Finally, as this process was conducted online using online tools, then there were technology-related issues. Miro did provide a shared working space in both cases, but was used differently – in UK case for both synchronous and asynchronous work, whereas for Eswatini was a tool for synchronous workshops and a record of consensus building. Additionally, in Eswatini there were technical issue accessing Miro – initially related to firewall configuration – but consistently related to bandwidth constraints. Moreover, for new users of Miro, it takes time to learn how to navigate and use tools, so greater attention needs to be paid to introducing the tool and how to use it before it is used as part of the co-design methodology process. Other online tools (e.g., Padlet) were found to work better for some later activities in the process, so careful consideration to the mix of online tools in each case is another key consideration for future application. Finally, we felt that the online tools failed to develop the same level of relationships, which as identified above is important for the success of this approach.

4 SUMMARY AND ACKNOWLEDGMENTS

In response to the research question, "What considerations are required to support an effective online process to co-design a work-based learning programme in Engineering?" then, through a collaborative auto-ethnographic methodology, we have identified four main considerations: 1) ensuring the correct organisational environments (industry and academia) for a co-design approach to succeed; 2) the importance of having appropriate people with the necessary knowledge and skills to lead that process (in both academia and industry); 3) that the Signature Pedagogy approach worked well to facilitate agreement on desired outcomes, but that the detailed aspects of the co-design methodology needed to be adapted to the working cultures and expectations. Moreover, the importance of reminding co-participants around the vision and benefits of this approach, was seen as vital; 4) that different technology tools can facilitate the online collaboration necessary for co-design, but being clear about how tools will be used, and aligning to bandwidths as well as proficiency in these tools is important for their successful use. These findings indicate that this co-design methodology is applicable in a significantly different context with the above identified adjustments.

The authors acknowledge the support of the UK Royal Academy of Engineering funding for this project under the Higher Education Partnerships in Sub-Saharan Africa programme.

ABSTRACT

ECIU University is an EU-funded European University initiated by a network consisting of 13 universities across Europe. At its core is collaborative learning and research on a European level in close connection with various stakeholders to tackle societal challenges. Learners are engaged in joint project work based on the approach of challenge-based learning (CBL). Here, learners are actively involved in a real and relevant setting. Teams are composed of learners coming from different cultural backgrounds, disciplines, and levels of progress in their individual studies. A challenge within the ECIU framework starts with a “Big Idea” in the area of the UN Sustainable Development Goal 11 “Sustainable cities and communities” that has potential for societal impact. ECIU University offers four types of challenges that differ in length and depth. Within this paper, the first run of an ECIU Strategic

Challenge, the most complex challenge type, is introduced. The Strategic Challenge is a six-month format that combines individual working phases while writing on one's master's thesis with collaborative working phases while cooperating closely in the team challenge. Hence, it offers a framework in which the progress of challenge and master's theses are expected to go hand in hand. The concept of how students collaborate in the Strategic Challenge builds up upon the Erasmus+ projects COLIBRI (Collaboration and Innovation for better, personalized, and IT-supported Teaching) and its follow up EPIC (Improving Employability through Internationalisation and Collaboration).

---

1 INTRODUCTION

The ECIU[2] University is an Erasmus+ funded alliance that brings together 13 European universities[3] and one associated member to address societal challenges faced by European countries. Students and university teachers from all ECIU partners, stakeholders from business and public organizations, as well as citizens come together to engage, investigate and act to find innovative solutions for real life challenges with real societal impact. The educational framework of the ECIU University offers a creative, inspiring, and meaningful learning environment in engineering education. It is based on the pedagogical approach of challenge-based learning (CBL). Within the framework, four types of challenges are offered: Nano Challenges, Mini Challenges, Standard Challenges, and Strategic Challenges [1]. The challenge types differ in their length resp. workload (30 hours to 360 hours) and depth (level of CBL phases). This paper introduces the first run of an ECIU Strategic Challenge. The pilot of the Strategic Challenge is a six-month format that combines participating in a challenge with the writing of individual master's thesis. The format has started in February 2022.

2 FRAMEWORK

2.1 Challenge-based learning in the ECIU context

Challenge-based learning provides an efficient and effective educational framework for learning to solve real-life challenges. The framework aims at the acquisition of disciplinary knowledge while developing transferable skills. Learners are engaged in team projects while being actively involved in a real and relevant setting [2]. The teams are composed of learners coming from different cultural backgrounds, disciplines, and levels of progress in their studies. With different stakeholders involved, CBL aims to find collaboratively developed solutions that are

environmentally, socially and economically sustainable [3]. Hence, the learning experience is international and intercultural, multidisciplinary, and collaborative. Within the learners-driven approach, students are enabled to take complete ownership of their self-defined challenge, cooperating closely with the teachers and (external) partners in a co-learning environment.

A challenge within the ECIU framework starts with a “Big Idea” in the area of the UN Sustainable Development Goal 11 “Sustainable cities and communities” that has potential for societal impact. The approach is made up of three phases: Engage, Investigate, and Act (Fig. 1). Constant documentation, reflection, and sharing is an elementary part of the entire process [1].

Fig. 1. CBL circle [4]

The engage phase is initiated by sharing the Big Idea, which is usually provided by (external) partners. Based on the Big Idea, the learners themselves define essential questions tackling related aspects according to their interest, or which skills and competencies they want to further develop.This leads to the creation of their individual actionable challenge, which is at the same time the result of the first phase. In the second phase of the CBL cycle, the learners formulate the basis of sustainable solutions to their individual challenges by conducting the actual research and analysis according to their skills and expertise. The investigate phase results in learning outcomes like reports and presentations demonstrating individual conclusions. Within the act phase, the learners implement and evaluate their solutions ideally with an authentic audience highlighting their societal impact [1].

The teacher in the overall framework guides the learners during the whole process. While promoting team culture, being challenging to the participants, and supporting learners to create actual impact, the teacher takes the role of a facilitator.

2.2 Idea of the concept

Combining the approach of challenge-based learning and writing a master's thesis shapes a novel and innovative pedagogical format. It combines working on a challenge in an international, multidisciplinary team with individual working phases when writing one's master's thesis according to home university guidelines. The concept of how students collaborate in the Strategic Challenge is based on the former Erasmus+ projects COLIBRI (Collaboration and Innovation for better, personalized, and IT-supported Teaching) and its follow up EPIC (Improving Employability through Internationalisation and Collaboration). EPIC aims to increase employability through closer collaboration between students, academia, and industry. It provides a framework for international student projects in close collaboration with companies [5]. The joint student projects in the EPIC framework deal with similar issues: different start and end times at participating institutions, different requirements from different institutions, assessment and documentation varies between institutions. To face these aspects, different models of collaboration were developed within the EPIC project that combine joint work and thesis writing [6]. These models serve as a basis for developing the Strategic Challenge collaboration framework.

3 PROJECT DESCRIPTION

3.1 Strategic Challenge as a unique master's thesis opportunity

The Strategic Challenge offers an exceptional opportunity for advanced master students to collaboratively work on a societal challenge in an international and multidisciplinary team while also individually writing a master's thesis that is linked to the topic of the challenge. Within the framework, the progress of challenge and master's theses are expected to go hand in hand and ensuring to benefit from one another.

As all ECIU challenges, the Strategic Challenge starts with a “Big Idea” in the area of the UN Sustainable Development Goal 11 “Sustainable cities and communities” and has potential for societal impact. The Big Idea in the case at hand is to develop a climate neutral campus in Europe with innovative ideas and bold solutions and thereby, advance climate protection and reduce CO_2 emission. Students are asked to develop concepts that enable their home university or any other university to reach a climate neutral campus in the future.

In the first realization of the described concept, each ECIU partner institution is asked to find one academic advisor and one master student to participate in the challenge. Participants are selected with respect to their readiness to begin their thesis and with respect to multidisciplinary. For the first run of the ECIU Strategic Challenge nine eligible students from seven ECIU institutions have been selected. Before the challenge officially starts the academic advisors are invited to a Supervisors Kick Off to learn more about the main challenge. As a result they are asked to inform their respective master student in order to get prepared for the challenge start: this means, to collect first ideas on a climate neutral campus in

Europe, however, not to elaborate on a concrete master's thesis topic yet. The actual topics are expected to be developed alongside the actionable ECIU challenge so that the master students are still flexible.

3.2 Phases and milestones of the Strategic Challenge

According to ECIU University's challenge-based learning framework, the Strategic Challenge includes three phases:

1. Phase of engagement: Students from ECIU partners enter the challenge team, narrow down the topic, develop essential questions, and define their actionable challenge.
2. Phase of investigation: With different stakeholders involved, students research and engage in activities to define a solution to the challenge. While collaboratively working in the challenge team students also work towards their respective master's thesis that are content wise linked to the challenge.
3. Phase of action: Solutions are prepared and master's theses are written. The challenge team opens the findings to society. This includes either the implementation of the outcome or delivering a product.

Fig. 2 illustrates the framework of the Strategic Challenge and shows how the three phases of CBL are combined with individual thesis writing.

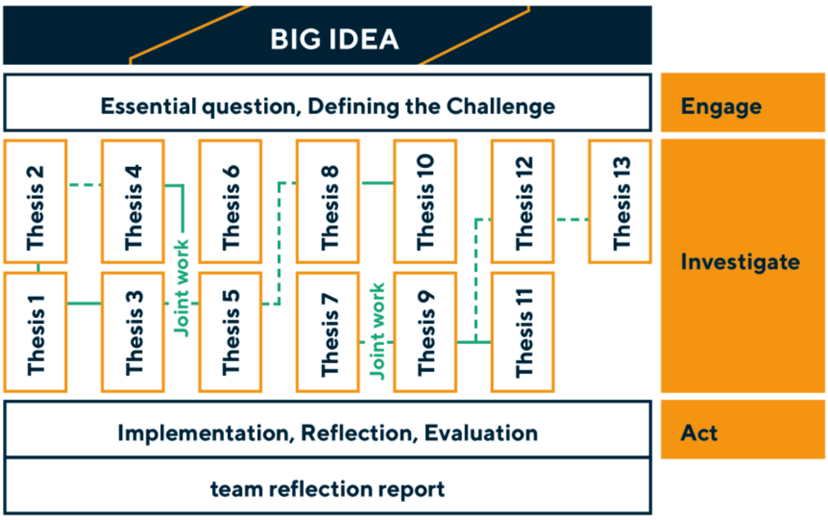

Fig. 2. Strategic Challenge framework [7]

The Strategic Challenge officially starts with a Kick Off event for the students. The online Kick Off marks the beginning of the engagement phase. Apart from getting to know one another and learning about the steps of CBL the Kick Off primarily aims at finding subgroups to form teams according to the students' interests and ideas for their master's theses. This is to facilitate that the student teams can develop an actionable challenge that can be linked to their individual theses respectively.

In the first ECIU Strategic Challenge, nine students from seven ECIU institutions work in three teams of three students each on in total three self-developed challenges based on the Big Idea of "Climate neutral Campus in Europe" (Fig. 3). The academic advisors are invited to join the sessions of the Kick Off to provide feedback to ideas. Also, they participate in a discussion on the supervisor's role in the overall Strategic Challenge.

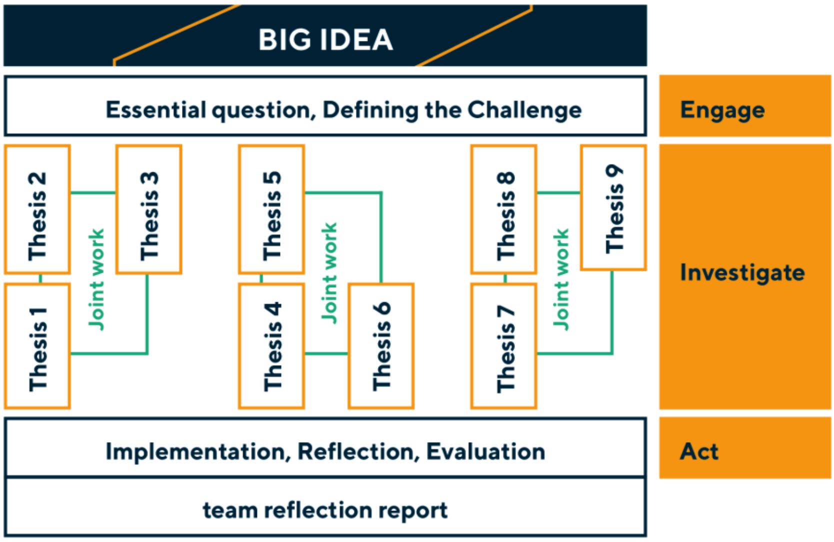

Fig. 3. Strategic Challenge 2022 [8]

The Strategic Challenge is structured by four milestone meetings for the whole group of students (one as a face-to-face meeting). Those allow the student teams to work self-determined on their individual challenge. However, during the engange phase weekly support is offered to the subteams to ensure that all teams get on the right path and manage to develop their actionable challenge. In the phases of investigation and action, biweekly support is offered to the teams to reflect e.g. on their team progress, stakeholder management, struggles, and final outcome. Also, various workshops related to team work and project work are offered throughtout the challenge to promote skills and competences required to successfully complete the project.

Continual reflection and documentation accompany all three phases. The students are asked to keep a team learning diary and submit a team reflection report at the end of the challenge. Also, opportunities to share (interim) results with the wider community are created.

3.3 Challenges of the design

The first run of the Strategic Challenge faced a few challenges that were at least attributed to the internationality of the participants. Due to different timelines and regulations of their home universities (different start points, different total duration, different submission dates) the students turned out to be less flexible concerning their thesis writing than expected. Hence, some students had already defined their thesis topic when entering the engagement phase as illustrated by figure 4. This challenges the approach of CBL that typically allows learners to individually move from a “Big Idea” to a concrete and actionable challenge. Hence, the engagement phase in the Strategic Challenge was limited since also the already approved topics had to be taken into consideration when developing a concrete challenge.

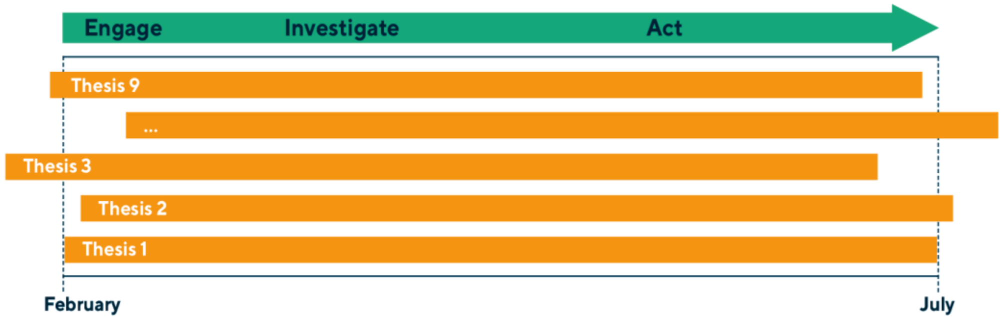

Fig. 4. Illustration of different timelines [9]

Different submission dates might have also affected the work process. While some students had to submit their thesis before the end of the challenge, others still have weeks beyond the closing event to finish their thesis. This might have had an impact on the groups’ progress and outcome.

In the learner-centered approach of challenge-based learning, the teacher usually acts as a facilitator. In the Strategic Challenge, the constellation is more complex as each student is additionally supervised in his or her master’s thesis by a local academic advisor. The supervisor’s role is primarily to supervise the thesis. Therefore, active communication and a clear allocation of roles are essential to enable a productive learning environment and to avoid potential conflicts.

4 CONCLUSION

The first run of the Strategic Challenge has been promising so far. The students worked in three subgroups on a challenge they had developed themselves from the Big Idea of "Climate neutral Campus in Europe". Although the engagement phase had to be adapted to the circumstances (some prior to the start of the Strategic Challenge approved master's theses topics) the students went through all further steps of CBL to the (planned) implementation or (initial) development of a product/prototype. The students’ commitment and the contribution they made to the project were great. Moreover, they further developed future skills like international team communication, project management, and co-operation with stakeholders. The exchange of ideas and experiences on a European level seemed to be inspiring for everyone involved. Hence, the first Strategic Challenge offered students not only a novel opportunity for writing a master’s thesis but also a unique learning experience. The main working phase is finished by now, however, the evaluation of the project is still running. First verbal feedback that we received in several settings was in general positive but also drew attention to challenging aspects of the format. Overall, the feedback indicates that the format of the ECIU Strategic Challenge is perceived as rewarding by the majority of the participants. Apart from a final online evaluation that is now in progress to find out how students and academic advisors value their participation, the group reflection reports will be evaluated to critically reflect on the concept and to derive potential improvements. In addition, interviews will be conducted with some of the partcipants to get a deeper understanding of what experiences they have made.

