This, however, limited the number of attendees to the number of weeks and students complained that only the topic they themselves presented was really mastered.

We here present a course and its first test that builds on these considerations to enhance learning outcomes in an open participant number format. We combined a departmental lecture series of expert talks with an active learning journal club in a digital environment. Initially introducing topics by experts from the field sparks interest, translates the research into different contexts and defines objectives (educational trajectory phase) [15] for the subsequent active learning & problem-solving phase, which is rounded by a seminar including peer-teaching and teacher instruction phases.

2 Methods

2.1 The current course concept was created in a three stage process. The first stage consisted of conception sessions of a professor and two teaching PhD students similar to the curricular spider web [16] following the rationale of increasing the participant number, whilst decreasing teacher time expense and most importantly enhancing the learning outcome for students. This step included reviewing the structured student feedback and teacher notes from running the previous course format for seven years, followed by literature research on formats like lecture series and journal clubs and concepts like active learning [7], peer-teaching [8,14] and problem-solving [9]. The resultant plan of the course was further refined in the following two ways:

2.2 The second stage included the acquisition of speakers for broadly predefined topics in the area of modern biological mass spectrometry, based on the content of the previous iterations of the course. The scientific publication to focus on was suggested by us and in some cases adjusted based on feedback from the speaker. External speakers were all chosen from the list of authors of the scientific papers we wanted to cover and approached proactively. In our experience, scientists have a general interest in propagating their field specific knowledge and techniques, especially to students. Besides altruistic reasons, the aspect of recruiting potential new master or PhD students can be compelling and is far from being a one-way road, as this also offers the students career options.

2.3 The third stage took place whilst running the course and based on student participation. We collected feedback and ideas for improvement at the end of every week, screened that immediately and categorised it into: unfeasible (ideas/wishes restricted due to e.g. limited expert availability, university regulations, time etc.), potential long term goals (ideas for next year's course) and potential immediate implementations (ideas that seem short term viable and potentially add value). Third category ideas were implemented and followed by feedback at the end of that week, so that we could decide if changes would be solidified or dropped again.

It took about six weeks into the course to find the right balance between student instruction and autonomous learning. The resulting final course concept is presented in the following section.

3 Results

3.1 Goals

When planning the course, we defined three main goals, elaborated in the following passages. To facilitate critical reading of scientific literature, we followed an active learning strategy. We used paper examples and tasks to emphasise certain caveats and foci when reading a scientific publication.

A second aim was to enhance general paper reading skills. Next to the natural progression by regular reading and discussing, two weeks into the course (after students read the first couple of papers) we discuss with the students how to approach a paper and mutually developed a reading strategy. This strategy suggested getting an initial overview of the papers' main points by perceiving the graphical content first, then understanding the abstract and figures, and finally reading the paper with a focus on the critical parts [17].

Thirdly, at the end of the course we want the students to be equipped with a large toolbox full of bioanalytical methods, problem-solving skills and an individual compartment for their own ideas, including the courage to think big. By giving them the opportunity to pre-familiarise themselves with these topics in a flexible environment, bringing them into contact with experts from these fields and finally encouraging them to apply the gained knowledge into new contexts every week, we expand their long-term skill set and strengthen their confidence in applying these.

3.2 Implementation

To achieve these goals, we developed a weekly schedule (summarised in **Supplement Figure 1)**, which is further explained in the next paragraphs.
The weekly paper and corresponding homework questions were uploaded on the universities' moodle based platform each Friday morning of the preceding week. To profit most from the expert session on Monday, students read the paper beforehand.
The expert's session consisted of a 45-min talk and a subsequent 15-min discussion with the students via Zoom. The talks included an introduction into the technology, examples of its application, personal side notes from the expert scientist and an inaugural part on the week's paper. The latter was especially important as it helped students to understand the paper's premise and set the objective (educational trajectory phase[15]) for the subsequent active learning phase. Students liked to hear these personal side notes and hands-on experiences, as it makes technical content more approachable and imaginable.
Students were then asked to re-read the paper and answer three questions regarding the paper until Wednesday night. Answering the following topic-related questions, across all twelve topics, made up 72% of the final mark.

1. "What is the core idea of the technology and how is it applied in the paper?"
2. "What application of the technology intrigued/inspired you and why?"
3. Examples for *general or topic-specific* third questions:
   "Explain the principle of the technology and what it is used for in easy words (like for a 12-year-old) preferably supported by metaphors or picturesque explanations". (*general*)
   "It is 2030, how did the technology used in the paper develop? How does it influence science and maybe even society? Write a brief future scenario!" (*general*)
   "What are differences between protein and mRNA coexpression data?" (*specific*)

The first two questions stayed the same, whereas the third question varied across each week and was more translational. According to student feedback, this seemed to give the right balance between consistent expectation and motivating variety.
Each week was finalised with a seminar (**Supplement Figure 2**) that started with an anonymously answered multiple choice activation question, usually a seemingly basic question on the paper's fundamentals. However, the polls consistently showed ambiguous outcomes, with substantial proportions voting for the wrong answers. We find this especially noteworthy, as even after reading the paper, listening to an expert on it, being able to ask questions and then having to provide written answers, these students frequently did not get the underlying core concepts. The results were shared uncommented with the students, which were then sent into 30-min breakout sessions with five to six students. They were instructed to discuss the activation question (peer teaching) and the answers to their homework questions. Back in the plenum, the activation question was then polled again. Interestingly, the vast majority now answered correctly! Subsequently, the pre-discussed homework questions were

shortly presented by randomly chosen students, complemented voluntarily in a discussion and rounded through additions by teaching staff. This further deepened the understanding of the core concepts. Student feedback steered the course towards more time within the breakout sessions and a concise plenum afterwards. So also the students became clear about the value of peer interaction.
Seminar participation was marked following a “points remain unless you abstain” system, meaning everyone gets full points from the start, only being lost when a participant is chosen by a randomizer tool and does not answer at all (most basic answers were accepted and used as discussion starters). This being communicated clearly at the course’s start created a seminar discussion environment without competition for speaking times (when participation would equal points), hence less overlapping content. This also encouraged preparation, and appearance of each student, and allowed the discussion to evolve more naturally and autonomously.

3.3 Feedback

Finally, students were asked to give their weekly feedback on the course structure, and the content and to evaluate their knowledge of the topic before and after the topic’s week. Students also commented on implementation of their suggestions.
Students viewed time requirements as demanding, but very fair. The course required regular time investment throughout the week, however the consistent structure with flexibility in-between helped to learn efficiently and plan their weeks in advance. The weekly time needed to access a paper fully and to answer the homework questions was very individual to each student, ranging mainly between 2-8 hours (**Figure 1**); however, oral feedback indicated that the time expense declined throughout the course progression due to improved paper reading skills.

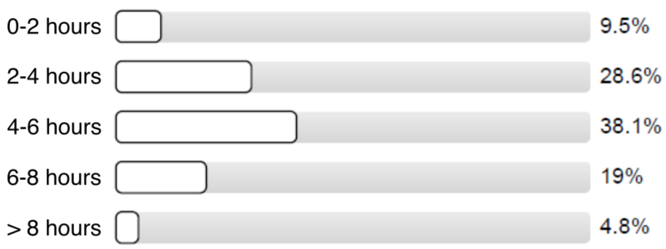

Figure 1: *Weekly time investment for students (acquired by the systematic university’s evaluation system at the end of the semester)*

This also applied for the teacher’s time investment; with growing experience, especially marking the homework questions became more efficient. One major workload on the teacher's side was the course preparation; guest speakers needed to be acquired, fitted into a suitable schedule, briefed on the concept and a suitable paper had to be proposed and/or mutually agreed on. Including the usual tasks like online course setup and material collection, one to two full-time weeks should be considered as preparatory work (however this should decrease on reiterations with the same guest speakers). Weekly time investment was necessary for the course

maintenance including paper reading and content generation (~1-2 h), moderation of the talk (1 h) and the seminar (2 h), feedback assessment and organisational matters (~1 h), and examination of the homework questions (~4-6 h) adding up to a weekly time expense of around 9-12 h. With 45 students in the course, this equated to ~15 min/student per week, with an improved learning outcome and student satisfaction compared to the previous concepts (~1 h/student per week).
We assessed student progress across all topics through weekly evaluation shown in **Figure 2**. We could observe a substantial increase of self-assessed knowledge levels from prior to afterwards across all topics. The ratings (x-axis) span from 0 (absolutely no knowledge) to 10 (expert knowledge).

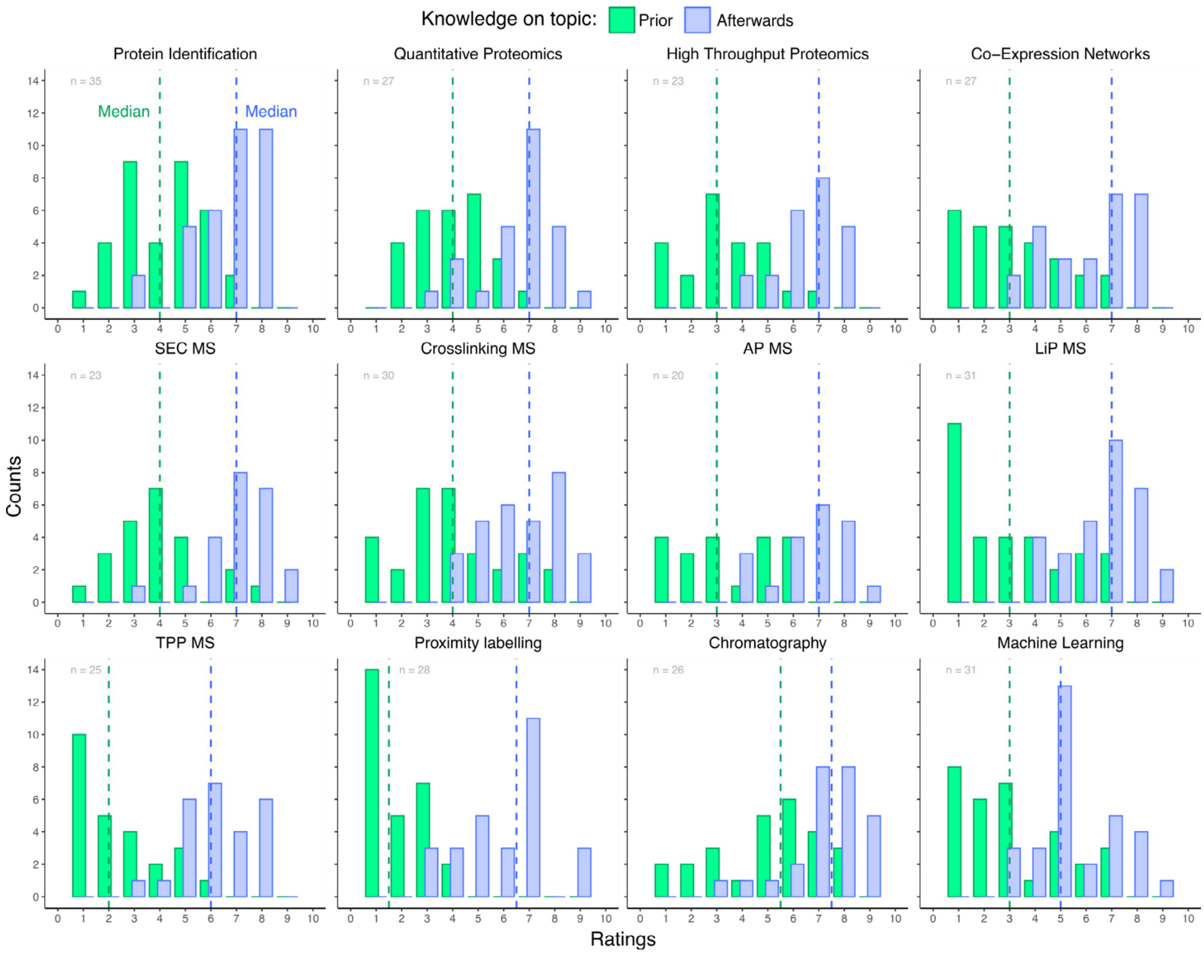

Figure 2: *Self-assessed knowledge level of students prior to (green) and after (blue) a topic-specific week, with medians given as dotted lines*

For the majority of topics, we observe an increase by 3 or 4 of the median knowledge level (dotted line) from 3-4 (prior) to 7 (afterwards). This is a marked improvement over the previous years, when students consistently complained about achieving limited progress. We also noticed increased precision and depth of answers given in homework and seminars as the course progressed. The average mark improved from 1.7 (WiSe 20/21, n = 12, old format) to 1.3 (WiSe 21/22, n = 45, new format) (*1.0* being the best and *5.0* being the worst possible). Overall, this data

supports the assumption to have enhanced the students' learning outcomes and skill set sustainably across all topics.
This assumption is further supported by the university's systematic final evaluation system, marking the course quality on average with *1.1* . Providing the course content in the format of a lecture series in combination with a journal club seemed very useful for students' learning success (*1.2*) and gave them confidence in having understood these (*1.6*), even though the overall content was perceived as more complicated than in other courses (**Figure 3**).

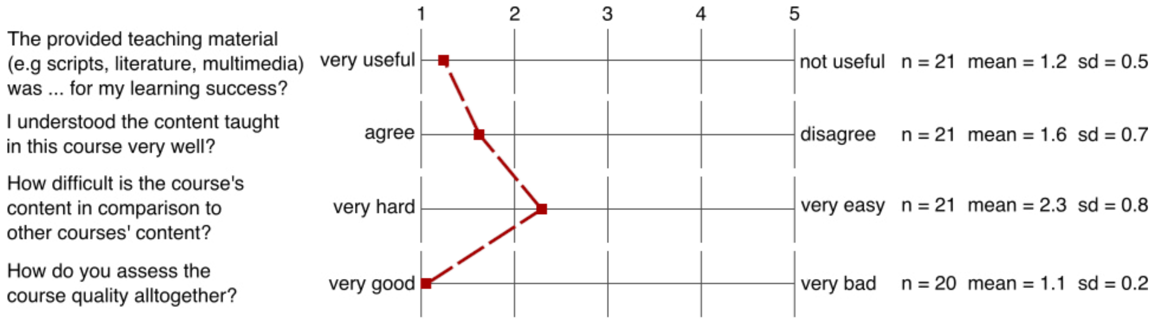

Figure 3: *Overall course feedback at the end of the semester (acquired by the systematic university's evaluation system)*

Lastly, it is also the students' qualitative feedback that shapes the course evaluation and its further development. Feedback like *"Thank you for all the Input! I learned a lot and will definitely recommend this course.", "This course is pretty much the first in which the possibilities of e-learning have been properly exploited"* or *"One of the most interesting and informative courses I have ever had"* encouraged us to consolidate this concept and to make it available for others through publication.
To outline some of the most frequent feedback we got (supported by frequency analysis [**Supplementary figure 3**]), most students were pointing out their interest and content ("interesting topic/discussion", "everything …[fine, good, great etc.]") and they were positive about the variety of content and formats ("new things/information", "good way", "different aspects", "third question"). Additionally, the majority affirmed adequate course pace or time expense ("enough time") and in the beginning, many pointed out a wish for smaller discussion groups ("many people", "smaller group"), which was complied by refining the seminar structure ("break out session", "small group discussion").

4 Discussion

The entirety of collected feedback suggests us having enhanced the learning outcomes across all topics considerably by remodelling the course into a departmental seminar series and journal club. We here rely on an extensive collection and interpretation of regular student feedback and the experience of our teaching perspective. However, we are aware that our study lacks a long-term comparison and a standardised learning outcome assessment. Such measures are currently being developed.

Furthermore, it has to be considered that the remodelling from a topic-centric "student peer teaching" concept towards a lecture series and journal club shifts the focus of trained soft skills from presentation towards paper reading, critical assessment and discussion. All of these are essential skills for scientists, though, our experience and received feedback indicate that we could achieve greater improvement within the literacy skill set, than previously in presentation skills. Note that the latter is being trained from elementary school on, whereas for most students, scientific reading and assessing is only a part of writing up their theses. We see a great necessity to help students approach scientific literature confidently. Many of them, even when close to finishing their studies, still feel demotivated or overwhelmed when researching literature [6].

Apparent improvements we could work out already refer mainly to the need of weekly summaries. The in-depth discussions and topical excursion in the seminar made it hard for some students to remain focused on the essentials, so that they asked for more frequent summaries. This could be achieved by ending a seminar by collectively defining e.g. the three most important points about the technology or answering the same summary questions for each topic. This would refocus the natural flow of the discussion into a digestible take-home message. From the teaching side, we identified as the main caveat the time needed for marking the homework questions. In the next course iteration, we will experiment with students having increased responsibility, to answer non-assessed topical questions and use the seminar discussion to evolve their answers. We will then use part assessments (e.g. every 3 papers) consisting of a mixture of multiple choice (similar to the activation questions) and partly free text questions (as described in 3.2).

In conclusion, the revised course achieved the defined goals. The now scalable, more student-autonomous concept enabled us to lift the participant restriction whilst showing substantially improved learning outcomes across the range of very specialised content. Instructors' absolute time investment decreased only slightly, however with student numbers quadrupled and learning outcomes increased, we consider this a great success.

5 Recommendation

Our course concept might serve as a blueprint for a departmental lecture series in combination with a journal club. We see this concept as being highly transferable, as the structure evolves around weekly building blocks that could be filled with any topic and corresponding speaker and literature. We happily encourage any educational team or lecturer to adopt the here presented concept and would in such a case just ask to reference us and, more importantly, to give feedback to us on its performance and potential improvements.

Technology (MIT) to develop a new academic program focusing on Artificial Intelligence (AI) training. Given the size and the diversity within the body of USAF employees, the goal of this collaboration is to design and implement an innovative program that will achieve maximum learning outcomes at scale for learners with diverse roles and educational backgrounds.
This program is now piloting and evaluating three different learning journeys addressing three different groups of USAF employees (USAF leaders and decision makers; technology developers; and daily frontend technology users). The learning journeys were designed based on each group's specific professional needs and academic backgrounds, and they include combinations of online synchronous and asynchronous courses and face-to-face activities. The program's pilot is currently underway and evaluation research findings are informing the next program iterations. The ultimate goal of this program is to formulate general recommendations on how to serve large numbers of diverse learners at scale in an optimum way. In addition to an evaluation pilot study, MIT experts on AI and the Science of Learning have been asked to review the program and their feedback will be integrated into the next program iteration.
This paper presents the three learning journeys as originally designed to serve the three first diverse cohorts of learners, as well as the plan for future improvement and implementation of the program.

1 INTRODUCTION

Artificial Intelligence (AI) is a rapidly growing field expected to change the way organisations and businesses operate, as well as how grand challenges of the future will get tackled [1]. As the AI field progresses the number of jobs in or in conjunction with this sector is also growing. Industries need upskilling programs for their employees, "universities are clamoring to create curriculum that can meet the demand for computer scientists with AI expertise", and governments are working to find ways to best educate the general public [2]. Approaches to AI education vary significantly. They include topics ranging from understanding of fundamental concepts, applications and solutions, to development of hard-core technical knowledge like machine learning, robotics and big data analytics. Technical knowledge is guided mainly by the engineering and computer science world, but there is an urgent call for timely discussions about societal and ethical implications of AI development and use [1]. Despite the urgent need for State-of-the-Art AI education, this field is at a nascent stage and there is still a lack of understanding regarding what the optimum ways would be to approach different professionals with different needs, along with the education of the general public.

Within this context the US Department of Defence (DoD) decided it is absolutely crucial to harness the potential of AI to positively transform all functions of the Department, while also supporting AI education related research and development targeting a broader body of learners. Realising this vision requires identifying appropriate use cases for AI across DoD, rapidly piloting solutions, and scaling successes across the whole enterprise [3]. The Joint Artificial Intelligence Center (JAIC) was the focal point selected for carrying out this vision [3]. As careful AI adoption in all operations would require both State-of-the-Art technology and a highly educated and trained body of employees it became clear early on that the DoD would need to closely collaborate with academia or other centers of innovation providing expertise on AI education, to design the appropriate educational resources and training programs [4]. Given the size of the United States Air Force (USAF) workforce (~680.000), the difference in employees educational (high school diplomas to graduate degrees), age (18-60), cultural backgrounds, and the difference in the nature of their daily working needs and operations (full spectrum of officer and enlisted ranks), in 2020 DoD decided to collaborate with multiple units of the Massachusetts Institute of Technology (MIT) and fund an AI Education research project that would explore the development of a set of different AI learning journeys targeting subgroups of diverse learners (for this paper each group will be called an *archetype*). Goal of this mixed-method research approach is to understand the learner experience regarding content, pedagogy, and educational technologies engaged in the learning process. Findings are expected to guide further iterations of the program as the number of learners will be scaling up. This concept paper will present the development and implementation of the first 3 learning journeys that started in the summer of 2020, and a plan for future improvement.

2 AI EDUCATION PROGRAM DEVELOPMENT

2.1 Background

To start this endeavour JAIC engaged in a primary analysis of the USAF body of employees and presented a set of 6 archetypes (see Table 1), as well as desired AI related needs, skills and competencies for each one of them. A description and analysis regarding desired AI competencies and learning outcomes per archetype, as well as expected levels of understanding can be found in greater detail at the 2020 DoD AI Education Strategy [4].

Table 1. Learner archetypes (Modified from [4])

Name	Descriptions
Lead AI	Decides policy and doctrine, including how AI tools can or will be used; builds AI vision and plan
Drive AI	Ensures appropriate AI tools and capabilities are developed and delivered
Create AI	Creates AI tools to meet current and future needs
Embed AI	Embedded with Employ AI, establishes AI systems and provides end-user support at tactical edge

Facilitate AI	Represents user to ensure appropriate AI tools are developed and delivered to address use cases
Employ AI	End-user of AI tools, provide feedback on and requirements for AI tools.

2.2 USAF - MIT AI Accelerator

In 2019 the Department of the Air Force (DAF) signed a cooperative agreement with MIT and jointly created the Artificial Intelligence Accelerator, hosted at MIT. In summer 2020 the USAF-MIT AI accelerator, involving staff from MIT Campus, MIT Lincoln Laboratory, the DAF, along with STEM education researchers from MIT Open Learning and the MIT Media Lab, launched the “Know-Apply-Lead” project, to design, implement, and evaluate 3 separate AI-focused learning journeys particularly targeting the aforementioned archetypes.

3 THE LEARNING JOURNEYS

3.1 Content

In the summer of 2020, a group of MIT faculty and staff, with an expertise on AI and STEM education, collaborated with JAIC to develop the first set of learning journeys. Three cohorts were formed including learners representing two archetypes each, who appeared to have similar working needs, interests and backgrounds, and would equally benefit by attending the same courses. First cohort includes learners from the Lead AI and Drive AI archetypes (L/D) traditionally focusing more on management and leadership of the organisation, second includes learners from the Create AI and Embed AI (C/E) being mostly technology developers and facilitators, and third includes learners from Facilitate AI and Employ AI (F/E) who are mainly AI technology end users. After examining the needs of each cohort, the MIT team proceeded to explore what appropriate AI related courses the group could leverage on from MIT’s online catalogue of resources, along with what would be the most meaningful development of custom-made exploratory courses and accompanying educational experiences. Discussions led to the design of 3 different learning journeys employing a variety of pre-existing, adapted, and new educational resources.

3.2 Pedagogy and Educational Technology

Educational research has already shown that online courses where students can access educational resources at their own pace and master topics and concepts before moving on to more advanced levels is an effective way to learn [5]. Hands-on authentic project-based and problem-based learning is another established way to master technical skills and applied practices [6]. However, existing online learning platforms often fall very short when needing to support automated personalised tutoring or collaborative hands-on projects. Considering the program scope and technological restrictions, the team decided to employ, study, and evaluate a combination of technology-enabled pedagogies and experiences, while combining online and in-person learning contexts for AI [7]. Furthermore, state of the art teaching and learning practices and theoretical frameworks have been employed in several aspects of each learning journey, such as active learning, memory retrieval practices, employment of low-stake quizzes, and presentation of worked/faded examples. Number of learners is also expected to significantly scale over time. Given the opportunity to leverage existing MIT resources while also developing new content, the group ended up offering 3 learning journeys that combined 5 learning modalities, that are now getting separately studied and evaluated (via 4 learner surveys spaced throughout the program, interviews to program staff, and "gap analysis" performed by MIT-USAF AI experts) to guide our understanding about optimum AI teaching approaches:

- *online asynchronous self-paced* courses about AI fundamentals were available to learners throughout the duration of the whole program
- *online asynchronous instructor-paced* courses (about 3-months in duration, each)
- *experimental courses* (online or in-person project and team-based courses, particularly designed to interweave technical and ethical content about AI, with a 3-5 days duration)
- *live online events* about AI offered by MIT to a greater audience (1-2 hours long webinars)
- *curated supplementary materials* available to learners to read or watch (spanning 30 hours of material)

Table 2. Learning modalities employed in the 3 learning journeys

Cohort	Learning Journey courses and activities (# of offerings)				
	Online asynchronous self-paced	Online asynchronous instructor-paced	Experimental Courses Online	Experimental Courses In-person	Live Online Events
L/D (N=100)	2	1 (select out of 2 options)	1*	1*	6
C/E (N=30)	2	1-3 (select out of 3 options)	N/A	1	6
F/E (N=100)	2	N/A	N/A	N/A	6

*learners could choose between one online or one in-person experimental course

To better support the program, and given that the learners had to enrol in different platforms to participate in various pre-existing online courses, the team proceeded to develop an access portal for learners. Through this portal the learners were directed to their own personalised learning path and could keep track of their progress, while the development team could also keep track of learner's progress and course completion status (using a self-report tool).

3.3 Learning journey content and timeline

Figures 1-4 present the 3 learning journeys along with the planned timelines showing various offerings to each cohort. The learning journey for the L/D cohort was offered to 100 learners and designed with an emphasis on AI business strategy, ethics and policy. The learning journey for the C/E cohort included 30 learners and had a greater orientation towards development of deep technical knowledge and the know-how of AI tech solutions with an emphasis on probability, statistics, and machine learning. The learning journey of the F/E cohort aimed to provide fundamental knowledge about AI to an end user of AI solutions. This cohort included 100 learners.

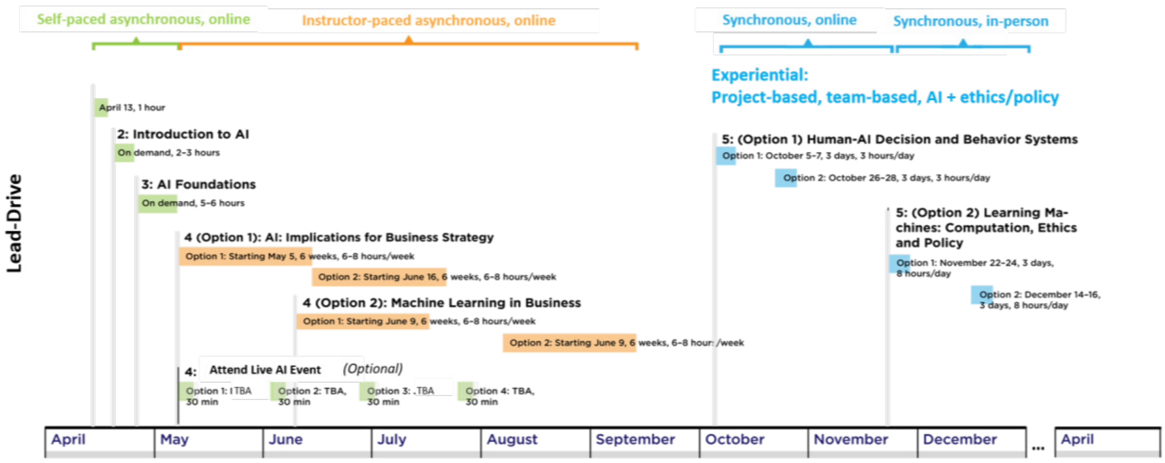

Fig. 1. Lead/Drive Learning Journey with an emphasis on AI business strategy, ethics, and policy

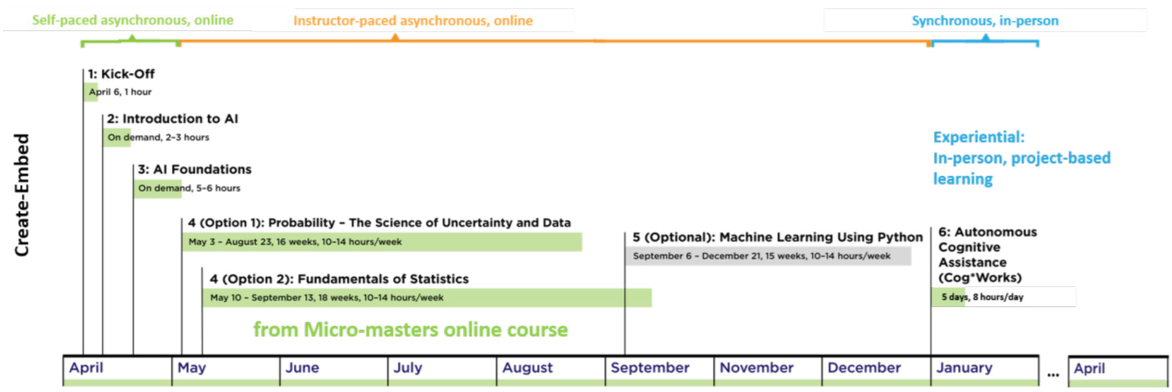

Fig. 2. Create/Embed Learning Journey with an emphasis on technical knowledge and know-how of AI solutions

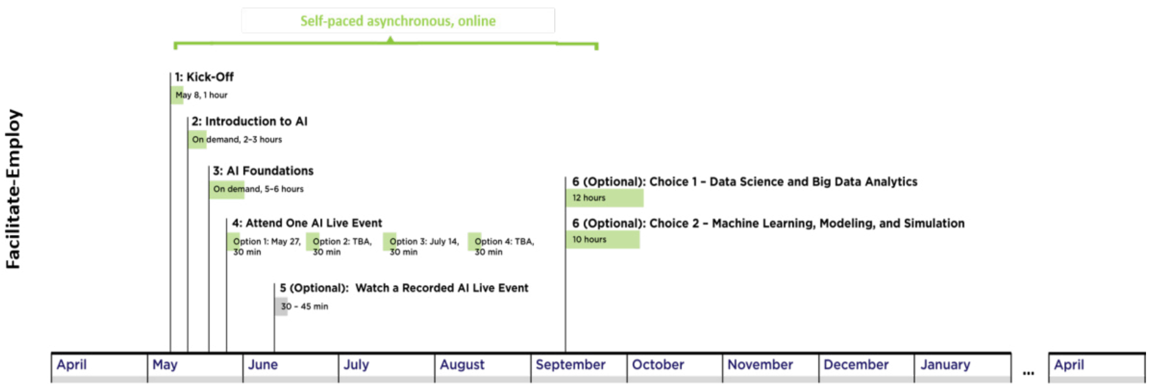

Fig. 3. Facilitate/Employ Learning Journey with an emphasis on developing fundamental knowledge about AI

Fig. 4. Screenshot of the 3 learning journeys as presented to each cohort in our AI Education Research Portal

4 CURRENT STATUS AND FUTURE ITERATIONS

4.1 Program completion and certification

April 15th, 2022 was the completion date for the first 3 cohorts participating in the program. Some activities were delayed due to COVID restrictions being imposed to in-person courses/workshops. Figure 5 presents the completion rate per cohort. Learners receive a certificate of completion if they have completed over 90% or the required tasks, videos, readings and low-stake quizzes (knowledge check-ins) of their learning journey (based on their responses in the AI platform self-report tool). Our team noticed that there were many optional tasks that had also been completed.