Based on these results, the concept of the Strategic Challenge will be optimized. The improvements will be implemented in future ECIU Strategic Challenges.

Conference Key Areas: *Ethics in Engineering Education*
Keywords: *ethics, engineering, education, social sciences, humanities*

ABSTRACT

Engineering education in the early 21st century is being transformed in many ways to meet the technological challenges of the future. In particular, the role of the humanities and social science in engineering coursework is under new scrutiny, as educators attempt to strengthen students' proficiencies in aspects of the profession including interpersonal and intercultural skills, assessment of broader impacts of technical work, and especially ethics. These developments are often framed as responses to the demands of employers and institutions, who view these 'soft' skills as increasingly relevant to the work life of technical professionals. In this concept paper, we wish to pursue a somewhat different line of thought: We will examine arguments from the philosophy of science and technology, and from the social sciences, about the value of teaching engineers (as well as other technical professionals) to think through humanistic, social, and cultural lenses. We will review a range of perspectives supporting educational reform along these lines, with a particular focus on work in the recent pragmatic tradition (including Sellars, Mitcham, and others). Having established a range of theoretical defenses for educational reform along these lines in engineering fields, we will then consider the distinctions among them and how these insights might be applied most effectively in engineering curricula. We will conclude by reviewing available evidence for the practical utility of such interventions. We hope, by situating current reforms more firmly within a principled framework of ideas, to provide deeper support for positive change in the education of future engineers.

1 INTRODUCTION

Why change engineering education? Our title question is meant to be somewhat provocative for a number of reasons. Foremost, we observe that engineering education might be expected to change continuously in response to new developments in technical knowledge and associated technological systems. Furthermore, continuous improvement is part of the accepted ideology of both engineering fields and contemporary institutions of higher education, making change an expected default condition for curricula in general. In these senses, the answer is obvious. However, here we are concerned not with this kind of process of spontaneous pedagogical adaptation, but rather with an intentional guided shift that has been conspicuous in engineering curricula for more than 30 years – particularly in the United States – toward greater inclusion of humanistic, social, and cultural subject matter in undergraduate engineering courses, or in elective coursework associated with engineering degree programs.

In that context, our question remains challenging to longstanding assumptions about the specialized nature of engineering knowledge, as a fundamental technical skill set. In addition, it calls for consideration of what the fundamental objectives of engineering education, and higher education more broadly, are and ought to be in the 21st century. It might also provoke responses from some quarters about how to assess the merits of engineering curricula (or, again, university curricula in general) and the outcomes that they produce. As such, an examination of recent trends toward broadening engineering curricula opens up a potentially productive discussion about both educational practices and the principles they represent.

Our primary interest here is in the relationship between engineering education on the one hand, as a specific form of institutionalized technical preparation, and general education on the other, as a process of providing individuals leverage to participate fully in a contemporary society permeated by technologies and engineered systems. Recent shifts – either proposed or actually adopted – in engineering education have conspicuously focused on strengthening the capacity of students in technical programs of study to include a greater depth of humanistic and social skills. These include developing capacities in such areas as communication, team dynamics, human-centered design, ethical reasoning, cross-cultural understanding, and analysis of social impacts. All of these can be (and are usually) justified by the demands of engineers' professional role in a highly technological society: The technical preparation of 21st century engineers is understood to entail working within distinctive social and institutional contexts that require skills that are oriented more toward interaction with other people than with the technological objects that engineers devise, produce, and maintain.

2 DISCUSSION

2.1 Demands for Design Knowledge

We begin this discussion by noting that curriculum changes such as those just described have been institutionally mandated by professional accreditation boards on the basis of feedback from professional societies and consulting bodies, industrial employers, and other stakeholders. In this sense, broadening the engineering skill set is straightforwardly a matter of demand, which has been solidified by evidence for the efficacy of such changes. To remain an accredited engineering program, ABET requires specific student outcomes related to social responsibility, including "an ability to design a system, component, or process to meet desired needs within realistic constraints such as economic, environmental, social, political, ethical, health and safety, manufacturability, and sustainability", pg.1 [1].

While there is an obvious logic to this line of thought, we want also to examine some more foundational arguments for strengthening the intersection between engineering education and general education. To begin, we note some observations about the limitations of putting social awareness into practice in an engineering context. Students may absorb and retain a consciousness of such considerations while still failing to develop effective ways of incorporating them into engineering work. Within design tasks, for example, students have difficulty in connecting social consciousness with user needs. Often, when students are responsible for identifying customer needs, their efforts are limited to the results of surveys and focus groups, in which relevant data is collected early in the design process often without subsequent iterations. Students typically treat the customer as a list of requirements that serve as an input to the design process. Within this context, interventions are needed to help students better think through details beyond survey results while striving towards socially conscious levels of understanding. Designers need both domain-specific knowledge and situation-relevant strategies to design effectively [2].

It is apparent that students need to know how customer or client information influences the design of products and systems even when the human-centered details are not explicit. This thinking can be enabled through an increased level of social consciousness, or an awareness of the impact that design decisions could have on the cultural, social, and emotional aspects of the end-users. In situations where the designers lack exposure to end-users, the mapping between user needs and product attributes is non-trivial and challenging for students. Thus, while adopting this approach may provide an added level of understanding about constitutive human factors, obstacles still emerge from the diversity of users and contexts that may be relevant from one situation to the next.

2.2 Fostering the Individual Engineer

Another perspective on broadening engineering design education, less focused on the needs and wants of users, might emphasize instead the personal development of the individual engineer themselves as the primary benefit. Societies more than ever are more knowledge-based with a drive for development of new competencies effective for rapidly changing global world. In a such global society, where everyone deserves the opportunity to be educated, the philosophers Rousseau and Dewey's educational models both emphase the learner's own motivation. As discussed by Noddings, Rousseau's open education model recommends building education on the interests of students, enriched with hands on experience, and learning by doing, feeling, observing and deemphasized formal lessons [3]. Dewey is also known for his work on the role of experience and its function in education. "Experience" in the context of education, for Dewey, is personal meaning and social interaction. Dewey wanted students to experience a personally unified curriculum – one that makes sense to them in terms of human experience and particularly, in terms of their own experience [3]. This train of thought recommends a broad and flexible curriculum primarily by virtue of the beneficial outcomes expected to accrue to the engineering student. In effect, both Rousseau and Dewey are arguing for engineering education to be construed as a process of *Bildung*, in which both technical and social skills are fundamental to the engineer's personal development.

However, this perspective still leaves a significant role for social interactions and experiences in driving the process. Design is an extremely social form of inquiry. Design is defined as a reflective practice as described by Donald A. Schon [4]. Major concepts of this model are surprise and reflection. A designer or student has a canonical way of doing and something unusual happens when these practices confront a new social situation that causes the student to reflect on the situation. Surprises come from the unpredictability of design situations and a designer engages in a reflective conversation with the context and materials, a process that may aid in developing a deeper understanding of the design problem [5]. The early stage in design and the iterirative nature of design in general, resembles educational model explained by Dewey and his emphasis on immersion and experience in education. It is also highly congruent with the spiral curriculum approaches often taken by educators to guide students through a developmental process within general education. Viewed from this perspective, engaged personal development is facilitated by repeated exposure to new contexts and interactions. Engagement and development over time mitigates some of the concerns noted earlier about engineering students' initially "transactional" approach to user-centered design.

Whether motivated primarily by questions of social consciousness or personal development, advocacy for broadening engineering education ultimately entails a renewed emphasis on the professional and ethical responsibility associated with the engineering profession. In an educational environment that strongly distinguishes technical knowledge from social or human knowledge, attending to both can easily appear to be a challenging task, especially if construed as the sole responsibility of the educated professional engineer. Consider: In learning the engineering profession today, students are encouraged and expected to consider the effects of their actions (and non-actions) including the economic, environmental, political, societal, health and safety consequences of their work, while also keeping in mind the manufacturability and sustainability of their structures and products. As Robin Tatu notes in discussing the book of Douglas, Papadopoulos, and Boutelle "Citizen Engineer": "A successful 21st century engineer must become "part environmentalist, part intellectual property attorney, part MBA, and part diplomat – not to mention an expert in an engineering discipline, a great teammate, and a skilled communicator" [6] (Prism, pg.52). Similarly, the National Academy of Engineering suggested in *Educating the Engineer of 2020* [7] that:

> Within the context of the changing national and global landscape, The USA National Academy of Engineers enunciated a set of aspirations for engineers in 2020. The future engineers have to be technically proficient engineers who are broadly educated, see themselves as global citizens, can be leaders in business and public service, and who are *ethically grounded*. The committee set targeting attributes needed for the graduates of 2020. These include such traits as strong analytical skills, creativity, ingenuity, professionalism, and leadership.

Presented with calls such as these for engineering education to instill such comprehensive and multivalent competence, both educators and students have struggled to fulfill the brief. This has led to extended controversies over specifics of curriculum design (spiral or across-curriculum models, standalone courses, discipline-specific requirements or interdisciplinary elective structures, etc.) each of which offers its own benefits and limitations for content, learning, and engagement. From the perspective of student engagement in particular, it is difficult to motivate students to take ethics education seriously as ethics is usually included in the engineering curriculum as an elective.

Further, the cases use as models in teaching engineering ethics are intended to reflect ethical problems that arise frequently in engineering under rather ordinary circumstances, but undergraduate students found these dilemmas too complext. However, real-life is complex, dynamic and embigous and it is important that students understand the differences between models and real life, and the importance of selecting the model which is appropriate for the situation. One way to overcome this tension is if case studies are limited and the main focus is on cases inspired by real interviews and guest speakers from professional engineers. This partial circumscription of the framework for ethical education facilitates disciplinary engagement (per the previous paragraph) but also provides an opportunity to rehearse different perspectives as models for real human-social situations.

2.3 Building Scientific Culture

In addition, the notion of engaging with complexity through models leads back to a perspective articulated by the pragmatic philosopher Wilfrid Sellars in his 1962 “Philosophy and the Scientific Image of Man” [8]. In that essay, Sellars addresses a fundamental issue regarding the epistemological divide between scientific knowledge (collectively designated the “scientific image”) and human-social knowledge (which he refers to as the “manifest image”) – interpreting each as models of the real world to be reconciled with one another in human experience. While Sellars was concerned primarily about how philosophy might function to mediate between the (apparently distinct) scientific and manifest images of the world, his analysis also offers a new perspective on how technical knowledge and humanistic knowledge might best be synthesized – an obvious concern in contemporary debates about broadening the engineering mindset in practice.

In brief, Sellars argues that the elements of the manifest image, which include such things as intentions and communality and which represent the intrinsically social-human side of reality, must be considered as subjects for inquiry through both scientific and humanistic lenses. The central position of ethics (principles of proper action) to these concerns should be obvious. Thus, the simple moral of Sellars' argument is that principles of good judgment and knowledge of how to act are at stake in our development of knowledge about persons. The shared concerns of humanity – both in our contemporary situation and perennially – encompass multiple sociotechnical dimensions. Sellars pushes us to recognize that addressing these considerations effectively must be a holistic enterprise. On his view, it is the purpose of philosophy, as a human endeavor to produce a synoptic view of these various dimensions of reality as a precondition for fundamental understanding of the world. Philosophy not to be thought of as an intellectual activity in isolation, but rather philosophical perspective serves as a mark of both personal education and cultural development. The emphasis is less on individual *Bildung* than on social progress through collectively shared knowledge. This is not an argument against disciplines *per se*, but a recognition of the value in bringing disciplinary perspectives into conversation with one another more effectively. This requires some level of shared education at the individual level, as well as coordination of communities of knowledge.

Bringing this train of thought back into contact with our concerns about engineering education, Sellars' viewpoint attempts to break down the division between technical and non-technical knowledge that looms so large in debates about how to broaden the engineering mindset to include human and social factors. In his own words,

> [T]he conceptual framework of persons is not something that needs to be *reconciled with* the scientific image, but rather something to *be joined* to it. Thus, to complete the scientific image we need to enrich it *not* with more ways of saying what is the case, but **with the language of community and individual intentions**, so that by construing the actions we intend to do and the circumstances in which we intend to do them in scientific terms, **we *directly* relate the world as conceived by scientific theory to our purposes, and make it *our* world** and no longer an alien appendage to the world in which we do our living [8].

Thus, in our context, the fundamental pragmatic argument that Sellars is making can be summed up as follows:

1) The historical development of science and technology has led to an apparent – but ultimately false - dichotomy between two worldviews: One founded in reason ('scientific image') and the other in human intentions ('manifest image').
2) Among the consequences of this false dichotomy is an externalization of ethics from technical work. This is a problem for engineering education.
3) Human-centered development of science and technology requires greater attention to the individual and collective phenomena of human experience.
4) New knowledge from the social sciences can serve as the fulcrum point for this reconciliation.

Ultimately, then, Sellars' perspective suggests that the key to developing the kinds of engineers being sought by advocates of change today is to embrace an interdisciplinary vision of knowledge that focuses in particular on sciences of humanity in all their apparent complexity. From a practical viewpoint, this would entail a greater pedagogical emphasis on boundary crossing and developing capacities to take multiple perspectives on real world issues, especially beyond a narrow conception of scientific knowledge, as well as a shift in priorities for associated research programs across the modern university. In other words, Sellars encourages us to think about issues in 21st century engineering education from the standpoint of comprehensive institutional change, not merely curriculum change.

This vision is strongly echoed in a variety of recent sources in the social sciences and humanities. For example, one recent review of the social sciences in the United States notes a number of characteristic conceptual foci guiding contemporary work, including 'comparative historical sociology', 'social causal mechanisms', 'new institutionalism' and the 'cultural turn'. Taken together, these emphases reflect several foundational principles: that social – and by extension sociotechnical – outcomes are best viewed as deeply and causally contingent on circumstances requiring case-by-case study within a context of social entities and institutions by means of a heterogeneous interdisciplinary array of methods. One of the key challenges involved in sustaining such inquiry is to coordinate and communicate among the various contributing fields. Another key point of reference is the National Science Foundation's recent survey, Rebuilding the Mosaic [9]. This synthetic treatment of prospects for productive investment in the social, behavioral, and economic [SBE] sciences notes an emerging focus on work with systematic, synthetic, problem-oriented, and data-intensive dimensions. It documents interdisciplinary transformations encompassing not only greater collaboration within and among SBE fields, but also stronger bonds with STEM and humanities fields as well. The four central thematic areas identified in the Mosaic study highlight issues of population, resource access, communication, and technology, and emphasize the challenges of tracking the social environmental mechanisms involved in the disparate paths of different cultures to material and intellectual stimuli; fostering interaction among technical communities and interested publics; and negotiating global versus local interests, values, and cultures. This cross-section of global ethics concerns represents an important connecting thread between inquiry in a wide variety of critical and interpretive disciplines. The same concerns are also articulated in Frodeman and Mitcham's recent call for a 'broad, deep and critical' interdisciplinarity spanning – and transcending – academic boundaries as a means of integrating contemporary knowledge for the formulation of better STEM policy [10].

3 SUMMARY

While this brief survey can only indicate some of the factors that motivate contemporary change in engineering education, we hope that we have at least indicated a few significant distinctions apparent in calls to broaden technical curricula to incorporate specific humanistic and social skills that are more traditionally associated with general education. These different – and potentially mutually reinforcing – motivations reflect an intersection of priorities from professional, pedagogical, and philosophical perspectives. At one level, attention to human-centered design practices has stimulated greater recognition of the value of social knowledge within the engineering workplace. At another, studies of educational engagement suggest that broadening curricula will foster a more satisfied individual engineer, thus making the profession more attractive to a greater spectrum of students. Further, philosophers of science have observed that the demands of modern technological society require new kinds of practical knowledge that are based in human and social factors. While oriented toward different positive outcomes, all of these stimuli point toward a congruent strategy for improvement in the education of engineers, with the common thread being that an ability to contend comprehensively with issues of values – at the level of the individual, the profession, and society at large – is increasingly required in today's world.