Fig. 5. Percentage of completion of all required tasks as of March 15, 2022.

4.2 Future Plans

Based on an initial first pilot evaluation study, described in great detail in [7], and also guided by recent findings from the Science of Learning field, plan for future improvement suggest work on the following areas:

- **Technology:** Improvement of accessibility and developing a program that will support single access to all courses.
- **Content:** Develop case studies and examples directly related to the learner organisation to provide better context and raise interest and engagement.
- **Pedagogy:** Redesign knowledge check-ins used in the asynchronous self-paced courses, to better support retrieval learning practices and enhance learning retention. Provide the F/E cohort with opportunities for live mentored sessions. Provide and better support community building and opportunities for peer-learning for all cohorts. Consider more opportunities for cross-cohort interactions, as well as interactions with learners from other military units.

Furthermore, a small group of the program staff will be interviewed to understand the logistical hurdles experienced by learners, and a group of MIT AI experts have been commissioned to perform a gap analysis on current curriculum and provide an additional set or recommendations about additional content and appropriate pedagogy. Overall, research findings will further inform updates to the future learning journeys.

Scope of this program is not just to evaluate various learning modalities but also to understand if and how they would best serve the program as the number of learners will keep on scaling. The group is now working on the aforementioned improvements and has also proposed two larger cohorts to start within the next year.

ABSTRACT

An opinion piece in Scientific American [1] discusses how a fraction of students ultimately complete a STEM degree and cites research [2] that disengagement with traditional calculus courses as one of the causes. It goes on to highlight examples of several promising calculus reforms and recommends that STEM faculty take the lead in introducing changes by collaborating and co-creating across disciplines to make mathematics more relevant and interesting to students.

Feedback from module surveys indicate that students learn much better when the link between theoretical and practical knowledge is captured and echoes pedagogical literature.

s.m.salim@swansea.ac.uk

doi:10.5821/conference-9788412322262.1373

The author introduces past experiences of active learning approaches to enhance the teaching of mathematics to first-year engineering students. Class discussions incorporate real-life engineering applications highlighting example problems from a wide variety of core engineering modules such as Fluid Mechanics, Vibration, and Mechanics of Materials.

The impact of this approach has not been directly measured and documented for the module being discussed here and is motivated by encouraging student feedback where they shared that they find the teaching interesting, fun, engaging, and interactive. The present concept paper therefore outlines how past pedagogical practice have influenced the enhancements in the delivery of engineering mathematics with a particular focus on interdisciplinary approach. It then goes own to demonstrate some examples of implementation and offers initial reflections based on student feedback. Finally, the author proposes future steps of detailing the effect on student learning experience via class surveys, interviews and making comparisons to comparably taught modules.

1 INTRODUCTION

1.1 Motivation

Galileo wrote: "*Philosophy is written in this grand book, the universe… [But the book] is written in the language of mathematics*." The study of engineering requires a substantial grounding in engineering principles, science, and mathematics. The gradual development of students' critical thinking and analytical ability to solve real engineering problems is the key to their future success [3]. A strong foundation in mathematics is therefore necessary to produce competent engineers who can confidently analyse and solve problems, employ analytical tools and techniques, design and innovate, and communicate their results.

Research about why students abandon degrees [2] suggests that traditional calculus courses are one of the main reasons. This tallies with anecdotal observations of declining competencies of mathematical ability in senior undergraduate students, with several engineering students struggling to do simple calculus in higher levels of studies, based on discussions and comments from academic colleagues. And alarmingly, a recent report, '*Charting a New Course: Investigating Barriers on the Calculus Pathway to STEM'* [4] adds that traditional approaches to calculus are partly responsible for the large proportions of women and students from minoritised backgrounds getting discouraged from pursuing STEM careers.

It's generally suspected that one underlying factor to these issues can be attributed to the lack of engaging and relevant material in describing, solving, and understanding the significance of mathematics in an engineering context. A publication recommends that STEM faculty prioritise collaborations and co-creation across disciplines to transform math classes [1]. The same article concludes by proposing that "math learning is fundamental to all STEM fields, but the opposite also appears to be true: the STEM fields may be central to making math learning effective for more students.

Student-centered pedagogies like problem-based learning, collaborative learning, process-oriented guided inquiry learning, and peer-led learning have been extensively developed and tested in response to the tried-and-test approaches to match the way we teach to the way students learn [5]. Studies have shown that active learning environments are more effective than traditional lectures [6]. And Mark Deakin [7] concludes that students value the link between teaching and research, placing particular weight on research led teaching and the bearing which it has on the quality of their learning experiences.

With these in mind, the present concept paper first briefly describes prior successes of employing CDIO framework in the design and delivery of engineering modules such as Computational Fluid Dynamics and Solid Mechanics. The positive impact of the past implementation motivated the use of the CDIO approach in the teaching of the current mathematics module. The paper outlines how this method has been adopted in the existing engineering mathematics module to make it more relevant, attractive, and interesting to learners and reports early results from observations and module surveys. Finally further work is proposed to structurally measure the effects of the introduced enhancements on students learning and progression.

1.2 CDIO

The paper will start with a summary of the CDIO approach and its benefits. CDIO is an educational framework that stresses engineering fundamentals set in the context of Conceiving, Designing, Implementing and Operating (CDIO for short) real-world systems and products. CDIO advocates active learning techniques such as problem-based learning to equip engineering students with technical knowledge as well as communication and professional skills. These techniques collectively promotes active and integrated learning experiences. The core philosophy of CDIO is to prepare engineering students who can engineer. Readers are encouraged to visit www.cdio.org to find out more. This has a bank of useful resources including standards, syllabus, and case studies.

1.3 Past Implementation and Student Feedback

The author has experimented with and implement different educational frameworks and has continuously adapted and refined his teaching on reviewing class performance and feedback. He has received very encouraging student feedback over the past decade such as *"The only enjoyable class throughout my studies is Solid Mechanics Class. Additionally, we were given the opportunity to work on an assignment in which, for the first time, I was able to apply my engineering knowledge to design a given task. This has never been done in any other Engineering classes and should strongly be taken into consideration"* referencing the CDIO approach employed. Another student from a subsequent cohort agreed: *"He's very good in explaining the theory behind each mechanics applied in engineering as well as in real life situation. He makes us think out of the box which is very good and indeed challenging. Keep up the good work!"*

The author's colleague attests: *"I believe his plan for assessment strategies proved very effective in motivating the students to develop and apply their techniques…and to act as real engineers in a way that would be sought by future employers".*

The knowledge, skills, and experiences gained over the years backed by positive student feedback and observable improvements in class performance helped refine the author's teaching practice and build his confidence. The next section describes how the past implementation and experience of CDIO principles influenced the teaching of mathematics. Then goes on to reflect on the impact on student learning initial feedback received from the cohorts.

2 ACTIVE LEARNING IN MATHEMATICS

2.1 Adopting CDIO in engineering mathematics

Pedagogical literature, student feedback and discussions with colleagues have highlighted the benefits of integrating theoretical knowledge with practical application which is the underpinning principle of CDIO. Drawing from cross-discipline research and engineering subject expertise the mathematic lessons are updated with real-life applications to introduce mathematical concepts, solve class examples, and demonstrate applications of the new contents being presented and discussed. The intention is to help learners relate to the subject matter, appreciate the relevance of mathematics in the wider engineering context, and in the process excite them to discover more and transfer knowledge.

2.2 Outline of the engineering mathematics module

The mathematics module (titled 'Engineering Analysis 2') is taught to 1st year undergraduate engineering students in their second semester and covers:

- Vectors
- Complex Numbers
- Ordinary Differential Equations
- Multivariate Functions
- Series and Sequences

The module's main aim is to provide the essential grounding in mathematical analysis techniques for engineering students with a focus on calculus which is the mathematical study of change.

2.3 Delivery plan

In the very first lesson students are introduced to the Navier-Stokes Equations as one of the unsolved Millennium Prize Problems by the Clay Mathematics Institute[2]. This is followed by discussion about various ways of solving engineering problems: analytical, experimental, and computational and the class finally go through the use of the Navier-Stokes Equations in the context of Computational Fluid Dynamics (CFD) with some real-life examples from senior student projects over the years. The intention of this is to encourage the first-year students to see the bigger picture and appreciate the end goal of learning all the mathematical techniques and how it will gradually equip them with the tools and skills to analyse and solve engineering problems in later level of studies.

The beauty of the Navier-Stokes Equations - which are fundamentally the conservation equations of mass (continuity), momentum (Newton's second law) and energy - are that they are multidisciplinary, and learners will come across them repeatedly in various forms and iterations in the other core modules of Thermodynamics, Fluid Dynamics, Solid Mechanics and so on, throughout their engineering studies.

As we progress through the 10 weeks of classes, we revisit the different aspects of the Navier-Stokes equation and relate them to the mathematic concepts we are learning thus threading all the topics together.

Two examples are presented below:

[2] https://www.claymath.org/millennium-problems

Example 1: Vectors (Chapter 1)

Fig.1. is a screenshot of the material hosted on Microsoft OneNote presented to the class when introducing the ‘Vectors’ topic. It includes example of student projects using CFD and linked to the Navier-Stokes Equations. The left image is of a student modelling the ventilation in a lecture theatre to evaluate the indoor air quality in response to the covid outbreak. The other two are simulations of a previous intake manifold used by the Formula Student race team and their proposed design change to enhance the volumetric efficiency. This gets the students interested, motivated and encourages them to appreciate the reason they are learning vectors.

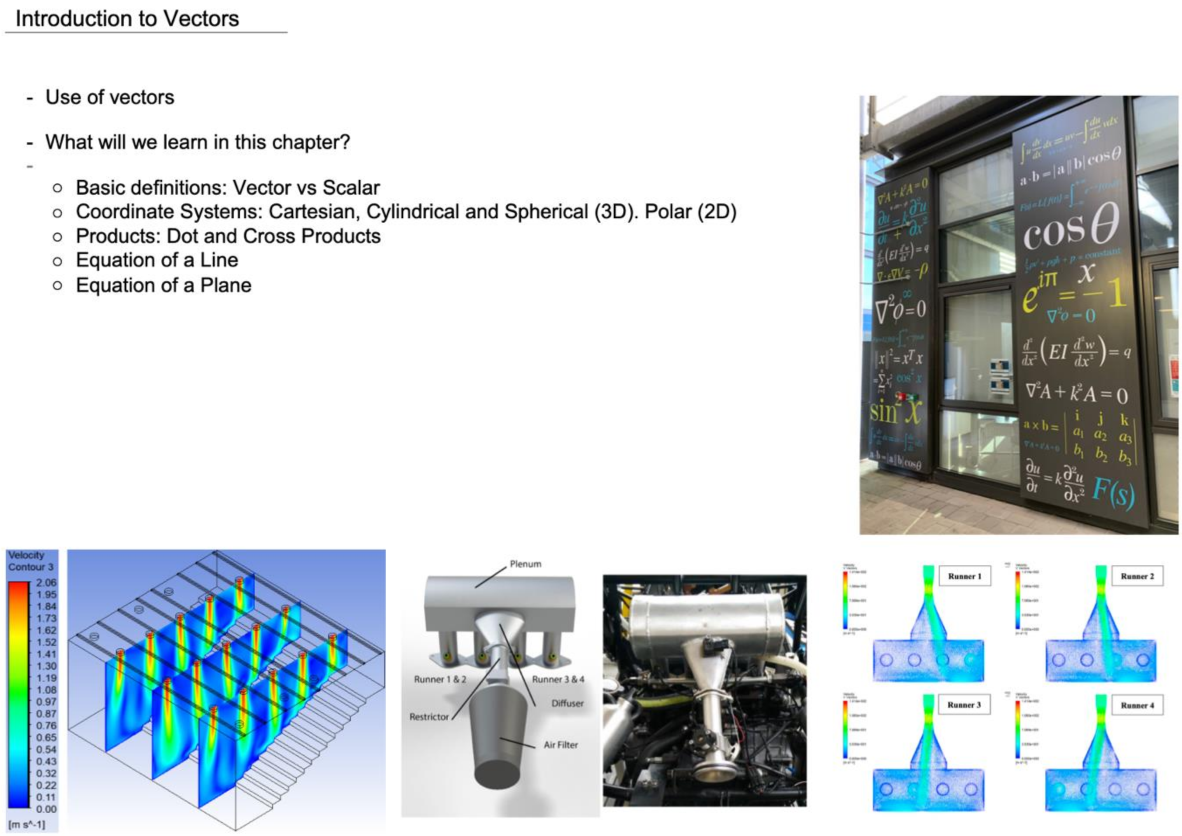

Fig. 1. Introduction to Vectors

Example 2: Multivariate Functions (Chapter 4)

Half-way through the ‘Multivariate Functions’ topic, we revisit the Navier-Stokes equation to demonstrate that acceleration (in $F = ma$) is a multivariate function of x, y, z and t and we proceed to employ the chain rule to derive the material derivative. This also links well with ‘vectors’ topic where we come across the dot product again. The other example to the left illustrates the conversion between cartesian and polar coordinate systems also covered in vectors and discusses composite functions and the chair rule.

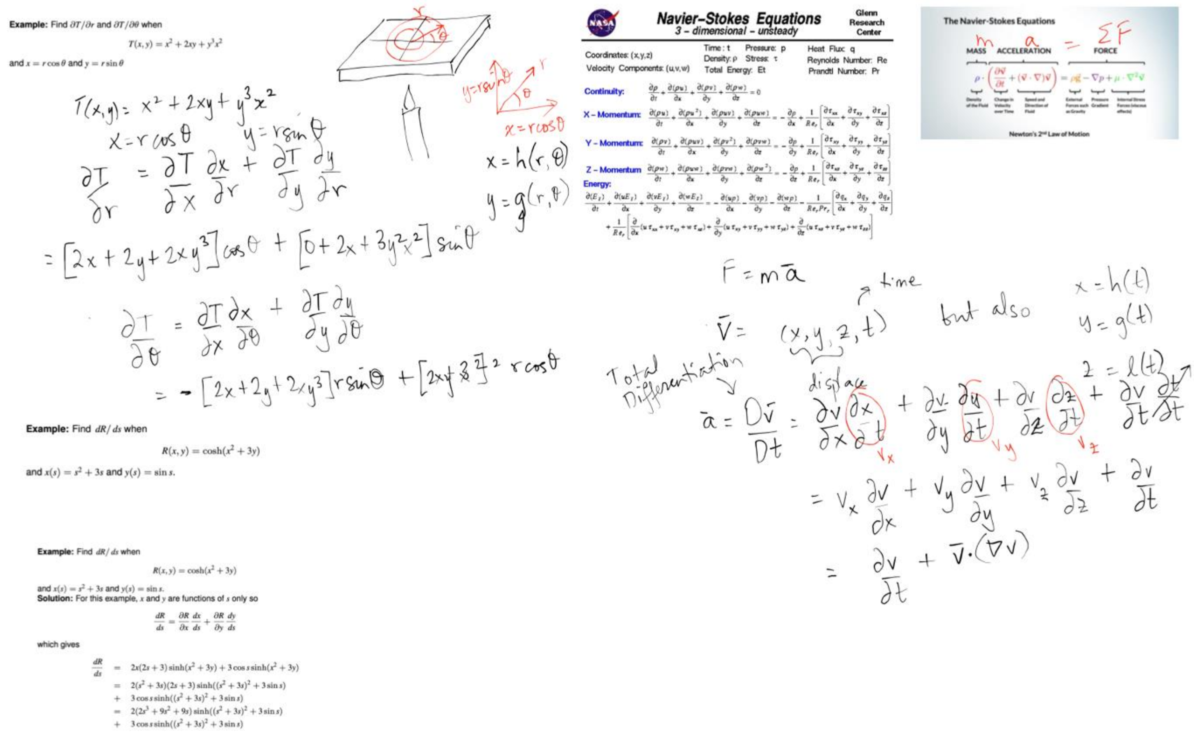

Fig. 2. Chain Rule for Differentiation of Multivariate Functions

3 REFLECTIONS

I've included student comments collected as part of the formal module feedback exercise from the past and current academic year for the module. This was obtained via a standardised survey deployed across the faculty using evasys+ tool (https://evasysplus.co.uk/). The comments below are in response to the open-ended question:

Q: Please name the one thing in the module which had the most impact on your learning.

I enjoy these lectures I feel like the lecturer has a passion for mathematics and it shows through his teaching.

I like the variety of ways he teaches his lectures (example classes, quiz classes, polls etc) as this helps me stay engaged and focused.

I like the use of the class notebook [Microsoft OneNote], it makes it easier to go back and revise some of the example problems covered.

I think sir is quite interactive. I understand very clearly and when I am stuck, he supports us.

Lecturer is very likable and approachable, and this shows in his lectures. Everyone pays more attention because he also makes the lectures more interesting and fun to attend.

Really enjoying the module so far. Good level of teaching and good structured live zoom lectures!

The lecturer is very engaging. He makes the lectures interesting and his passion for the subject is very clear, making lectures more enjoyable. The lectures are very interactive.

Love coming to this module. The lecturer is really enthusiastic and passionate about what we are being taught. The content is being taught at a good pace. I really appreciate the chances to ask and answer questions throughout the lectures and the fact it is made sure everyone understands before we move on.

The keywords: passion, interactive, engaging, fun, interesting and of course the best compliment: love reassures me that students are benefiting from and enjoying the teaching approach. The author attributes these positive comments to the use of real-life engineering examples to explain and bring to life the mathematical techniques. He draws in content and applications from other engineering subjects and research activities making the module truly inter- and multi-disciplinary.

The positive student feedback support the opinion piece in Scientific American [1] which suggest that “math education researchers consider more relevant and engaging curriculum to be an important strategy for increasing persistence rates particularly among students traditionally excluded from STEM fields, such as Black, Latinx and Indigenous students, as well as women.” The same article gives an example from Wright State University’s where academics focused on preparing students for calculus by emphasising ‘engineering motivation for math’ rather than changing the module content.

4 FUTURE WORK

The Scientific American publication continues by arguing that “the shift toward more practical applications of calculus is missing one key academic endorsement: publication in widely-read journals, if the success of the courses is examined academically at all.”

One can deduce from the student feedback that the adopted teaching approach of incorporating material from other core engineering subjects and emphasising real-life applications very likely contributed to the positive satisfaction with the currently discussed module. It will therefore be interesting to conduct more pedagogical research via surveys and interviews and comparing against similar modules (the teaching of the engineering mathematics is split in to 3 separate cohorts due to large numbers of engineering students – over 600 in total).

The author also proposes to investigate to what extent the revised teaching delivery plan has had an impact on the students learning by interviewing completed cohorts as they progress to their next level of studies (Year 2 and 3, respectively) and will include questions that draws comparisons to related modules, particularly the preceding engineering maths module delivered in the previous semester and to pre-university maths studies such as A-levels and/or Foundation programmes.

There will be specific questions related to the inter- and multidisciplinary approach and real-life examples, and whether this has better prepared them for modules such as Fluid Mechanics and Mechanics of Materials that they have encountered in the later years of studies.

ABSTRACT

The industry demands skill-equipped engineering graduates who could be efficient enough to adapt to face the challenges of uncertainty posed by a lack of skills and resources. Accreditation boards have identified problem-solving, teamwork, communication, etc. as the workplace required skills. However, industry/employers feel that the engineers seem to lack problem-solving, teamwork, etc. To groom these skills, experiential learning (EL) platform provides hands-on practice. Thus, the study aims to gain insights into the need of experiential learning to integrate learning and experience. The study, qualitative in nature, focuses on the essential skills, specifically problem-solving skills, against the applicability of experiential learning. Experiential learning allows engineering students to get a hands-on approach to practise their acquired skills to understand industrial needs and constraints. In the given context, problem solving helps in knowing what is learnt and what needs to be learnt.

1 INTRODUCTION

In 2018, the Organisation for Economic Co-operation and Development (OECD) raised two well-reasoned questions: what knowledge and skills future engineers require; and how instructional systems can help develop that knowledge and skills? This being an unavoidable issue tends to seek attention on multiple facets. Employers and various agencies, after having understood the essentiality of such skills, give high importance to problem-solving skills (86%) followed by teamwork (79%) among the key future skills (Hristov, Minocha & Sreedharan, 2018). Only 33% of employers feel that graduates possess the necessary higher-level skills and knowledge that they are looking for in their industry. Supposedly, engineering programmes must prepare engineering graduates for the practice of engineering at the professional level (IEA, 2021). However, employers and industrial representatives seem to be congruent in their understanding that the graduated engineers lack specialised knowledge as well as employability skills, the expected learning outcomes of engineering education.

Some of the assumptions associated with skills are: the skills develop on their own during the learning phase; their understanding and acquisition is implicit; explicit efforts are not needed; and only technical aspects need attention. Various stakeholders are making conscious efforts to draw attention to skills, their finer aspects, implementation, urgency, and benefits Accreditation boards (IEA, 2021) have identified twelve skills: engineering fundamentals, knowledge of a particular domain, environment and sustainability, design, problem-solving, the engineer and society, independent work settings, lifelong learning, teamwork, communication, conflict management, and ethics.

Engineering education seems to address essential life and career skills to deal with financial pressure, career opportunities, time management, workplace etiquette, and other necessary skills. Engineering education, being technical in nature, needs to be more practice oriented. Learning-oriented involvement (to observe, analyse, interpret and solve) of students in experimental data, a case study, a complex real-world problem, etc. (Prince & Felder, 2006) makes students active agents. Theory-based teaching, outdated curriculum, academic environment isolated from industry work (Hristov, Minocha, & Sreedharan, 2018), etc. lead to lack of skills. Various benchmark and policy statements emphasise creative and critical problem solving skills. Problem solving skills, recognized as one of the key concepts of the learning framework (International Engineering Alliance (IEA), 2021) (https://www.ieagreements.org/assets/Uploads/IEA-Graduate-Attributes-and-Professional-Competencies-2021.1-Sept-2021.pdf), is still a big challenge for Indian engineering education (Büth et al., 2017). The employees who can work in groups to identify problems, sift solvable unsolvable problems, understand causality, form problems, take calculated risks, and be resourceful enough to solve uncertain, ill-defined, and unthought-of problems, apparently seem to be an asset to any industry.

Learning seems to comprise a complete set of contextual skills. Experiential learning (EL), comprising active as well as reflecting learning, helps learners acquire knowledge, understand theoretical concepts, foster complex problem solving, develop other skills, apply previous knowledge to current problems, and attain superior performance. EL techniques (theory-practice integrated), such as problem based learning, project based learning (Savery, 2015), make learners realise that problems are valuable; difficulties and problems lead to learning; and knowledge is applied in real life. Thus, the study aims to gain insights into the need of experiential learning to integrate learning and experience. The questions addressed are:

- Which skills are required the most by industry?
- What are the types of experiential learning techniques?
- Does the curriculum of premier institutes of India give space to EL?
- How experiential learning enables developing the skills in the Indian context?

2 METHODOLOGY

The study, qualitative in nature, focuses on the development of problem-solving skills against the applicability of experiential learning. Deductive approach was used to extract skills and EL from literature review. Inductive approach was used to analyse curriculum documents of the two leading premier institutes (higher education) of India, based on the pedagogical approaches: teaching techniques, learning environment, content, and assessment.

3 SKILLS OF ENGINEERING GRADUATES

94% of employers termed problem-solving and teamwork as the two top skills urgently required in their sector (Hristov, Minocha & Sreedharan, 2018). There is an improvement in teamwork but problem solving still remains a challenge (Sting, 2016). Problem solving is a complex yet systematic process with criticality to address a dynamic issue and seek multifaceted and open ended solutions (Priemer et al., 2019). Problem-solving skills is not only about process (stages and strategies) but also about problem (nature and context) and solution (types) (Sangwan & Singh, 2021).

The process has two to five stages; each stage has specified strategies. Reflection is one of the important stages in the process. Learners should be able to describe, explain, design, and produce with what they know, understand, think, and believe. The complexity and difficulty of problems are relative, depending on the learner's own existing knowledge, strategy application, and situated context. Thus, the approaches and teaching-learning techniques need to be explored to find their effectiveness in improving problem solving skills.

4 ROLE OF EXPERIENTIAL LEARNING IN ENGINEERING EDUCATION

Despite intense focus on multifaceted aspects, students seem to lack exposure to practice-based higher education curriculum and pedagogies (Hristov, Minocha, & Sreedharan, 2018). The challenge is not only to infuse domain specific and disciplinary insights but also to make the learners competent. Skills (and outcomes) comprise three concepts (problem solving process constituents): head (intellectual development), hand (skill development), and heart (modes of thinking, habits of mind). Intellectual development enables engineers to analyse and evaluate; skill development eases tools usage to manipulate the knowledge; and thinking habits sharpen motives and strategies for learning and performing.

All three elements (teacher, learner and environment) impact skill development. Real work environment/practical experience must comprise active and interactive actions in teaching-learning. An integrated framework of problem-solving, addressing domain-specific, complex, and interdisciplinary problems (Priemer, et al., 2019), can equip the learner not only with the theoretical knowledge (concept of 'what' - deductive approach); but also with the situated knowledge application ('how and why' - inductive approach).

Conducive environment encourages students to re/construct knowledge through metacognition - the process of assessing their own understanding and performance through reflection - a stage of EL cycle (Venugopal, Singh, & Devika, 2019; Kolb & Kolb, 2017). Metacognition corresponds to problem solving. Next, heterogeneity of learners changes the role of learners and teachers; same instructions and same environment cannot check performance variance. EL (student-centred pedagogy) provides a platform to learners to realise and assess their own learning, errors and improvements, and changes the role of teacher as a mentor and the role of learner as a performer.

EL theory (Kolb & Kolb, 2017) has four stages: experiencing, reflecting, thinking, and acting. Experiencing is necessary for learning. EL involves both active and reflective learning (learning by doing, experiencing, discovering, and exploring). Reflecting, an iterative learning experience, develops self-awareness, a part of the problem solving process. In the EL curriculum (like PBL), projects enable students to identify and analyse multidisciplinary problems and problem-solving processes, develop critical thinking skills, and experience deep learning (a comprehensive grasp on the meaning) (Edström & Kolmos, 2014). Prior knowledge, knowledge organisation, motivation, skill development for mastery, goal directed practice and feedback, interaction between learner development and course environment, and approaches monitoring and adjustment are the principles of EL. The EL techniques - problem based learning (PBL), Project based learning (PrBL), Research based learning (RBL), Inquiry based learning (IBL), Case based learning (CBL), and Discovery based learning (DBL) - cater to engineering education particularly (Camacho, Valcke, & Chiluiza, 2017; Savery, 2015; Prince & Felder, 2006). Subsequent to the identification of types of EL, the study compares these six techniques (see table 1) in the context of suitability of engineering education and problem-solving skills. The comparative analysis is based on the four parameters such as role, encouragement, practice and hands-on-experience, and learning outcome (skills) (Hristov, Minocha,

& Sreedharan, 2018). Besides these four, one more parameter (discipline applicability) was identified through literature.

4.1 COMPARATIVE ANALYSIS OF EL TECHNIQUES

Abducitve (mix) approach, learner-centred pedagogy, and active learning are predominant in all EL techniques. PBL and RBL contribute to the development of problem solving skills to the maximum followed by PrBL. These three learning techniques do contribute to the development of problem solving skills to a higher level (Singh et al., 2019; Winarti & Waluya, 2019; Efstratia, 2014). PBL (being engaged, hands-on experience) makes learners challenge things, develop a deeper understanding of the subject, and enhance deep learning. (Hristov, Minocha & Sreedharan, 2018). Learners become more active, self-dependent, and owners of the learning process in PBL and RBL than PrBL; facilitator guides the students with ideas, methods, and tools in PBL (Edström & Kolmos, 2014).

Teacher acts as a facilitator (student centred - contemporary) than a conventional lecturer (teacher centred - traditional). In EL techniques, learners receive sufficient scaffolding (both support and supervision followed by gradual withdrawal of the support and feedback (multidimensional, non-evaluative, timely, specific)) as a powerful driver.