Keywords: *prestige, engineering wave, engineering knowledge, disruptive innovation*

ABSTRACT

There is no doubt that in the EU and the USA, engineering education has completely lost its previous prestige. The finest youths have shifted away from aspiring to become engineers towards aspiring to become professional economists and businessmen. It has been forgotten that the enterprises for machines, which are best understood by engineers, are the backbone of every national economy. Furthermore, the lack of human capital capable of managing their economy efficiently, as well as supporting their internal activities, will lead not only to us observing a shift of the finest youths steering away from engineering but also a shift away from a sustainable economic future.

This paper presents a new approach that will bring back the previous and well-deserved prestige of the all-important engineering education, a prestige connected to the names of Henry Towne, Frederick Taylor, William Deming, and all the engineers responsible for the three engineering waves in the development of the fundamental scientific knowledge of economy. However, we find ourselves on the brink of a fourth engineering wave in the development of the fundamental scientific knowledge of economy. A wave connected to the Bulgarian-based Institute for Systemic Economic Engineering, which has successfully developed a systemic universal model of the enterprise for machines, a model widely thought to be impossible to develop, but if developed successfully, would bring economic changes equal to the combined magnitude of the economic changes brought by all the previous engineering waves and would form a new type of professional defined by the term “systemic economic engineers”.

1 INTRODUCTION

For us, engineers, it is a well-known fact that the world we live in would not be as we know it today without the enormous advances of the industry for machines[2,3]. It is perfectly clear that today, the industry for machines represents the basis for the operation and development of all other industries. If some unknown force suddenly wiped out all machines in our contemporary world, this would lead to a devastating calamity comparable to a nuclear war.

The fact is that the modern world owes its level of development precisely to the industry for machines. But it would be impossible to establish, maintain, or develop the industry for machines without the existence of a huge multitude of engineers. This status of the industry for machines as leading in the development of all other industries means that engineering positions must be of the highest level of importance and be desired by the most qualified young people in the modern world.

And while this was the case for the majority of the 20th century, in the 21st century this significance and hence prestige have been questioned. The technical universities in the Western world find it increasingly difficult to fill their student quotas, while the industry has been experiencing "acute hunger" for engineering personnel. At the same time, we observe huge growth in all kinds of socio-scientific professionals and, above all, professional economists.

With this concept paper, we will briefly outline the causes of the shocking loss of prestige of the engineering education, but most importantly, we will present a concept for a Fourth engineering wave in the development of the fundamental scientific knowledge of economy, which aims to reorient the population back towards the engineering profession.

2 METHODOLOGY

The methodology for developing the current *concept paper* is as follows:

The method of sourcing *"secondary data"* is used multiple times – this is done to obtain data on the state of the engineering education "past and present".

The methods *"library research"* and afterward *"in-depth analysis"* of selected parts of their content are dominant in the current *concept paper*. Using these methods, we will prove to the scientific community that there is a great necessity for the creation, development, and mass dissemination of a new quality of fundamental scientific knowledge of economy through a Fourth engineering wave in the development of this knowledge. A wave that is of key importance in the restoration of the prestige of the engineering profession, but also for securing the future development of our world.

---

[2] **Machine** - In the context of the term industry for machines, "machine" is the umbrella term that covers all of the various kinds of machines, which include: mechanical, electrical, computer, automotive, aerospace, hydraulic, etc.

[3] **Industry for machines** - the multitude of enterprises providing machines and spare parts to all industries as well as the multitude of enterprises providing services for those machines.

3 BACKGROUND

3.1 The state of the engineering education at the beginning of the 20th century and the three engineering waves in the development of the fundamental scientific knowledge of economy

By 1903 the United States of America and Europe were producing thousands of engineers per year, compared to the insignificant number of business personnel (about 30 people). [1] [2] The engineering profession was particularly celebrated during that period due to the fact that most Western countries were in the process of industrialization, with the U.S.A. at the forefront of this process. Many famous engineers stood behind the industrialization of that time. But optimizing the management of all these enterprises for machines required the development of a new type of knowledge to complement the technical skills of engineers. A necessity emerged for knowledge of the principle set up and way of functioning of the enterprise for machines, which would derive universal approaches to management. Such knowledge — towards the end of the 19th century — was absent. The realization of the absence of such understanding gave rise to the *First engineering wave* in the development of the fundamental scientific knowledge of economy[4].

This wave is associated with the names of the engineers Henry Towne and Frederick Taylor, two prominent members of the American Society of Mechanical Engineers (ASME). Henry Towne reached the conclusion and declared in his work “The Engineer as Economist” (1886) that *“(Shop management) should come from those whose training and experience has given them an understanding of both sides (viz.: the mechanical and the clerical)...* ***for the reasons above indicated, particularly from mechanical engineers.****”* [3] The First engineering wave creates, develops, and disseminates knowledge of operational modeling of the production processes in an enterprise.

The First engineering wave is followed by another two. The Second engineering wave of development of the fundamental scientific knowledge of economy covers the 1930s, 40s, and 50s. It involves the creation, development, and dissemination of knowledge of production management focused on quality. It is associated with the names of the US engineers Walter Shewhart, William Deming, and Joseph Juran.

By 1950, the number of engineering graduates compared to business and economy graduates was almost equal, but still in favor of the engineers. Dozens of people were fighting for a single place in the technical universities, and the West held a “comfortable” leadership position in a geopolitical plan.

The Third engineering wave covers the 1970s, 80s, and 90s. It involves the generation, development, and dissemination of knowledge of computer-integrated modeling of the sales processes, manufacturing processes, and manufacturing supply processes.

The key concepts for this knowledge are MRP I (Material Requirements Planning) and MRP II (Manufacturing Resource Planning). MRP I refers to knowledge of computer-integrated modeling of the sales processes, manufacturing processes, and manufactur-

[4] The knowledge about management of the enterprise processes is fundamental for the knowledge about management of the enterprise economy.

ing supply processes without taking into account the production capacity of the enterprise. MRP II refers to the same type of knowledge; however, it also takes into consideration the production capacity. The Third engineering wave of development of the fundamental scientific knowledge of economy stems from the work of two IBM engineers – Joseph Orlicky and Oliver Wight.

The purpose of all three engineering waves was to address the deficit of knowledge of the management of the economy of the enterprise for machines. Even though they provided extremely useful practical solutions, they had not reached a holistic knowledge of management; holistic knowledge, which consisted of unified theory and terminology about the principle set up and way of functioning of the enterprise for machines. It is not clear why American engineers abandoned that goal. The emergence of ERP, the successor of MRP, should have been a step in this direction, but by that time the positions of "ideologues" who affected the direction of development had become the representatives of the different economic schools. They integrate various "business" modules to the classic MRP system. However, this approach leads to the significant departure of the functional constructs of all modern ERP systems from the cognitive universalism, which is inherent in the functional construct of every pure, application-free MRP system.

Nevertheless, it is precisely the three engineering waves and the serious achievements of engineers that gave rise to the United States as a world economic power, as well as the "economic miracle" of Japan after World War II.

3.2 The state of the engineering education today

In recent years, we have observed a huge "outflow" of students from technical universities in the West. An outflow, that is paradoxical, as it is the engineering profession that allowed the Western world to become a world leader. For technical universities, it has become increasingly difficult to fill their quotas of engineering majors due to a lack of candidates. According to data for 2020 at the Technical University of Sofia, the enrolled number of students is only 50 % of the university's total capacity, even though the entry requirements are as low as possible (admission in the program is dependent upon a matriculation exam in the Bulgarian language). [4] This is not an isolated case and unfortunately, it is not only happening in Bulgaria. It is a fact throughout the Western world. Even technical universities in countries with rich manufacturing history, such as Austria and Germany, cannot fill their universities' capacities. Why do we say the Western world? Because in the East - China, Japan, and South Korea - the situation is rather different, as shown in Figure 1. Meanwhile, the Western industry is experiencing an "acute hunger" for engineers and technical specialists. Therefore, we need to ask the question *"Which majors related to the management*

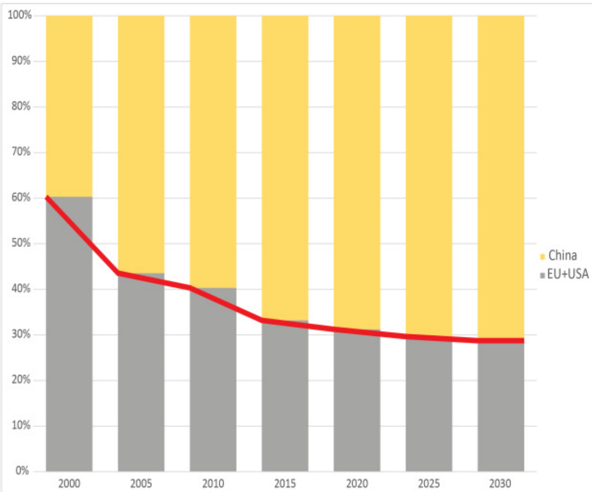

Figure 1. The trend of development of engineering personnel in the Western world and China.

of the real industry do students pursue?" The answer is the disciplines related to economic science - *Economics, Business and Management, Entrepreneurship,* etc.

In the United States during the 2018-2019 academic year, 426,000 undergraduates graduated with a Business and Economics major, and only 190,000 undergraduates graduated with an Engineering major. In the EU, the situation is no different: 459,000 graduates with a Business and Economics major and 280,000 with an Engineering major.[5] [6] The quality of incoming students in the engineering majors is also questionable. In 2004, for every 100 applicants, only 20 were admitted to the TU-Sofia, while in 2021, there was no competition whatsoever. [7] And as we know, quality is found in the competition. As of today, in the Western world, the number of undergraduates in business and economics disciplines has increased by a factor of 10 since 1950 and engineering only by a factor of 3. Perhaps the Western world's loss of leadership in the global economy to the advantage of China is not accidental either.

3.3 Causes of the loss of prestige in the engineering education

The reasons for the loss of interest in the engineering field to the benefit of the economic field are numerous. The very word "Management" in the Business Management degrees gives the impression that it provides students with high-quality management skills and abilities. Indeed, it is a fact that an economics degree is required to undertake a managerial position. Another reason is the fact that an engineering degree is much more difficult to complete than an economics degree since economic science lacks uniform theory, terminology, and systematic upgrade of knowledge.

However, there are also more global reasons, such as the political ideology of the *knowledge economy* adopted by the West between 2000-2010. According to the Lisbon Strategy, the countries in the West should *"get rid of the outdated manufacturing and to focus on innovation,"* and above all, focus on the services sector – financial services, legal services, and consulting services for "effective management of the economy". Thus, candidates began to shift from engineering professions to a range of social science professions, especially professional economics, and we can observe this decline as shown in Figure 1.

This is all the more unwise because by giving up the industry for machines and the development of numerous and capable engineering professionals, Europe and the United States are voluntarily giving up their geopolitical leadership position. Furthermore, it is becoming more and more evident how they are losing their advantage in innovation and even worse - becoming extremely dependent on China's industry for machines. A fact that was made clear during the "COVID 19" crisis. What does the future hold? The cultivation of countless social scientists and, above all, professional economists at the expense of engineering specialists will lead the Western world to the inability to maintain and develop its current industry for machines, which would eventually lead to industrial collapse. But why can't we rely on modern economists to create, develop, and disseminate practically effective scientific knowledge for the management of the existing industry for machines?

Our in-depth studies of the numerous parts of the modern fundamental scientific knowledge of economy show that the most significant ones (from a practical point of view) are: knowledge of accounting, knowledge of productivity and quality management, and knowledge of production planning and control by utilizing the MRP algorithm. The first was the work of a monk, and the other three were the work of American engineers. Among these, and all other parts of the fundamental scientific knowledge of economy, there is a lack of unified theory and terminology that would allow graduates of this field to speak a common managerial language. For comparison, the state of medical science was similar before the introduction of the systemic anatomical and physiological model of the human body. This means that in the age of digital information technology, the fundamental scientific knowledge of economy is still at a scholastic level of development, compared to the level of development of the fundamental scientific knowledge of medicine. A fact that is reflected in numerous quotations from the great engineers before us:

Henry Towne, 1886: *"(Management of works as a science) is unorganized, is almost without literature, has no organ or medium for the interchange of experience, and is without association or organization of any kind.";* [3]

Oliver White, 1981: *"…but where in our manufacturing economy is a school on how to run a manufacturing business in all of its facets? What about the subject of manufacturing itself? … There is not even a well-defined body of practical knowledge on the subject. There are virtually no college textbooks that address the subject from a practical viewpoint."* [8]

What about today? Our survey of economics students from the leading business universities in Bulgaria has shown that economics students, even when allowed to use specialized literature, are incapable of providing a uniform explanation of the objective meaning of terms such as *economy* and *economic science*, *goods* and *service*, or explain the principle set up and way of functioning of an enterprise for machines. One disregarded reason for youth unemployment lies precisely in the fact that our educational system produces graduates who are incapable of meeting the demands of the labor market, both in terms of professional orientation and in terms of the quality of their preparation.

Today we are witnessing how after enrolling in economics and business majors, Europe's youth with the greatest potential do not receive practically useful knowledge for managing the real industry. It turns out that the European educational system has been turned into a machine for intellectual and professional distortion of its most valuable human resources. It sounds absurd, but this is a fact. A fact, which presents a grave issue for the future of the European world.

3.4 A concept for a Fourth engineering wave in the development of fundamental scientific knowledge of economy

Today we live in the age of the so-called '"Industry 4.0". An age when many new technologies are expected to emerge and be produced in "smart factories". This poses a serious problem for the entire Western world, namely that modern economics education does not provide practically useful knowledge for re-engineering already existing enterprises, or for creating entirely new ones. At the same time, a huge number of young people are directed precisely towards an education in economics in search of this kind of knowledge. Unfortunately, it is not possible to rely on the elder generation that created the vast industry for machines of the West, as these people are either retired or no longer among the living. The currently existing huge shortage of engineers and technical specialists is of no help either. Thus, the Western world is faced with the task of creating an industry for machines of a higher quality without the know-how for this process and without sufficient engineering personnel to fulfill it. This is a prerequisite for a huge division between the West and countries like China – where the specific knowledge is also missing, but their enormous engineering armies and models derived from practice, which they duplicate with phenomenal speed have already earned them the title of “new technological leader”.

This means that we, the engineers, especially those at the head of the engineering organizations of our Western World, need to take cardinal measures responsibly and quickly in order to return the interest, and hence the prestige, in the engineering education and to direct more and more young people back towards it. This can be realized through a Fourth engineering wave in the development of fundamental scientific knowledge of economy. A wave that would complete the work of all the great engineers before us and would consist of the creation, development, and above all, dissemination of a new class of digital technologies for managerial modeling of the economy of the enterprise for machines. Technologies whose functional construction includes knowledge of a universal model of the economy of these enterprises, which describes their basic structure and way of functioning as a systemic object and subject.

4 RESULTS:

4.1 Is it possible to create a universal model of the economy of the enterprise for machines?

Perhaps we also would not have arrived at the concept of a Fourth engineering wave if we were not convinced that such a model really exists. One such model, the only one we are aware of, is the result of more than 20 years of efforts by the Bulgarian Institute for Systemic Economic Engineering (ISEE). During all those years, the main goal of ISEE was to prove to the world that a new generation of holistic ERP systems can be created. ERP systems that are currently available on the market (without exception) are built on the basis of a fragmented (scholastic) fundamental scientific knowledge of economy – knowledge that we have repeatedly found to have large functional gaps.

In this regard, the new ERP systems are completely different. Their engineering design is based upon a holistic fundamental scientific knowledge of economy, which provides a clear understanding of the principle set up and way of functioning of each enterprise for machines as a systemic object and subject. This knowledge is available in the form of hundreds of pages of theory and terminology. This difference opens up the possibility for the new ERP systems to entirely outperform the systems that are currently available on the market. This superiority is clearly observed through a direct comparison between the current prototype of the new holistic ERP system created by ISEE and all currently-available ERP systems. All developments made by ISEE were subjected to practical testing in functioning enterprises for machines.