PBL is not a simple application of the methodology that may be transferred to the classroom without making structural changes. Implementation of EL techniques like PBL needs consideration at all three levels: teacher/learner, course, and organisation. This represents the shift in classroom culture. Implementation of EL into engineering education helps achieve the learning outcomes, as it leads to the development of problem solving skills required at the workplace. Overall, it has been found that EL provides a platform to the teacher/learner to develop and improve problem solving skills.

Table 1. Comparative analysis of EL techniques

EL techniques: Types → Parameters ↓		**PBL**	**PrBL**	**CBL**	**IBL**	**RBL**	**DBL**
Role	**Teacher**	Facilitator	Coach	Instructor	Facilitator	Facilitator	No guidance
	Learner	Very Active	Less Active	Active	Active	Very Active	Active
Encouragement		Very High	Moderate	Low	High	Low	Moderate
Practice and	**Product oriented**	Low	High	Low	Low	Low	Low

hands-on experience learning	**Process oriented**	High	Low	High	High	High	High
Learning Outcome (skills)	**Analytical**	High	High	High	High	High	High
	Decision-making	High	High	High	High	Moderate	Low
	Team work	High	High	High	High	High	High
	Problem solving	High	High	High	High	High	High
	Self-directed learning	High	High	Low	High	High	High
	Self-awareness and management	High	Moderate	Low	High	High	High
Applicability in disciplines		Education	All areas of education	Law, medicine, business management, teacher education	Science education	All areas of education	School education

4.2 Analysis of Curriculum of engineering education in Indian context

The analysis of curriculum of Indian institutes of engineering education would help in developing basic understanding about the concept of graduate attributes development holistically. For this, the curriculum of high ranking, fully government universities such as Indian Institute of Technology (IIT) and private university such as Birla Institute of Technology and Science Pilani (BITS) were analysed based on the documents available in the public domain as well as interacting with the past and current students of these institutes. The analysis was performed on parameters of teaching techniques and learning environment, content, and assessment.

Teaching techniques and learning environment: Both universities have classroom environment and industry internships within the curriculum. The internships provide the opportunity of a real work environment to the students for a very short period. The Indian engineering graduates are taught based on input-output orientation (PrBL approach). Most of the core courses have laboratory classes but unfortunately these laboratory classes have input-output orientation, which does not foster real life environment problem solving skills. Though the faculties in these universities are highly qualified but lack industrial exposure, a probable reason for the gap between theory and practice in teaching-learning. Theoretical basis of Indian teachers is very strong but they fall short of new developments (Hristov, Minocha & Sreedharan, 2018). BITS Pilani, known for innovation in teaching and learning, particularly in India, provides full semester project courses (study, laboratory, design, special projects, etc.) to cater to the students' learning in newer or advanced areas. BITS Pilani also has a minimum seven-month internship with industry while IITs have short duration internships.

Content: The curriculum includes foundation courses (engineering, mathematics, sciences, humanities, technical arts, and application oriented courses), core (compulsory disciplinary), discipline electives, and open elective courses, indicative of content rich curriculum to develop the required skills among engineering graduates. Core courses develop strong fundamental knowledge in particular domains forming the part of theoretical knowledge. Also, the students admitted in these institutes have highly competitive entrance examinations, ensuring high quality students.

Assessment: The assessment is done majorly through written examination (mid semester, end semester, continuous assignment, quiz, etc.) and practicals (experiments, viva-voce, quiz, etc.). The written examination at BITS Pilani is both open book and close book. The questions in the open book are application oriented, with more flexibility to construct prior experience based knowledge. Open book examination develops application oriented learning and knowledge transforming ability.

The analysis also reflects that with the current teaching approach the Indian engineering graduates are likely to lack problem solving skills. The Indian higher education institutes have to redesign their laboratory classes based on open ended experiments rather than input-output based experimentation. Overall, it can be stated that current pedagogy, predominantly PrBL, is not solely sufficient to develop problem-solving skills. Based on the analysis of the lack of problem solving skills, the study recommends integration of EL aspects in the teaching-learning techniques and environment to develop and improve problem-solving skills.

- More exposure to practice and problem solving along with self-awareness
- Engagement of learners in an authentic environment
- Need to bring familiarity with the cultural aspects of EL techniques in comparison to traditional teaching-learning
- Need to arouse interest and motivation among learners to solve the problem with an emphasis on reflection

The present study recommends an experiential learning integrated teaching-learning for problem-solving skills development and improvement.

5 SUMMARY

The accrediting boards, academicians, and practitioners have acknowledged the importance of good problem-solving skills along with adequate knowledge of self-reflection and self-awareness. Problem solving skills, found lacking in Indian engineering graduates, tops the set of skills needed for survival and success in industry/workplace. EL techniques sharpen problem solving skills through authentic learning situations such as learning factory, virtual laboratory, simulation, etc. Linking learning approaches and strategies with a real work environment empowers engineering training, research, and education.

DEVELOPING FUTURE ENGINEERS WITH BROAD VIEWS AND DEEP SKILLS – THE EMERGENCE OF A NEW T^2-CAPABILITY PROFILE

Juha Saukkonen
JAMK University of Applied Sciences
Jyväskylä, Finland

Conference Key Areas: *Curriculum development, Lifelong learning*
Keywords: *capability, education, skills, competencies, cross-disciplinarity*

ABSTRACT

Companies are increasingly stressing their need for recruits and employees who can understand the company strategy and operations on a wider scale and with an integrative mindset, as opposed to siloed departments, jobs, and people possessing those jobs.

With new digital technologies, new organizational forms such as team-based organizations and virtual teams as well as Human Resource Management practices like job rotations, there are increasing opportunities for cooperation and integration of people with different backgrounds and skillsets, as the interplay between marketing (business function) and R&D (engineering function).

However, having the company practices and infrastructure "right" for holistic and cross-disciplinary work does not suffice. The professional preparedness of the practitioners has to support this new paradigm as well. The solution has been proposed to be T-shaped capabilities, where the vertical line represents the deep expertise in one area, and the horizontal line overview expertise to better understand processes outside one´s domain. This is an improvement to I-shaped capabilities, where the connecting horizontal integration is missing.

The paper propagates for a prospective upgrade to the T-shaped capability model, the T^2 capability profile. The core idea - derived from interviews with industry managers - is that two horizontal lines differ in scope. The societal/business megatrends demand a set of non-contextual understanding of issues such as sustainability, quality as well as basic technical and financial literacy, and the other horizontal line is made of company-and industry-specific processes. To conclude, the opportunities to foster T^2-capabilities in (engineering) education get discussed.

doi:10.5821/conference-9788412322262.1105

1 INTRODUCTION

1.1 The concept of capability profiles

Capability profiles in the realm of human resource management (HRM) and knowledge management (KM) are not a new issue of discussion and research. The early stages of capability profile discussion were centered around depth (of expertise) vs. width. People were assumed to possess either the vertical capabilities that lead them into a deeper and deeper knowledge of their area of expertise (like a business function like quality management or a branch of science/engineering, such as software engineering or artificial intelligence. This deep yet now wide capability profile (that has reach only in the vertical dimension) got a symbol and name of the I-shaped capability profile. Some people and jobs were claimed to ask more for a horizontal view, i.e. ability to act across business functions and knowledge areas. This integrative capability profile with just horizontal reach was labeled as a "hyphen"(-)-shaped capability profile, also called generalist (vs. specialist). Typically these capabilities were seen to be of demand in the higher ranks of the organization, where the responsibility areas of managers grew to cover multiple business functions.

Lately, the developments arising both from organizational evolution as well as from changes in job markets and younger generations' values about work and careers have risen into discussion the need to re-look at the capabilities needed and achievable. Some proposals have propagated a professional profile standing on two pillars, the so-called π-shaped (Greek letter "pi") capability profile [1]. The essence of the construct is well visualized in its name carrying the symbol of two vertical expertise and in addition ability to see the organization's processes and linkages between expertise areas (the horizontal bar in π). Logical reasoning for the new profile is the intrusion of technology and digitalization into all corporate functions, so, to act successfully as a digital marketing manager, one must master both the technology ("digital") and well as its domain of usage ("marketing"). Likewise, a technology developer like a software engineer should understand not only technology (like Artificial Intelligence=AI) but also its intended usage cases and areas, like digital marketing powered by AI.

Another proposed model is the V-shaped professionality, where the two expertise areas are more permanently intertwined, connected, and even converged. In his 2022 paper [2] Oerther describes the need for this new model as a call for "humanitarian technologists", who are better equipped to solve complex societal challenges e.g. in areas of sustainability.

1.2 The shift from I- to T-shaped capability profile and its evolutions

The most common depiction of an ideal capability profile for a modern professional is the T-shaped capability profile. The fundamental idea is well readable in the name of the profile: A T-shaped professional has got deep expertise in one area to offer to

the organization, but can also disseminate that knowledge to experts in other domains for common benefit as well as acquire knowledge from other areas. The need for a T-shaped professional has been studied and theorized in many different areas ranging from the medical sphere, entrepreneurship, innovation, and engineering education [3], [4].
Due to the presence of the T-shaped capability profiles in the discourse since the 1990s, it is understandable many modifications and enlargements to the base construct have been proposed. Many of them have focused on adding to the model capabilities parallel to both vertical and horizontal dimensions (Figure 1), stating e.g. how in the vertical reach an individual should possess expertise on more than one domain or system and in the horizontal reach be able to apply that knowledge to more than one context (industrial and/or socio-cultural).

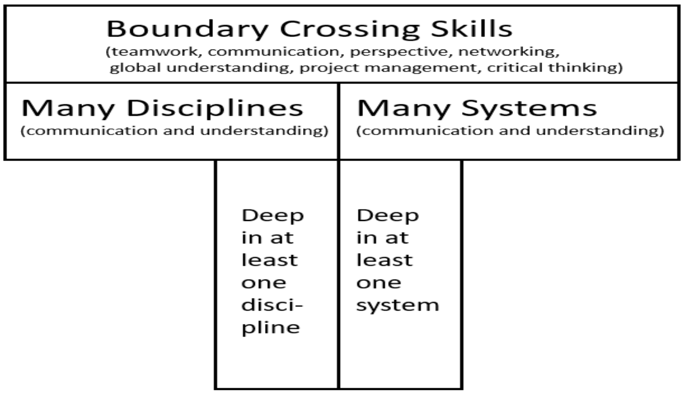

Fig. 1. Example of extensions to the T-shaped capability model [5]

This paper aims at evaluating the models proposed in terms of their relevance to the current and anticipated operating environment of engineering professionals. The paper also proposes a new improvement on the T-shaped capability model and discusses the role Higher Education Institutions (HEIs) can have in the development and supply of the new T^2-shaped professional to industries.

2 METHODOLOGY

The paper at hand relies on its arrival to conclusions on various pathways of inquiry. To start with, a brief synthesis of prior research and conceptualization is offered as well as its merits and possible shortcomings get discussed. Secondly, the author utilizes the constructional pathway, where a new model is introduced as derived from logical reasoning that relies on the author´s observations of societal, organizational, and technological change. Finally, the identification pathway pre-tests the model with thematic discussion with stakeholders in a) technology-based companies and b) educators in HEIs. The participants in the thematic interviews were selected with purposeful convenience sampling. The experts were chosen to represent both the technology and business point of view – both in the case of the company as well as

HEI participants. The industry stakeholders represented the following industries and positions in them: ICT-development/CEO, Energy Technology/Senior Quality Expert, New Materials/Business Development Director, and Machinery/Chief Financial Officer. The education stakeholders with whom the discussions were held operate in the programs of Logistics Engineering and International Business Management, on top of which the author has done observations when acting within a program of Technology Business and Futures Foresight. The author´s dual role as a designer of the model and observer of the reality is a potential bias. However, this selectiveness characteristic of conceptual and interpretative qualitative research is all-natural in the early stages of the development of a framework. In the further stages of validation, further development of the model and its practical instantiations more rigorous methodology, sampling, and implementation will be applied.

3 RESULTS

3.1 Overview and assessment of the prior work on capability profiles

The current discourse on capability profiles strongly propagates widened area of expertise as a plausible characteristic of an employable and successful employee of today and the future. However, the ideas of multiple areas of deep expertise – like in the case of π-shaped and enlarged T-shaped capability profiles contradict the trends of continuing specialization and technological development that force the companies and the professionals in them to focus their efforts to gain a competitive edge. The concept of multiple or boundaryless careers suggests that the Y- and Z-generations will not only change the company they work for multiple times on their career journey or just move up the corporate ladder, but will also make notable horizontal moves and leaps in their career trajectory. This will over time lead to multiple expertise profiles for an individual in some cases where a person moves to a different field of action (e.g., from production to procurement) or from one industry to another (e.g., from consumer electronics to aviation industry. This type of double expertise is however a result of a long career rather than a valid requirement for all let alone young recruits. Likewise, it is not a realistic target for education, since the birth of two or more true expertise areas would mean a substantial lengthening of study times. The societal pressure and demands for education efficiency are pushing the development in the opposite direction.

Furthermore, the capability profile models in hand do not make a claim on the layer in which the “wide” combinatory capabilities should be applicable. In reality, the processes in which one’s special areas connect to the expertise of others are context-sensitive, i.e. dependent on the industry or even a specific company where work takes place. Looking at the issue from the engineering angle, the same expertise of software engineering connects to other functions and professions in different ways in the case of medical technology vs. in the e-commerce platforms.

Finally, the models are rather unspecific in what counts as a capability. Also, the concepts of system, culture, and process are quite fuzzy, just like the boundaries between them.

3.2. The new T²-capability model to elaborate on and its implications for HEIs

The findings of the previous work as reviewed in Section 3.1. were based on logical reasoning. The utility of the models proposed in prior literature was mirrored by the other trends and challenges for modern organizations as introduced by research. In the principle of Socratic dialogue, the tensions between the models (thesis) and findings of current and foreseen forces for organizations and jobs (antithesis) in them, a new prospective model combining the findings gets proposed in this paper (synthesis).
The T²-model borrows its name from the main structure of the model, where the reality-bounded view of one true expertise (the vertical line of the letter T) is enriched with two layers of combinatory/generic capabilities (see Figure 2). The horizontal layers differ in two ways: 1) The contextuality of the capability, and 2) The level of expertise required in those layers.

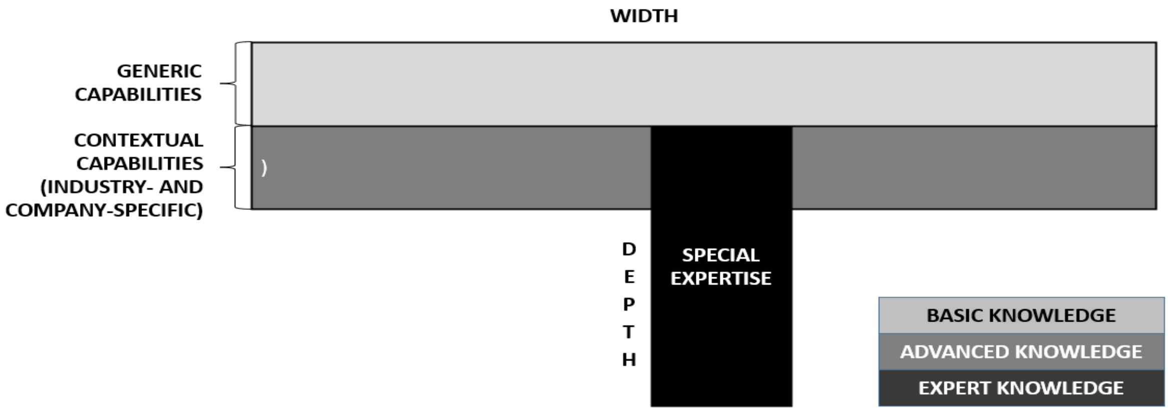

Fig. 2. Structural model of T²-capability profile

The T²-model suggests that the truly relevant combinatory capabilities e.g. in engineering jobs are made of the ability to understand and communicate the connections between one’s expertise and function to other fields of knowledge *within context.* Context refers to the application area and operating environment of the organizational knowledge, that tends to be specific to both industries (“clock speed” of an industry, value/supply chains, the role of standards and regulations, etc.) as well as to companies (different business models within an industry utilize different pieces of knowledge and in different ways). This context-dependent layer that goes for wider understanding does not need the match the depth of the specific professional expertise one possesses.
The upper and more generic, i.e. non-context dependent knowledge is needed for basic understanding of key concepts, their definitions, and relationships. This type of knowledge on issues such as quality, sustainability, etc. serves for one´s ability to

participate in discussions on the subject area and forms a base on which one can deepen the use of this generic knowledge in the context and further into their field and profession.
Based on the discussions with industry experts and engineering education practitioners, the following instantiations of T^2-capability profiles for software engineering capabilities as they manifest in two different context domains of digitalization were ideated (Figures 3 and 4) to test the feasibility of the model proposed. The stakeholders in the industry represented differing business functions (quality management, procurement, logistics, strategic management, financial management) just as the higher education stakeholders came both from business and technology faculties (and from different streams in them). Both the context-dependent as well as generic capabilities introduced were sourced from these stakeholders and applied to the framework with a manufacturing company in mind.

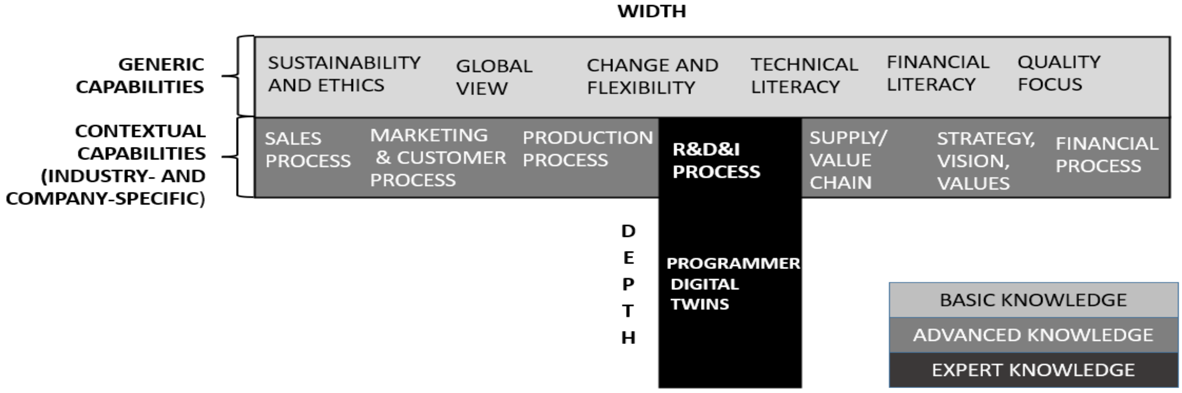

Fig. 3. T^2-capability profile for software skills in Research and Development

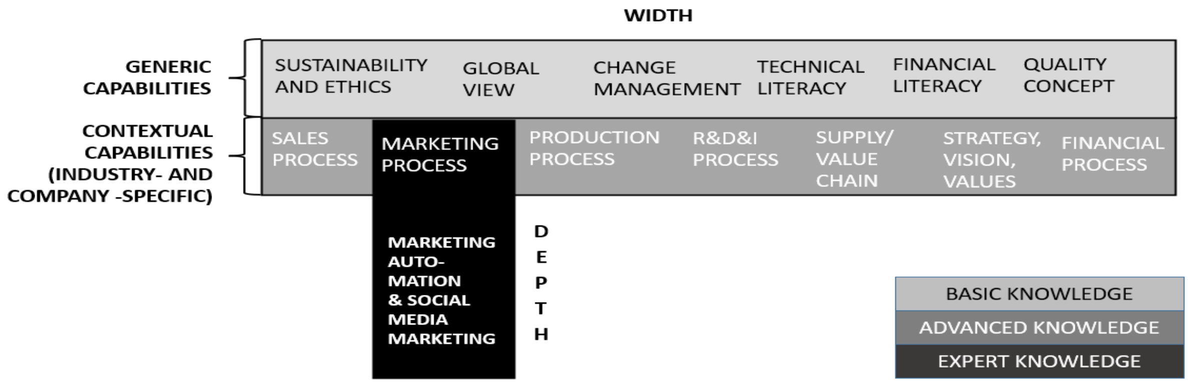

Fig. 2. T^2-capability profile for software skills in Marketing

Ironically, higher education institutes (HEIs) have traditionally been well equipped to contribute to both the most generic and most specific capabilities. In the early stage of the studies, learners across domains get introduced in their basic courses to the fundamental principles and key lexicons of multiple domains, after which the move to specialization studies aiming at narrow but deep professional skills takes place. The structure of HEIs divided into faculties, schools, and further study programs reflects

this specialization and siloing of knowledge. Depth and deepness in an inherent nature of top-level research – the other main function of HEIs – but serves badly the needs of the cross-disciplinary nature of the world of work. Furthermore, due to practical issues of scheduling and premises (separated campuses), even the generic skills are often taught in a way that does not bring people (both teachers and students) from different domain areas together.
Hackathons, case competitions, business simulations, and entrepreneurial (when team-based) incubation are some practices that HEIs and even some companies have deployed to foster the "T^2-mindset". However, these events and learning spaces typically involve a limited total student cohort and the ones engaged are often self-selecting themselves to these learning instances due to their T^2-mode already existing. For the remaining ones the horizontal, combinatory capability building is left to companies, who promote width of knowledge by trainee and talent onboarding programs and by job rotation. It is worth noticing that the contributing stakeholders from business organizations and education saw both technical and financial "literacies" – basic knowledge in key concepts and processes in the fields of technology and economics – as generic capabilities needed across functional domains and thus attached to the capability profile of any expert. This finding proposes to open up the educational offerings of business and engineering schools to a wider variety of students to enhance future collaboration and shared knowledge within organizations. Likewise, internationalization should be a knowledge possession of each individual in a modern networked world of work.

4 SUMMARY AND ACKNOWLEDGMENTS

To conclude, the new model once deployed by joint planning between HEI departments as well as between HEIs and companies would prepare and motivate the HEI learners better for their careers and add to their job market value and flexibility. In addition, altering the HEI learners early on to the combinatory views and experiences would create benefits for employers by the wider usability and mobility of the workforce, thus increasing resilience to changes in the operating environment and allowing lower (re)training cost of the employees. The author aims to continue the work by creating more industry- and job-specific models and empirically testing the feasibility of the model both in HEI and industry settings.

ABSTRACT

The 4I4U project[2], which runs through 2022, aims to engage the community of citizens made up of students between the ages of 15 to 23 in the urban mobility of the future while empowering them to become actors of change who can participate in the development and evolution of their city. Led by a European Consortium composed of two cities, Barcelona in Spain and Toulouse in France, as well as education entities from high school to universities and clusters of companies in the field of urban mobility, and co-funded by the EIT Urban Mobility, the main objectives of 4I4U focus on raising awareness among young citizens in the context of urban mobility, developing their capabilities to become actors, highlighting their needs and finally creating a

doi:10.5821/conference-9788412322262.1419

methodology and an environment that help students from ideation to action for the mobility of the future. The objectives of 4I4U are achieved by planning a set of seminars, round tables and brainstorming sessions to raise awareness or understanding of different aspects of urban mobility. To move from ideation to action, small groups of students design and produce a first ideation to understand and be able to project themselves into the proposed solution. This activity will be carried out under the mentoring of cities and industrialists, using the means of training institutions.

1 INTRODUCTION

1.1 Citizen Engagement of young people

The aim of citizen engagement is to ensure that users are part of the ideation process by achieving social and gender inclusion and stakeholder engagement, creating an opportunity to experiment and share information on urban mobility. 4I4U focuses on students aged 15 - 23 as they are rarely involved in the ideation process. Moreover, one of the added values compare to previous experiences for example in India-ICT standardization European project [1] on the smart city part is that they do not just experiment new products, system of services and try to create a new one by themselves as done in cities of Delhi, Kanpur, Bangalore, Chandigarh, Pune, Goa. In 4I4U, they not only try to develop an idea, they also have a phase of improving skills and exchange ideas in urban mobility with a strong connection with researchers, city services, and mobility companies. This allows them to advance in urban mobility and feel included.

1.2 Context

Partners of the project in both cities were willing to involve young students in the area of urban mobility, including university students, not necessarily from the civil engineering field, and high-school students. The common goals are to rise awareness and empower them as citiziens to act and be part of the solution for future mobility in our cities. Barcelona and Toulouse have some historical ties in both sides of the Pyrenées, also a common focus in teaching students who could work in the automotive or urban mobility sector with a sustainable mindset.

1.3 Goals and Scope of the 4I4U Project

The community of citizens made up of students aged 15 to 23 has and will have a growing impact on urban mobility. Making students aware of this issue as early as possible will have an important effect for the future, both in everyday life but also in the following generations.
We believe that young citizens are not involved in this issue because they think they cannot have an impact on the city. They do not master the process that goes from the awareness of a need, the formalization of an idea, the integration of the right actors and contacts to finally have impactful results. However, it is necessary to adapt the tools that are put in place to interest them and put them in a position to be protagonists of the necessary changes and innovations.
More specifically, the objectives of 4I4U are:

- OB1 Raise awareness of young citizens on the context of urban mobility with the help and expertise of teachers and trainers, city services and industrialists in this field.
- OB2 Develop the capacities of students to become actors of future urban mobility with the creation of networking between students, city and industry on this topic.
- OB3 Be able to highlight the needs and hope of this class of citizens.
- OB4 Create a methodology and an environment to help students from ideation to action in this field.

The scope of the activities focus on

- Propose, implement and evaluate a methodology based on a set of tools (seminars, round tables, workshop) addressed to the student population between 15 and 23 years old in a co-creation process tutored by city services, industrialists and academics. The use of these tools and, above all, the fact that they are part of the ideation process, will allow students, not only to be informed about science and innovation with different classes, but to be empowered and feel actors of urban mobility projects.
- The proposed methodology and activities are developed in two cities with specific and common events. The development of skills through access and exchange with experts, the identification of levers through the presence of city services and industrialists in this field, the networking to bring together all the players around the same approach should enable this population of citizens to understand and change their thinking and behavior in terms of urban mobility.

1.4 Towards a new future in engineering education

The 4I4U project includes some elements that can contribute to the future of engineering as it tries to engage engineering students in city challenges by involving them in the ideation of solutions and at the same encouraging younger students, who are currently in high school, in this design thinking approach. The focus is on citizen engagement and urban mobility and bringing together two cities close enough but from two different countries. The methodology of the process is explained below.

2 METHODOLOGY

2.1 Implementation of the Project

The project is divided in three tasks. The first task aims to understand and increase students' competencies in the field of urban mobility. It creates transdisciplinarity groups of students. This task specifically addresses objective OB1. The second task aims to create, produce ideas and think about their implementation. It addresses objective OB2 of the project. Finally, the third task creates a synthesis of the methodology implemented and the results in terms of ideas and proposed actions. This task integrates the dissemination of the events and the results of the activities. It addresses objectives OB3 and OB4 of the project.

Task 1. Networking debate and problem finding

This task concerns the sharing of information and the networking of the various participants at the beginning of the project. Its objective is to share information on the existing situation and the solutions envisaged around the world, but also to report the problems perceived by people in each partner city. The goal is to have well-informed and motivated students. It takes the form of events with focused seminars, discussion forums that can be shared or specific to each partner city. The events require of setting up the necessary structures, organizing the recruitment of external speakers, managing students and creating a space of physical and virtual conviviality conducive to exchanges. We rely in particular on a digital tool called DecidiUM and social networks to fuel and maintain exchanges. Seminars for example on the evolution of cities, the challenges of mobility, the city and the citizen, the industrial perspectives on mobility.

Task 2. Ideation phase and selection of proposals

This task is dedicated to the ideation phase by each group of students to propose a solution to an open problem that has been debated in the previous phase with citizens and stakeholders. The problem solved could be specific for Toulouse or Barcelona or for both/any cities. Educational establishments provide their equipment and fablab. The objective is to obtain a prototype demonstrating the philosophy of the proposed solution without having a level of operational maturity.
During a **final workshop at the** end of the year, each group will demonstrate their solutions and obtain various feedback to improve their proposal. They will present their idea and prototype in front of a jury bringing together different actors: users, cities, manufacturers, incubators, etc. The jury selects the best solutions. Each city together with the stakeholders decides about the future of the proposals.

Task 3. Assessment of the ideation and engagement process

During the beginning of the project, the program has been refined in terms of events and communication [2].
At the end of the project a summary of the process implemented and the results obtained will be made. CARNET experience in other projects [3] will help develop and assess the methodology for evaluating the ideation and the engagement of students in urban mobility. Partners will collaborate in the drafting of the good practices guide. This guide will produced and distributed on the Erasmus platforms, the EIT Urban Mobility community, and in the multiplier events organised by each partner for dissemination purposes.

2.2 Expected Impact

Environmental:
The methodology of working will raise awareness of young generations of students to the need that future urban mobility should be sustainable and active. The approach is to imagine that the project ideations that the students are going to be involved in are sustainable. We estimate that at least 3 of the ideas selected by the jury will have an impact on the environment. The change of scale in production will allow for the development of local employment but above all will avoid the transport of semi-industrialized parts around the world.
Economic:

The expected outcomes and impacts are the possible creation of products on the domain of the future mobility, an opportunity given to ideate in the city an innovative solution and help to argue for finding founds, the production of forms with easily shared techniques, the perception of which is easily understood by all thanks to a work of popularisation of information and maintenance and finally sharing new ideas with industry. We expect at least 2 ideas that have a real impact and economic potential for commercialisation.

Social:
We expect more than 200 students involved in 4I4U in different degrees of implication. So far around 21 posters and videos have been created by ISDAT students, as explained in section 3.5, and 10 telecom engineering students have develop an app, as explained in section 3.4. The hackathon organized in Barcelona in December will gather around 150 students from Toulouse and Barcelona. Activities with high-schools in Barcelona are planned for the fall semester involving engineering students as "ambassador" of the project. We have to add to this numbers other students that have attended the seminars so far.They will become well-informed and increase their capacity to become actors of the future urban mobility and more generally actors of the city. Moreover, connection will be made between the different visions of the city from: learners, citizens, city management, companies and teaching entities. Furthermore, common work for high school students, undergraduate and postgraduate students can encourage high school students to project their future as citizens engaged in sustainable activities in their cies. Finally, teachers will also increase their knowledge on this topic and be able to integrate this experience in their courses.

3 ON-GOING RESULTS AND EXPECTED RESULTS

3.1 Seminars shared between the two cities the First Semestrer

Twelve hybrid events are held simultaneously in Toulouse and Barcelona. These seminars, round-tables and brainstorming sessions have taken place in order to understand different aspects of urban mobility and raise awareness on the subject as it can be seen in the topics of the events that follow.[3]

1. "Draw me the Automobile of the Future for Urban Mobility" by Jean Luc Maté on February 15th 2022 4PM.
2. "Project Design from the perspective of city services for citizens" by Ángel López on March, 3rd 2022 5PM.
3. "Non-Financial Report of ICT projects" by Eva Vidal, on March, 8th 2022 at 2PM.
4. "Autofiction, a biography on the automobile object" by Olivier Peyricot on March 9th 2022 at a6PM

[3] All seminars could be found on the following link: https://engage.eiturbanmobility.eu/processes/Project4I4U/f/41/meetings?filter%5Bsearch_text%5D=&filter%5Bdate%5D%5B%5D=&filter%5Btype%5D%5B%5D=&filter%5Bactivity%5D=&filter%5Bactivity%5D=all

5. “The role of Technology Innovation in Urban Mobility” by Jordi Ortuño on March 17th 2022 at 5PM
6. “Challenges for sustainable urban logistics” by François de Bertier on March 24th 2022 at 4:30 PM.
7. “Smart mobility. Urban Mobility challenges” by Ángel López on March 31st 2022 at 5PM.
8. “When smart mobility means smart infraestructures” by Pierre Emmanuel Maire on April14th 2022 at 5PM.
9. “Female mobility patterns” by Imma Ribas on April 28th 2022 at 5PM
10. “5G technology and smart mobility” by Bruno Pouget, Frederic Gardes, Stéphane Vialle and André Bottaro on May 12th 2022 at 4PM.
11. “Mobility 4.0. and cognitive ergonomics: thinking about the human in an autonomous and connected environment” by Céline Lemercier on May 16th 2022 at 4PM.
12. “Urban mobility and Pollution Citizen Maps. Young Population study in Barcelona” by Universitat Politècnica de Catalunya on May 19th 2022 at 5PM.

3.2 Barcelona Activities (current and to be done)

A core group of 10 final year undergraduate students in the area of Telecommunication Engineering, not related to urban mobility, automotive or environmental studies, are taking a 12 ECTS challenge-based course during the first semester of 2022. The proposed challenge is to develop a product/service with the following requirements: to estimate the exposure to pollutants while moving around the city in their daily life, especially when they go to study; to raise awareness among the young population between 15 and 23 years old about the carbon footprint caused by the means of transport they use; finally, to use the knowledge in their own studies as a way to see that urban mobility is a transversal field where any professional can contribute. As a product they decided to create an app that shows three alternative routes to go from one place to another in the cities of Barcelona and Terrassa, that is, the fastest route and two alternatives with less pollutant exposure. The app also shows the carbon footprint generated according to the chosen route and depending on the mode of transport. The app contains projections of carbon footprint estimates for 1, 5 and 10 years. Finally, a ranking, as a game between friends from the same high school to see who is the "champion" generating less emissions in their daily mobility around the city. This project has required them, first of all, to become aware themselves of the environmental, social and economic impact of pollution through their own research study and by attending parallel seminars organized by 4I4U. Thanks to this awareness of the magnitude of the consequences of pollution, they are now ambassadors and together with 4I4U partners they visit high schools to show students younger than them their own experience in acquiring knowledge and on the other hand in their contribution by developing an application that can help this awareness and at the same time have fun. The university students also want to get feedback on the product they are developing.
Some results of their own work are presented to the university community at the last 4I4U seminar in Barcelona.

3.3 Toulouse Activities (current and to be done)

Following the networking phase, a first set of solution proposals in the form of posters and videos was produced by ISDAT. This material will be exhibited and shown to other students from other establishments to give them a first ideas of solution (idea0) and allow them to co-construct either from this first batch of ideas or from new ideas, their will propose their final proposal of idea (idea1) for the end of June. We will then begin the mentored implementation phase of the various ideas (idea1) by industrialists, city services and teachers. In December, groups will finalise their first prototypes (proto1). A jury will evaluate these prototypes and select those that can have a real impact and a possibility of deployment in the city. Students will then be able to gather around these few selected prototypes to improve them and move on to a prototype version (proto2) that can be deployed and used by a subset of citizens in real-life situations in the city.

3.4 Common Activities and Assessment for the Second Semester

Common Activities for the Second Semester

Beyond the sharing that takes place in the first semester, during the seminars, we wanted the students to also benefit from the richness of their different cultures between Toulouse and Barcelona. For this, a 2-day event will allow them on the one hand to attend together at a conference and exhibition on urban mobility in Barcelona and on the other hand to share the knowledge they have acquired during the project 4I4U on a one-day and night hackathon on short projects on urban mobility involving technologies of connected objects, communication and design (see for example A humanitarian technology hackathon [4] and some good practices in [5]).

Assessment

The 4I4U assessment of the ideation and engagement process includes the quantification of three main aspects: 1) Social impact 2) Environmental impact and 3) Feasibility .

1) Regarding the social impact the assessment will focus on how university students from 18 up to 23 years old understand and increase the transversal fields related to urban mobility. Considering the students of secondary school and University the assessment is focused on building the awareness of sustainable mobility for the youngest and increasing it for the oldest taking into account the effects of a non sustainability mobility.

2) Regarding the environmental assessment, for instance, in one of the projects it is based on pollutant parameter measurements of the students' mobility patterns. This is achieved by an app created by a group of students.

3) Feasibility assessment is based on how this project can be repeated in time or how the environment and the social impact can be reproduced through the outputs of the project and thanks to citizen associations which are aligned with 4I4U values.

4 CONCLUSIONS AND PERSPECTIVES

The first results of the project show that the choice to have developed an offer of face-to-face seminars, streaming and recording makes it possible to adapt to this audience of 15-25 year olds who consume information at their own rythm. The final conclusions will have to wait until the end of the project with the implementation phase done and the final feedback from the partners involved and the students on the whole of what they have learned and achieved. Nevertheless, the first presentations of the concept to college, and undergraduate school outside the project have aroused an interest in this type of approach with a desire to participate in future editions.

ABSTRACT

Modern higher education needs to provide skills needed in working life, such as entrepreneurship, besides the more traditional technological competence. The Boost

[1] *Corresponding Author: elisa.sayrol@upc.edu*

doi:10.5821/conference-9788412322262.1335

I&E Project[2] was developed in 2020 and 2021 with the aim of generating a set of guidelines for innovation and entrepreneurship challenge-driven projects for master's programmes. The added value was created by collaborating and exchanging best practices among higher education institutions in seven different countries, with the aim of developing students' skills with an international perspective and exposure to the knowledge triangle. The implementation of Boost I&E would allow learning about the advantages and disadvantages of different approaches in a practical way, while courses on urban mobility were provided. The activities involved more than 100 students over two years.
The experience concluded with the adoption of a set of guidelines based on best practices, covering several aspects. Most emphasis was placed on the methodology of the course, on sharing activities and on finding best practices and implications for stakeholders. Our experience can be useful for universities that want to open up their students to I&E.

1 INTRODUCTION

In the last 15-20 years, there has been a push to renew higher education, shifting from a technical knowledge-focused paradigm to a model that, without losing scientific and technological competence, also provides skills needed in practice. Students need to be trained to meet the demands of society at large. Students from all disciplines need to be trained in discovering the most relevant needs of their communities, defining alternative solutions, choosing the most impactful ones based on approaching users and other stakeholders and, finally, designing and developing the chosen solutions; this last step being the only one usually carried out in traditional curricula. There are many societal needs that can be addressed through this approach, such as all those mentioned in the UN Sustainable Development Goals (SDGs) [1], which are reflected in the EIT's Strategic Objectives for Urban Mobility [2]. Urban mobility is one of the themes best suited to this new approach, as the urban population as a whole is the target and many of the stakeholders are public institutions. It would therefore be reasonable to emphasise human- and user-centred design in the curricula, while promoting our students' skills in social innovation and entrepreneurship so that they become the drivers of change in our communities.
The Boost I&E project was developed with the intent to investigate such aspects in the context of urban mobility within various European universities. The consortium partners already had experience with different types of teaching and learning activities suitable for this purpose, but not with all of them and not to the same extent. A practical "learning by doing" approach was proposed:

- Each institution adapted a suitable existing course (or developed a new one), using different methods and a common topic on urban mobility.
- Teaching experiences and learning outcomes were shared through meetings, faculty exchanges, and joint events with the students from the different institutions.
- The results and process were analysed and a set of guidelines was proposed for designing appropriate teaching and learning methods for I&E education, mainly focused on Masters programmes.

[2] Co-Funded by EIT Urban Mobility

1.1 Existing alternatives to deploy I&E education

The more relevant alternatives that could be considered for develop I&E skills within a course or part of a course are the following:
- *The Case Method*. A set of cases are presented that have a real basis but are tailored to be useful for learning. Solving the cases forces the students to make decisions that can be compared to the decisions made in existing ("traditional") solution [3].
- *Project-Based Learning (PBL)*. Although it allows for different definitions and implementations, the most comprehensive is the replacement of part of the teaching methodology of one or more courses with a project that forces students to search for information, learn methods, and make decisions that will provide them with learning outcomes that are coherent with the objectives of the course.The cases are usually artificial and are defined by faculty members and not by external stakeholders. [4]
- *Product Development Project (PDP)*. A team of students carries out a project to develop a product or service to solve a challenge that is usually specified by an external organisation (e.g., from the industry or public sector). Although this modality is more suitable than the previous one for the objectives of this project, most PDP carried out in engineering schools start from requirements and even specifications based on decisions already made by the external entity. The user approach is thus limited and part of the creative phase may be lost. [5]
- *Challenge-Based Learning (CBL)*. In this case, usually, a very open challenge is provided to the team by the external organisation. Usually a Design Thinking methodology is used. The team of students must carry out an in-depth research to discover the users' needs related to the challenge, choose the most relevant ones, define different solutions, and choose the most appropriate one, developing a proof-of-concept prototype. Decisions in all phases should be based on feedback from users and other stakeholders. [6]
- *Hackathons and Intensive Courses*. They are shortened versions of a CBL course, with more or less open challenges. The hackathon carries out the whole process in a short time, for example two days, and the intensive courses can last 1-2 week(s), which can be separated over the semester. [7]

1.2 Context

Most institutions within Boost I&E implemented one or more of the learning modalities described in the previous section, although in most cases students from the same or closely related disciplines were included.
The most relevant features in relation to Urban Mobility are:
- following a user-driven environment;
- defining the challenges together with actors from the urban mobility sector;
- developing innovative ideas that can result in a start-up or that can be transferred to existing development platforms;
- training graduates with a set of skills suitable to transform innovation into a socially driven paradigm according to the EIT's overarching learning outcomes.

1.3 Goals and Scope of the Boost I&E Project

The purpose of the Boost I&E Project was to experience and recommend New Guidelines for an I&E Challenge-driven Academic Activity for Master's Programmes with the added value of boosting performance through collaborating and sharing best practices across institutions, focusing on developing students' I&E skills with an international perspective and exposure to the Knowledge Triangle.
The following objectives were effectively addressed to achieve this goal:

- Objective 1 - Propose initiatives for I&E challenges at academic level. Most universities participating in the project already had some experience of 'learning by doing' approaches, presenting open challenges to their students. Some institutions had specific I&E rooms to develop innovative solutions to real challenges with the participation of local stakeholders.
- Objective 2 - Real challenges for urban/urban mobility actors. One of the main points of this initiative was to add an extra value to the courses by making challenges faced by the Urban and/or Urban Mobility Actors occurring at European level.
- Objective 3 - Innovation and Business Mindset. The challenges presented were real-life and therefore the solutions had to be approached from a business perspective. The whole process had to be guided by observers from the business world.
- Objective 4 - Share best practices. The best way to improve the performance of the challenge project was to share methodologies and best practices to improve the project courses in each institution.
- Objective 5 - Sustainability and Scalability Mindset. As cities may face similar problems, the proposed approaches should focus on deploying sustainable and scalable solutions in a global market.

So far, there have not been many examples of international experience sharing among I&E spaces. Most challenges are usually identified and developed locally and with local stakeholders [10] or if they are international, are not embedded in courses [9]. By sharing challenges that are similar but have a different context in each city, students develop skills to better cope with global markets. Moreover, this experience helps to enhance the capacities of faculty members who lead academic I&E activities and disseminate this way of teaching in their own institutions in the framework of courses included in the curricula.

The intention is to extend the results of this project to other academic units within the consortium, and once the guidelines are well established, they can serve as an example for other higher education institutions. One of the particularities of urban mobility compared to other fields is its multidisciplinary perspective and the participation of cities, which propose to work on challenges that are very close to the needs of citizens.

2 METHODOLOGY

2.1 Implementation of the Project

Figure 1 shows the different phases of the project with regard to the activities in 2020 and 2021. The projects had a duration of one year and two editions were implemented. During the second year, additional partners joined this initiative, which can therefore start from the experience gained in 2020.

The **Kick-off Meetings** were held in early January 2020 and early January 2021, respectively, with representatives from all academic partners in order to establish the academic framework for the development of the project.

Train-the-Trainers events were intended for university teachers and managers of educational programmes involved in entrepreneurship education. The Train-the-Trainer sessions were based on experiential learning principles and were designed as a short entrepreneurship course, using teaching approaches and methods previously tested by Aalto Ventures Programme. In 2020 it was held at the beginning of the year, in 2021 in mid-March and with a different focus.

I&E Challenge Development, during the first semester of the year from the beginning to the end of the course in each institution, student teams worked on their solutions

Their work was not only supervised by academic staff, but also by representatives of companies and cities. Each institution could also integrate lectures on different aspects of I&E and relevant topics related to the problem to be solved.
Exchange of faculty observers, the original aim was to visit other institutions face-to-face. Because of COVID-19, this was changed to online meetings to share experiences, virtual visits to the courses, student presentations including final presentations, and partner questionnaires to gauge the opinions of the other institutions.

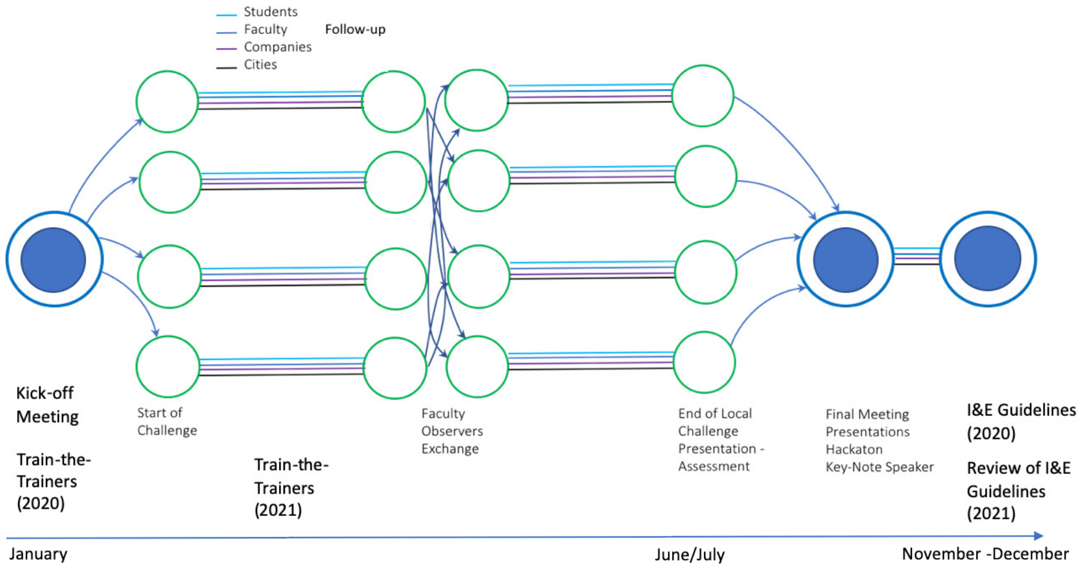

Fig. 1 Implementation Process of Boost I&E. Circles represent milestones, whereas lines development of activities and arrows relationships

At the end of the Local Challenge, students presented their solutions and the evaluation was carried out. At the final presentation of the students' projects, representatives of cities and local businesses were also invited in order to provide first-hand feedback on the innovation potential of the proposed solutions. The learning outcomes were evaluated. The best team from each university was selected to go to the final meeting.
The **final meetings** were held online in 2020 and face-to-face in 2021. The following activities were devised:
- Invitation of relevant keynote speakers.
- Presentation of the results of student teams from each institution. Prizes for the best teams. Invitation of a representative of the cities and representatives of companies.
- Hackaton, named "Urban Mobilithon", where mixed student teams were assembled to work on a challenge to be solved in the host city. Invitation to Representatives of the City and Representatives of Public and Private Stakeholders.
- Academic meeting of representatives to draw final conclusions

Guidelines for the I&E Challenge-Driven Academic Activity for Master Schools. After the activities, the partners worked on defining best practices. Therefore, Guidelines for International Cooperation I&E Challenge-Driven Projects in Urban Mobility were drafted.

2.2 Observed Best Practices

The activities carried out at each institution were assessed by the other partners, with the goal of identifying the most relevant best practices, ranking them by affinity

and included in some way in the general guidelines of Boost I&E. These practices are as follows:
- Planning for a good balance of technical and I&E skills
- Working with strong links to stakeholders
- Creating multidisciplinary teams
- Including sufficiently broad challenge topics to encourage creativity and autonomy
- Breaking up the challenge into sub-challenges, when many students participate in the course and the challenge allows it
- Challenging students to conduct interviews with many users and stakeholders
- Pushing students to get a good understanding of customer needs
- Pushing students to work out a rationale behind each decision
- Inviting relevant guest lecturers
- Performing intermediate checks of the challenges
- Visualising other teams at universities solving similar challenges
- Promote the achievement of a result that is ready to be piloted
- Sharing best practices with other partner universities
- Getting the support and encouragement of the leaders in the academic institution and making the links with other courses and the curriculum in general

3 SUMMARY OF GUIDELINES

The guidelines include features identified on the basis of lessons learned from implementation and exchange of best practice between institutions. It is strongly recommended to follow CBL projects. These features are summarised in the following subsections. For more information, the full version of the guidelines can be downloaded from [8].

3.1 Teaching and learning activities

Challenge-Based Education is mainly based on cooperative and experiential activities. The student teams have to carry out field research and conduct interviews with users, customers and experts. This requires time of autonomous work between sessions and in some phases a period of a week is not enough to collect and process the information.
Regular short presentations in the classroom, to get feedback from the teachers/coaches and from the classmates play a big role in the learning process.
On the other hand, it is also useful to share ideas in a different environment than the classroom and look at different solutions in similar processes. Hackathons and inter-institutional activities offer the chance to get to know different points of view and learn different tools.

3.2 Time distribution of the activities

Courses spread over a full semester are preferred. There is also a trade-off between breadth (scope) and depth. For example, courses of 5 or less ECTS allow for a reasonable range of I&E learning outcomes, but are limited to concept-level developments (need-solution-business idea). For deeper results, larger courses (10-12 ECTS) are a better choice. Combinations between an ideation course and a technical development project course with the same challenge is also an option.

3.3 Multidisciplinarity

Multidisciplinarity and diversity are essential in CBL and Design Thinking education. The possibility of including truly multidisciplinary students in the teams (i.e. not only different engineering disciplines but also architecture, business, design, arts or social sciences) adds tremendous value to the innovativeness of the courses, but it is usually not easy to organise because it requires cross-school or cross-university collaboration. It is also about having different ways of thinking. Multidisciplinarity can include diversity (gender, age, culture, nationality, etc.) and organisational complexity.

3.4 Challenge Selection

In urban mobility, many stakeholders are public institutions or public transport operators. Common projects involve a request for a public tender. The I&E possibilities in this framework are therefore limited.
To work on CBL, we need to ask stakeholders to propose more open projects. It is advisable that the challenge belongs to a live or near-future project of the stakeholder. If challenges are generic, they need a lot of time to converge. Therefore, challenges should be open, but not excessive. Another possibility is to work on campus-based challenges with their advantages and limitations.

3.5 Role of the external stakeholders

The role of the representatives of the external companies or institutions is essential. They have less effect if they only act as guest lecturers or external observers. The effect is greater if they behave like clients or contractors. A similar effect is achieved if part of the I&E training workshops is given by staff from the knowledge transfer unit of the university or by external innovation consultants.

3.6 Assessment of CBL Projects

Team rating seems to be the main tool for assessing CBL projects. Several institutions use it without individual assessment, while others include an individual modulation in relation to the team rating. External stakeholders give an opinion but do not participate in the assessment.
The individual modulation can have up to three contributions: Supervisors/coaches collecting evidence (participation, effort, value); assessment by the team leader (if any); and peer assessment, via a rubric. Apply peer assessment only if there is no agreement in a team negotiation.
It is difficult to give an absolute mark to all activities.

3.7 IP, Sponsorship

In most universities, the intellectual property of the project results belongs to the students. Conflicts may arise when an external institution or company sponsors the project. There is a trade-off between giving the student an incentive and getting relevant challenges and implications from the companies. Sponsorship of CBL ensures more involvement on the part of the company. The case for UM may be simpler, as public stakeholders in this field do not ask for IP ownership. Open projects proposed by public institutions may provide more opportunities for students' initiatives. Intellectual property is just one potential benefit for an external partner. The cooperation between sponsors and students during the CBL project is a competitive advantage in talent recruitment. Additionally, sponsorship can also be part of the companies' social corporate responsibility initiatives.

3.8 Sustainability and Engineering Ethics

UM is suitable for training socially oriented engineers. Seminars on sustainability, with specific reference to the UN SDGs, are also recommended. Sustainability analysis of their projects is a must, including social, environmental and economic aspects.

Business and Engineering Ethics should also play a role in I&E courses. Not only for the implications arising from the use of technology, but also for the mission, governance model and value chain of the business models developed by the student teams.

3.9 International Perspective

The possibility of cooperation between universities from different countries makes it possible to observe course development and share best practices. When the challenges are similar, it is easier to compare methodologies and activities and take note for current or future editions. Students observing students from other universities, with the practical solution of sharing this online in the middle of the semester, allows them to observe directly and possibly apply different perspectives to improve their own projects. They also get an idea of cultural issues and different legal structures. Sharing presentations from stakeholders or other invited speakers gives them a chance to broaden their international and triangular exposure. Organising Hackathons (Mobilithon) as a final activity, preferably face-to-face in a particular city and facing different challenges, boosts their motivation and establishes their I&E skills.

3.10 Self-assessment of I&E skills

We delivered surveys for self-assessment of the students' I&E skills, both before and after the courses at some universities. The comparison shows an overall slight improvement in the perceived level of I&E skills of students. For instance, one of the universities surveys results show that the number of students who think they can present creative ideas has increased.

3.11 Additional Features

Learnings from COVID-19 confinement

There were limitations to the lessons from the COVID-19 pandemic restrictions: difficulties in conducting user interviews and testing prototypes in the field and no possibility to visit other courses face-to-face (F2F) to observe practices. However, there were learning points that may be useful even if face-to-face returns: mastery of online meeting platforms (Zoom, Meet, ...); remote user interviews and surveys; prototyping and testing based on multimedia representations of the ideas; etc

Opportunities for Master Students to pursue an Entrepreneurial Career

Challenge solutions are usually not ready to be marketed. Some students have shown interest in going beyond the project. We can offer them support and information: by introducing them to the university's incubators; the cities' incubator programmes; and, in particular, the EIT Urban Mobility Accelerator Programme.

4 CONCLUSIONS AND EVALUATION OF RESULTS

Most emphasis of the project focused on the sharing of activities and looking for best-practices and finding stakeholder implication. Although all elements were discussed, in the future, we have to focus on some issues, as sharing best practices for evaluating I&E skills before and after students have taken the course, sharing how assessment was carried out, or even to increase stakeholder implication and sharing talks by experts.

ABSTRACT

The main objective of the EDINSOST2-SDG project is to introduce sustainability and the Sustainable Development Goals (SDGs) in Higher Education. The project focuses on Engineering degrees, Education Degrees, and the Business Administration and Management degrees of the Spanish university system. The project has four main objectives: (O1) Identify the SDGs in the EDINSOST sustainability competency maps

[1] *Corresponding Author*

(SCM); (O2) Improve the learning outcomes of sustainability and SDGs in the degrees related to the project; (O3) Faculty training in Education for Sustainability and SDGs; and (O4) Analyse the students' learning in Sustainability and SDGs during their training at the university. The current project began in 2019 and is scheduled to end in December 2022. This paper presents the main results achieved so far in the O1. SDGs have been included in the SCMs previously designed by the EDINSOST project. Each SCM learning outcome is related to a set of UNESCO learning objectives and UN indicators of the SDGs. As EDINSOST2-SDG results, the SCM has been simplified to make it easier for teachers. A pilot project is currently being carried out at the UPC-BarcelonaTech to analyse ten engineering degrees using this simplified SCM. The results of the pilot project will be presented in June 2022, but the preliminary results show that the reduction in the number of learning outcomes has been a key aspect to motivate those responsible for the different degrees involved in the pilot project to use the SCM as a tool to introduce sustainability in their degrees.

1 INTRODUCTION

The university has an important role to play in an eco-social transition that is essential to overcome the major challenges our society faces as part of nature [1]. As an institution dedicated to the creation and transmission of knowledge, the university may lead the way towards a culture of sustainability, through research and teaching [2] and from the experience and learning of the university community itself. To this end, the integration of Education for Sustainable Development (ESD) in Higher Education (HE) contributes to the development of sustainability-related competencies of students and university staff. Competencies such as critical and creative thinking, systems thinking, collaboration, action and problem-solving skills contribute to the training of potential eco-social change agents.

The United Nations 2030 Agenda identifies the need to integrate the Sustainable Development Goals (SDGs) into university curricula [2] as a service to society. This integration represents an opportunity for interdisciplinary and transdisciplinary collaboration in education, research, and innovation, oriented towards the 17 SDGs. The new global framework "Education for Sustainable Development: Towards achieving the SDGs" or "SDGs by 2030", adopted at the 40th session of the UNESCO General Conference [1], encourages the introduction of the SDGs in HE.

The increasing commitment to EDS of more than a thousand HE institutions is reflected in more than thirty international declarations and initiatives [3]. Yet the syllabus of the world's universities is still far from achieving a sustainability orientation. Sustainability is often present in isolated experiences and initiatives that do not reach the learning of all students [4]. Universities should strive to expand and improve teaching-learning actions beyond the usual teaching practices [5], since it is in this area where the greatest difficulties arise for both teachers and students [6]. On the other hand, some studies (in this case focused on the field of engineering) show a lack of social commitment as students' progress in their studies [7], [8], indicating that the challenge is even greater in engineering [9]. It is therefore essential to move towards curricular sustainability in the University System, allowing critical reflection, fostering interdisciplinary collaboration, and learning the necessary skills so that the university community can catalyse change towards a more sustainable society.

Different research groups have worked from many points of view and at many levels on the competencies needed to meet the challenges of sustainability and the SDGs. These works have led to the UNESCO Education Guide for Sustainable Development Goals: Learning Objectives [10], which presents eight key competencies for sustainability: Systems thinking, Anticipatory, Normative, Strategic, Collaboration, Critical thinking, Self- awareness competence, and Integrated problem solving. The Guide proposes 15 learning objectives for each of the 17 SDGs, classified according to a three-level taxonomy: Cognitive, socio-emotional and behavioural.

The Executive Committee of the Conference of Rectors of Spanish Universities (CRUE) defines in its "Guidelines for the Introduction of Sustainability in Curricula" four sustainability competences considered essential in the curricula of higher education degrees [11]:

- C1: Critical contextualization of knowledge by establishing interrelations with social, economic, environmental, local and/or global problems.
- C2: Sustainable use of resources and prevention of negative impacts on the natural and social environment.
- C3: Participation in community processes that promote sustainability.
- C4: Application of ethical principles related to the values of sustainability in personal and professional behaviour.

Different perspectives are aligned with the mentioned UNESCO and CRUE competencies for sustainability [9] in engineering. The Barcelona Declaration [12] of the International Conference on Engineering Education for Sustainable Development proposes the competencies that engineers should acquire in order to face the sustainability challenges. The accreditation agencies for engineering degrees (ABET, ENAEE, Canadian Engineering Acreditation Board) also recognise the need to incorporate these competencies and propose a series of learning objectives.

The EDINSOST projects, financed by the Spanish State Program for R&D&i, arise from the need to promote ESD in Spanish universities. In two consecutive projects, EDINSOST and EDINSOST2-SDG, more than sixty researchers have carried out a highly multidisciplinary work between twelve universities in three fields of knowledge: Engineering, Education, and Business Administration and Management. The research has been contextualised and applied in all the participating universities. Both projects are carried out with the aim of integrating sustainability into the curricula of the participating universities by designing innovative teaching-learning actions, evaluating the knowledge of the teaching staff in sustainability and designing a training strategy for them, and discovering the competency level in Sustainability of current graduates in the Spanish university system.