A number of scientific discoveries were made as a result of the testing activity, two of which have the most significance. Both are defined as "cognitive engineering platforms" for understanding of the enterprise of machines as a systemic object and a systemic subject simultaneously. The first cognitive platform provides knowledge for the understanding of an enterprise for machines in its capacity as a systemic object, which exists as a result of the synergy of five functional systems. The visual representation of the cognitive platform created by ISEE for the understanding of an enterprise for machines as a systemic object has the form of a cross and is called the "Industrial Cross" (Figure 2). The second cognitive platform provides knowledge for the understanding of an enterprise for machines in its capacity as a systemic subject. Within the second cognitive platform, the enterprise for machines is considered as a complete subject, characterized by an inherent, hierarchical system of five types of knowledge, including a system of responsibilities for continuing its own existence. The visual representation of the cognitive platform created by ISEE for the understanding of an enterprise for machines as a systemic subject has the form of a tree and is called "The Tree of Industrial Cognition". The knowledge of the universal model of the economy of an enterprise for machines is extremely extensive and is not within the scope of the current paper. It is presented in the book "Business Model Ontology: The Basis for Digital Reform of Economic Science".

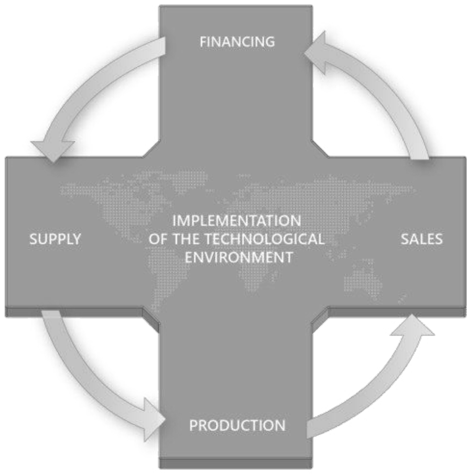

Figure 2. The Industrial Cross

4.2 Results of the implementation of the holistic ERP system, bearer of a universal engineering model, within enterprises for machines.

The developed knowledge of the universal engineering model and the holistic ERP system built on its basis have been applied and experimented within mid- and large sized enterprises for machines in Bulgaria and Russia. Once the engineering staff mastered the knowledge and application of the ERP system, they were able to carry out activities within their enterprises at a significantly lower cost of resources and within a shorter period of time than the much more experienced international consultants. Some of the experiments included:

- Large-scale re-engineering of an enterprise for hydraulic cylinders, consisting of more than 500 workers. During the re-engineering process, more than 70% of all workplaces were restructured and relocated. Notably, this process was completed without any suspension or even delay of the production processes.

- Assimilation and modernization of the constructive and technological documentation of axial piston hydraulic pumps and motors and their subsequent implementation in production, technology which had previously never been produced in the Balkan Peninsula. The results of this experiment are spectacular: five young machine engineers, who did not have any prior experience in plant design but were very well versed in the ISEE ERP system, managed to design, build, and ensure the operation of the extensions of the technological environment of two plants. They accomplished all this for the same amount of time and money that foreign consulting companies required to simply update the product documentation.

These, as well as other such results, have proven that after only several months of study of the universal model of the enterprise for machines, engineers with no substantial experience in managing enterprises can achieve practical results that even the most renowned professional economists cannot accomplish[5].

4.3 Potential outcomes of the Fourth engineering wave in the development of fundamental scientific knowledge of economy.

We will try to briefly present the potential effect of the theoretical and practical study of knowledge of the functional construct of the holistic ERP systems by students studying engineering majors.

The people who should consider this knowledge to be of the highest priority and should study this knowledge are engineers, and more precisely machine engineers[6], as the real professionals who create, develop, and manage the industry for machines. This view is in complete agreement with the concept of "The Engineer as Economist" – an idea born in the late 19th century that led to the three engineering waves in the development of the fundamental scientific knowledge of economy, but which has remained incomplete to this day.

The only viable chance for a dignified and equitable development of the Western world by reducing the technological lag in comparison to China is through the realization of a Fourth engineering wave in the development of the fundamental scientific knowledge of economy. This wave will lead to the finalization of the work of the American engineers, Henry Towne and Frederick Taylor. A finalization, crowned by the emergence of a new generation of machine engineers, which we define as "*systemic economic engineers*".

A *systemic economic engineer* is any professional machine engineer who, as a result of purposeful education, has acquired fundamental and specialized engineering knowledge in a certain field of the industry for machines, and has also acquired theoretical and practical knowledge of the new class of holistic ERP systems. The *systemic economic engineer* - as a result of several months of theoretical and practical study of the functional construct of the holistic ERP system - forms a cognitive potential for managerial modeling of the economy of the enterprises for machines, which is far superior to the one possessed by even the most renowned professional industrial economists. A superiority, which is expressed in the conscious understanding and application of:

(1) knowledge of the principle set up and way of functioning of the enterprise for machines as a systemic object and subject;

[5] The experiments and some of the results are presented at https://isee.bg/en/.

[6] **Machine Engineer** – a practitioner of machine engineering. Machine engineering is the branch of engineering that involves the design, production, and exploitation of all types of machines. "Machine engineer" is the umbrella term that unites all those engineers dealing with machines, which include: mechanical, electrical, computer, automotive, aerospace, hydraulic, etc., engineers.

(2) practical knowledge for development of highly effective strategies for future economic development of the enterprise for machines with a focus on anticipating the development of its innovation potential;
(3) practical knowledge for the development of highly effective programs for training, retraining, and motivation of the staff of an enterprise for machines – programs that aim toward the realization of the strategies for future economic development of the enterprise for machines;
(4) practical knowledge for auditing enterprises for machines in order to assess the current and future development of their economy and to generate ideas to increase the effectiveness of this development;
(5) conceptual knowledge for the creation and development of a truly effective accounting model of the economy of the enterprises for machines;
(6) knowledge for the management of the cost and quality of a product and the ability to conduct a technological analysis of the process of creating the goods and services sold, while offering different options for implementing this process;
(7) practical knowledge for the development and management of projects for implementation of systems for lean manufacturing (Single-Minute Exchange of Die – SMED) of goods and services sold by the enterprises for machines;
(8) practical knowledge for the planning and management of the execution of engineering and reengineering of enterprises for machines or large parts of them.

5 THE CONCLUSION

The Fourth engineering wave in the development of the fundamental scientific knowledge of economy will lead to the finalization of the work of all engineers who have dedicated their lives to the previous three waves in the development of this knowledge. A finalization, crowned with the emergence of a new generation of machine engineers – *systemic economic engineers.*

It is the managerial advantages of the new knowledge of a universal engineering model of the economy of the enterprise for machines that will bestow huge prestige to the engineering profession, which will naturally attract the young people who want to engage in industrial management. The emergence of *systemic economic engineers* and the shift of the human capital of the Western world back to engineering, the natural environment for cultivating quality executives for the industry for machines, will bring our Western world back to its morally responsible, creative foundations of the early and mid-20th century. The same foundations that made the Western world the technological and economical leader of the whole world.

All this must happen through the mass dissemination of the new quality knowledge for managerial modeling of the economy of the enterprise for machines. This dissemination should first be extended to all technical universities, and subsequently, the knowledge of a universal model should become a standard for enterprise management. A standard controlled by the best technical universities of our world.

The responsibility to make all this happen rests upon us, the engineers, and the engineering organizations concerned about both the future of our profession, as well as the future of our world.

ABSTRACT

Lappeenranta-Lahti University of Technology (LUT) offers its teaching staff various pedagogical training courses. This paper describes the first module, “University Pedagogy, Basic Module (10 ECTS), and its feedback and results. The module itself was compiled in collaboration between two universities: the ordering university LUT and the delivering university Tampere University of Applied Sciences (TAMK). In pedagogical training it is important to teach as you preach. The participants should be able to experience themselves all the methods, principles, and skills they are supposed to acquire during the training. It is difficult to learn to activate students or to become student-centred only by listening to lectures. Therefore, the teaching methods should be in line with the learning goals and the participants should be active doers and learn hands-on rather than be passive listeners. The Basic Module

doi:10.5821/conference-9788412322262.1235

contents focused on two main aspects: general activating pedagogical skills and teacher's digital tools and their use from pedagogical point of view. First, the basic elements of the pedagogical module are presented together with its structure. Second, the results of participants' experienced learning gains in different categories of the contents are presented together with their perception of the importance of different parts of the content.

1 INTRODUCTION

1.1 Pedagogical training in LUT University

At LUT University teaching staff is not required to have pedagogical training - having a PhD in teacher's own field of research is the only strict requirement. However, pedagicial skills are valued and seen important by the university and therefore LUT offers the teaching staff the opportunity to take pedagogical training courses. The studies consist of one 10 ects basic module followed by optional optional orher courses, e.g. "*Supervising Doctoral Studies*", "*Interaction and teaching presence*" and various other courses in co-operation with other Finnish universities. Teachers will receive a certificate of their teaching skills, and they can use that in their performance discussions within the department or use it otherwise in their life-long learning plan. The goal of the training is to develop and support LUT teaching and research staff's pedagogical and teaching skills, enhance interaction skills and strengthen teacher identity. The 10-credit basic module is bought from other organization (TAMK) and the optional courses are provided by LUT University.

1.2 Activating methods in teaching

Active learning covers a variety of instructional methods which engage students as active participants instead of (passive) listeners of lecturing. Active learning is usually defined as any instructional method that engages students in the learning process. Thus, engaging and activating students during their learning process are the core principles of active learning [1]. In science, technology, engineering and mathematics (abbreviation STEM), examples of active learning methods are i.e. simulations, demonstration, laboratory work calculating, group discussion, peer instruction, taking online exercises, self-assessment, quizzes, using clickers and polling to collect individual and group opinions and explanations and so on. Such instructional methods promote students' own activity and taking responsibility of their own learning process. Instead of passively listening to a lecturing, students actively do learning activities and process information in various ways. They also need to present their ideas and conceptions to their peers in discussions. Different studies have highlighted benefits of active-engagement learning methods. Prince [1] has found support for all forms of active learning examined in his studies. Freeman et al. [2] carried out a meta-analysis of 225 studies that had reported course scores and passing rates in STEM courses, and they compared results of studies between traditional lecturing method and active learning methods. Their analysis indicated that using active learning methods can increase passing rates and course scores. Deslauriers et al. [3] has shown improved learning outcomes in a large-enrolment physics class when using pre-class reading assignments, pre-class reading quizzes, in-class clicker questions with student-student discussion, small-group active learning tasks and targeted in-class instructor feedback. Especially, they found that active learning methods have great benefits with small groups, but it is effective for all group sizes. Wieman has found similar positive effects [4]. In addition to active-engagement methods, also self-regulatory skills are also often connected with active learning. Research has shown that when mastering own learning process, learning outcomes are typically better [5, 6].

2 ARRANGEMENTS AND CONTENTS OF THE PEDAGOGICAL TRAINING

2.1 Participants

The module was offered to teaching staff of LUT University. From the applicants, 22 were chosen based on the urgency of the need for the training and on their ability to commit to the working on the module. Despite the commitment requirement, the number of participants dropped a little after the beginning and 20 participants continued to the end of the first semester. When the semester changed, 17 participants continued studying on the module. Figure 1 presents the overall activity on the module, based on the weekly sum of log events in Moodle, together with the number of active participants. The activity is found to be strongly correlated with the assignment deadlines and contact days, which are show later in Fig. 2.

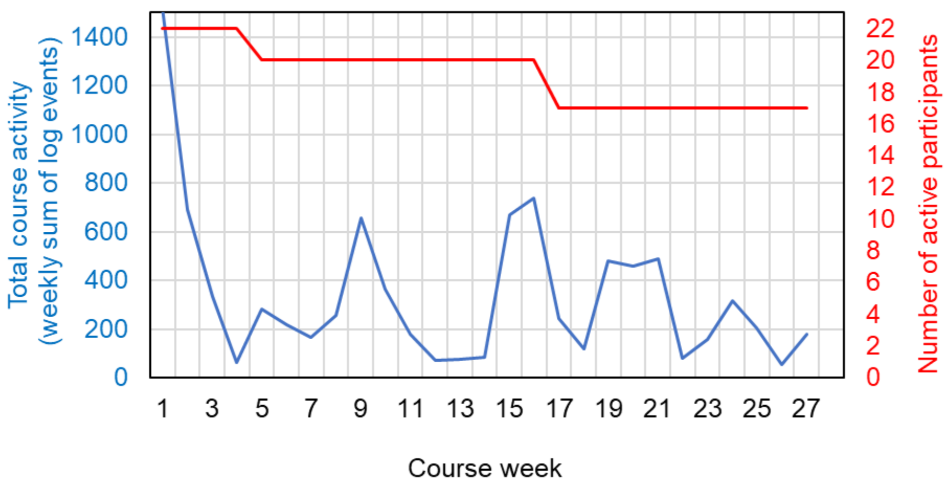

Fig. 1. Weekly sum of Moodle log events (left axis) and the number of active participants (right axis) as a function of course week.

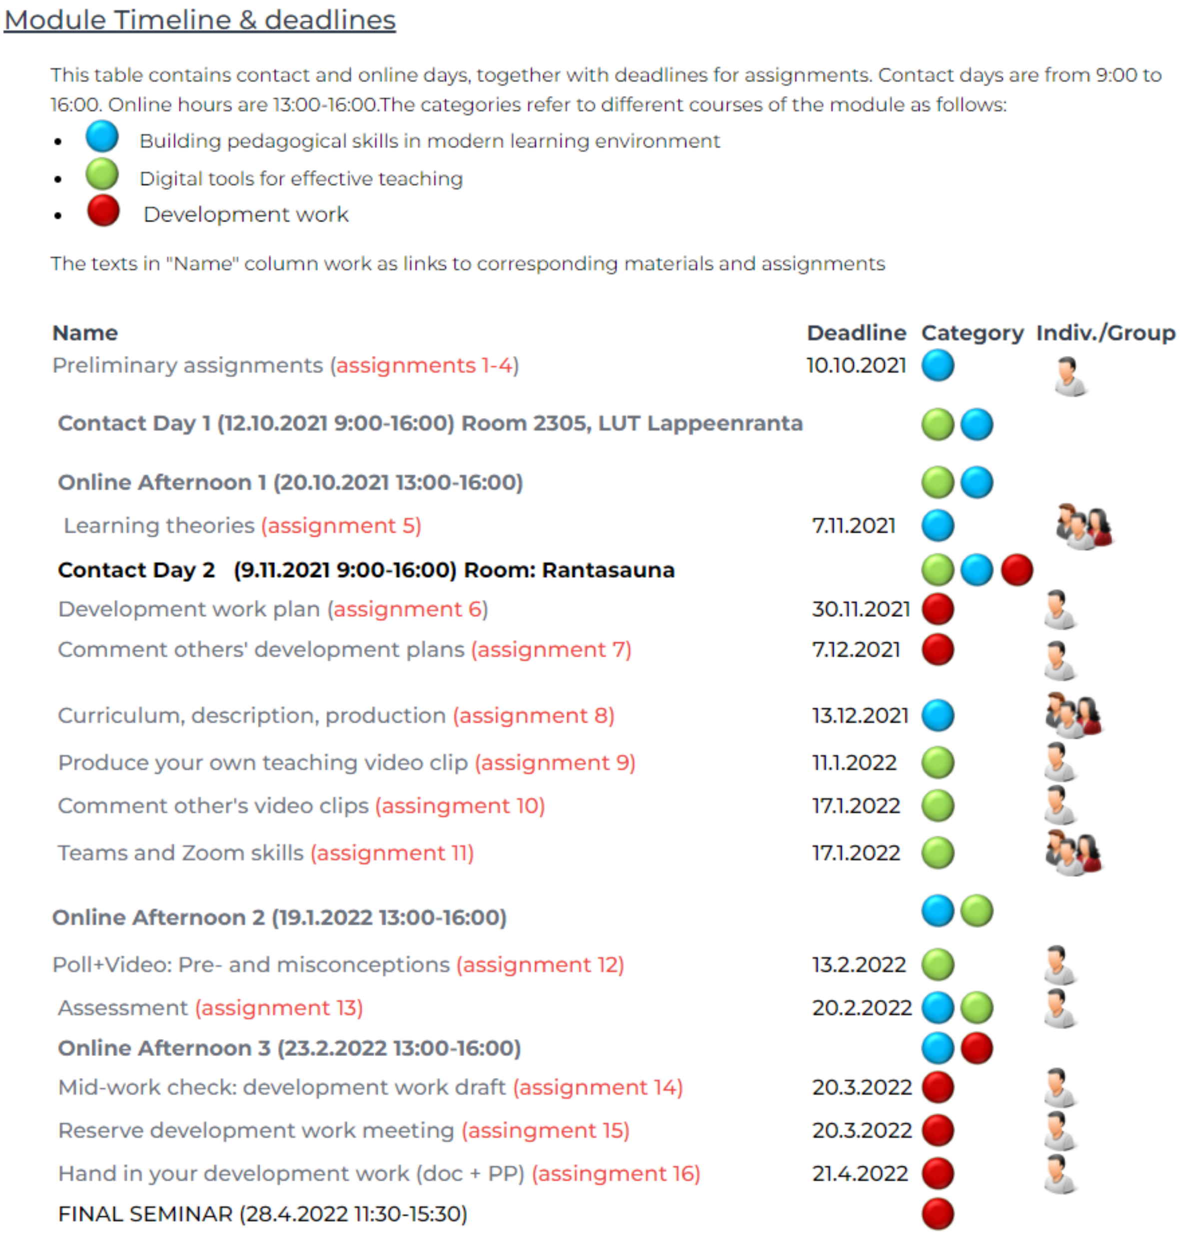
2.2 The module: "University Pedagogy, Basic Module (10 ECTS)"

The first part of the pedagogical training was arranged as a 10 ects module, called "University Pedagogy, Basic Module". Teaching consisted of three contact days, three online afternoons and online guidance sessions. Studying was mostly done online in groups and individually between the contact days and online sessions. For clarity, the materials were divided in three parts and collected under the following titles: "Building pedagogical skills in modern learning environment", "Digital tools for effective teaching”, and “Development work”. All these three themes formed an intertwined and coherent entity, and they couldn’t be accomplished separately. Instead, participants were expected to accomplish the whole study module of 10 ects as a whole. To help the participants to keep on track and to meet the deadlines, all assignments were shown as a timeline list in the beginning of the Moodle contents. The lines of the list were links to the corresponding material, assignments or site in the Moodle. A screenshot of the timeline is shown in Figure 2.