Based on the sustainability competencies defined by CRUE [11], the EDINSOST project [13] developed Sustainability Competencies Maps (SCM) for the three areas of the project [14] and evaluated pedagogical strategies and appropriate evaluation instruments to develop the sustainability competency. Three years later, the need to incorporate Education for the SDGs in the same three areas resulted in the approach of the EDINSOST2-SDG project. The project developed two other tools for the introduction of sustainability in the university system. The first, the "Map of sustainability presence" of a degree, shows the percentage of presence of sustainability competencies in the curricula. The second one consists of a questionnaire that, for each competency, asks about the level of ESD that students perceive they have acquired. The comparison of the result of both tools allows us to glimpse the effectiveness of the incorporation of ESD and the SDGs to a degree.

However, this effectiveness should be validated through direct assessment of student learning. At the same time, the project is working on the development of a database of open educational resources (OER) related to the SCM, on the design of a teacher training course, and on tools that allow the introduction of ESD in final degree projects.

The incorporation of ESD and the SDGs in university degrees is not trivial. Strategies must be modified to integrate courses, activities, and content in the different degrees in a systematic, interconnected, and coherent way [5]. Several of the participating universities in EDINSOST2-SDG are implementing initiatives to achieve this integration. In 2021, the Universitat Politècnica de Catalunya (UPC-BarcelonaTech) started a pilot project in ten degrees to introduce sustainability in their curricula using the EDINSOST2-SDG methodology. The pilot project represents an opportunity for sustainability competencies to be normalised as part of university engineering education [15]. Management teams and teaching staff have been involved in the implementation of the EDINSOST2-SDG tools in each degree: SCM, Map of sustainability presence, teacher training courses and OER database. During this process, a problem inherent to the SCM presented in [9] has arised: in degrees where there are no sustainability experts, teachers have been reluctant to use the SCM due to the large number of learning outcomes it contains (53). To solve this problem, the EDINSOST2-SDG team has simplified the SCM to make it easier to understand and use. This paper presents the work developed to achieve this goal.

2 METHODOLOGY

The Engineering SCM of objective 1 of the EDINSOST project was presented in [14]. The SCM is structured based on the four CRUE sustainability competencies, which are subdivided into seven competency units (CU). Each of these seven CUs is defined using the Simplified Miller Pyramid [16] as the taxonomy of learning. This is a taxonomy of three domain levels: know, know how, and demonstrate + do. For each domain level of each CU, the set of learning outcomes related to sustainability that an engineering graduate must acquire on completion of their studies are defined.

The EDINSOST project had considered multiple sources of information to create the SCM, but the SDGs were not among these sources because their publication coincided in time with the work done during the project. For this reason, in the EDINSOST2-SDG project it was decided to update the SCM to take into account the SDGs. The result, together with the validation process of the new map, can be found in [9]. In total, the new SCM has seven CUs and defines 53 learning outcomes. This is a very high number, which makes it difficult to implement the SCM in an engineering degree. For this reason, a process of simplification of the SCM was carried out, so that the number of learning outcomes was significantly reduced. This allowed obtaining a SCM of only 28 learning outcomes. Having a reduced number of learning outcomes not only simplifies their introduction in the curricula, but also makes it possible to reduce the number of questions in the surveys to build maps of the presence of sustainability in a degree (objective 2) and to analyse the perception of students about their own learning (objective 4). It also allows having to develop a database with less number of OER (objective 3).

The way to reduce the number of learning outcomes has been to combine several learning outcomes into a single one whenever possible. For this, two considerations have been taken into account. The learning outcomes to join:

- must belong to the same CU and to the same domain level
- must deal with similar aspects, so that the result of their union is natural

For example, the following learning outcomes:

- Include indicators in their projects for measuring social impact (e.g., Social Life Cycle Analysis, ISO 26000, Directive 2014/95 / EU for non-financial reporting).
- Take into account in their projects and actions safety, health and social justice criteria (e.g. ergonomics, accessibility, user experience, equity, diversity, common good, transparency, human rights, gender perspective, needs of the most vulnerable groups, discrimination, dignity, fight against corruption).

have been joined in a single learning outcome in the simplified MCS:

- Takes safety, health, and social justice criteria into account in their projects and actions and includes indicators to measure social impact.

As it can be seen, the process has also served to simplify the writing of the learning outcomes, which makes them clearer for teachers.

To relate the learning outcomes with the SDGs, the relationship matrices of the learning outcomes with the learning objectives of the SDGs defined by [10] and with the goals of the SDGs [2] have been used. These matrices had been initially developed for the MCS presented in [9] so it has been necessary to simplify them. To do this, each learning outcome of the simplified SCM has been related to the learning objectives of UNESCO [10] and to the goals of the SDGs with which all the original learning outcomes were related (from the MCS of 53 learning outcomes).

3 RESULTS

Table 1 shows the simplified MCS structure and an example for the Competency C4: Application of ethical principles related to the values of sustainability in personal and professional behaviour, with its three Learning Outcomes at different learning levels.

Table 1. Example of the simplified MCS for Competence C4.

Competency	C4. Application of ethical principles related to the values of sustainability in personal and professional behaviour.

Dimension	Holistic
Competency Unit	CU4.HO. Acts according the ethical and deontological principles related to the values of sustainability
Level 1- know	C4.HO.1.x. Knows their professional deontological code, the main ethical dilemmas and the laws and regulations related to sustainability. C4.HO.1.y. Knows the concepts of social commitment and corporate social responsibility, its possibilities and limitations.
Level 2- know how	C4.HO.2.x. Is able to identify and critically evaluate the implications of the ethical and deontological principles related to the sustainability values in their professional domain and to critically evaluate the social responsibility of companies' activities.
Level 3- demonstrate and do	C4.HO.3.x. Is capable of exercising their profession, and of actively participating in responsible action in the entities in which he/she develops their profession, taking into account ethical principles related to the values of sustainability (e.g. equality, justice, precautionary principle, prevention of damage, responsibility towards present and future generations, protection and restoration of a healthy environment, social, economic and environmental human rights).

The analysis for all 28 Learning Outcomes of the simplified SCM with the SDGs Learning Objectives and SDG indicators shows that they cover all SDGs but SDG2- Reduce Poverty. The more represented SDGs in the SCM are: SDG4 - *Quality Education,* SDG9 - *Industry, Innovation and Infrastructure* and SDG 12- *Responsible Consumption and Production*, which make sense for engineering education. Table 2 shows, as an example, the relation between the Learning Outcomes for C4 and the SDG.

Table 2. Example of the relation between learning outcomes of the SCM and SDG for Competence C4.

The simplified SCM is currently being piloted in 10 degrees at UPC-BarcelonaTech in order to effectively introduce sustainability learning in all University degrees.

3.1 SUMMARY AND ACKNOWLEDGMENTS

In this paper some results of objective 1 of the EDINSOST2-SDG project have been presented. The reduced Engineering Sustainability Competencies Map (SCM), which contains 28 learning outcomes that all engineering students should have acquired on completion of their studies, allows curriculum designers to introduce sustainability and the SDGs, and makes it easier for teachers the design of related activities. The learning outcomes of the SCM include the UNESCO learning objectives and the goals of the SDGs related to engineering. We want to thank the work of all the members of the EDINSOST2-SDG project, and in particular the components of the engineering working group. All of them have made this work possible.

ABSTRACT

A major challenge in engineering education is to empower students to use their acquired technical skills to solve real-world problems. In particular, methods of

[1] *Corresponding Author: johannes.schleiss@ovgu.de*

doi:10.5821/conference-9788412322262.1258

Artificial Intelligence (AI) need to be studied as tools in their respective application contexts. This puts pressure on university lecturers concerning the didactical design and elaboration of a course, and requires them to move towards a practice-based learning approach. Moreover, working on real-world problems leads to uncertainties for the lecturer and their students. Before and during the course, it is not always clear which methods will be used to solve the problem, respectively which competencies the participants need to acquire.

Therefore, we propose to combine two established approaches: a project-based learning approach and the use of digital, curated learning content provided by Open Education Resources (OERs). We hypothesise that a practical study project solving a real-world problem using a combination of OERs and project-based learning is beneficial to AI education. Furthermore, we show implementations of our concept in three different courses.

The first results indicate that student-centred tasks lead to high intrinsic motivation. At the same time, lecturers have to deal with a modified and extended role: They are no longer the broadcaster of knowledge but rather a guide within the learning process. Using the combination of OERs and project-based learning, the courses are attractive and exciting for students and lecturers without becoming unmanageable.

1 INTRODUCTION

1.1 Motivation

The use of Artificial Intelligence (AI) as a tool and assistance is growing and requires engineers to enhance their digital skills including data and AI competencies. Thus, higher education institutes must complement current engineering curricula with these competencies.

Current approaches to teaching AI are mostly algorithm-oriented, meaning that the learning goal of a unit is teaching a class of algorithms in one particular context, whereas earning the competence of choosing and adapting known methods to a given real-world problem is neglected most of the time. Thus, students first get to know an approach or a methodology to solve problems in a class and the transfer to real-world problems is only a minor aspect. This is not a sufficient preparation for real-life situations, where engineers are required to handle complex situations “on the fly” [1]. In our volatile world independently acquiring context-specific knowledge on demand (often called “ad-hoc” learning) becomes a key competence. This cannot be achieved through the classical “stockpiling of knowledge” but only through learning by doing [2].

With AI as a tool, it is even more important to teach it in its applied context using real-world problems and projects [2]. However, designing a practice-based university course that is interactive and stays up to date with the latest trends remains difficult. Moreover, integrating projects in courses leads to situations where it is not always clear which methods will be used to solve the problem and which competencies the participants need to acquire for them.

In the following, we discuss how a practical study project solving a real-world problem with AI tools can be implemented using a combination of project-based learning (PBL) and Open Educational Resources (OERs). We hypothesise that the use of OERs in PBL can combat uncertainties in the process of a project for students and teachers. Moreover, we argue that the use of OERs in a PBL setting changes towards an on-demand use, which in return changes the role of the lectures. To support our hypotheses, we implement the idea in three different courses and provide the first lessons learned. We discuss our initial findings on the changing roles of lecturers and their effect on students and give an outlook on the next steps.

1.2 Project-based Learning

The idea of practice-based learning is not new and was proposed in multiple forms, one of the most prominent being project-based learning (PBL). PBL means dealing with a subject matter based on a concise, self-contained, project-based task, that is solved independently. The focus is not only on finding an original solution but also on planning and conducting the solution process itself, including compiling and acquiring the relevant information and materials.

The PBL approach is suitable wherever the application of knowledge to a practical problem is involved. Thus, it is extremely helpful when dealing with the complex methods and approaches that AI poses [3]. In comparison to traditional engineering classes, where a given problem is solved with given methods, PBL requires students and lecturers to deal with uncertainties. These are similar to the uncertainties that will occur later in real life: at the beginning, it is not entirely clear whether the project will work out as expected and which approaches will be successful.

The decisive advantage of PBL as an instructive approach lies in the direct and intuitive learning experience for students. Once learners have gone through a PBL solution and implementation process, it often does not only have a positive effect on their motivation. Knowledge acquired through PBL is usually also remembered better due to the high degree of personal involvement. The learning process is more intense and practical pitfalls that are missed in purely theoretical considerations can be (fore)seen and dealt with by employing a PBL application [4].

For lecturers, the use of PBL approaches poses multiple challenges. First, methodological and didactic planning and organisation are more complex and time-consuming as a wide range of material has to be made available to address the uncertainty of the projects and the heterogeneous learning preferences. The project outcome and possible solutions are not always clear in the beginning and lecturers have to take into account heterogeneous learning preferences and states of knowledge of their students. Second, for lecturers in the field of engineering who want to incorporate AI applications into their teaching in order to convey AI skills, there is the additional challenge of integrating knowledge from other disciplines. Third, students need support for planning projects, adjusting plans when necessary and developing solutions.

Students, as well as lecturers, have to deal with an immensely increased complexity and a general openness of the process when it comes to project-based learning. Yet the chances for fostering capacity-building outweigh these challenges. In the following, we demonstrate how the integration of OERs in teaching can support project-based learning, especially with respect to interdisciplinary AI competencies.

2 APPLICATION-ORIENTED TEACHINGWITH PROJECTS AND OERS

2.1 Integrating OERs in Teaching

OERs are learning media that are free to use. Usually, the material is digital and developed by others. OERs can be both individual materials such as texts, images, or videos on a specific topic, as well as curated content that is compiled into entire courses.[2]

For lecturers, the advantage of using such material is that they can rely on quality-assured content, which allows one to integrate content from a different discipline into one's teaching without preparing educational content like textbooks or lectures for each topic. Furthermore, it is not possible to have deep expertise in all fields that are related to one's own work. OER can help solve this problem. This is especially relevant when integrating AI competencies in domain-specific course settings. Moreover, such a dynamic and open teaching setting creates a new and uncommon situation for lecturers. Their role changes from being a knowledge broker to being a learning coach. The lecturer is no longer solely responsible for explaining the content but becomes a learning companion who guides the students through their individual learning process. Consequently, studying with OERs also empowers the self-responsibility of the students.

From a didactic perspective, integrating OERs causes a new organisation of the learning process that forms a learning pyramid, illustrated in Figure 1. Lecturers, students, and the object of learning usually form the so-called didactic triangle in which the learning process is organised [5]. When digital educational material is used additionally, the triangle forms a three-sided tetrahedron as described by Prediger et al. [5]. However, we argue that the digital lecturers who are the creators of the digital educational material also influence the learning process. Thus, the learning process forms a didactic pyramid of teaching.

Lecturers in such a setting are confronted with a multitude of challenges. At the same time, integrating OERs in teaching opens up space for more self-directed learning and for learning settings that enable a highly interdisciplinary, practical acquisition of knowledge and skills. In the following, we show how the integration of OERs differs in a project-based learning scenario.

2.2 Using OERs in Project-based Learning

There are multiple ways of integrating OERs. In a classical way, they can be used for self-study before a class. Thus, students consume and study selected material as a prerequisite before their class, and the lecture is used to deepen and apply the studied material (so-called "Flipped Classroom") [6]. In this context, a lecturer needs

[2] An example for curated AI learning opportunities is the AI campus, available at *ai-campus.org*.

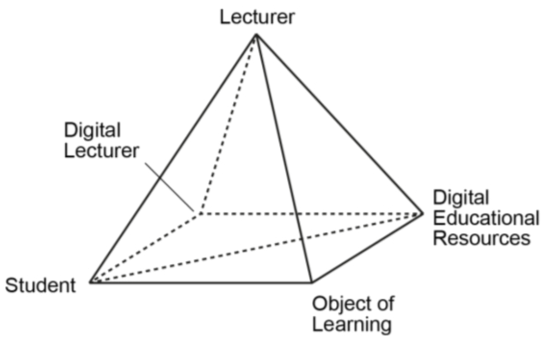

Fig. 1. Didactic pyramid of teaching that extends the didactic triangle of lecturer, student, and object of learning with an additional digital lecturer and digital learning material.

to communicate the learning goals and guiding questions clearly or curate the material for the students (see for example Fig 2-C, prep. phase).

In the project-based learning setting, the use of OERs is *on demand* throughout the project, as illustrated also in the implementations in Fig. 2. Here, students have access to a (curated) library of material and study selected material based on their individual needs. This fosters self-directed learning and allows for a more individual, practice-based learning experience in the different phases of a project. Furthermore, relying on OERs as knowledge broadcasters allows to provide a broader range of specific project topics that would be not possible to cover as an individual lecturer. At the same time, students are still accompanied by their teacher, who helps them understand the external content and answers open questions.

The use of OERs in PBL is especially useful in interdisciplinary settings like AI in engineering, where the classical domain know-how is combined with new data-driven methodologies. Furthermore, it can address heterogeneous groups of students, different levels of experience and even interdisciplinary project settings. To exemplify the use of OERs in a PBL setting, the next section discusses the implementation of *on demand* OERs in three different courses and summarises our lessons learned.

3 IMPLEMENTATION

3.1 Research Project Seminar

An implementation of the concept of a research project seminar was done in a project seminar (5 ECTS-CP) focusing on developing an algorithm that can track an arbitrary moving object over time. In the project, we incorporated collaboration and competition using teams consisting of 24 students from computer science, medical engineering, and AI. As the audience was very heterogeneous, OERs were a central theme to supplement the individual’s knowledge at the beginning of the seminar (see Fig. 2-A). In the first phase, the lecturer selected a range of OERs as a prerequisite of the course.

Throughout the course, every student had the aim to implement a tracking algorithm. In this phase, students had the opportunity to access further OERs on relevant topics around tracking algorithms. However, this was not mandatory and based on their needs. The lecturer supported finding the right material for the respective student groups by providing guidance and pointing to general and more specific OERs.

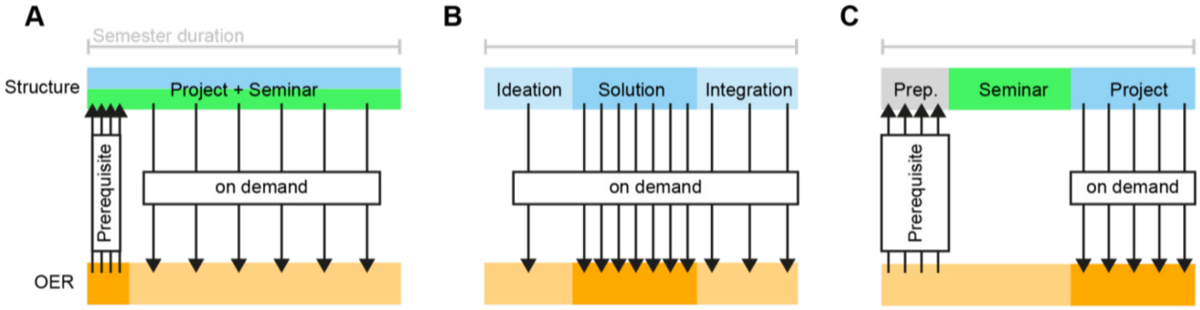

Fig. 2. Overview on discussed implementations of teaching AI competencies with OERs and projects: A) Implementation as a research project seminar, B) Implementation as product engineering project, C) Implementation as a block project seminar. Arrows indicate if students were provided with OERs as a prerequisite or used them on demand.

To succeed in the seminar, the student groups needed to collaborate within their teams to find a common team solution. At the end, each student presented a paper or created their own OER related to the project topic. The latter should foster the creation of new, specialised high-quality OERs which could be potentially used in future semesters. However, the quality of the student-created OER varies.

3.2 Product Engineering Project

The implementation was done in product engineering projects (5 ECTS-CP) for students from mechanical engineering in their 4th or 6th semester without previous knowledge of AI. Here, the concept of fully on-demand OERs was tested (refer to Fig. 2-B). The projects aimed to teach students an understanding of how smart, data-driven products work and how to include AI components in engineering products. Exemplary project topics varied from developing a machine that sorts LEGO bricks, developing an autonomous car control in a car simulator, or implementing games with AI components in online environments.

Since the overall goal in the course was teaching product development, the project started with a definition and ideation phase, where the requirements to the solution and the fulfilment criteria were specified. Next, the development followed the traditional way of product engineering by defining functions and their relations as a basis for partial solutions that shall be investigated. When using this development approach, it is not clear beforehand what part of the solution uses an AI component and how the component is integrated into the overall system. Therefore, the students accessed required material and knowledge needed to develop their solution on demand as OERs. Thus, the knowledge transfer was not provided through classical lectures with clear, defined topics but through flexible on-demand OERs.

3.3 Interdisciplinary Project Block Seminar

Another form of integration was done in the interdisciplinary seminar on the topic of AI in Neuroscience (3 ECTS-CP). The aim was to equip participants with the knowledge and ML tools to analyse electroencephalography (EEG) data. The small, heterogeneous and interdisciplinary group consisted of eleven students with backgrounds in computer science, psychology, and neuroscience as well as different semesters.

Similar to the block research project described in Fig. 2-C, the seminar had three phases: self-preparation, seminar days, and a project phase. It combined the idea of an inverse classroom concept with PBL. OERs were used in two parts. First, in a curated form as a prerequisite for the preparation of the seminar and second, on-demand as support during the implementation of the project phase. By integrating OERs in the seminar, the participants were addressed based on their background and needs. Furthermore, the seminar days could be used for group work rather than knowledge transition, focussing more on applying the knowledge.

3.4 Lessons Learned

From implementing the courses and evaluating them in open discussions with the participants, we can already derive the following lessons learned:

- Students perceived the integration of digital material as helpful, especially highlighting the flexibility of short videos and other forms of material, such as podcasts.
- Students experienced self-directed learning and autonomy as satisfying and self-affirming.
- Investing time at the beginning of the course in discussions and definitions of goals and tasks pays off in the remaining time of the course. Moreover, it also allows students to embrace the openness of the process.
- Using OERs allows lecturers to integrate AI content into the particular domain without the need of preparing their own learning content for all possible topics.
- Working on practical problems helps the students to gain a hands-on understanding of the underlying AI concepts.
- Projects help to teach AI in its relevant, domain-specific problem context and support students to understand the benefits and limitations of the technology.
- The availability of high-quality OERs for the specific project context and experience level is a limiting factor (especially in the fast-moving field of AI).

4 DISCUSSION

4.1 Changing Role of Lecturers

The integration of OERs into a course or a project causes a new situation concerning the role of the lecturers. They are no longer the only lecturer in the course, because of the digital learning content that is created and partly conducted by another digital lecturer. First, this means giving up some of the control a lecturer usually has during a course. Second, it also requires the lecturers to re-interpret their own role when it comes to dealing with external content that is neither from their own discipline nor designed in their own teaching style. Experiencing different teaching styles, different ways to present knowledge, and different levels of difficulty can be helpful for students. At the same time, it can be a challenging, new situation for the lecturers who need to become mentors, learning companions and curators rather than being the single source of knowledge. It is, therefore, important to reflect and communicate the role in the learning process.

The use of OERs and projects also bring different advantages for the lecturers. First, there is the obvious benefit of relying on curated material, which is helpful in a field that is not part of one’s own expertise. The knowledge transfer of certain topics is partly outsourced to domain experts. Second, the use of external material can save time in the course preparation and in more resource-intensive settings like project-based learning. It might even be the only way to cover the possible wealth of learning material at all. Done right, the lecturer has more time for discussing and conducting, which becomes the new key function of the lecturer.

4.2 Effect on Students

Challenges are not only imposed on the lecturer when using project-oriented approaches in class. Students also have to adapt to the new learning situation and have to leave a consumer’s role in favour of a more active self-concept as learners. Suddenly being responsible for one's own learning process, for the organisation of real-world tasks, communication, and structuring problems may be challenging, especially for students in earlier semesters.

The lecturer has to bear this in mind when planning a course. It includes providing students with material or guiding questions to enable them to master processes and tasks in a self-directed way. Some students may be able to succeed here with nearly no help. Others may need more attention or help at a certain point. Thus, the lecturer has to focus more on individual learning and adaptive learning designs, when choosing material and creating tasks for the students. Tasks have to be formulated very clearly and precisely to prevent misconceptions. Clarifying the goals and possible questions right in the beginning is very important and may well take more time than in other settings. Yet afterwards, students should be able to act more or less independently without constant input from their lecturer.

5 CONCLUSION AND OUTLOOK

In this paper, we proposed to combine OERs and PBL to teach applied competencies in an engineering context focusing on the example of AI competencies in engineering. We combined the open format of a project with a curated form of on-demand open education content. Furthermore, we presented three different ways of implementing the combination in courses across levels and disciplines focusing on integrating AI into different domains. The first results and lessons learned indicate that using OERs and PBL can be a useful way to extend existing teaching formats towards more practical and applied learning with a manageable effort. This also suggests an additional benefit of sharing high-quality open educational content.

Our findings are limited to the experience from the three implementations. Thus, further work is needed to generalise the concepts and provide more evidence on the effects on students and lecturers.

ABSTRACT

The use of Artificial Intelligence (AI) in engineering is on the rise and comes with the promise of cost reductions and efficiency gains. However, classical engineers often lack the necessary skills to implement data-driven solutions. At the same time, computer scientists lack the required understanding of engineering systems. Thus, we need to extend the current set of competencies of engineers across the boundaries of disciplines to include competencies of Artificial Intelligence as well as skills necessary for interdisciplinary work. In this paper, we propose a competence profile of a so-called AI Engineer that combines the expertise of AI systems in the context of engineering. Based on perspectives from literature and interviews with experts from industry and research, we highlight the most important set of competencies across the professional, methodological, social, and self-competencies. The contributions of our paper can act as a reference point for developing and advancing future engineering curricula. Furthermore, it serves as a guide for professional self-development.

1 INTRODUCTION

1.1 Motivation

Artificial Intelligence (AI) is a powerful tool and is seen as enabling technology in many use cases. Hence, there is a growing interest in applying AI in engineering applications such as increasing energy efficiency, optimising processes, quality management, and predictive maintenance [1]. The rise of AI and digital tools also changes the competence profiles of the next generation of engineers. The value of digital innovation and data-driven processes lies in the intersection of disciplines. Thus, more than ever, strong interdisciplinary learning is required, integrating competencies across the boundaries of disciplines [2,3].

Recent studies have investigated changing competence requirements in the engineering discipline [2,3,4,5], competence requirements for developing and working with AI [6,7,8,9], and general future skills [10]. However, there is currently no work on which competencies are required across the boundaries of disciplines to work and develop solutions at the intersection of AI and engineering. Furthermore, established engineering competence profiles, such as the CDIO syllabus [11], ABET [12], and EUR-ACE [13], do not yet address the integration of AI competencies in engineering curricula. Thus, this paper aims to answer the question *which professional, methodical, social and self-competencies are needed in these future roles of AI in engineering.* We hypothesise that the next generation of engineers does not solely focus on one domain but needs an interdisciplinary skill set that includes digital and AI competencies. We refer to this generation of future engineers as *AI Engineers*.

We address the question by developing a competence profile of an AI Engineer that is based on perspectives from literature as well as interviews with experts from industry and research. Our work aims to be a reference point for further adoption of the engineering curricula in the future and a guiding point for engineers that want to upskill themselves.

The paper is structured as follows: The next subsection clarifies the used terminology and background. Section 2 describes the methodological approach. Section 3 gives an overview of the competence profile and the supporting literature and interviews. Last, we discuss the findings and limitations and conclude with an outlook.

1.2 Terminology and Background

In this paper, we use the term *competencies* as the ability to act in and cope with context-specific demands [14]. In the context of education, we emphasise the development of competencies to act within certain professional environments. Following [14], we can roughly distinguish four categories of competencies:

- *Professional competencies* describe the specific knowledge, skills and experience to carry out the professional function.
- *Methodological competencies* represent cognitive skills that can be applied across situations and are required for mastering complex tasks and problems.
- *Social competencies* characterise knowledge, skills and abilities to accomplish goals in social interactions.

- *Self-competencies* describe skills and behaviours that relate to the self-awareness and behaviour of a person and influence their working practice.

In the context of AI, different roles can be defined, for example, AI developer, AI user and AI observer [7]. Accordingly, when selecting relevant competencies, it is also necessary to define the applicable role. In the following, the focus lies in finding the relevant competencies for the developer role. Another important factor to keep in mind is that roles depend on multiple factors, for example, the industry and the size of a company lead to a focus and also a more broad or specialised profile.

2 METHODOLOGY

The research question was answered using a qualitative content analysis based on semi-structured expert interviews and an explorative literature review. To understand the developing occupational field of AI engineers, the aim was to combine scientific perspectives from literature with practical insights from the industry. In this context, recent literature studies and the reported experience of associations provide an overview of required competencies, whereas the experience of the experts supports and supplements these with practical insights.

For the expert interviews, we selected industry partners who work on the intersection of AI and engineering and come from different industries. These include manufacturers of logistic systems, engineering service providers in mechanical engineering and IT, pharma companies, automotive manufacturers, applied science, and IT consultancies. Next to the different industries, we considered that the interviewees come from small, medium and large companies and performed functions in a variety of areas (data science, strategic business development, IT strategy, software development, collaborative factory, business process management, consulting). More than two-thirds of the interviewees were in a leadership position. A total of eleven guided online interviews were conducted by one of the authors. The interview questions focused on the general understanding of AI, current and future use cases in the respective companies, challenges in the use of AI, and the question of professional and interdisciplinary competencies required in the field of AI. The interviews were recorded and transcribed for further analysis.

The literature was selected using various search terms such as "competence", "competency", "skill", "engineering", "artificial intelligence" and "machine learning". Scientific studies, as well as reports of associations, were considered and results from German-speaking as well as English-speaking countries were used. In total, nine different sources [2,3,4,5,6,7,8,9,10] were examined, which are also mostly based on literature surveys and qualitative interviews themselves.

Both the expert interviews and the sources from the literature were evaluated using qualitative content analysis. The competencies were filtered out and assigned to the competency areas of professional competencies, methodological competencies, social competencies and self-competencies. Last, subcategories were formed and the most mentioned competencies were selected and described as part of the competence profile.

3 COMPETENCE PROFILE OF AN AI ENGINEER

In the following section, we give an overview of the competencies and the supporting literature and interview extracts. Fig. 1 summarises the competencies across the different categories and gives a more detailed description of the individual competencies.

Fig. 1. List of competencies with their description in the four categories of professional, methodological, social and self-competencies.

Competency	Description
Professional Competencies	
Data and AI Knowledge	Handling and understanding of the fundamentals of data and AI technologies, as well as the ability to employ tools and models to analyse them.
IT Competencies	Designing, building and programming applications (with intelligent functionalities) and the ability to deal with respective frameworks and platforms.
Interdisciplinary Domain Know-How	Understanding of the technical foundations, physical components, and technical and business processes in the application domain.
Methodological Competencies	
Process- and System Thinking	Structuring, analysing, describing, modelling and optimising (AI) processes and systems.
(AI) Problem Solving	Recognizing and dealing with complex problems and situations and having solution strategies for them (that can involve AI).
AI Reflection	Reflecting the impact of AI technologies, for example with respect to ethics, legal, safety and social aspects and understanding one's own role in it.
Social Competencies	
Interdisciplinary Communication and Cooperation	Communicating and cooperating in an interdisciplinary team setting, or with people of different cultures and experience levels. Ability to adapt the communication and working style to the respective environment and team.
Change Management	Managing and shaping change processes, supported by the ability to communicate value, listen, inspire, and resolve fears.
Leadership and Decision Making	Ability to organise, coordinate and manage teams, and the ability to make decisions within the boundaries of the current responsibilities.
Self-Competencies	
Learning and Curiosity	Ability to individually acquire contextual knowledge from different sources and the interest, curiosity and openness to learn new topics.
Creativity	Developing novel, innovative solutions and questioning the "status quo" of processes and ideas.