Module Timeline & deadlines

This table contains contact and online days, together with deadlines for assignments. Contact days are from 9:00 to 16:00. Online hours are 13:00-16:00.The categories refer to different courses of the module as follows:

- Building pedagogical skills in modern learning environment
- Digital tools for effective teaching
- Development work

The texts in "Name" column work as links to corresponding materials and assignments

Name	Deadline	Category	Indiv./Group
Preliminary assignments (assignments 1-4)	10.10.2021		
Contact Day 1 (12.10.2021 9:00-16:00) Room 2305, LUT Lappeenranta			
Online Afternoon 1 (20.10.2021 13:00-16:00)			
Learning theories (assignment 5)	7.11.2021		
Contact Day 2 (9.11.2021 9:00-16:00) Room: Rantasauna			
Development work plan (assignment 6)	30.11.2021		
Comment others' development plans (assignment 7)	7.12.2021		
Curriculum, description, production (assignment 8)	13.12.2021		
Produce your own teaching video clip (assignment 9)	11.1.2022		
Comment other's video clips (assingment 10)	17.1.2022		
Teams and Zoom skills (assignment 11)	17.1.2022		
Online Afternoon 2 (19.1.2022 13:00-16:00)			
Poll+Video: Pre- and misconceptions (assignment 12)	13.2.2022		
Assessment (assignment 13)	20.2.2022		
Online Afternoon 3 (23.2.2022 13:00-16:00)			
Mid-work check: development work draft (assignment 14)	20.3.2022		
Reserve development work meeting (assingment 15)	20.3.2022		
Hand in your development work (doc + PP) (assingment 16)	21.4.2022		
FINAL SEMINAR (28.4.2022 11:30-15:30)			

Fig. 2. Moodle timeline, assignments and deadlines.

The learning objectives were described as skills – after completing the module the participants are able to: 1) Use an interactive and instructive working method, 2) Build courses and material in pedagogically meaningful way, 3) Select suitable pedagogical methods, 4) Select suitable education technology for the students depending on the situation and learning environment and Justify the choice of this technology, and 5) Assess learning and competencies in varying ways.

The topics covered were (at the title level):

- Learning Theories
- Activating teaching methods
- Curriculum development
- Different aspects of assessment
- Video tools
- Polling as an activating method
- Learning analytics,
- Pre- and misconceptions,
- Learning management systems
- Own teaching videos.

The idea of the “Development work” was to take the learned skills and the acquired knowledge into use immediately. The participants were asked to choose one of the courses they are currently teaching or will be teaching in the near future. They needed to make a plan how to improve the course contents, arrangements, teaching methods etc. according to their own needs. First, they were asked to describe the current status and define the needs for improvements concerning the course. Second, they needed to describe the pedagogical background behind their decisions for improvements. And finally present their solutions for tackling the challenges they had on their course setup.

2.3 Teach as you preach

“Teach as you preach” means that you use the same activating methods with your students (participants) in practice what you expect them to use later in their teaching career. Rather than lecturing or delivering information about engaging and activating teaching practices through traditional approaches, the very same methods are in use on the course and thus the participants can have own experience of the methods from students’ point of view. When starting a new topic, the facilitators first gave a brief introduction. This was accompanied by polling the prior understanding of the topic. Anonymous polling was used to create a safe learning environment in which every participant felt safe to bring her/his opinion to the discussion. When contradicting points of view emerged, group discussions were initiated to widen the perspectives of all participants, including that of the facilitators. Many of the assignments included group working, discussions in small groups, self- and peer evaluation of the participants outputs etc. For example, when dealing with different learning theories, the participants were first asked to study individually, then collect a summary of the characteristic features of different theories in small groups. After this they were asked to evaluate different parts of the ongoing course “University Pedagogy, Basic Module” and the actions of the facilitators from learning theories perspective. Which parts of the teaching were based on socio-cultural learning theory? How can you tell? Which actions and assignments had characteristics of connectivism? How can you tell? etc. Similarly, when discussing about how to build a clear and pedagogically planned Moodle site, the participants were given an evaluation rubric and asked to use it to evaluate the very course “University

Pedagogy, Basic Module”. This was then again followed by a discussion of the findings and different points of view. Since the participants came from engineering departments, many of the activating demonstrations and examples were picked also from engineering education.

3 RESULTS

3.1 Feedback survey

Microsoft Forms was used to collect the feedback about the module and participants’ personal perception of their own learning of the topics. Most of the questions were presented on 7-point Likert scale accompanied with optional free text field. The number of questions was purposely kept low and thus the average answering time was 13 minutes. The answer rate was 65 %, calculated from the active participants at the end of the study module.

3.2 Learning gains

The perceived learning gain was measured by asking the participants two questions about the course contents and topics: 1) “How much do you feel that you know about the following topics/skills at the moment?” 2) “How much do you feel that you knew about the following topics/skills at before this 10 ects basic module?”

The answer distribution to the first question is presented in Fig. 3. Most of the participants seem to consider their current knowledge of the topics to be way above neutral (4), some even at the level of expert.

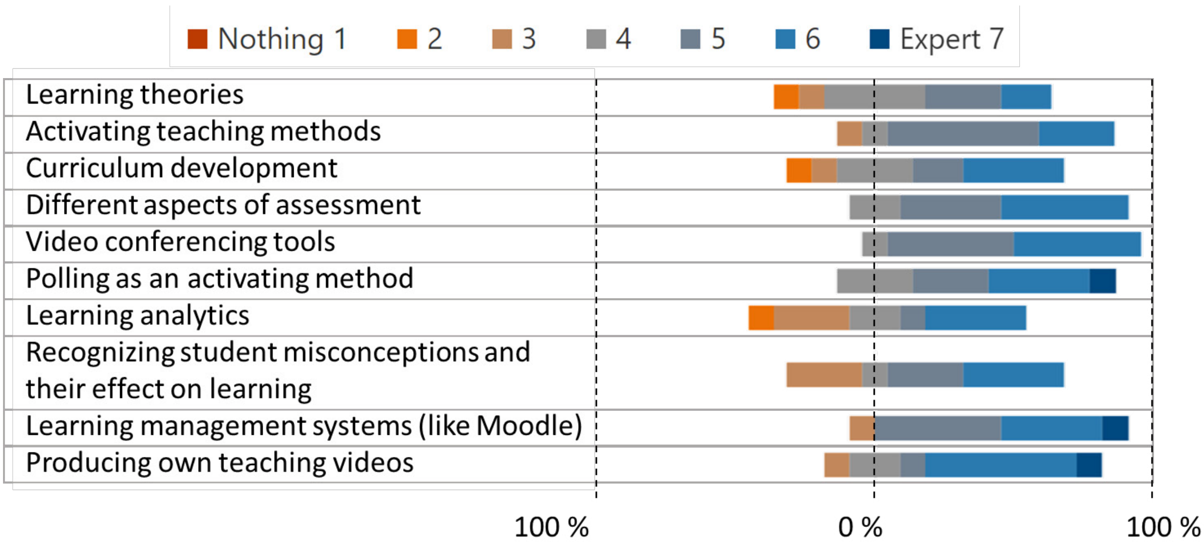


Fig. 3. Answer distributions to question “How much do you feel that you know about the following topics/skills at the moment?”. 1= Nothing, 7=Expert.

The perceived knowledge before the module is presented in Fig. 4. Not many of the participants were familiar with the course topics and many of the answers are either 1 or 2 (nothing or almost nothing). Thus, the study module served its purpose and the participants feel that they have learned a lot. This perceived learning gain is presented in Fig. 5. It is calculated by taking the averages of answers to different topics from figures 3 and 4. The beginning of the arrow represents the answer average before this study module and the end represents the average after it. Thus, the length of the arrow shows the average perceived gain in a certain topic.

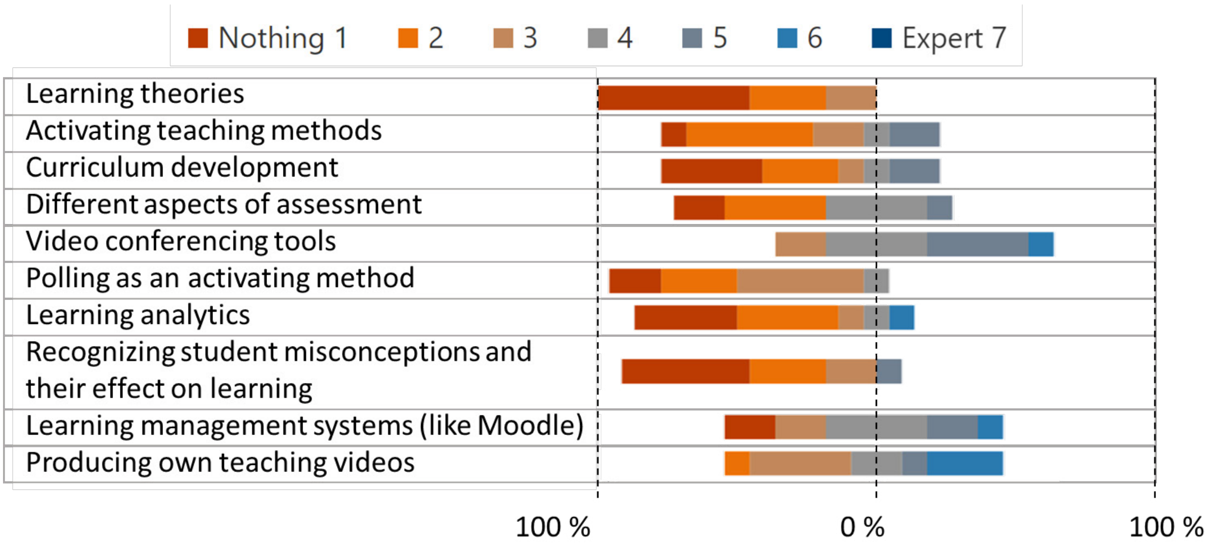

Fig. 4. Answer distributions to question "How much do you feel that you know about the following topics/skills before this 10 ects basic module?". 1= Nothing, 7=Expert.

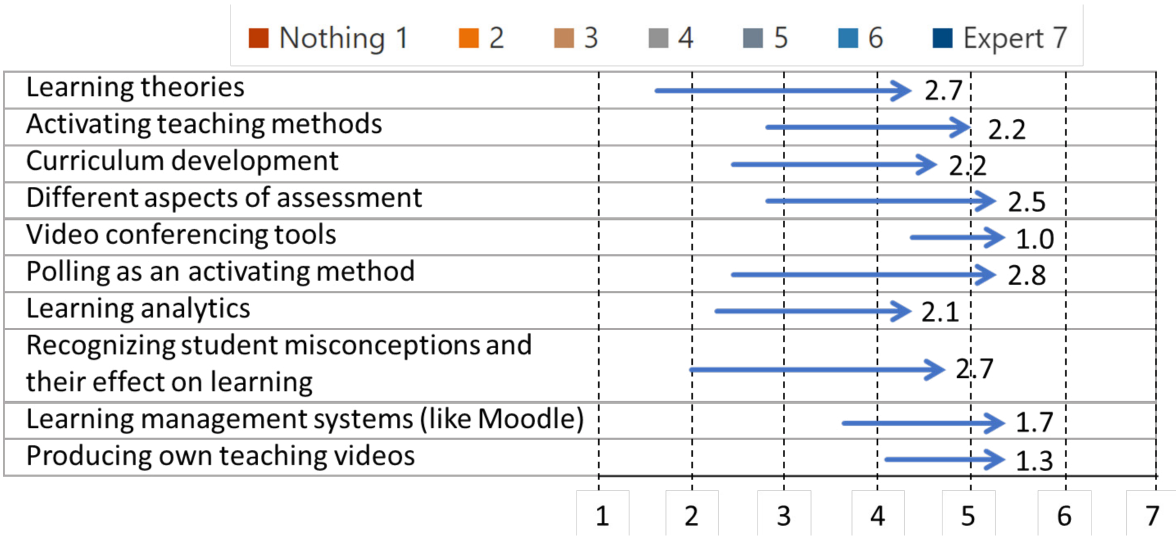

Fig. 5. Perceived learning gains on different topics of the study module.

In many of the topics the gains were remarkably high: polling (2.8), learning theories (2.7) and misconceptions (2.7). On the other hand, video conferencing tools and producing own educational videos were already familiar to the participants, probably due to the Covid-19 pandemic, and thus the gains were the smallest.

3.3 Importance of the module topics

The participants were asked to evaluate the importance of the different topics covered in the training in a scale 1 (not important at all) to 7 (very important). The answer distributions and averages are shown in Fig. 6. The two most important topics were Moodle and production of own educational videos. These choices are quite natural, since Moodle is used to deliver courses, teaching contents and assignments and videos are one main content delivery method. In these topics the learning gains (Fig. 5) were not the highest, but at the same time the levels were high. This tells that these topics are considered very relevant and necessary even though the participants were already rather skilled in them before the training module. The two topics that the participants were the least familiar with were learning theories and student misconceptions. The latter gained also rather hight score in the importance rating (6.0) and its learning gain was among the top three (2.7). Thus, it seems that the participants realized how much of a barrier misconceptions form to learning - an essential point of view in constructivistic learning theory.

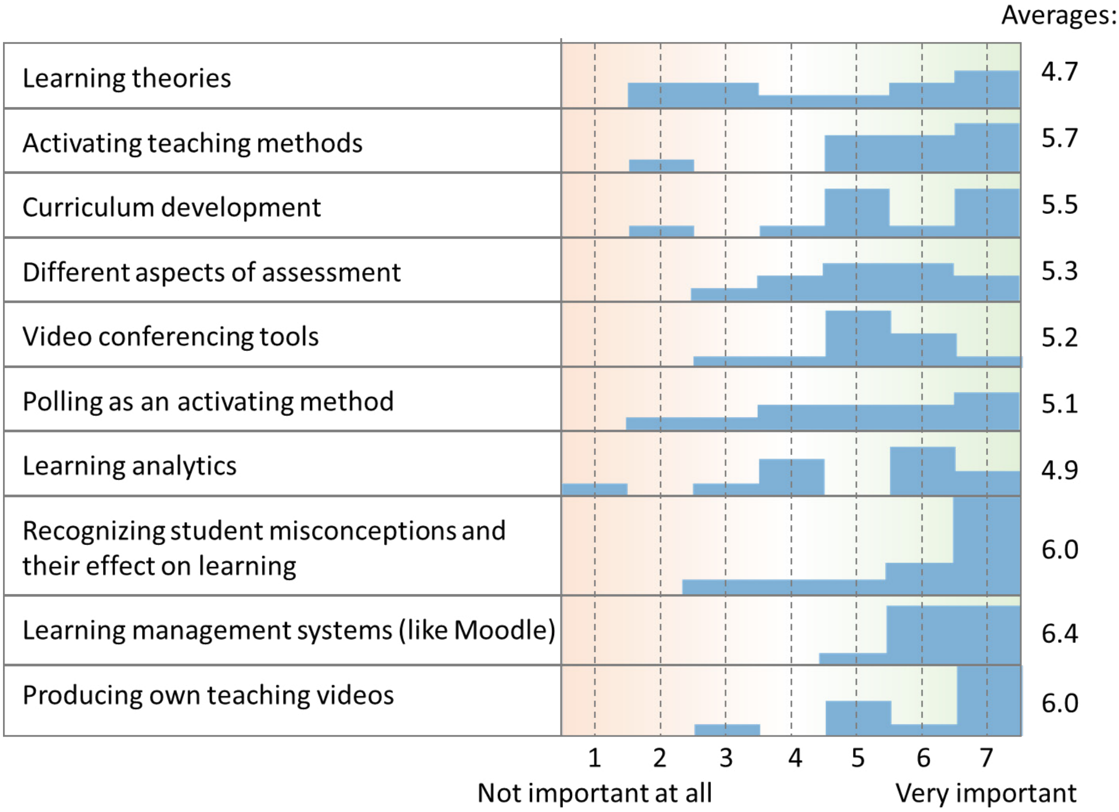

Fig. 6. Participant answer distributions and averages importance of the different topics covered in the pedagogical training.

4 SUMMARY AND CONCLUSIONS

We have briefly shown what kind of elements the pedagogical training had, what kind of topics were covered and how the “teach as you preach” principle was applied in facilitating the course. The participants’ experienced learning gains were found to be rather high and the participants found the topics relevant for their teaching career. It would be interesting and informative to interview the participants after a couple of years of teaching career: how would they then see the course and the skills it provided? What impact the pedagogical training had on their teaching career? Etc. Unfortunately, these questions can be answered only in the future.

Conference Key Areas: *Sustainability. Sustainable Development Goals.*
Keywords: *digital era, challenges for education, new competences, social responsibility*

ABSTRACT

New challenges in the field of digital transformation and content conveyed in the education process, in particular engineering sciences, triggered a discussion on the identification of issues focused on forms of cooperation with recipients using the available tools and taking into account the individual predispositions and knowledge of students related to their soft and hard competences. The subject of the paper is an attempt to identify students' soft competences on the basis of observations during the digital transformation period in 2020-2021.

Technology has a significant impact on education, but also human and social factors have a significant impact on shaping the new future of universities, especially those with an engineering profile. The experience of the last 2 years shows the need for an integrated approach to the education process, which should take into account the content provided in combination with a properly selected form of cooperation with recipients using the available tools and taking into account the individual predispositions and knowledge of students (attention should be paid to the so-called soft and hard skills).

doi:10.5821/conference-9788412322262.1405

1 INTRODUCTION

Educational processes, in particular in the field of engineering sciences, are clearly associated with the digital transformation in the life of societies on a global scale, as well as with changes taking place in industry and broadly understood business. An important document indicating the occurrence of various types of changes in the world and the need for systemic action is included in the United Nations 2030 Agenda for Sustainable Development (SDG, 2015).

Digital transformation is the result of a combination of information, communication and artificial intelligence, which is associated with transformation in thinking and acting, as well as interoperability and a transdisciplinary approach to perceiving and solving engineering problems. In (Guerduer et al, 2022), the authors state that the skills of students and educators in the learning process are key. There is a shift away from classical skills (reading, writing, arithmetic) to new skills and competences focused on big data (data mining, sharing, modeling) and related to critical creative thinking and the possibility of human interaction with intelligent machines. Moreover, it has been found that students are currently able to obtain specific knowledge from sources other than traditional forms of communication at the university and are able to pass the exams of the course without having to attend formal classes.

In the paper (Guerduer et al, 2020) it was stated that the currently developed cyber-physical systems (CPS, Cyber Physical Systems) are a significant challenge for the education process with an engineering profile. It was found that solutions aimed at a different form of delivered content should be sought in connection with the interdisciplinary integration of data and data labels with digital programs and educational methodologies, taking into account the need for quick adaptation to changing working conditions.

The paper (Doyle-Kent & Watson, 2021) proposes the idea of a global engineer type who works in an international socially diverse environment requiring hard (technical) and soft (non-technical) skills. Related to these challenges are the need for lifelong learning, in particular the need to learn in real work environments.

The paper (Pursula et al., 2005) presents the concept of the development of virtual universities in Europe. It was found, inter alia, that with virtual teaching, new pedagogical issues will be released, as the work environment will be significantly different from that to which lecturers and students are used to.

In the paper (Miranda et al, 2021), the authors formulate conclusions regarding the challenges for the engineering education process in the period of digital transformation. The conclusions concern the development of: competences (especially critical), new learning methods, digital tools (information and communication technologies), infrastructure for education.

Technology has a significant impact on education, but also human and social factors have a significant impact on shaping the new future of universities, especially those with an engineering profile. New challenges in the field of digital transformation in the field of content conveyed in the education process, in particular engineering sciences, triggered a discussion on the identification of issues focused on forms of cooperation with recipients (students) with the use of available tools and taking into account the individual predispositions and knowledge of students related to their soft skills and hard. The subject of the paper is an attempt to identify students' soft competences on the basis of observations during the digital transformation period in 2020-2021.

The paper presents the observations of the effects of introducing a new learning environment (digital, and earlier learning process and achievements) in connection with the psychophysical properties of the student and the acquisition of knowledge and good practices in the new complex reality. Formulating the methodology of education in the new reality is not an easy issue and constitutes a significant challenge for educators in connection with new business models. Development of the presented issues is planned in the future.

2 OBSERVATIONS AND RESULTS

The global pandemic situation forced in 2020 a rapid digital transformation of educators and the available infrastructure for the education process of students. An additional effect of the situation that has arisen is the discussion on a new approach to education processes perceived jointly in relation to: the addressee (the resources of available knowledge, competences and skills, their health and mental state, educational susceptibility and motivation), evolutionary changes in the labor market in a global system and anticipated needs in terms of the competences and skills of employees and academic teachers (resources of substantive knowledge, competences and skills, health and mental condition, knowledge and practice in the field of methods and tools useful in the education process, motivation). This paper presents observations and conclusions from the period of rapid transformation of the process of training engineers from traditional (in-presence) to remote digital (on-line).

The following research issues were identified::

1. strengths and weaknesses of remote or mixed learning (limitations in the implementation of practical and blackboard classes, targeted debates, consultations, distribution of educational materials, lecture formula);
2. methods of activating students to the learning process, ways of becoming interested in a specific topic of classes;
3. selecting appropriate methods for conveying the educational content;
4. digital techniques in the education process and digital competences of the teacher and student;
5. planning classes / training;
6. the essence of the pedagogical approach to students in the education process;
7. personality characteristics of students and educators;
8. loneliness of the educator and participant of didactic classes / training;
9. fatigue and burnout of partners in the education process;

It was noticed that the formula of webinars and online meetings allowed for the construction of a new space for conveying specific content, and also for group debates focused on good practices in the education process, getting to know meeting participants, the possibility of being listened to and positively motivated to act. The formula of debating and educating with the use of digital techniques was the expected solution after a long period of physical isolation of the participants of the education process and a specific form of social therapy.

A new digital community of academic teachers and students was created, who together began to discover new issues (phenomena, areas for development) important in the process of education and professional work. For example:

1. difficulties in reading and listening to the transmitted content with comprehension and assimilation. The expectations of students in terms of special substantive care, targeted counseling and shaping and supporting the process of making targeted decisions are observed.
2. personal competences of the educator and student expressed, among others, by: self-awareness (recognizing emotions, self-esteem), self-management (stress, coping with stress, self-motivation and self-discipline), building relationships with the listener (communication, conflict resolution), empathy (emotional type: the ability to feel other people's mental states, cognitive type: the ability to adopt the way of thinking and perceiving reality by other people), assertiveness (having and expressing one's own opinion without aggressive behavior while maintaining good social habits), the ability to make decisions (problem solving, analytical thinking, responsibility).
3. methods of activating educators and students to the learning process, building a relationship between the student and the teacher, appreciating the pedagogical aspects of the teaching process, intergenerational communication.
4. storytelling in education. Building a specific targeted plot around the product / technical object (object, operation, functions, power supply, disturbances) using the commitment and emotions of the recipients (students) and their positive associations or creating specific needs among them.
5. procrastination in education. Voluntary, deliberate delay in carrying out the intended actions resulting in a short-term improvement in well-being, followed by time stress in connection with the ability to accurately and correctly perform the planned activity. Emotions and impulsiveness (including the desire to obtain immediate reward) negatively affect the concentration and own management of the perception and time senses (the consequence is postponement of the task and possible negative emotions). Depressive and dysthymic disorders as well as anxiety disorders associated with possible failure (expressed inability) are observed, which lead to frustration (specific protection of self-esteem), passive-aggressive behavior and the phenomenon of professional burnout.
6. living under stress and seeking strong sensations resulting in the illusory awareness of mobilization to meet a difficult challenge with perfect implementation.
7. anxiety about failure or success, helplessness or isolation and intimacy.

8. digital wellbeing in education (digital wellness). Digital well-being of lecturers and students who implement the educational process, related to the promotion of maintaining their healthy lifestyle with the use of available digital technologies. Example of negative impact of digital technologies: abuse of social media, educator and student productivity (maintaining the balance between work / education and private life).

The presented selected issues require the development of solutions (methods and tools), and then the formulation of a methodology for transferring knowledge and practice in a systemic manner that fits into the current and future business requirements.

The paper has a reflective character in which digital and soft student skills are analyzed.

Today's reality forces us to look for teachers who teach new advanced technological systems. In particular, trainers who teach how to code human behavior, clarifiers that link technology and practice, leaders who can explain the technology used, supervisors who maintain advanced twin systems oriented towards sustainable development in practice.

Education changes people and infrastructure, ensures people's well-being and is a source of intellectual and economic development. A systemic approach to education and safe human activities in a specific environment is related to sustainable development. Education for sustainable development should be a source of knowledge and conscious human action focused on the individual and community, prepare young people for the ability to undertake transformational activities for sustainable development

3 SUMMARY

Education never ends. The experience of the last 2 years indicates the need for an integrated approach to the education process, which should take into account the content provided in combination with a properly selected form of cooperation with recipients using available tools and taking into account the individual predispositions and knowledge of students (pay attention jointly to the so-called soft and hard competences). The proposed systemic approach to the issue is in line with the United Nations 2030 Agenda (in particular, goal 4: good quality of education) in terms of promoting a sustainable lifestyle and educating about sustainable development throughout life. The cooperation between educators inside and outside the university is easier, their joint purposeful mobilization is easier. The learning paradigm and teaching methods require improvement with a focus on digital transformation of educators and infrastructure in the process of educating students. New digital technologies should also be taken into account, for example: mobile computing, the Internet of everything combined with machine learning.

Engineers with specific knowledge and competences are key in achieving the sustainable development goals set out in the 2030 Agenda. New integrated technical, social, environmental and economic challenges are formulated before the engineering staff. Meeting the new challenge is possible as a result of implementing holistic engineering education combined with innovations oriented towards sustainable development. The consequence is the need to build engineering programs that inspire creativity and new creative thinking.

With the process of technological development, the society and its successive generations are also changing as they interact with the Internet and its services and, to a certain extent, autonomously. Noticeable psychophysical changes in society translate into the need to pay attention to the so-called soft skills of students and lecturers, which require improvement. The article attempts to identify students' soft competences on the basis of observations during the digital transformation period in 2020-2021 that require inclusion in shaping hard competences. Moreover, attention was drawn to the necessity of lifelong learning with the use of available resources as well as digital tools and methods, a transdisciplinary approach to the educational process, and the improvement of human-technology-environment interactions.

ABSTRACT

We propose a method that uses an emotion analysis for PBL education. The emotion analysis is a method of analyzing a person's emotions from the person's remarks or facial expressions. In this method, teachers understand the situation of students from the results of the emotion analysis and give accurate advice.

PBL education often involves group activities. The students conducted groups discuss, propose ideas, select ideas, and make the products. However, not all students are able to participate in discussions and express their opinions. It is the teacher's duty to provide guidance to such students. Therefore, we propose the use of the emotion analysis techniques to identify and guide students who have problems, such as those who cannot participate in discussions. The method is possible for one teacher to grasp multiple groups at the same time and to help developing the students' ability to learn.

Under COVID-19, face-to-face classes were restricted. Online classes using Zoom etc. have also been introduced in PBL education. In online classes, it is difficult to grasp the situation of students. This was a big difference from face-to-face classes. So we looked at ways to keep track of the situation for all students. This is because the gap between students who are willing to take classes and those who are reluctant to take classes has widened due to the shift to online classes. As a result of the adaption to the classes, the number of students who actively participate in the classes has increased. The effectiveness of the proposed method was confirmed.

doi:10.5821/conference-9788412322262.1143

1 PBL EDUCATION UNDER COVID-19

The educational environment has changed a lot under the influence of COVID-19. The Japanese government issued the first state of emergency and expanded it all over the country in April, 2020. Figure 1 shows the poster that explains the items that should be followed to prevent the spread of COVID-19. The important instruction is "Avoid the three Cs"! Which means to avoid Closed spaces, Crowded places and Close-contact settings. In response to the state of emergency, Kanazawa Institute of Technology (KIT) forbade the student from coming into all the campuses. Classes were started as online classes on April 20. Group discussion in the classroom indispensable for PBL became impossible.

In the Covid-19 vortex, PBL education changed its teaching format from face-to-face to online classes. The problem there was so the difficulty of group activities in online classes. The problem with group activities was that when students were divided into several groups and worked in groups in breakout rooms, the teacher could not fully grasp the students' situation. The teacher can check each group in turn in the breakout room, but the teacher cannot see the whole group at once. To solve this problem, we built a system to support PBL education called "automatic meeting minutes creation system," which is part of AI teacher [1, 2]. AI teacher has a function to keep audio recordings of group activities as text. By utilizing this function, the teacher can give appropriate advice to each group [1, 2, 3]. However, it is time-consuming to understand students' situations from texts. Therefore, we added emotion analysis [4] to this function to improve the teacher's ability to grasp the situation visually.

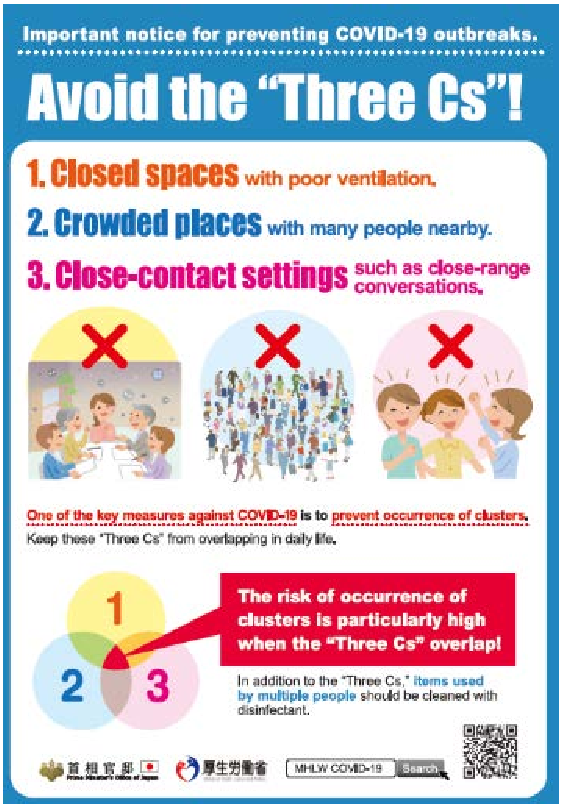

Fig. 1. Items that should be followed to prevent the spread of COVID-19

1.1 “AI teacher” system configuration

We are developing "AI teacher" for Project/Problem Based Learning (PBL) education using coaching technology. Figure 2 shows the overall structure. The goal of AI teacher is to provide all students with the best possible support and help them reach their full potential. Since it is difficult to increase the number of teachers in charge of classes, we decided to use AI technology.