3.1 Professional Competencies

Data and AI Knowledge - As a central point, various authors highlight the handling and analysis of data, such as Data Analytics and Data Science [2,3,4,6,7,8,10]. Furthermore, some authors explicitly state the understanding of AI technologies, in particular Machine Learning (ML) [2,6,7,8]. In this context, it is important to understand the mathematical foundations, such as statistical knowledge, as well as the benefits and limitations of models [2,8]. Furthermore, understanding and using the currently available tools and libraries is mentioned [8].

Six of eleven interviewees mention the handling and understanding of data. Particularly, they refer to pre-processing, structuring and uniting data from different systems, as well as an assessment of data quality. On the topic of ML and AI, the interviewees point out the ability to build and deploy models. This includes understanding different types of models with their benefits and limitations. Moreover, few interviewees state the value of having a “building kit” of tools for various use cases and data types. Furthermore, the interviewees value an understanding of the mathematical foundations of ML and the model parameters.

IT Competencies - In the context of Information Technology (IT) competencies, an understanding of digital tools and technologies as well as computer science basics is found important [2,3,4,5,7]. More specifically, multiple papers point at the fluency of programming languages, design patterns, platforms, frameworks and libraries, next to an understanding of software engineering [2,5,6,8,10].

The IT competencies are supported through the expert interviews. Around two-thirds of the interviewees put forward the importance of an understanding of software engineering, the application development of intelligent functionalities, and how AI as a building block engages with other code elements. Furthermore, some interviewees state user-centric (application) development and agile software development.

Interdisciplinary Domain Know-How - One common theme in the literature is the integration of interdisciplinary skills and knowledge [3,4,5,8]. Accordingly, multiple authors put the focus on having a foundation in one core engineering discipline, especially when AI is integrated with a physical interface or hardware such as a robot [2,5,6,7].

The interviews are aligned with the importance of understanding the domain, especially the underlying business and technical processes, and the engineering basics. One interviewer refers to it as the most important skill, as the value of AI comes only from the combination of Data Science and domain know-how.

3.2 Methodological Competencies

Process- and System Thinking - Another group of competencies highlighted by literature are process- and system competencies, especially for processes controlled or enhanced by AI [5,6]. More generally, two papers mention system thinking [2,3] and Huang et al. [9] add logical and abstract thinking as high-level competencies.

The interviews emphasise the importance of understanding and contextualising business and technical processes. An example is the ability to analyse, structure and break down processes and systems. Moreover, around half of the interviewees mention system and process thinking. This goes along the lines of understanding the boundary conditions in the domain, the drivers of the process and what data could be used to optimise it.

(AI) Problem Solving - Multiple studies mention problem solving competencies [3,5,6,8,10]. More generally in this category, Huang et al. [9] endorse observation skills and analysis skills, whereas Gottburgsen et al. [3] highlight the ability to deal with complexity.

The answers from the interview can be clustered around problem understanding and problem-solving with AI. Next to the importance of understanding and working from a real defined problem within a business context, it is important to have an idea of the boundary conditions, tools, and data available to decide if an added value can be derived from using AI.

AI Reflection - From the engineering perspective, the literature highlights the importance of assessing technology and its social, legal, and ethical impact on the development [3,6,7], capacity for judgement [10] as well as responsible action and the ability to reflect the effect of one's own actions [3,6,7]. Accordingly, the ability to judge, reason, analyse and draw conclusions is mentioned [9]. AI reflection is supported through knowledge of (digital) ethics and an understanding of the legal basis and norms, such as data protection [3,7,10].

One key cluster in the interviews is the understanding of the impact of using AI in the application context and the assessment of the usefulness of AI in this context. Moreover, two interviewees explicitly state the ability to develop explainable AI models to allow the translation of the AI models into understandable user language and gain trust in the model’s decisions.

3.3 Social Competencies

Interdisciplinary Communication and Cooperation - The literature mentions the ability to communicate, cooperate and work in teams with people from different disciplines, cultures and levels of experience [2,3,5,6,7,8,10]. Next to communication and cooperation between different stakeholders, two papers also highlight the importance of explaining AI behaviour to various user groups [5,7]. Moreover, competencies for dialogue, conflict management, and digital collaboration fall under this category [10]. The foundation of interdisciplinary communication and cooperation can be described in the ability to adapt communication and working styles [2,6,10].

These competencies are also supported by more than two-thirds of the interviews. Here, the interviewees emphasise adaptive communication and cooperation with different target groups, as working on AI systems is usually at the intersection of multiple divisions. Moreover, the communication aspect is seen as very important to gain acceptance with the final user and to understand the requirements of different stakeholders.

Change Management - Kirchherr et al. [10] state the development of strategies to execute transformation, especially with respect to group dynamics, group cultures, networks and systems. Similarly, André & Bauer [6] mention the communication of potentials and limits of AI, and supporting the change process by removing fears and coordinating the expectations of various stakeholders.

More than half of the interviews support this competency and see it as one key competency. It is mentioned in various forms such as to inspire people, present added value, formulate success stories, address concerns, listen to people, manage expectations of different stakeholders, resolve resistance, convince and sell. The underlying message is that integrating AI in systems and processes requires a transformation of the existing processes (and sometimes even culture) which makes it necessary to also manage the change process next to the technological process.

Leadership and Decision Making - The literature mentions the ability to organise, coordinate and manage teams, and the ability to make decisions within the boundaries of the current responsibilities [5,6,8].

This group of competencies was not directly stated in the interviews.

3.4 Self-Competencies

Learning and Curiosity - The literature highlights the ability to learn and independently acquire contextual knowledge [2,3,5,9]. Furthermore, André & Bauer [6] emphasise the curiosity and willingness to learn how to work with ML and AI systems. In this context, two studies stress the need for openness to new experiences and technologies in the changing world [2,7]. Moreover, Kirchherr et al. [10] encourage digital learning such as processing digital information from different sources and using learning management systems.

Three interviewees stress the importance of self-learning and lifelong learning, especially in the context of the fast-moving field of AI. From their perspective, it is a key competency to know where and with what methods one can find help and stay on top of current technological developments. Moreover, the fascination and curiosity to discover new insights were brought up.

Creativity and Innovation - Multiple studies express the importance of creativity and innovation competencies, such as developing novel ideas and improvements through questioning the “status quo” and critical thinking [2,5,9,10]. From a company perspective, this also requires a failure culture [7].

This is also supported in a few interviews, mentioning the eagerness to systematically experiment, the resilience to failure, patience and drive in finding solutions to complex problems as well as thinking out of the box. Moreover, questioning existing processes is stated. One interviewee explicitly states the difficulty for engineers to think out of existing control loops.

4 DISCUSSION

The presented competence profile confirms the initial hypothesis that an interdisciplinary set of competencies is needed to integrate AI systems in engineering and highlights the most relevant competencies for the role of an *AI Engineer*. First, the professional competencies show that to develop AI systems for the engineering domain, a combination of Data and AI knowledge, IT competencies, and interdisciplinary domain know-how is needed. Second, the methodological competencies indicate the importance of process and system thinking, problem solving as well as the ability to reflect on the implications of using AI. In the category of social competencies, interdisciplinary communication and cooperation gain more importance with more cross-disciplinary working teams. Furthermore, managing and leading people through accelerated change and transformations is essential. Last, self-competencies in themselves gain importance through the accelerated change among industries, above all the ability to learn and independently acquire knowledge. Some of the mentioned competencies are also of increasing importance in other subject areas and are already included in the scope of previous education of engineers or computer scientists. However, they need to be brought together into one novel profile of an *AI Engineer* that combines the expertise of AI systems in the context of engineering.

The trend towards interdisciplinary profiles and competencies also needs to be reflected in engineering education. This can be, for example, achieved through interdisciplinary and cross-disciplinary projects or the integration of topics from different industries in the engineering curricula. Furthermore, the importance of methodological, social and self-competencies needs to be further strengthened and incorporated into the technical subjects.

The significance of our findings is limited by two factors. First, *AI Engineer* is not yet an established role and can be found in different forms across company sizes and in literature. Depending on the envisioned role, different competencies might get assigned different importance. We try to overcome the limitation by selecting interview partners and literature from different perspectives, for example, literature on competencies for engineering in Industry 4.0 and AI literacy competencies. Second, our interview sample is relatively small and currently represents only German companies. Thus, there is a need for more investigation to what extent the proposed profile can be generalised.

5 CONCLUSION AND OUTLOOK

In this paper, we proposed a new interdisciplinary competence profile for AI in engineering, based on findings from the literature and interviews with industry experts. The competencies support the hypothesis that AI in engineering needs interdisciplinary access. Next to solid professional competencies in AI and the domain, our findings show a high relevance for interdisciplinary communication skills and strong methodological competencies, such as system- and process thinking.

Based on the initial competencies, further work involves a definition of required levels for different job profiles. Moreover, the competence profile can serve as a reference for competence-oriented study development and in designing a curriculum for people learning these competencies from scratch or people who want to upskill themselves. This can also include more research around the question of well-suited competence-oriented teaching methods in the engineering and AI field.

ABSTRACT

This work is directed towards the improvement of programming skills for students on the 2nd semester of Electrical Engineering (EE) BEng signed up for the “Digital Electronics and Programming” (DEP) course. The goal is to support students who tend to drop out in the first half of the semester or give up and not show up at oral exams. In our research hypothesis we state: Decreasing and eliminating negative emotional experiences will increase student’s self-efficacy thereby lowering dropout. We experiment with a programming process guide in text and video to gain students' capability in solving programming problems and increase metacognitive awareness. Additionally, we measure students' emotional experience of programming by using a special self-assessment vignette inquiry. For comparison purposes we introduced the same measurement methodology in 2021 on the courses where there is no focus on the process guideline. The results show a positive effect on lowering the negative emotional impact when students use a programming process guide. The article describes the theoretical background based on literature studies for both the process and the students’ self-assessment, and discusses results achieved in relation to the findings in the literature. The preliminary results are described in [8] and in paper here we present recent outcomes for the autumn 2021 and spring 2022 semester over 9 weeks.

1. INTRODUCTION

1.1. Observation and theorical foundation

Several papers [1][2][3], show that strong students' self-efficacy has an influence on their ability to learn programming and tackle many kinds of problems which arise (compiler message, logical faults, etc.). Students with a lower self-efficacy have a higher negative self-assessment. During the last 7 years when the DEP course has been offered, we have observed that 10 - 20% of the students give up or do not

doi:10.5821/conference-9788412322262.1200

show up at the exam. The literature describes several criteria by which students evaluate their programming abilities. For example, prior experiences, speed of solving assignments, grades, social comparisons, and whether their program works, expectations in fluency [2] [3]. Furthermore, students’ performance compared to other students, where students construct their perceptions of ability compared with other students, for example in group/teamwork. These factors may have an impact on how strong the negative or positive self-assessment is and thereby influent students’ self-efficacy. Self-efficacy is part of the Bandura’s [4] social cognitive theory and described as: “to believe in one’s capabilities to organise and execute courses in action required to produce given attainments”. Gorson. J et.al.[1] studied why students think they are bad at programming by using self-assessment by using 13 moments of programming. The study was carried out in computer science courses for novice programmers at. 3 universities. They concluded: “We also found that the frequency with which students negatively self-assessment correlates with their overall self-efficacy in their programming courses.” Studies about self-assessment and self-awareness in computer science courses inspired us to do the project within Scholarship of Teaching and Learning (SoTL).In SoTL work we try to find answer to the research question: “Can metacognitive processes help students to gain more self-confidence and thus continue to be active during the course?” and one of the hypotheses leads to the statement: “Lowering negative emotional experiences increase self-efficacy.” For helping students in programming assignments, problem solving and for seeing if it could lower the students drop-out during the semester we introduce a process in programming hands-on assignments to show and guide how to solve programming problems inspired by Loksa [7]. The process is based upon literature study [5],[6] discussing learning processes when dealing with programming problems, self-efficacy, and self-confidence when programming. Next, we measure students' self-emotional experiences using a self-assessment tool inspired by Gorson ‘s et.al [1] work for measuring the emotional impact when programming. We customized this framework for measuring quantitatively of what degree students emotional impact changes due to receiving help from our guideline to be more self-confident and get less negative influence. At the same time be motivated to follow the course and go to the exam. The self-assessment is done by using 13 moments of programming which a professional would come through. Therefore, it is relevant to use at our bachelor (Diploma-engineering 3½ year program) studies in Electrical Engineering and IT (Information Technology) and Electronic Engineering studies. Gorson et. al [4] also posed 4 general questions in a survey for qualitatively testing self-efficacy. Due to limited time and constraints, we do not focus on this in our studies. Neither we do not measure self-efficacy in programming as Steinhost et al. [5] In contradiction to Gorson, we use the vignette questionnaire survey 3 times during the semester for testing if the introduction of a process in programming helps students to have fewer negative feelings when dealing with programming and thereby, we assume that the less negative impact has a positive impact on the self-efficacy. It is not in the scope to measure the self-efficacy by tools as suggested and used in [5]. We did start the experiment in the autumn 2021. In O. Schultz et. al [8] we show results by using process guidelines instead of using the Moments of Programming Vignette survey.

Conclusion was that using the process guideline lowers the negative self-assessment.

1.2 Programming processes

Learning how to program involves more than just syntax, control, and data structures. It also involves mental scaffolding around the learner where the learner can place knowledge and become metacognitive aware [7]. That means the student understands where one is in the problem-solving process. Several studies describe and discuss problem solving stages when dealing with programming. Loksa. D et al and Prather et. al [6][7] investigated metacognitive awareness for novice programmers and they identified 6 specific stages in learning to solve programming problems. The stages are: (1) reinterpret the prompt, (2) search for analogous problems, (3) search for a solution, (4) evaluate a potential solution, (5) implement a solution, (6) evaluate the implemented solution. That study and other studies [3][6] lead to our process being introduced for 2nd semester students in the first week and used repeatedly when solving the assignments. The programming guideline process introduced to students on 2nd semester EE from first class-lecture is adjusted according to the DEP course content and hands-on exercises to be carried out by students. The process used is presented below:

1. Read the whole assignment. Does the assignment make sense?

2. What could a solution to the task /subtasks look like? Outline the solution with pseudocode and / or a flow-chart.

3. Imagine a simulated execution of your hypothetical program / parts of the program. Use your pseudocode and flowchart. Simulate running the hypothesis program. Does the expected happen?

4. What can the C-code for the sub-task / task solution look like?

5. Open Microchip studio, start a new project, select GCC C executable, give the project a suitable name and place the project somewhere where you can find it again. Press ok. Choose to use an ATmega2560. Program the solution you have found for each sub-task found under 2.

6. Does the program perform the hypothetical run-through performed in 3?

The subsequent process steps help students to focus on problem refinement and narrow to the solution which unloads unnecessary confusion and thoughts about overall assignment.

1.3 Didactics used in the Digital Electronics and Programming (DEP) course

The experiments are done in DEP course. The content consists of a digital electronics programme supported with practical programming tasks with focus on microcontroller interfacing peripheral devices. Observations and surveys from students are collected and shown in section 3. The students must understand how to read a complex datasheet and use the information to set up microcontroller-registers by C-programming language for the distinct kinds of interfaces. Compared to standard C-programming courses it requires also comprehensive understanding of electronic device manufacturer documentation and the way of essential information transformation from datasheet to a program. The teaching method used in this course is blended learning. Before each lecture, the students are asked to watch a video about the topic for the coming class and take a quiz about the content in the video and the related chapter in the course-book. Students work on 5 different assignments for 13 weeks, and 4 of the assignments are for hand-in in pair groups. For each assignment they hand-in a report documenting various aspects of the programming work. The requirements for taking the exam are all submitted reports approved as well as the answered quizzes taken during classes. The exam is oral where students randomly choose one question out of six from the digital electronic field and they present orally the answers to the question. Furthermore, the examiner asks questions related to C-programming part in the last assignment

2. Data collection

2.1 Characteristics of the classes in subsequent years from 2017 to 2021

Gradings of the classes since 2017 up to 2022 have been analysed for finding the exact numbers of students dropping out at the examination. The data is listed in the Table 1 and described below

year	stud. spring	not met	median	average	std. Div.	stud. autumn.	not met	median	average	std. div.
2017	64	6	7	7.25	3.96	29	6	7	6.86	3.95
2018	64	7	7	7.50	3.46	25	3	10	7.86	3.82
2019	49	15	10	8.23	2.92	33	14	10	8.78	3.55
2020	52	10	7	7.40	3.00	25	4	7	7.80	3.29
2021	59	10	7	7.38	3.64	34	9	10	8.84	2.93

Table 1. Students' enrolment statistics in particular year.

The course is taught twice a year, Spring and Autumn. The column “stud. spring" and “stud. autumn" shows the number of students enrolled to the exam. Next is shown number of students who do not show up. The grading scale is pass: 02, 4,7,10,12 (excellent) and not pass: -03 and 00. The median grade-values are shown together with the average grade and the standard deviation. Table 1. shows the grades are higher in the smaller classes but the standard deviation is greater. The number of students who do not show up is little greater in the autumn. The students in the autumn semester are more diverse in background as some have been working fulltime before studying. That could explain the larger drop out. Overall, if the process introduction can bring some of these students to the exam, then it could mean less students drop the exam, due to stronger self-confidence. Process introduction in autumn does not show any changes as 26% did not enrol to the exam. Even in 2020 15% did not enrol to the exam.

2.2 Measuring emotional impact

Purpose in this work is to measure if the process guideline helps students lowering the negative self-assessment and thereby continuing the course and participate in the examination.

The 13 moments of programming with the vignettes in [1] is translated into Danish. We have made a pre-test on students before using the 13 moments of programming vignettes. Based upon that we adjusted the vignette belonging to each moment of programming, we substituted the names with 1st and 2nd person singular subject pronouns. Due to the time, we had for the experiment we use Google form to collect results and thereby the scale from 1 to 6. Where 1 means less negative impact and 6 is most negative impact. In the Gorson study they used a scale of strongly agree for the most negative impact and most positive impact as total disagree. We do not directly use the positive impact. We assume less negative (1) is reflected as positive and gains more self-efficacy. The survey is carried out in the 1st lesson and 7th in autumn and 8th lesson in spring and the 3rd one is done in the last week 13th (last lecture). The full text for the 13 moments of programming with vignette statements is presented in [9].

3. Results

3.1 Answers to the self-assessments

The population in the autumn was 27 students in the 1st survey and second survey 22 students. In the spring 46 students participated in the 1st survey and the 2nd survey 33 students answered. The 1st survey is done during the lesson 10 minutes after start. The survey is performed without influence from the teachers. The 2nd survey was carried out in the middle of the semester during the lesson after the first break. The participants are also asked about their programming experiences and what programming language they know. They have an opportunity as well to comment upon the vignette survey. These extra answers show the appr. 50% are novices and 50% had been programming before enrolling on the education from 1 to 8 years more and less. The moments of programming shown below are indicated by letters from A to M:

A. A Simple Error.
B. Start over.
C. Do not understand the error message.
D. Stop programming to plan.
E. Get help from others.
F. Spending time looking up syntax.
G. Spending time planning in the beginning.
H. Spends a lot of time solving a problem.
I. Do not know how to get started.
J. Spends a long time finding a simple mistake.
K. Struggling to find the error.
L. Unable to complete within expected time.
M. Do not understand the problem of the task.

In most of the moments except B, I and M, the self-assessment is measured on the general programming work, where the compiler and IDE is used. And the process guideline does not address that. Whereas during the semester students should be more used to the IDE and the compiler, therefore lowering the negative-self-assessment. For each moment from A to M there is a vignette. An example of vignette related to M is: “You solve your programming task. You do not understand what the task asks you to do. You feel sad and frustrated because you cannot even understand the question. How much does it affect you?". The vignette for each moment of programming can be seen in [9]. In this paper we present the self-assessment data of moments of programming shown in table 2 where we found the greatest changes and scores in the autumn 2021and compared with the data from spring 2022. In Table 2 data is compared for self-assessment on five moments of programming, and the data is compared to data in Goron’s [1] study ([10] show results for all 13 moments of programming). Data shown in Table 2 is created by choosing to use scores of 4 and up to 6 interpreted as negative which may have the most impact on the self-efficacy. We present only moments with highest scores. In general, the Table 2 data have the same orders of magnitude as Gorson’s study [1]. The moment: C.” Do not understand the error message” are also having a negative emotional effect together with moment I. “Do not know how to get started,” moment L. “Not being able to finish in time” and moment M. “Do not understand the problem of the task.” The moment C has decreased by 10% lower for the spring class which may be because students get used to the IDE and the compiler messages. But it is not happening in the Autumn semester. For the moment L “Unable to finish in time.” the score is lowered in Autumn but increased in spring semester, which may be in a relation to workload from the other courses. The process introduced should lower the negative self-assessment for moment I where the figures show for the autumn class, but not for the Spring class. Also, for moment M self-assessment score should be lowered due to the process introduction as seen decreased by 6% for Spring and 36% for the Autumn The moment K Struggling finding the error assessed less negative score as expected during the semester, as students get used to the compiler messages

Moments of programming	Week 1 F21	Week 7 F21	Week 1 S22	Week 8 s22	Gorson [1]
C. Do not understand error message:	44%	55%	72%	61%	62%
I. Do not know how to get started:	70%	59%	67%	66%	84%
K. Struggling to find the error:	56%	14%	35%	30%	59%
L. Unable to complete within expected time:	48%	32%	46%	57%	50%
M. Do not understand the problem of the task:	77%	41%	72%	66%	79%

Table 2. Negative self-assessment in % of total participant.

The data has also been analysed regarding the students’ background in programming before the study start. The results are shown in Table 3 and 4. The data is split into students who have no programming experiences before the study start and students who have experience in programming before study start. Data shows here that the novices have a higher median value, and the 75% quartile is higher compared to students who had been doing programming before the study. It shows over time when you get more experienced you also act more professionally, and the negative self-assessment is lower. Regarding moments I to M the novices also self-assess more negatively than the experienced students. And novice students in spring does self-assess more negatively for moments I and M, compared to Autumn semester students. Moment M "Do not understand the problem of the task may also address capability of student's understanding of the assignment text. That shows teachers need to be very aware of formulation of assignment

Experiences - not novice				no experiences - novice		
vignette	25%	50%	75%	25%	50%	75%
C	2.00	3.0	5.00	4	5	5
I	2.75	4.5	6.00	5	6	6
L	1.00	3.0	5.00	3	4	6
M	2.00	4.0	5.00	4	5	5

Table 3. Quartiles for the Spring semester class data split in novice and not novice.

Experiences - not novice				no experiences - novice		
vignette	25%	50%	75%	25%	50%	75%
C	1.0	2	3.0	2.0	3	4.0
I	2.0	4	4.5	2.5	4	5.0
L	2.0	2	3.5	2.0	3	4.0
M	2.0	3	4.5	2.5	4	5.5

Table 4. Quartiles for the Autumn semester class split in novice and not novice.

3.2 Survey about the process

In the 10th week of the semester, we asked students about the uses of the process. We asked these questions in a written survey: **a.** How much does the process help you understand what the program / sub-program should perform, **b.** How much confidence the process gives when you need to program, **c**. Was it clear from the start of the course what the process was to be used for? On a scale from 0 to 6. And in spring 2022 we added two questions more **d**. Does the process guide increase your problem-solving skills in programming? **e**.: will you faster solve programming problem without process guide?" The Table 5 shows that 47% to 55% of students find the process useful when using scores 4 up to 6.

Year	N. stud.	a >=4	b>=4	c>=4	d>=4	e>=4
Autumn 21	19	9 (47%)	10 (52%)	12 (63%)		
Spring 22	31	17 (55%)	11 (35%)	8 (26%)	18 (58%)	3 (10%)

Table 5. Evaluation of the process Spring 2022 and autumn 2021.

The question b. about confidence shows a different picture. The class in autumn finds it raises the confidence, but only 35% in the Spring 22. The answers to the question c if it was clear what the process should be used for, indicates that even the process actively was used from 2nd week in the Spring semester only 26% understand it. Better in the Autumn by 63%. Therefore, we need in the future to explain better why it is important for students to use process and how to work with it. The question d. is only asked in the spring for getting more understanding about how much support the process gives students. 58% of the students find it helpful in problem solving. Only 10% find it as a waste of time by answering question e.

4. Conclusions

We find the changes in scores analysed in the autumn indicate lowering scores for the moments of programming during the semester, by introducing the process guide in the course (DEP) and students' self-assessment using the 13 moments of programming with vignettes [9], We can conclude the process could have an impact on students lowering negative self-assessment for the moment M and I as the self-assessment is lower at the end of the semester. But the formulation of assignment text may also have an impact. It can be concluded students with experiences before the study have less negative score in self-assessment. Which confirms that the moments of programming are defined from the way a professional works and therefore students with a previous background are more used to tackling the moments of programming. From the Table 5 we see that students find the process useful approximately 50% and 35% to 52% of students find the process gives more confidence. From Table 1 the students not participating in the exam do not show any changes in the Autumn, therefore lowering the score of negative self-assessment by using a process guide is not proved. But running process guide in more semesters could change the picture. The “moments of programming” self-assessments tool is useful for evaluating how the students are confident with the general programming, IDE and compiler progress during the semester. Further work must be carried out in the coming semesters to really observe the effect of the process guideline.

ABSTRACT

EngiMath is a 3 ECTS online course in engineering mathematics, in seven different languages, and it is the main and practical output of the ERASMUS+ project entitled "Mathematics online learning model in engineering education" in which the authors were participating. The course is integrated with Learning Management Systems such as Moodle and it is compatible with other platforms using Learning Tools Interoperability.

Once the project is finished, authors undertake, with the support of the Institute of Education Sciences at the Universitat Politècnica de Catalunya-BarcelonaTECH (UPC), an innovation project, **EngiMath@UPC**, with three practical objectives: a) to incorporate EngiMath into the teaching activity of the widest as possible range of students at UPC, b) to gather students and faculty feedback regarding the tracking of materials and their performance in the student training process, and c) to statistically

[1] Corresponding Author

analyze the data collected in order to validate and adjust the follow-up of the materials. In connection with the above mentioned objective b) a training course addressed to the math professors has been prepared at UPC.

The paper introduces, on the one hand, the EngiMath course as an online open educational resource for the academic community benefit, and on the other hand, analyzes the valuable feedback given by the training activity participants. Details on the online course implementation as well as main conclusions will be presented and discussed throughout the document.

1 THE ENGIMATH ERASMUS+ PROJECT

EngiMath, *Mathematics online learning model in engineering education*, is an ERASMUS+ innovation project granted in the 2018 call Cooperation for Innovation and the Exchange of Good Practices KA203 - Strategic Partnerships for higher education. The project (run from November 1st, 2018 to August 31st, 2021) aimed to create and develop shared medium for materials suitable for web-based assessment of mathematics for various types of engineering education curricula.

The EngiMath consortium was integrated by the following Higher Education institutions: Tallinna Tehnikakorgkool (TTK UAS, Estonia, coordinator), Instituto Politecnico do Porto (IPP, Portugal), Universidad del País Vasco (UPV/EHU, Spain), Universitat Politècnica de Catalunya (UPC, Spain), Letterkenny Institute of Technology (LYIT, Ireland), Politechnika Koszalinska (PK TUK, Poland) and Universitatea Tehnica Cluj-Napoca (UTC, Romania). Complete information on objectives, intellectual outputs, dissemination activities and contact can be found at https://sites.google.com/tktk.ee/engimath.

Contributions of the EngiMath project included a) a comprehensive report on pedagogical analysis for online assessment of mathematics for partner countries and needs of engineering mathematics, b) a 3 ECTS online course in engineering mathematics in seven different languages (English, Spanish, Portuguese, Catalan, Polish, Romanian and Estonian) and c) a mathematics online assessment model in order to engage the student voice more in the learning process [1-2].

2 THE ONLINE ENGIMATH COURSE

2.1 Introduction

The aim of this course is to promote the development of basic and structured knowledge and practical skills in the mathematical area of Linear Algebra, specifically in the sub-areas of Matrices and Matrix Calculus, Determinants and Linear Equations Systems related to Engineering. The direct target groups of the Project include students in engineering mathematics programs at higher educational institutions, academic staff teaching engineering mathematics in tertiary programs and research academics in the areas of technology-enhanced learning and online learning.

Stronger student engagement or improved student engagement are common instructional objectives expressed by Higher Educational Institutions. They aim, in particular, at reducing the early dropouts of Science, Technology, Engineering, and Mathematics (STEM) studies and to involve students in their own learning process.

Finally, the EngiMath online course, implemented in Moodle and fully open, consists of a basic course on Linear Algebra composed by three topics: Matrices, Determinants and Linear Equations Systems. Firstly, an initial Introduction to Engineering Applications serves as a motivation. Secondly, each topic contains learning materials (26 Lessons), practice tests (2 Quizzes per Lesson) and at the end of each topic there is an Assessment Test. The final grade is the average of the three topic-specific assessments. At the end of the course the student is kindly requested to give his/her feedback for further development and improvement of the course. Fig. 1 allows to identificate the components and the sequence of the course.