Students can use chatbots of AI teacher as virtual teachers. They can ask questions that they wonder about in class. Students can also request advice when students are not sure what to do next. The chatbot will provide suggestions based on accumulated past examples. The faculty member checks if the answer is given correctly and registers the answer if there is a problem. This process will help to ensure that good answers are given.

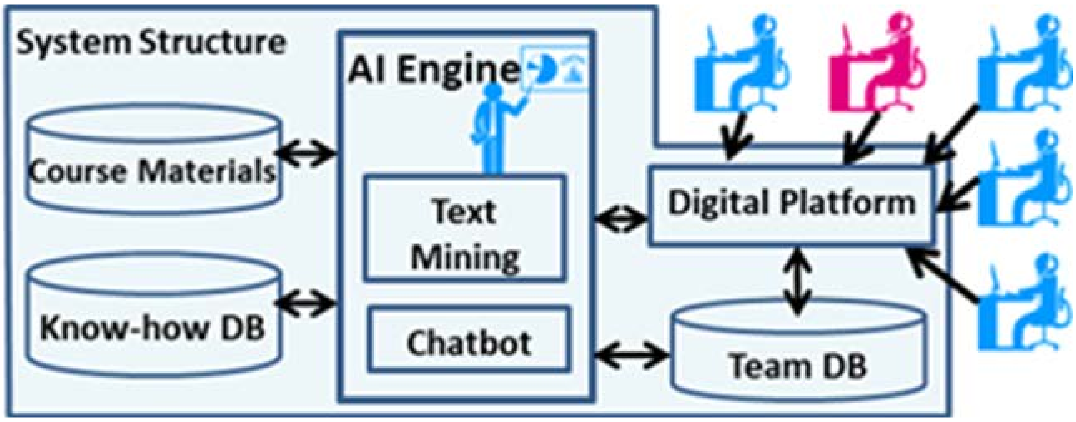

Fig. 2. “AI teacher“ configuration

We used AI teacher's minutes function to solve the difficulty of understanding students' attitudes toward the class, which was a problem in online PBL classes [2]. The minutes function allows teachers to keep all of students conversations in text form. It also records who said what. This makes it possible to keep track of the situation even if the teacher is not present. The ability to create a summary from the minutes also makes it easier to understand the content. In addition to these functions, we have added the ability to understand the students' situation through the emotional analysis. Figure 3 shows an image of the emotion analysis results displayed on the screen. Teachers can monitor student status at a glance.

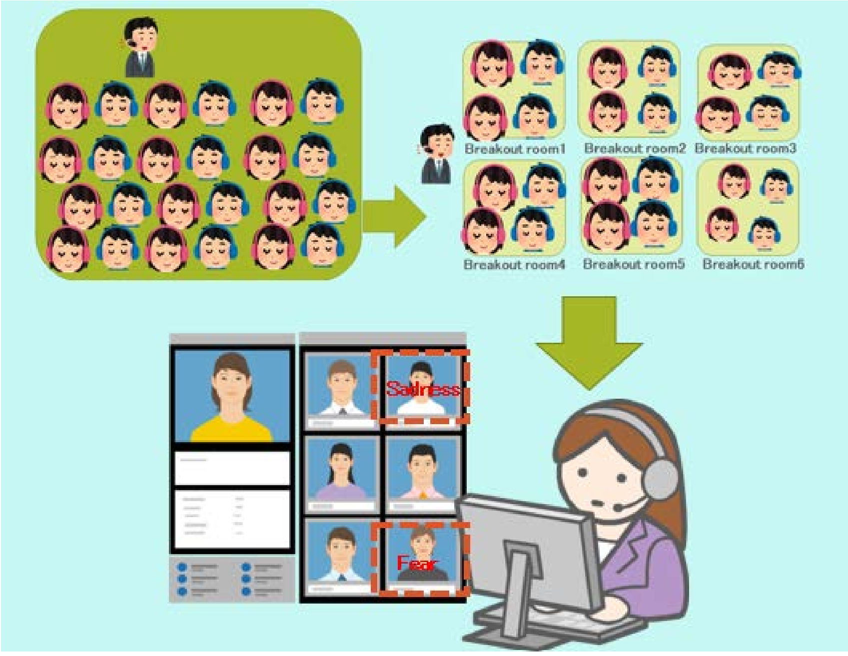

Fig. 3. Using emotion analysis to solve the difficulty of understanding students' learning attitudes in online-based classes

1.2 Emotion analysis

There are four main types of emotion recognition AI today as follow.

- "Voice emotion recognition AI" is a mechanism that recognizes emotions by analyzing physical features such as "voice intonation" and "voice loudness" without depending on a specific language such as Japanese or English.
- "Sentence emotion recognition AI" is a mechanism in which AI reads and analyzes sentences (text) input by humans by natural language processing to judge emotions.
- "Facial expression emotion recognition AI" can read the emotions of the other person from the facial expressions, just like humans do in normal communication. The mechanism is to use a camera that can capture small changes in movement to read the size of the line of sight and pupils and infer human emotions.
- "Biological data emotion recognition AI" is an AI that recognizes human emotions based on data such as biometric information, brain waves, heart rate, and vitals.

We used the sentence emotion recognition AI because it was easier to use online[4, 5, 6, 7, 8].

For the emotion analysis, 8 emotion scores of "anger, fear, disgust, joy, sadness, anticipation, trust and surprise" are extracted and normalized based on the positive and negative evaluations that evaluate the positiveness of students and the basic 8 emotional ideas. We use two popular theories of motivation: the“hierarchy of needs” of Maslow (1943)[6] and the“basic motives” of Reiss (2004) [7] to compile 5 coarsegrained and 19 fine-grained motivation categories, shown in Figure 4. Our system allows them to check the state of the discussion using colors.

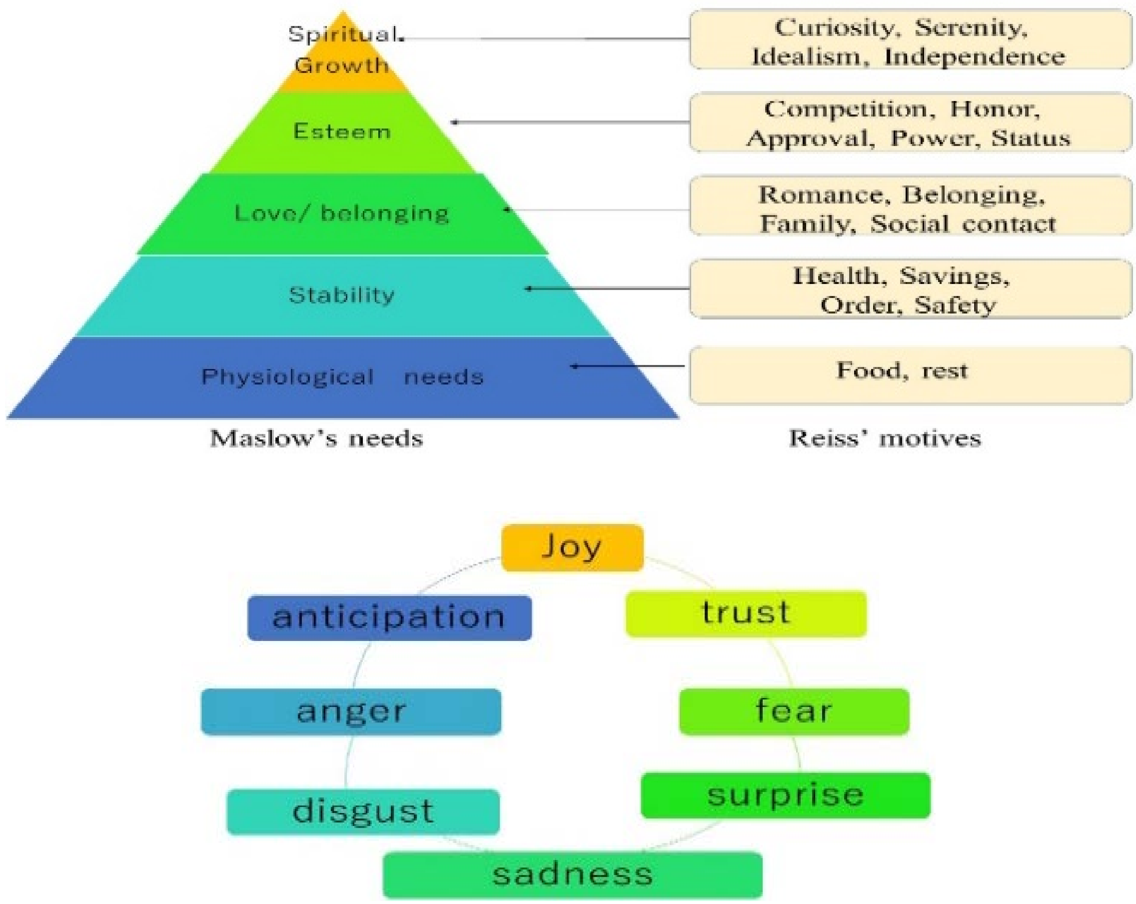

Fig. 4. Theories of motivation (Maslow and Reiss) and emotional reaction (Plutchik)[5].

2 EMOTION ANALYSIS FUNCTION OF AI TEACHER

In this paper, we will introduce the mechanism and effect of group activities supported by AI teacher. And we explain the automatic meeting minutes creation system which is a part of AI teacher. In particular, we introduce the function of notifying the teacher of a student's emotional changes. And we explain the results of its use.

When actually using the automatic meeting minutes creation system, it was difficult to grasp multiple groups at the same time by reading the texts of meeting minutes, and we came to the conclusion that a mechanism that can grasp the situation visually and intuitively is necessary. Therefore, we examined the application of emotion analysis technology.

Automatic meeting minutes creation system performed emotion analysis on the text data, and visualize the results by color. The teacher looks at the screen, If there are many negative colors, teacher read and understand what the students are saying and gives advice. Figure 5 shows the Image of the results of positive and negative evaluations. Figure 6 shows the flow of the automatic meeting minutes creation system for evaluating the student's attitude to participate in the meeting. Students had a meeting by Zoom.

Speaker	Utterance
A	Today I would like to consider an idea.
B	OK。 Where do you start?
C	How about listening to ideas in turn?
D	Eh. I don't like it.
E	It's not good.
A	It's my turn at first.

	Positive
	Neutral
	Negative

Fig. 5. Image of the results of positive and negative evaluations

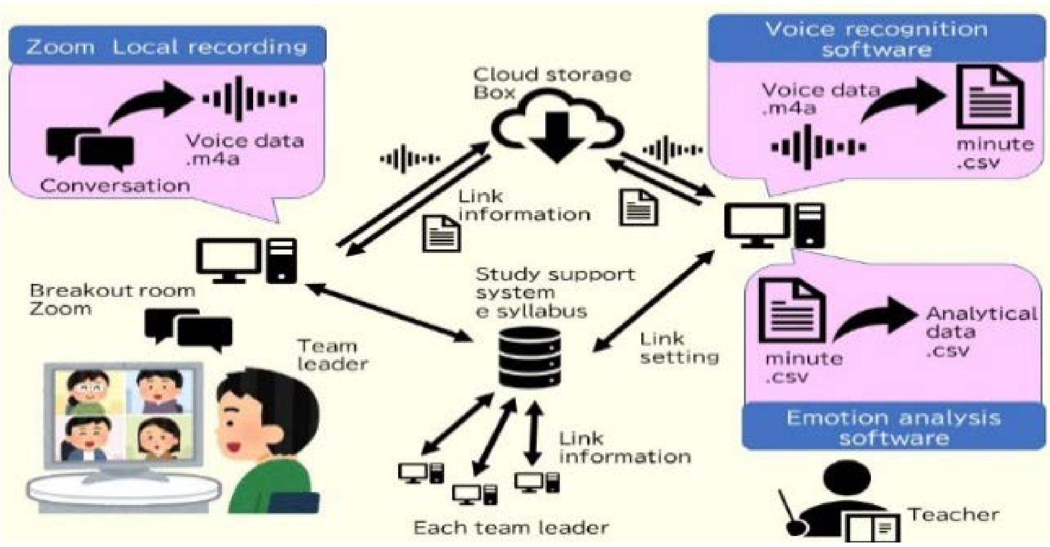

Fig. 6. Flow of Emotion Analysis in a class using Zoom

3 EVALUATION RESULTS

We used an AI teacher automatic meeting minutes creation system in an actual online class. We took a questionnaire at the end of the class. The results are shown in the figure 7. It is a comparison of the class that taught with the AI teacher and the class that did not use the AI teacher. The red bar indicates the degree of satisfaction with the class. We can see that the class using the AI teacher is more satisfying. The teacher commented, "I understood the content of the discussions in each group and it became easier to proceed with the classes." He also says, "Students seem to feel that the teacher supports all the students in detail, and the students are very satisfied." Another teacher noted, "The minutes made it easier for teachers to keep track of what was going on with each team. The assumption that minutes would be taken encouraged reluctant learners to speak up. It increased the involvement of reluctant learners in team activities."

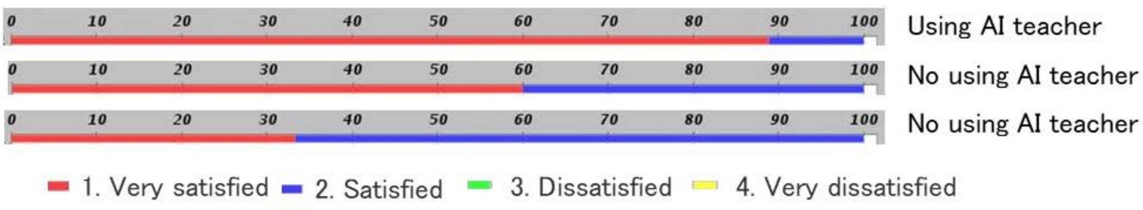

Fig. 7. Questionnaire results regarding classes satisfaction

We asked the teacher to use the emotion analysis function of the AI teacher after the end of semester. The teacher commented, "It is necessary to consider how to use the results of emotion analysis, but I think it is effective for grasping the situation of students."

4 CONCLUSION

We have built a system to support PBL education called AI techer and are currently testing its effectiveness in actual classes. We have also introduced the emotion analysis technology into PBL education and examined methods for evaluating students' attitudes toward participating in meetings.

From 2020, due to COVID-19, we have been going to use online communication tools such as Zoom to provide online PBL education. The problem at this time was that when students were divided into multiple groups and working in groups in breakout rooms, teachers could not keep track of what was going on with the students. The teacher could check in with each group in turn in the breakout rooms, but could not see the whole group at once. This was a major difference from face-to-face education.

Therefore, we used the AI teacher automatic meeting minutes creation system to record all conversations in the breakout rooms. This enabled teachers to check the progress of each group to see who was taking the initiative and who was not participating well. In addition, by utilizing emotion analysis, it is now possible to understand students' emotions. From the evaluation results, it was confirmed that the system is effective in grasping students' attitudes.

ABSTRACT

Remote working enables organisations to have location- and time-independent business processes. Working life practices should also be applied in higher education. Lapland University of Applied Sciences' ICT education in Finland met the challenge by developing an online internship concept that improves cooperation between the university and industry and promotes the content and quality of education. This paper describes the experiences of the research project of online internship models. Oral feedback from students (N = 12) and companies (N = 6)

were analysed along with the online internship concept during 2021. The concept includes three types of process models. Based on the idea that business and industry representatives are active players in the process. The supervising teachers and technical support staff of Lapland University of Applied Sciences (UAS) acted as a support network. Results confirmed the notion of the usefulness and suitability of the concept for the purpose. The marketing of the concept was supported by a process website. The challenges found focused on, for example equipment resources and the pedagogical skills of industry representatives. The concept can be generalised regardless of the field.