Fig. 1. Course sequence

2.2 Engineering Applications

In order to motivate and encourage students towards independent learning in mathematical topics at the beginning of the course there are some examples of Engineering Applications (in Civil, Electronic and Mechanical fields). On the one hand, they connect basic concepts of mathematics with relevant topics of Engineering. On the other hand, they propose and state contextualised problems which are solved stepwise using EngiMath tools and procedures.

2.3 Lessons

EngiMath course has adapted the PAR (Present, Apply, Review) model for online learning [3]. PAR structures the lesson by presenting new material, allowing the student to apply the learning followed by a review of the learning. This structure may be utilized several times within a lesson to maximize the learning potential. Persistence and attrition factors were also taken into account when designing the course [4]. The course adequately combines formative and summative aims in the e-assessment strategy [5].

The course is composed by 26 Lessons and is divided into three Blocks:

- Block I: Lessons 1–14. Matrices and Matrix Calculus
- Block II: Lessons 15–22. Determinants
- Block III: Lessons 23–26. Linear Equations Systems

All the theoretical concepts are presented in a very simple and comprehensive manner. Many examples are used to support the theoretical material. In total, there are more than 400 slides with over 3900 animations. Details in Fig. 2 and Fig. 3.

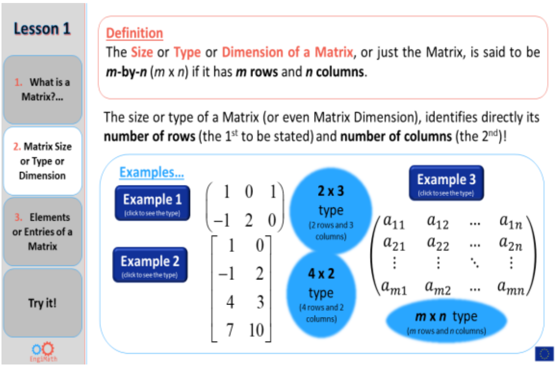

Fig. 2. Slide of Lesson 1

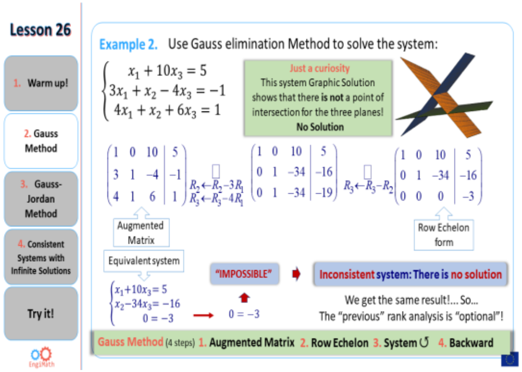

Fig. 3. Slide of Lesson 26

Furthermore, in each Lesson the student has the opportunity to check his/her skills using the “Try it” quizzes. These quizzes are composed of over 120 questions of different types: True or False, Multiple Choice, Matching, Correspondence, etc). Each question provides a step by step solution in order to help the student to arrive at the right answer. Fig. 4 and Fig. 5 show an example of a quiz and a quiz feedback.

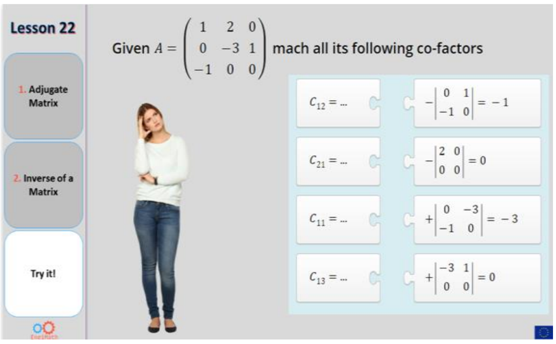

Fig. 4. “Try it” quiz

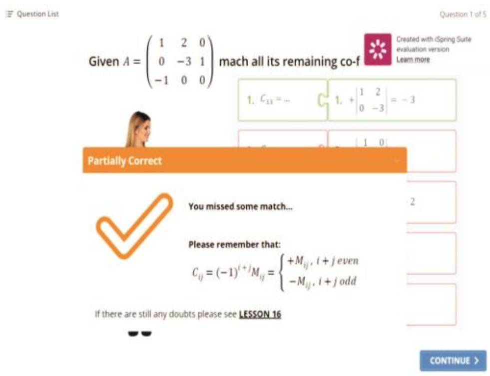

Fig. 5. Example of quiz feedback

By using iSpring, the 26 powerpoint Lessons were transformed into e-courses, producing 26 SCORM packages that were uploaded into the Moodle platform.

2.4 Practices Materials

Regarding the practical materials, with the background experience applied to the frame of Erasmus+ project EngiMath, a huge question bank has been developed for the online engineering mathematics course.

Special attention was paid to the development of STACK (System for Teaching and Assessment using a Computer Algebra Kernel) questions and step-by-step teaching tasks that give students a certain logical sequence of mental actions that must be performed to solve the problem. Based on the objectives of the practical quizzes for each lesson, a testing model was compiled: a technological matrix containing competencies selected for practice and testing. For each competency, questions were created. Regarding the variability, in order to ensure the development of different practice experiences and tests, and also to allow randomness in the definition of the practical quizzes, each of these questions has, in average, 10 versions.

The question bank consists of more than 4500 questions, 2148 for practice in lessons and 2382 for assessment. There are close-ended type questions and open-ended type questions. Exhaustive feedback has been provided for each question (Fig. 6).

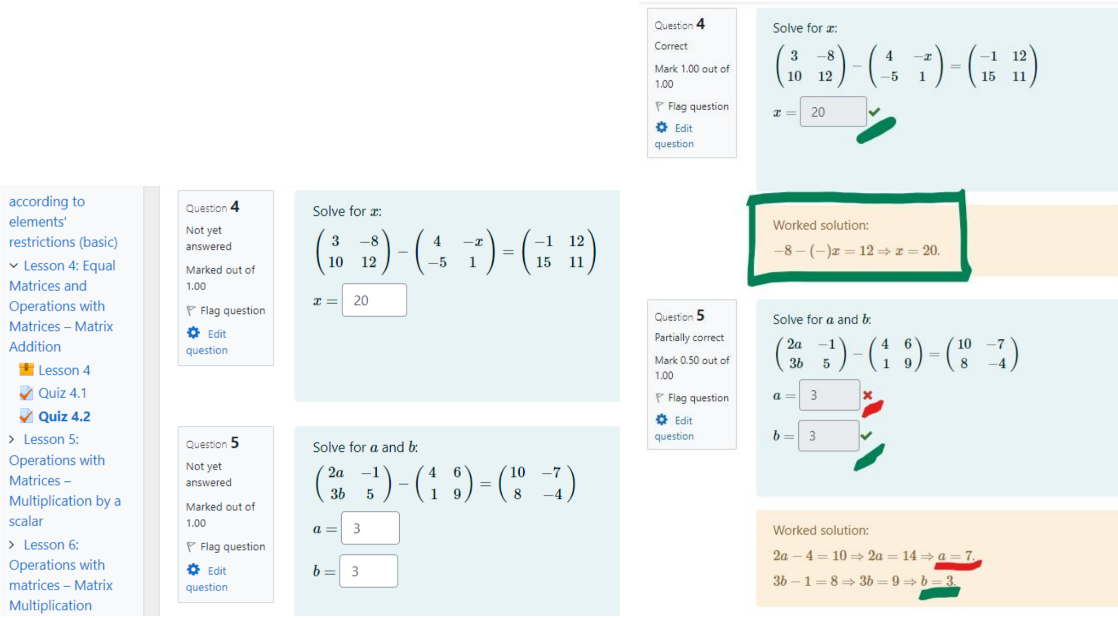

Fig. 6. Quiz 4.2 and feedback

2.5 Assessment Tests

At the end of each Block student is invited to take a 90-minute Assessment Test in order to obtain the qualification of the corresponding topic. The grade of the Block is the maximum of those obtained in the three attempts allowed in the assessment test.

Assessment materials are a consequence and interconnected to the previous activities. As one important role of online technology is to facilitate teaching and promote learning and in the context of the EngiMath online course (or any other online assessment task) only the student/user can know if the learning requirements are being fulfilled. In this sense it is necessary to ensure a form of summative assessment (as well as already pointed out for the case of training in the previous section) that validates the work developed without too much entropy caused by external to the covered contents issues.

2.6 Course Feedback

Through a Google Form students are invited to give their feedback about different aspects of the course:

- general impression of the quality of theoretical, practice and assessment materials,
- the quality of graphics, the structure of the course and the presentation method of concepts,
- the level of difficulty of the presented materials and
- the interaction with the teacher.

Open questions on the three issues of the course they liked the most and the three issues that could be improved are also included.

3 TRAINING COURSE

3.1 Workshop Structure

According to the aims of the EngiMath@UPC project, in order to disseminate among the mathematics community at UPC, either the project or the online course, a training activity was organized, targeted to the math teachers (specially to Linear Algebra ones). The title of the activity was “EngiMath. A European project for UPC students” and it was planned as a 6-hour online workshop.

The schedule of the workshop was as follows:

a) an inicial 2-hour session for the introduction of the EngiMath project and the online course,
b) an estimated 2-hour homework on working in detail (from a math teacher perspective) one or two lessons of the course, and
c) a final 2-hour session for the joint discussion on the perceptions and comments (pros and cons) about the worked materials.

First session was mainly informative and descriptive of the project and the course as a main output. For the homework, participants had two days in order to deal with a preassigned lesson and provide the corresponding feedback. In the second session, the instructor described the results of the feedback and promoted an active and general discussion on the design and structure of the course, contents presentation, procedures, questions database and assessment strategy, in order to derive the main conclusions on validation and update of the materials. Last session also allowed to invite participants to be active part in the EngiMath@UPC project during the second semester of the 2021-22 academic year.

Teachers accessed the online course, available in Catalan, Spanish and English, via an External Tool implemented in the Moodle virtual campus allowing them to directly link the materials locate at the TTK University of Applied Sciences’ server in Tallinn (Estonia).

3.2 Participants

The workshop proposal received a total of 27 registrations and 22 professors attended the sessions. Among the 22 attendees, 19 (86.4%) fruitfully contributed with their homework, feedback (similar to the one described in the subsection 2.6) and active discussion. Figures are based on the feedback provided by them.

Participants' profile: a) affiliation: 17 (89.5%) Dept. of Math, 2 (10.5%) others, b) online course language: 16 (84.2%) Catalan, 3 (15.8%) Spanish, c) age rang: 5 (26.3%) in [40, 49], 12 (63.2%) in [50, 60] and 2 (10.5%) above 60.

3.3 Results on Quality Issues

Fig. 7 and Fig. 8 display bar charts from the collected responses on quality for the EngiMath materials and resources. It can be seen, when grouping the two higher categories (4 and 5 in the Likert scale, colored green and purple, respectively) that the scores are really satisfactory in each item:

- Materials: Theoretical: 94.7%, Practice (84.2%) and Assessment (84.2%)
- Resources: Graphics: 78.9%, Structure (100%) and Presentation method (100%)

This findings state the good performance of the output and validates a high-quality standard of the EngiMath online course.

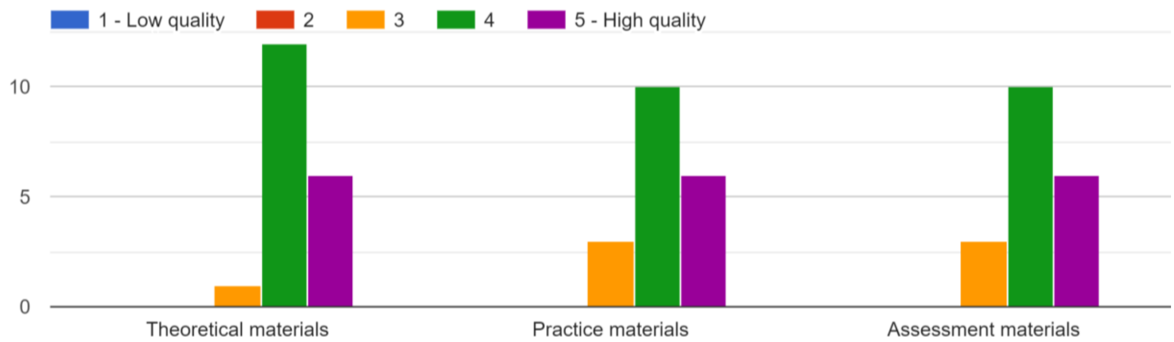

Fig. 7. Bar chart of the materials' quality feedback

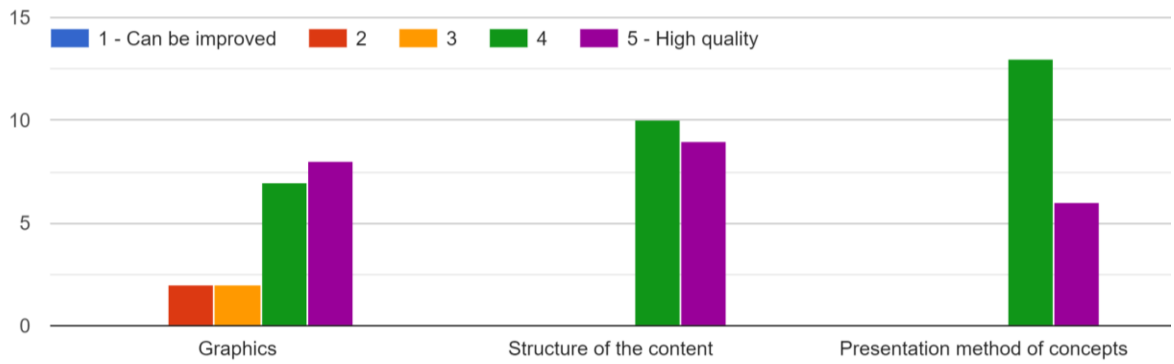

Fig. 8. Bar chart of the feedback about the designing resources' quality

4 FINAL CONCLUSIONS

Concerning the participants' positive experience, the answers focus on the following aspects (sorted from more to less frequency of responses)

a) Clarity, conciseness, progression and summaries in explanations.
b) Volume per lesson. Brief, which prevents giving up in the middle of the lesson.
c) Illustrative exemples. Helpful to understand the theory.
d) Fully coverage of the subject and different levels of difficulty.
e) Project and platform by themselves.

When proposing issues to be taking into account for improving the current version, proposals include (sorted from more to less frequency of responses)

a) Correct errors in the answers or feedback in the tests. In particular in the assessment tests.
b) Reduce overly calculative exercises (or too many boxes to fill) and add reasoning questions.
c) Avoid repetitive exercises.
d) Allow to follow the program in a non-sequential way.
e) Incorporate some additional software like Mathematica, Matlab, Maple, SAGE, Geogebra, etc

ACKNOWLEDGMENTS

This work has been partially supported by the European Union under the ERASMUS+ programme (2018-1-EE01-KA203-047098) and the 2021 call for teaching innovation projects of the Institute of Education Sciences at Universitat Politècnica de Catalunya-BarcelonaTECH. The authors are very grateful for the commitment and involvement of the partners in the EngiMath consortium as well as the fruitful collaboration of all the teachers who have participated in the training course. Special thanks to Raúl Galdeano for his dedication to the EngiMath@UPC project.

Conference Key Areas: *Sustainability, Sustainable Development Goals, Cooperation for Development*
Keywords: *Sustainability, Environment, Artisanal Mining, Cooperation for Development, Engineering, Education, Sustainable Development Goals*

ABSTRACT

Future engineers, in addition to technical knowledge, should incorporate in their academic curricula aspects that contribute to make mining a sustainable activity. This will contribute to changing the concept that society has about mining and to be a socially accepted activity. In the mining engineering studies at the Universitat Politècnica de Catalunya (UPC), students have the opportunity to develop cooperation projects together with professors and other staff members. They all collaborate with artisanal miners from different underdeveloped countries, mainly from Latin America, and contribute to making mining more environmentally friendly. Moreover, they have the opportunity to acquire a social sensitivity that can be of great importance during the development of their professional career. This study presents some experiences of undergraduate, master, and doctoral students in cooperation activities in mining. The projects were developed as a collaboration between UPC and universities or NOGs in Latin America. The activities have been carried out in underdeveloped areas where mining is practiced with a high environmental impact and poor use of resources. A survey among the participants in the projects shows the students' favourable perception of this activity.

1 INTRODUCTION

The supply of mineral raw materials is essential for the well-being and growth of the economy and society. Thus, today's high technological development is accompanied by an increasing need for, and dependence on, a large number of metals. Currently, 30% of the metals that we use are recycled; the other 70% must come from mines. So, it is clear that we have to mine, but we have to do it sustainably.

In mining schools, there is an emerging awareness of the responsibility to train engineers with values that ensure that sustainability is always present in their activities. Future mining engineers must reconcile the requirements of the economy, the environment, and society. Therefore, the inclusion of sustainability in education represents a great opportunity to train engineers with a sense of responsibility for the future. In order to obtain raw materials in an optimal way and with a minimum impact on the environment and in a safety work conditions, the different activities involved must be carried out based on in-depth scientific and technological knowledge.

At the Universitat Politècnica de Catalunya (UPC) students are trained to be future professionals in mining engineering. In this case, in addition to acquiring scientific and technological knowledge, the training also includes the acquisition of social values, which will be of great importance in the future development of their profession. To this end, every year we carry out cooperation projects in mining areas from developing regions, where mining is still a long way from being sustainable. The Centre de Cooperació per al Desenvolupament (CCD) is a UPC body that every year launches calls for cooperation projects in which students, lecturers, and staff of the university can participate and carry out work to cooperate with institutions in developing countries and thus contribute to their development. It is based on the premise that the University has the responsibility to be actively involved in the promotion of solidarity and equity among people and the promotion of better human and sustainable development in the world, supported on its activities of teaching, research, and the transfer of knowledge and technology. In this regard, the UPC incorporated sustainability skills into the curricula [1].

This work presents the cooperation projects carried out through the Mining Engineering section of the UPC between 2012 and 2021. In this period 20 projects were developed in the Mining Engineering section and about 40 students were involved in these cooperation activities. They moved to the study areas where they carried out the planned cooperation activities. Projects aimed at improving tin mining in Bolivia and gold mining in Peru and Bolivia are presented as case studies.

The projects involve participants from Spain and the beneficiary countries. Part of the development of the projects is carried out in the mining areas of the developing countries, where the students, together with their professors, carry out the assessment of the mining activities and a sampling for the development of the research. In addition, here they have the opportunity to work alongside with miners, local university professors and the population of these communities. Once back in Catalonia, the research associated with the project is carried out at the university. Often, this research is part of the degree, master's or doctoral thesis of the students participating in the projects.

2 BACKGROUND

A sustainable mining operation must be safe, economically profitable, efficient in the use of mineral resources, and environmentally clean [2]. To achieve these targets, it must combine the extensive scientific and technological knowledge with care for the environment and the health of workers. In contrast, artisanal mining is carried out by cooperatives, and even by the individuals, with limited scientific and technological knowledge, which does not allow it to be done efficiently [3]. The exploitation of resources under these conditions entails physical, biological, social, and economic issues. Examples in Peru and Bolivia highlight the generation of acid drainage, mercury pollution, high levels of occupational hazards, and low recovery during the processing of the ores. Rational and optimised exploitation of deposit is only possible if their geology, mineralogy, and type of deposit are known. On the other hand, ore chemistry and liberation characteristics allow the selection of the most effective processing methods to maximise the recovery efficiency and prevent environmental pollution.

Artisanal mining significantly contributes to the economy of developing countries and provides work for many of its inhabitants, creating employment opportunities and reducing poverty [4,5]. There is, therefore, a need to improve the conditions under which artisanal mining takes place. For artisanal mining to be sustainable, miners need to be empowered through carefully designed training programs [6,4] and to share with them the most appropriate processing techniques and how to carry them out. However, it is also necessary to know the detailed mineralogy of the ores and gangue at the mining sites.

On the other hand, one aspect that should never be overlooked is the pollution caused by mining activity. Several institutions and non-governmental associations explain to miners how the pollution produced during their mining activity affects to the environment and to the human health. However, this information does not encourage them to make changes in their methods. Miners will consider changing their practices if they perceive that this will increase their economic benefits [6].

3 METHODOLOGY

In order to assess the impact of the cooperation projects on the students, a survey among some of the participants was carried out. It is also relevant to present their views in a time perspective, allowing them to better assess the influence of these experiences on their subsequent activities. Seven survey questions are presented here:

1. Do you think that Development Cooperation projects are a good and enriching professional complement for students?

2. Do you think that Development Cooperation projects are a good complement on a personal level?

3. Do you think that the projects in which you participated provided solutions (total or partial) to the problems they addressed?

4 Do you think that the experience in Development Cooperation projects will influence possible future career decisions?

5 Would you like to repeat the experience of Development Cooperation projects?

6 How many of the 17 SDGs (2020-2030) have been positively influenced by the Development cooperation projects you have participated in?

7 Summary in a few words the experience of the Development Cooperation projects

4 RESULTS

4.1 Case studies

4.1.1 Gold mineralisation and processing in Bolivia and Peru

The collaboration with artisanal mining was carried out in the Arequipa department of Peru and in the La Paz department of Bolivia. Local mining is mainly underground, done through galleries excavation, except in the Mapiri area, from Bolivia, which is of alluvial type. In both cases, miners use mercury as gold recovery method. The studies were focused to determine the main characteristics of the deposits, as the tectonic structures, mapping of the orebodies, gold grade and mineralogy and chemistry of gold and associated minerals, in order to propose the most appropriate processing technique. Studies were also carried out on mining safety and environmental pollution. The influence on the health of the miners and their families was assessed by analysing the mercury content in their hair. These results have been presented to the miners along with proposals to reduce the use of mercury in the short and long term. They were very concerned about the results presented and, at least in some cases, some measures to reduce mercury exposure were implemented.

4.1.2 Tin and indium mineralisation

Tin production is the main economic input of Bolivia. Collaboration with several cooperatives was carried out for the study of the geology of the deposits, the detailed mineralogy to increase efficiency in the processing plants, and the environmental pollution produced by the mining activities. As a result, the miners were provided with a detailed knowledge of the geology and mineralogy of several mines. This made it possible to establish the metals of interest in each case and their characteristics for recovery. Thus, for example, it was shown that tin is found in some mines in significant quantities in the form of the stannite mineral. However, in the Bolivian processing plants usually, only cassiterite is recovered, and stannite is removed into the tailings. Another important result was the determination of significant amounts of indium and rare earths, which are critical metals, in many of the deposits. The importance of this finding is strategic, not only for Bolivia but also worldwide.

4.2 Students valorisation of the projects

The responses of the seven questions are presented in Figures 1 and 2. The first five questions were set as double choice answers. All the students agree that Development Cooperation projects are a good and enriching professional complement for students and that participation in projects of Cooperation for Development is a good complement on a personal level. Most of the respondents (90%) agree that the projects in which they participated provided total or partial solutions to the problems they addressed (Figure 1). All of them agree that their experience in Development Cooperation projects will influence possible future career decisions. The total of respondents would repeat the experience of Development Cooperation projects.

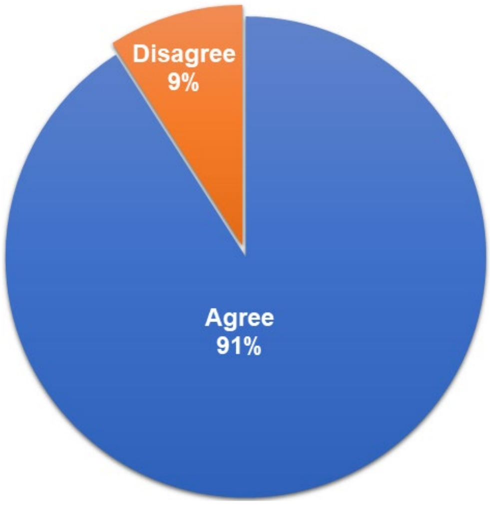

Fig. 1. Responses to the question of the projects of Cooperation for Development are a good complement on a personal level.

Question 6 aims to observe how the participants perceive the influence of the cooperation projects they have carried out on the achievement of the 2030 Sustainable Development Goals (SDG). All respondents consider that the projects they have been involved in have contributed to achieving some of the SDGs 2020-2030. Mainly SDG 8 "Decent work and economic growth", but also SDGs 3 "Good health and well-being", 6 "Clean water and sanitation " and 13 "Climate action" (Figure 2).

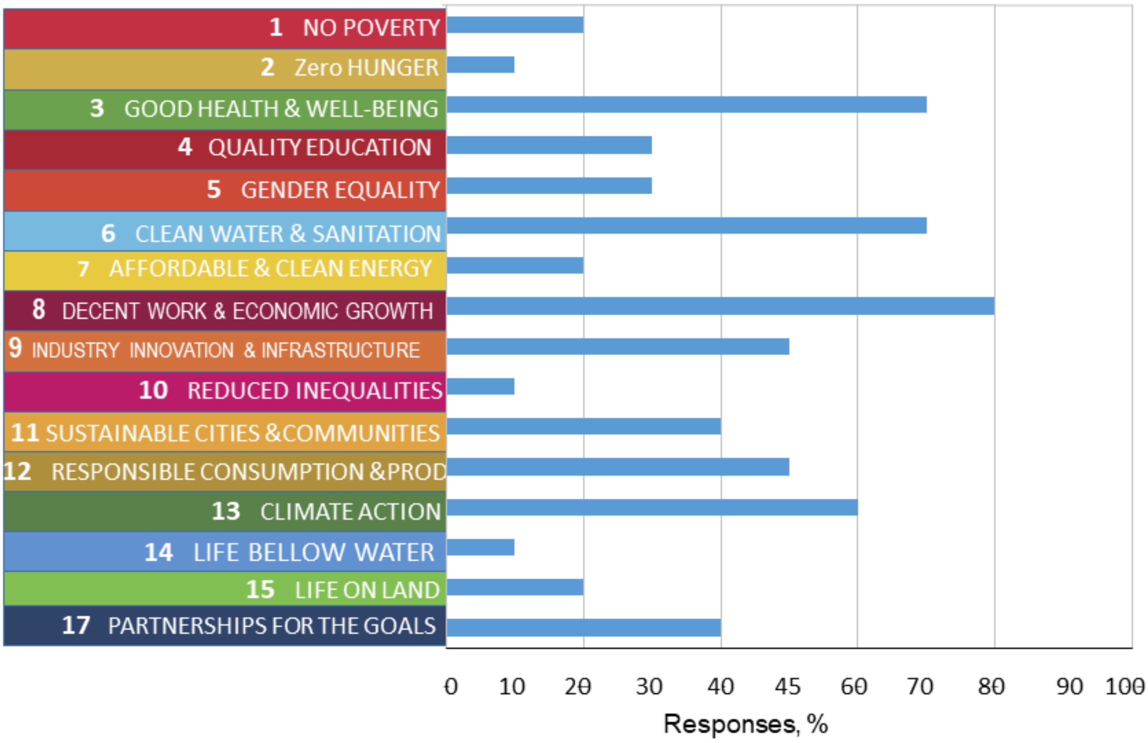

Fig. 2. Impact on the SDGs 2030 of the cooperation projects carried out according to the participants surveyed.

In reference to the experience of Development Cooperation projects students emphasised that the projects gave them considerable experience, both on a personal level as well as professional. In addition, they expressed that the first hand contact made them empathise with the communities in developing countries.

Respondents believe that it was a really good experience to have the opportunity to apply the concepts learned in classroom to real cases. They point out that having the opportunity to share knowledge with colleagues and experience the limitations of some projects and see how to deal with them made development cooperation projects an amazing experience. Therefore, they consider that it was an experience that helped them to improve as professionals. All the respondents agreed that it was an unforgettable, enriching experience that they would like to repeat.

4.3 Overall assessment of projects

The implementation of the cooperation projects has had a positive impact on both the students and the beneficiaries of the cooperation. On the one hand, the surveys show that the students have acquired a high degree of social sensitivity, an aspect which will be fundamental in the development of their profession. In this context, sustainability criteria are increasingly being applied.

On the other hand, the research carried out has given the miners a better understanding of the characteristics of their mining activities and how they can improve them in order to achieve better yields and less environmental and occupational health and safety impacts.

Local researchers have also been trained, so that universities in developing countries have the skills to conduct research that directly affects the people around them.

5 SUMMARY AND ACKNOWLEDGMENTS

Development cooperation projects have been mainly undertaken in Peru and Bolivia. These projects have made students more aware of the problems caused by mining around the world. It is well known that mining actions interact directly with the environment by extracting non-renewable resources. Therefore, future mining professionals must be aware of the importance of building environmentally friendly mining activities. To conclude, it is believed that sustainable mining activities can lead to the development of more sustainable and fair communities.

This work has been carried out with the support of the Centre de Cooperació per al Desenvolupament (CCD-UPC), which financed the Cooperation projects. We thank the NGO Mineria per al Desenvolupament for its contribution to the development of the projects.

ABSTRACT

In engineering education, and in work life in general, the past two years have been struggling with Covid-19 pandemic. When considering studying, learning, and working, the teachers and other facilitators have been forced to create innovative methods for online working, aiming to good work efficiency, student engagement, and learning results. Along the development of various online working possibilities, it has been noticed that especially interaction among participants in synchronous online sessions is a challenge. Even if some participants are actively discussing and working in online sessions, some participants remain very silent and indistinguishable. Furthermore, even though the technical tools for online working and learning have developed rapidly during the recent years, technical problems still exist quite often.

There are numerous ways for increasing interaction in online sessions, including, for example, asking questions, using camera, utilizing chat or third-party applications like Padlet, and small group discussions in breakout rooms. In this paper, we will present how we utilized Zoom-stamps in two types of workshops. The basic idea in utilizing Zoom-stamps was to increase interaction and communication among participants and help them to further develop ideas created and discussed in the workshop. The lessons learnt from the first type implementations were considered when planning the second type implementations. We will describe the pros and cons of the Zoom-stamp utilization in synchronous online working as well as share our future development ideas.

1 INTRODUCTION

The covid-19 pandemic forced about all educators in all education levels to transform their teaching online. The switch from classroom teaching to remote teaching took place almost overnight. The covid-19 situation has been ongoing now over two years, and during this period, the educators have rapidly and intensively developed online teaching and studying methods.

The tools and practices for online teaching has been enormously developing all the time during the past two years, both for synchronous and asynchronous learning events and assignments. It has been noticed that one challenge in synchronous online teaching is the lack or difficulty of interaction and communication during the classes [1, 2]. In traditional face-to-face learning events interaction is easier and comes more naturally. The rapport building is easier in face-to-face than in synchronous online learning sessions [3]. It is effortless to join a discussion when you see other people around you, and you can also see their body language. For an individual student it is quite easy to stay silent and indistinguishable in synchronous online classes, especially because due to our regulations we cannot require videos to be turned on during the learning events, thus many times you cannot see the other participants at all, and their facial expressions and body language remain unseen, hence easy ways for increasing interaction and communication among participants are really needed.

Numerous ways for increasing interaction in synchronous online sessions have been developed and tried in practice, including, for example, asking questions, using polls, using camera, utilizing reaction features, utilizing chat or third-party applications like Padlet, and small group discussions in breakout rooms. These all have benefits and disadvantages, and they all suit very well to some purposes. For example, reaction features are a good way to give instant feedback to the issue on hand, and many students find writing on chat as a very easy way to express themselves during an online session. In this study we will tell our experiences about using Zoom-stamps in synchronous online workshops to boost interaction among participants and to help them to further develop the ideas created during the workshops.

2 ONLINE SYNCHRONOUS MEETING TOOLS

There are multiple options for videoconferencing, teaching and researching online, such as Zoom, RemotePC Meeting, GoToMeeting, ClickMeeting, Microsoft Teams, Cisco WebEx, Blackboard Learn Ultra, Skype, and Google Meet [4, 5, 6, 7]. The videoconferencing systems have many similar properties, but there are some differences also, and these platforms are developing all the time.

Many researchers have found Zoom to be a very good videoconferencing system, for example, Fatani piloted two platforms (Blackboard ultra and Zoom) and chose Zoom, because “easier navigation and fewer interruptions, connection dropouts, and audio-visual problems” [4]. The participants in Archibald et al’s study preferred Zoom to other videoconferencing platforms [5]. Furthermore, the reported benefits include ease of use, cost-effectiveness, accessibility, timesaving, security options [3, 5], and flexibility [8].

Zoom offers an easy-to-use online platform for interactive and synchronous teaching [4] and research [3, 5]. It allows different innovative features, such as annotation tools, polls, and breakout rooms [9]. Furthermore, it provides video and screensharing [4], chat and whiteboard. These multiple features can help interaction in synchronous online teaching. Even though Zoom is a very liked video meeting platform, also negative experiences and thoughts exist. Serhan has found that students sometimes find that Zoom makes learning experience and learning motivation worse [8]. For more information on Zoom and its features, see https://zoom.us/.

Zoom and Teams are available in our university, and therefore they are the most familiar videoconferencing systems for us. Both work well in synchronous online teaching, but some properties that exist only in Zoom make it our choice, especially for large student groups. The favoured properties that lack from e.g., Teams and Google Meet are versatile annotation tools that can be used as well with whiteboard as with screen sharing. The Zoom’s annotation tools include a stamp-tool. There are some annotation tools in e.g., Teams and Google Meet, but not very many, and they can be used only with whiteboard, not with screen sharing. Furthermore, we have noticed in practice, that if the synchronous online session participant number is big, approximately over 50, the Teams is continuously having network connection problems when used from a home network. Zoom can handle a larger number of participants without network problems. Of course, this depends on the network, and this problem does not exist in all cases.

3 UTILIZING ZOOM-STAMPS

During Covid-19 pandemic we organized workshops and discussion groups using Zoom. We used Zoom-stamps for voting in the workshops and discussion groups. We could not use the Zoom's poll tool to cast votes, because the ideas to be voted on were created during the workshop sessions. In addition, so many ideas were produced in the workshops that it would have been too time-consuming to create the poll in the middle of the session.

Already in traditional inclass sessions, as well as in online sessions, many kinds of student response systems have been used to activate students, to get their opinion on the issue, or to test their knowledge about the subject on hand. However, these systems need teacher's preparation of the questions before the session. Hence, they are not suitable to situations, where the subject is developing in the session and there is no time to create polls during the session.

The stamps are in Zoom's annotation tool. They are only available in Zoom's desktop application. If participants are attending a Zoom session via mobile phone or an internet browser, the annotation tool is not available. This caused some technical problems during the workshops and discussion groups.

3.1 Study setting 1: Workshops

We organized five workshops in Zoom where the main purpose was to create new ideas on the topic in hand, and to discuss and further develop these ideas. The participant number in these workshops varied between 5 to 15, and in addition five to six organizers participated in the workshops.

The workshop flow was the same in all the workshops:

1. Silent thinking and writing on a shared whiteboard related to the question presented.
2. Free discussion about the ideas that the participants had created. At the same time, one organizer grouped the ideas on the screen.
3. The participants were asked to give different shaped Zoom-stamps to the idea that was the most pleasant (heart shaped stamp), the most innovative (star shaped stamp), and the most challenging (question mark shaped stamp).
4. Discussion on the stamps: Why the participants gave the stamps to the specific ideas.

Participants were asked to vote for the most pleasant, innovative, and challenging idea by placing a proper stamp next to the written idea on whiteboard. Many of the participants clearly enjoyed giving stamps to the ideas, and in this way their individual voices were heard. Giving stamps also boosted the conversation, it was easy to talk about the thoughts behind the stamps. In Figure 1 is an example of how the screen could look like after workshop phase 1, when the ideas are written on the screen. In the Figure 2 is an example screen with stamps, this could be the case after workshop phae 3. In both the Figures 1 and 2 you can see also Zoom's annotation tool. The real situation on the screen was often not as clear as the examples in Figures 1 and 2, mainly because the participants did not use the colours in any planned way, and in addition many times there was really a lot of ideas, subideas, etc. on the screen. So, the screen was sometimes quite full.

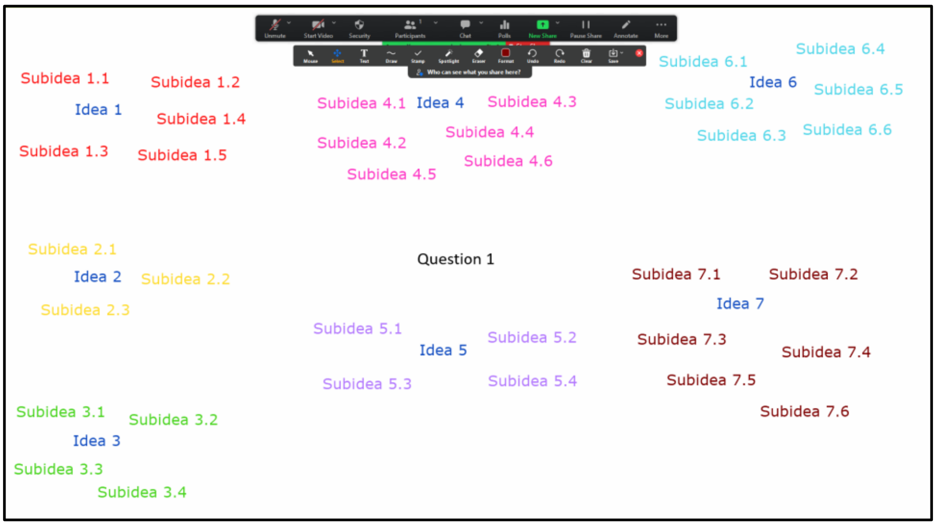

Figure 1. Example of the screen with ideas.

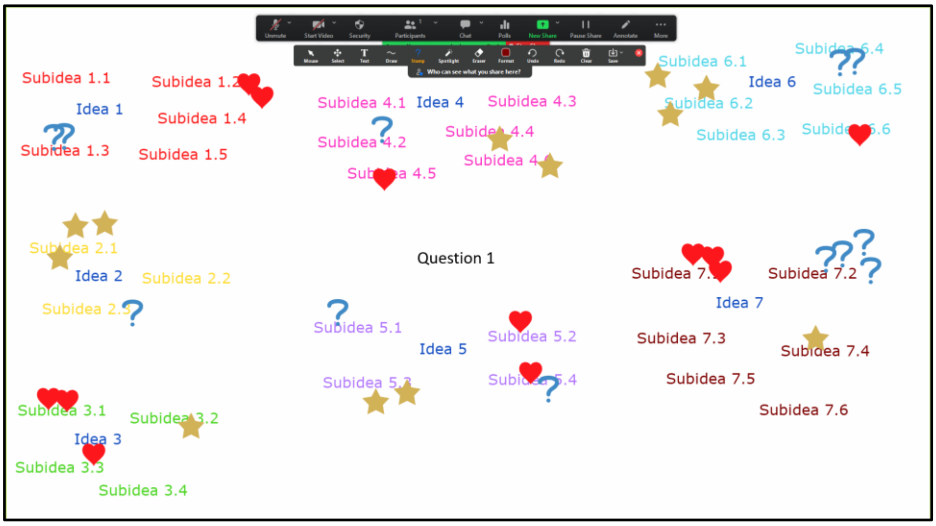

Figure 2. Example of the screen with ideas and stamps.

Even though the Zoom-stamps were found good in increasing interaction and boosting the conversation, some problems occurred. The participants that were not using a Zoom desktop application did not have the annotation tool, where the stamps are. The problem was solved by asking these participants to write in the chat to which idea they want to give their stamps, and then one organizer sat the stamps to the right place on the whiteboard. Furthermore, another difficulty was that it was sometimes hard to place the stamp to the right idea on the screen, because in some cases the whiteboard was so tightly filled with the ideas, that the stamp hit many of them at the same time. Many times, there were lots of stamps simultaneously on the screen, and they got mixed and buried under each other. This was because every participant gave three stamps altogether, and in workshops with a larger number of participants this resulted in a stamp-mess. Thus, it was difficult to distinguish which idea each stamp was aimed at.

We found that thorough informing and clear guidelines are important to smooth flow of the workshop. In this first implementation round we had instructions, but even more would have been needed. Overall, the Zoom-stamps showed their potential in synchronous online sessions. The process needs some development to avoid the problems that existed in this first implementation round. Hence, we decided to use stamps again in discussion groups.

3.2 Study setting 2: Discussion groups

Two focus group discussions were organized for 12 participants to create, evaluate, and develop ideas for prototype development. This focus group study was organized according to the methodology suggested by Hamilton including the sections of "create", "evaluate" and "develop". We will report the "evaluate" section that utilizes the usage of stamps for voting in detail [10].

With experience from the Workshop setting 1, we decided to pilot the study and test the technical procedures. Casting fewer votes was considered more efficient and resulted in less confusion among the participants. As a result, we decided to have the participants to vote for two ideas that they felt were appropriate for further development.

After the "creating" -section, participants were asked to look at an extensive list of options they had created before the workshop and during it. They were then asked to vote on the two they felt were most suitable to develop further. Unlike in the first workshops, the Zoom-stamps were now asked to be placed on top of the written option to make it easier to identify which word the stamp was targeted to. Despite careful preparations, technical problems occurred in voting and a few participants (using mobile devices) could not use the tool. They were asked to vocalize their opinion; one organizer added their votes to the list. An option of using the chat was also provided, but none of the participants used it for voting. In each focus group, three of the most voted ideas were selected to further exploration. The voting was considered successful for the purposes of the study. However, it was noted that those who had problems with placing the stamps may have felt rushed to do so as solving the technological problems took a lot of time resulting in less time to evaluate the options. After the study, we asked the participants to fill in a university's subscription to Office 365, Microsoft Forms, to elicit further ideas and to give feedback in general. While two participants commented on the technical challenges, most participants felt that technical problems are somewhat inevitable and did not interrupt the flow of the discussions greatly.

4 SUMMARY AND ACKNOWLEDGMENTS

In this study we found that using stamps is an excellent way to reach independent votes during teaching or for research purposes. Zoom-stamps increase engagement and provide a tool, in which the participants' individual voices can be heard. Zoom-stamps also help in building rapport among participants and teachers. Careful preparation and prior testing are needed to achieve a smooth synchronous online session flow. It is recommended to use Zoom desktop application instead of web browser or mobile devices to diminish the occurrence of technical problems in synchronous online learning events. It is necessary to give the participants information at the beginning of a session that technical issues may occur, especially when using mobile devices (such as smartphones and iPads). In such cases it is important to have a plan to overcome the issues, such as an assistant present to help. If participants cannot use Zoom's annotation tool, the participants may vocalize their opinions or use chat option. When an independent vote is needed, as sometimes is in research, providing a phone number or e-mail to cast a vote (to maintain anonymity) is advised. Furthermore, it is important to give the participants enough time, so that there is some time considered also for covering the possible technical problems.

Even though information is in general a good thing, based on our experience, we do not recommend providing excessive information on how to use the stamps before the session, as it may confuse some participants. However, we found that it is extremely important to give clear and comprehensive guidelines for the session, e.g., it is important to tell, how the Zoom-stamps should be placed on the screen to gain the wanted result. Furthermore, we found that Zoom-stamps are quite difficult to target to a particular word if the whiteboard is full of text. Hence, using stamps for voting is easier when there is enough space between the words written on the whiteboard, and when the number of stamps altogether is not huge on the whiteboard.

Overall, even though the Zoom-stamps are only one of Zoom's annotation tools, we found them very efficient in interaction and communication boosting in synchronous online sessions. They are easy and simple to use, and the participants clearly liked them.

This work was supported by the Academy of Finland (decisions 332168, 337861).

Keywords: *work-based learning, programme co-design, curriculum co-design, online collaboration, Signature Pedagogy*

ABSTRACT

Greater collaboration is required between universities, industry and society to provide the engineering education that will tackle society's challenges. Work-based learning (WBL) programmes offer an industry-aligned, academically-informed education to support such socio-economic development. Co-design of such programmes is vital with responses to the COVID-19 pandemic innovating alternative ways to design programmes. Knowles et al (2021) [1] outlined an approach to online programme co-design in the UK university context, framed using Signature Pedagogy and through online conferencing and Miro (online whiteboard). Subsequently, the approach has been utilised to co-design a WBL degree programme in Electrical Engineering in Eswatini, supported by Knowles and other UK and Eswatini colleagues.

This paper compares and contrasts cases from UK and Eswatini, and from this address the research question, "What considerations are required to support an effective online process to co-design a work-based learning programme in Engineering?" A collaborative autoethnographic methodology based around field notes, observations and reflections is used to allow exploration across pedagogy, technology, work practices, expectations and challenges.

Many aspects of the approach worked well in both cases (for example, effectiveness of Signature Pedagogy, Miro as shared space), whereas differences arose related to limitations in the synchronous use of technologies, and readiness to adopt an

[1] *Corresponding Author: C.J.M. Smith. Email: Christopher.Smith@gcu.ac.uk*

outcome-focused approach. Addressing these differences, along with balancing progress against full participation and having clear expectations of participants, are key considerations in online co-design of WBL programmes. Moreover, the approach of Knowles (ibid) has shown to be adaptable with potential for broader adoption.

1 INTRODUCTION

Engineering must be at the heart of providing solutions to the societal challenges of the next decade and beyond, and to do so then engineering education has to adapt [2]. This change must happen across the spectrum of delivery modes to meet the needs of individuals, organisations, the economy and society – from full-time to lifelong learning. Additionally, engineering educational approaches must now support the development of a more holistic engineer and engineering graduate, and that authentic learning experiences offer clear potential to achieve this goal. Moreover, greater collaboration between academia and society is required, whether to provide challenges, to develop required transversal skills, to support ongoing employability or to learn how to work with and address complex, 'wicked' problems.

In terms of current engineering curricula and outcomes, there exists a long history of employers' dissatisfaction with the capabilities of graduate engineers, and by implication the academic system which produces them [3]. Moreover, newly qualified graduates often feel 'incompetent' [4], and experience difficulty in transitioning into the workplace as graduate engineers [5] [6]. This is perhaps unsurprising, given that that there is little, if any, correlation between academic performance and success in the workplace [7]. It should, perhaps, be noted that the call for graduates who can 'hit the ground running' with appropriate skills is contested; indeed, previous studies suggest that education is about 'higher skills' which equips students to be leaders in their chosen professions [7] [8]. On the other hand, there is some argument that the development of workplace skills is better done in the workplace [9].

Work-based learning (WBL) is a form of partnership between academia, students and organisations (typically industry) that is and will be an important mode of engineering education to meet the above challenges. WBL embraces different forms of engagement, from placements and internships to a fully co-designed (and co-delivered) programme – a challenge in itself [10]. In terms of co-creation in higher education research has typically considered the dyadic partnership between students and learners and the various levels of engagement [11], whereas in WBL there is a need to engage all stakeholders throughout the design and delivery. In terms of co-creation of WBL programmes, then there are some general guidelines [12], but a gap in terms of models of programme co-design, specifically around work-based learning. Co-creation of programmes is challenging as it involves working across boundaries (whether these are organisational, language or epistemic) and to reap the full benefits of collaboration requires an approach that will facilitate genuine dialogue and consensus building between the partners. Additionally, programme design is complex, as is underpinned by a mixture of wider educational theory including Outcome-Based Learning [13], Concept Mapping [14], and discipline-specific theoretical approaches which have emerged out of Engineering Education Research (for example [15]). Disappointingly in Engineering, course design is often criticised as being too content focused and a sum of its modules (inputs) [16], rather than a coherent and authentic learning experience [9].

To address the potential deficiencies in collaborative programme design, Signature Pedagogies [17] represents an important epistemological standpoint as it encapsulates an applied pedagogy in which the *habits of 'head', 'hand' and 'heart'* are central drivers in how the curriculum is designed and delivered [18]. These are derived from the things that professional engineers do ('hand'), what they believe and their worldview ('heart') and how they think and engage with knowledge and practice ('head').

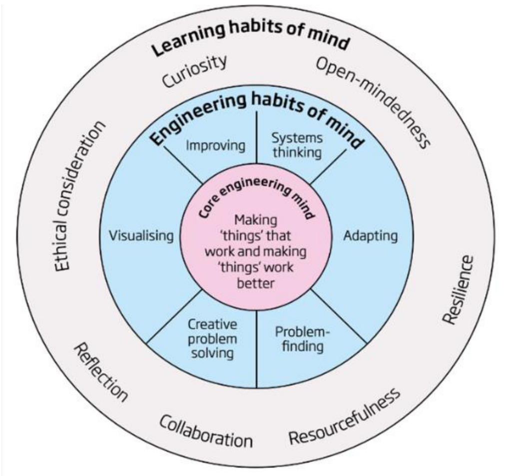

Figure 1. Engineering Habits of Mind Lucas and Hanson [19]

Taking this notion one step further and grounded in the Engineering Habits of Mind concept (Figure 1) [19], the approach developed in The University of Warwick represents a holistic model of student development. The focus is on the graduate characteristics in three distinct yet interlinked pillars of curriculum design, representing the affective, cognitive and functional aspects of education that are given equal consideration in developing a more connected and 'holistic' curriculum [20]. This approach has particular applicability in co-design spaces as industrial partners are uniquely well-placed to contribute to the understanding of graduate characteristics in the three areas which are relevant to their context.

Despite Signature Pedagogies having been around for a significant amount of time [17], there has been little evidence of attempts to significantly operationalise the concept beyond it 'informing' course design in largely unspecified ways. This means that the approach taken in this paper relates to a fuller operationalisation of the concept than has hitherto not been the case in the Engineering. The initial implementation of Signature Pedagogy to co-design of an Engineering WBL programme (in the form of Degree Apprenticeships) in the UK has been previously introduced [1]. The onset of COVID-19, when one Degree Apprenticeship was going through significant redesign and another about to enter the design phase, meant that a previously face-to-face approach of workshops, allowing for team building and constant adjustment of artefacts such as flip charts, post-it notes and diagrams to reflect the progress of the thinking needed to be re-imagined. The first challenge was to find an online collaborative environment which allowed for the easy and intuitive creation, combination and re-combination of artefacts representing ideas, concepts, and processes. Upon investigation several design platforms were identified as viable options with Miro being selected as it was simple, intuitive, had good tutorial support to help staff get up to speed, and was free for academic use.

The second challenge was to adapt the process to an online environment. The principal adaptations were made as follows:

1. ***Using the online space:*** recognition that tolerance for working online is lower than in face-to-face situations. More but shorter group sessions were organised to avoid fatigue.
2. ***Supporting active engagement:*** The team was trained in the use of Miro and the sessions carefully facilitated to ensure that everyone was able to use the tool efficiently, and that everyone was contributing
3. ***Rebalancing the workload:*** elements of the work which had previously done in-workshop were set as homework with detailed guidelines and clear deadlines to allow the next workshop to continue. Staff facilitating this co-design approached, monitored and summarised the work done prior to the next session.

The online co-design methodology is shown below:

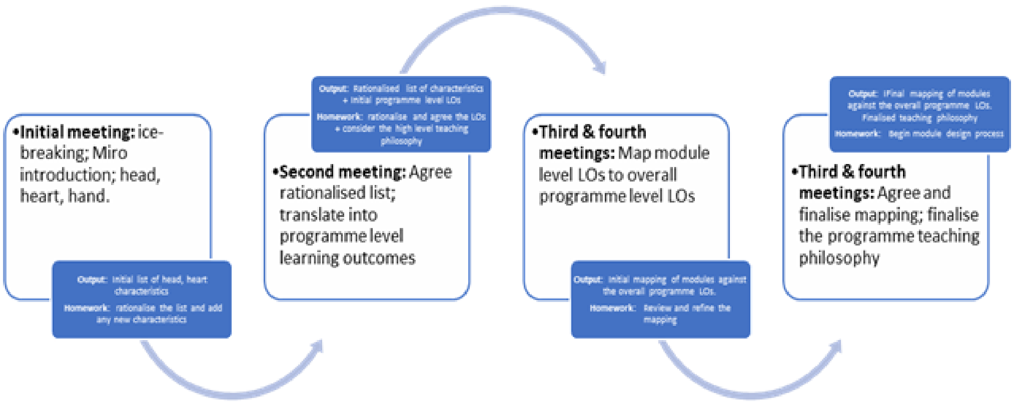

Figure 2. Standard online co-design process

In terms of institutions, then The University of Warwick is a member of the Russell Group of research intensive Universities in the UK. Situated in the middle of the UK and has almost 30,000 students registered, it is highly ranked in international league tables, including in employer reputation and targeted by UK employers. The specific unit within The University of Warwick has had a strong focus on academic-industry links, with co-creation being central to its accredited programmes with international employers.

University of Eswatini is located in a small country based in Southern Africa, classified by the World Bank as a lower-middle income country having a young-aged population. However, the distribution of wealth is highly skewed with nearly 60% of the population, predominately from rural areas, living below the poverty line **(**living on less than US$1.9 a day**)** with 20% being considered extremely poor. University of Eswatini has three campuses with 7000 enrolled students across 40 Bachelor's and Masters' degree programmes, as well as two PhD programmes. Its programmes are typically four years in duration (with Engineering being five years), being mainly traditional academic programmes – either delivered on campus or through distance learning. In the context of this paper, then University of Eswatini has limited experience in the creation of co-designed WBL programme in Engineering, but through a Royal Academy of Engineering funded project that began in 2019, it has committed itself strategically to develop a range of WBL programmes, starting with Electrical and Electronic Engineering. It is in this context, that the methodology previously applied at The University of Warwick was selected to support the co-design during COVID-19 at University of Eswatini, thereby offering an opportunity to compare and contrast the implementations between the UK and Eswatini contexts.

Consequently, this paper aims to answer the question “What considerations are required to support an effective online process to co-design a work-based learning programme in Engineering?” Next, the methodology will be outlined before the initial findings from this research will be detailed, with conclusions and next steps being outlined finally.

2 METHODOLOGY

A qualitative methodology was chosen to answer the above research question, by seeking to capture the experiences and insights from those leading the co-design process. In this research, the authors are both researchers and active participants in the process, so collaborative autoethnography has been chosen as it allows reflective and reflexive consideration and shared sense-making of lived experiences. Autoethnography is a qualitative research methodology that has emerged from the authentic exploration of under-represented voices, but it is increasingly being used in areas of professional practice. The research involves the self, a process and culture, and offers an approach that goes beyond autobiographical (personal ‘stories’), as auto-ethnography is about interpreting those stories/experiences – the interplay between the individual and others. As co-design involves different stakeholders, then the interaction between individuals and their context is an important dimension of success. Collaborative auto-ethnography emphasises more clearly the collaborative aspect – where participants seek to explore, outline (and potentially make sense) of shared experiences [21].

Throughout the co-design processes, the co-researchers have made notes about the process, their reflections and experiences – along with what worked well and what worked less well. The co-researchers then have used these notes to write an individual reflection around the experiences that sought to capture views from before the co-design process started (previous approaches to programme design) to their experiences of the online co-design process in Eswatini. These individual reflections were then shared with each other, reviewed separately by each co-researcher, commented on and then individual observations were discussed together in online discussions to extract the main considerations (differences and similarities) between the two implementations. These shared perspectives and insights around key considerations are shared in the findings section.

3 FINDINGS

The discussions around the individual reflections highlighted several shared perspectives that are relevant to the research questions, namely the considerations that influence the on-line co-design of a WBL programme, these being 1) Organisational environment; 2) People and culture; 3) the co-design methodology and 4) Technology and its use in the co-design process. In terms of sharing the findings, we identified that in the case of Eswatini that the knowledge transfer around the co-design methodology and designing the programme happened contemporaneously, so our findings provide insight into both the methodology, and around factors that influence its adoption.

Firstly, any programme development takes place within an organisational context that includes the systems, policies and processes, administrative structures, relationships and roles and responsibilities. It was common in reflections to acknowledge that the existing university programme development processes were often seen as bureaucratic and overly content focused. Additionally, that these processes relied on a small group of academics, with varying levels of engagement with industry and other stakeholders, so any new programme (re)developments were often iterative rather than a stepped change. In essence, don't rock the boat. In contrast, co-design resulted in positive examples of co-operative development that created a shared vision and collective accountability - a positive aspect for the ongoing health of the programme. We recognised that policies and procedures and their embodiment in practice are important, as this can provide a shared language and set of expectations, e.g., around outcome-based design. Without that collective understanding, then collaborative design is more challenging, so establishing common ground between participants is key.

Where commonality is not present then recognising that there is an ongoing change process was viewed as another key consideration. For example, the engaged form of shared development mentioned above required a change – in outlook, and in methodology – and often having the right people in place. Management of change requires sustained levels of senior management support, leadership, time and resources, and accompanying training. The readiness to change is also important. In the case of Eswatini, then having an externally funded project was supportive to such an endeavour, whereas in the UK new standards and a clear institutional vision for a new model brought about a shift in mindset and approach in the team (industry and academia).

Additionally, in co-design, there are not just intra-organisational dynamics but also inter-organisational relationships. In the context of change, then the reflections and discussions highlighted positive and trusting relationships as crucial: between colleagues, across internal organisational boundaries and between organisations. For example, in the case of Eswatini, then key relationships amongst industry and academic colleagues was vital, particularly when there were frustrations (e.g., around pace and progress, as well as understanding their role within the process); they were the lynchpins. The co-design methodology did provide opportunities for sharing and building confidence in each other, but as trust was growing through this process, then we felt that levels of engagement in workshop activities were influenced accordingly.

Encompassing this last point, around relationships and trust, then the second area was around people and culture. Specifically, the importance of having the right people in place, with the required vision, knowledge and relational skills was identified. Whilst leadership - "*champions*" (C2) - was known to be important traditionally, the broader set of skills for co-design amongst academic programme development leaders was expressed by several of co-researchers. As mentioned above, colleagues in Eswatini were learning about the process at the same time as using it. However, core members at University of Eswatini had gained a deeper understanding of WBL through a placement in the UK and ongoing knowledge exchange, and this knowledge around the vision for WBL and the co-design process was key for maintaining progress and answering questions from their academic and industry colleagues. Additionally, these change champions were vital to bridge the differences between industry and academic colleagues, and to highlighting uncertainties and how best to adapt the methodology. In the UK, having both champions in industry and academia was found to benefit the process. Furthermore, the influence of different working cultures on how participants engaged with the development process was evident – with greater asynchronous discussions in Eswatini, as compared to the directness in the UK case in synchronous activities "*I have time in my diary so let's get this done now*" (C6).

The third area was around the co-design methodology. The underpinning concept – Signature Pedagogies – was found to be applicable in both cases. It encouraged greater collaboration and engagement between academia and industry with a focus on the outcome of the programmes, and not on content. Differences between the two implementations emerged around the balance between synchronous workshop activities and asynchronous/offline development – with the UK activities being more focused around synchronous workshop activities with less done off-line, and in Eswatini considerable progress on 'homework' between workshops was achieved (facilitated by change champions mentioned above). As discussed below, some of these differences in implementation may be due to technology limitations, but may also reflect that colleagues were learning about the methodology and applying it concurrently, so the inter-workshop meetings provided a space to reflect and take forward the activities. The time for this new approach was identified as unexpected (due to the need for greater collaboration) with a lesson being that reminding colleagues about the overall vision, process and benefits needed to be repeated several times. Related to this, the division of labour (between industry and academia) represented a change in previous working, with differences between the two cases evident (UK were more comfortable being involved with details of programme design, whereas in Eswatini after agreeing overall programme outcomes, the expectation was for academics to develop the detailed programme for review by industry). Such differences potentially reflect that various levels of engagement are possible in co-creation [11], and that engagement throughout the process appears to be dynamic. Such variation in engagement (and therefore perceived progress) needs to be managed well.