1 INTRODUCTION

1.1 Teleworking trends

Internships are an essential part of ICT engineering studies. Digitalisation and the proliferation of telework also call for a review of the professional training included in the studies. The COVID-19 pandemic changed the research design, such that constraints on gatherings and telework recommendations, as well as the response of companies to the former, increased the need to transfer student internships remotely.

In the statistics Finland 2018 Working Conditions Survey, 28% of employees said they work remotely and that 16% of jobs would have allowed them to work remotely, even if they did not do it for one reason or another. Moreover, 3%of employees said their employer did not allow telecommuting [1]. In other words, just over half (54%), or over a million employees, did not consider teleworking possible in their jobs in 2018. This was the response of most teachers, among others [1].

Telework has been exceptionally widespread in Finland during the COVID-19 pandemic, even on a European scale. It has been made possible by well-functioning telecommunications connections, a business structure that emphasises information work and, the fact that binding to the Finnish people alone has suited well.

During the great human experiment caused by the pandemic, about half of the Finnish employees as best worked remotely. In spring 2021, a further 42% were teleworking, of which 8% - including teachers - said they had worked remotely at some point during the pandemic [1].

Even before the COVID-19 pandemic, teleworking had become more common in Finland from 2013 to 2018, posting an increase of 12%. Growth certainly continued during 2019, with the digitalisation of working life accelerating the detachment of work from time and place. In five years the share of teleworkers has risen from 16% to 28% [1].

Educational institutions have begun to recognize the potential of virtual internships in gaining professional qualifications [2]. Virtuality offers organizations the opportunity to find talent globally and internationally [3]. It has been found that the advantages are the same whether the training is performed remotely or FTF (see e.g. [4]).

However, online internship poses challenges for project management and especially for the project manager [5].

1.2 The PracDis project

The PracDis (Practise at a Distance) project was launched at Lapland University of Applied Sciences, Finland, to improve cooperation between the university and companies by enabling remote internships for ICT companies. The project was implemented as a collaboration between ICT engineering and business information technology training. It was launched before the COVID-19 pandemic, but its importance was emphasised during the pandemic. The PracDis project developed a concept for distance learning that considers the perspectives and needs of both students and working life. It also expands the concept of internship to study work. This paper describes the latter part of the project, including the piloting results of the the developed concept. Its background study and concept construction are described in more detail in [6].

This publication is a continuation of a previously published study [6]. It presents experiences with the implementation of the concepts described in the previous work. The following sections describe the methodology and results of the survey. Finally, there are some reflections and recommendations for organisations that may want to try or apply the policies developed during the process.

2 METHODOLOGY

2.1 Developing the concept

The study described in this paper is the second phase of a research in which the concept of an online internship model was developed. The first phase was presented in [6]. The concept was introduced in 2021 and the functionality of the models was piloted with industry and company, the results of which are reported in this paper. To clarify the methodology, the models are first presented in this section.

The concept includes three different models (Table 1) for location-independent internships depending on the student's personal use of time. It works both in the case of one student and as a team or project work implementation. The pilot studies were implemented in 2021 following the process models of the three concept models according to Table 1. A total of 6 business pilot studies were conducted, of which 5 were micro-enterprises and one large scale enterprise. Thresholds following Article 2 of the European Commission (2020) were applied to the classification of enterprises [7].

Table 1. Pilots and number of participants

Model of online internship concept	**Description**	**Participants in pilot**
Model A Online Internship: Individual format implementation	The student completes the internship as an individual within the credits specified in the curriculum for the internship	5 companies, 5 students (2 pilots interrupted)
Model B Extended Online Internship: Individual or project format implementation	In addition to the credits allocated to the internship, the student also completes the studies of the professional subject according to their requirements.	1 company, 3 students
Model C Academy Model: Project format implementation	The student completes the professional subjects according to the curriculum during the semester. The student team is disconnected from the regular tuition and timetable for the semester.	2 companies, 5 students

The process for model C is shown in Figures 1, 2, and 3. Figure 1 illustrates the process for the starting phase of model C, in which the student team and industry representatives work together to develop plans to complete the project with the goals of both parties in mind. Communication and documentation take place on a common teamwork platform, such as MS Teams.

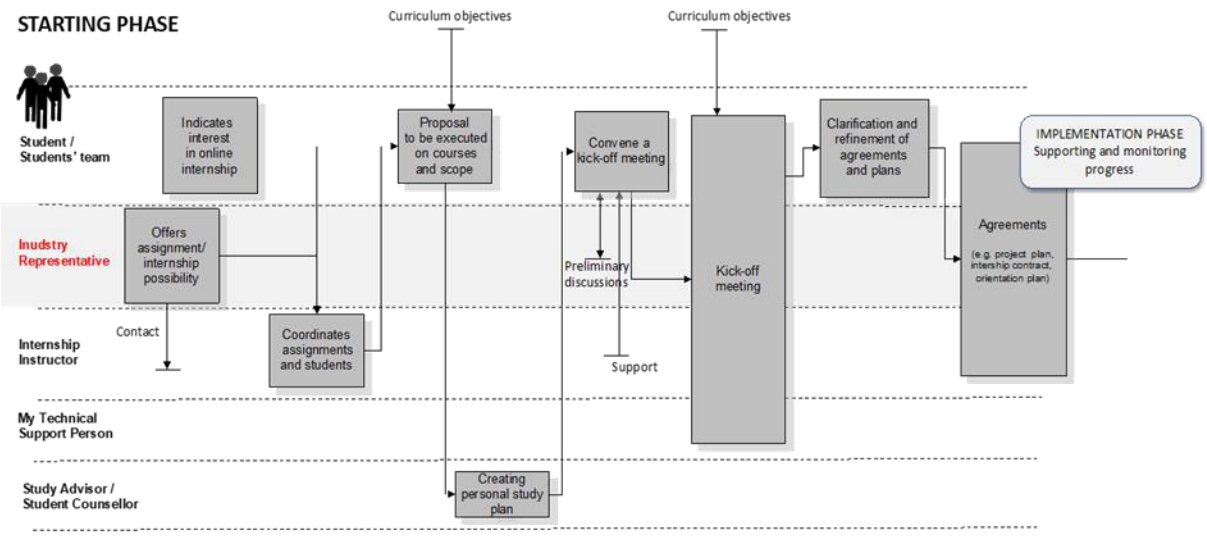

Fig. 1. Process model of the starting phase [1]

In Figure 2, the project is carried out iteratively using agile methods such as Scrum [8]. In addition to the teamwork platform, version control tools and digital development tools are shared. Progress is regularly monitored through reviews. The university's technical support person and internship instructor will support project implementation and process when necessary.

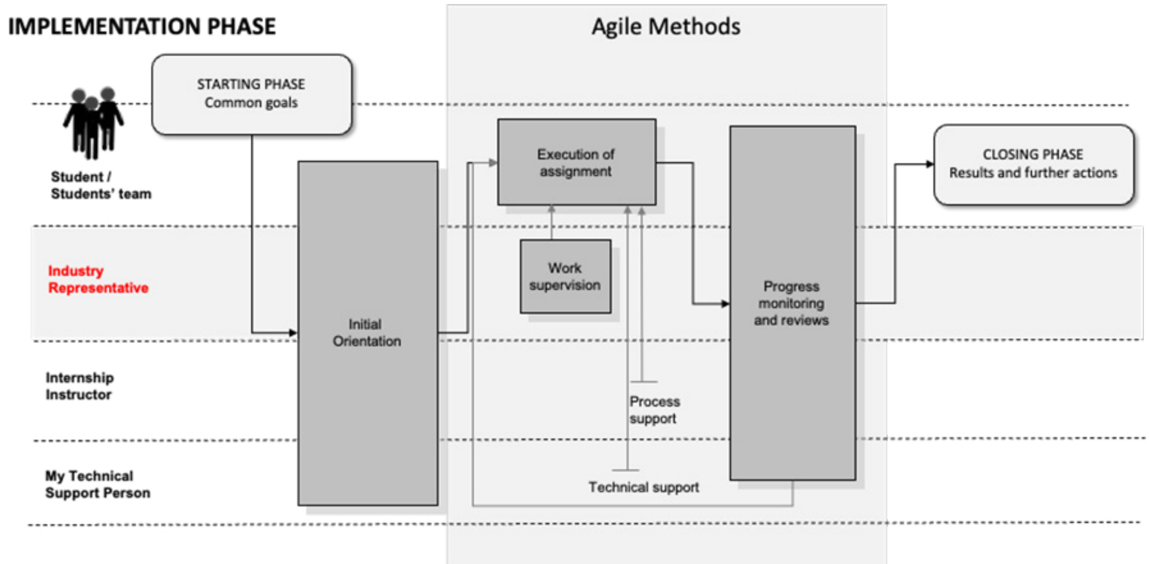

Fig. 2. Process model of the implementation phase [6]

Figure 3 shows the closing phase of model C, which includes, in addition to the evaluation, a decision seminar or event in which, in addition to the summary, mutual feedback takes place. Furthermore, students are encouraged to create a demonstration, such as a video trailer, poster or brochure, that will be published on the organisation's page or another service for students to use as a reference in their job search. For the institution, it works, for instance as a merit for university industry cooperation.

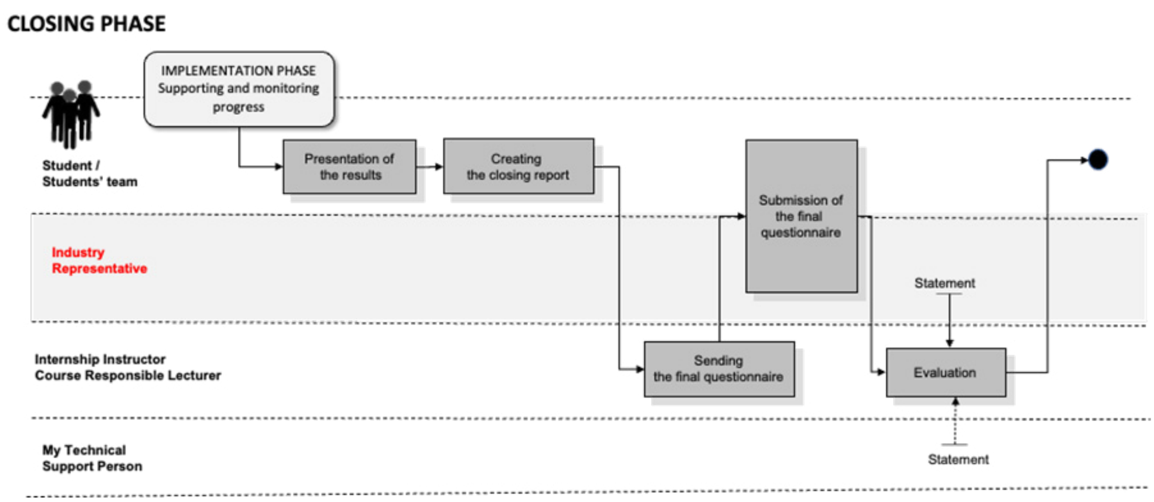

Fig. 3. Process model of the closing phase [6]

The thoughts, expectations, and experiences of the students and the participating companies were collected throughout the process. The majority of feedback and experiences were received orally at the progress review or in the final seminar included in the processes. Students and company representatives were free to share their experiences, successes and failures, as well as ideas for developing concepts. A memorandum was prepared for each session, in which comments and suggestions for improvement were recorded. The contents of the memos were compiled into a single document and the material was analyzed using content analysis methods.

3 RESULTS

3.1 Model A

According to the feedback from the student concerning model A, the internship period went well and the employer was committed to the activity. Students perceived receiving enough information about the internship but had only a few situations where support from the institution was needed. They were particularly pleased to be able to complete the internship online, but some of them felt that their personal computers were not efficient enough for the purpose smooth editing videos requires a powerful graphics controller. thus, the availability of necessary equipment during the internship should be agreed upon with the employer.

According to the employer's representative, the internship likewise went well. Information was sufficient on how the internship was progressing, what was happening at each stage and what the goals were. The process models were clear to understand. According to the company representatives, students’ adaption for online work proceeded smoothly. However, companies may not be able to act in online learning if they lack the understanding and ability to provide, lead and operate communication activities. The suggestion was that online working and communication should further consider an introduction and orientation phase for the industry representatives, for example, through a training package/information.

Two of the model A internship periods were interrupted for the students' reasons. In addition, the interruptions may have been affected by the initial challenge and lack of necessary support.

3.2 Model B

In the case of model B, students reported gaining more experience in project work, programming, taking responsibility and interaction skills. Their expertise also deepened, especially in considering the needs and requirements of the end-user. The students suggested that the educational institution and the companies should further increase their cooperation. Indeed, the pilot led to the recruitment of one student. The challenges mentioned were that the online support provided by the institution was not used at all during the pilot, though the possibilities for its use on the team communication platform existed. The existence and importance of support and the institution's stakeholders must be further emphasised in the future.

3.3 Model C

The students and companies were also satisfied with the implementation and results of the pilot of model C. Students received positive feedback. There were no specific suggestions for improving the process. However, one company suggested that ICT education should pay even more attention to the security aspects and management in all courses. On the basis of the research results, the following areas for development will be examined in more detail in the further development of the model:

- Extent and coverage of initial orientation
- Deeper involvement of the company in the initial orientation
- More extensive presentation of tools and methods
- Clarity of objectives
- Increased number of reviews and feedback opportunities

4 SUMMARY AND ACKNOWLEDGMENTS

The online internship concept was piloted in six separate pilots by ICT students of Finnish UAS in cooperation with companies. Pilots followed the processes of all three models. Support was provided by the supervising teachers and selected technical support persons of the institution. Pilots were conducted using MS Teams as the team collaboration platform with all parties involved. The results of the pilots conducted were positive. Students and companies were satisfied with the process and the results, and no special development targets occurred. Some of the the challenges focused on the equipment resources available for students and the online supervising capabilities of entrepreneurs.

To prevent interruptions, it is necessary to provide adequate support and guidance and ensure social contacts, especially in the initial stages. Model A is particularly sensitive to interruptions because the student works alone without peer support and a project team. In model C, the team support that comes with project formality can help the student. Lack of social contacts or threshold may prove to be a risk to model A. According to a Nordic study by real estate expert [9], the extended COVID-19 period has reduced the popularity of large-scale telework and partly taken away its benefits. The study also found that productivity initially increased, but the lack of social interaction began to feel heavy [9].

The role of companies in the concept is emphasised not only in the role of the substance expert but also in the roles of the employer, mentor, reviewer and motivator. Experienced employees in companies act as mentors to students. Company representatives have also been recruited as volunteer mentors for students [10], in which case, the company does not seek or achieve business added value.

Giving and receiving regular and constructive feedback promotes learning, increases motivation, and produces a positive learning experience [11]. Regular progress reviews provide regular feedback [12], allowing support needs to be identified and potential problem areas addressed early.

The introduction and generalisability of the concept under study in higher education depend on many factors. This particular concept is likely to be directly transferable or adaptable to educational cultures where teleworking and distance learning are already widely used in business. Additionally, cooperation between companies and universities in teaching or research should be strong so that cooperation at the level of organisations, especially individuals, works naturally. At best, distance learning can serve the common interests of business and higher education. A highly educated workforce is expected to integrate into companies and higher education institutions can leverage corporate knowledge and expertise, as well as update their teaching and research content. The results of the study are compatible with earlier publications [13].

This publication is a part of the PracDis project (2019 - 2021), which was funded by the European Social Fund, grant number S21814.

ABSTRACT

Industrial companies expect engineers to take an external and critical look at their activities through reflexive practices. Recognising the criticality of reflexivity, Project Based Learning approaches include assignments for students to implement reflexive approaches on their projects. However, it remains unclear in the literature whether those assignments help the students experience the value of reflexive practices or if students consider them as academic exercises. In this concept paper, we present a new teaching module that intends to make students experience the value of reflexive practices for engineers.

In this module, an industrial partner asks a group of master engineering students to design and implement a Proof-of-Concept (POC) to help the company explore an innovation field. This eight-week project is mainly conducted within the company. Teachers act both as coaches through regular meetings and as experts through lectures focusing on specific engineering reasoning (statistics, modelling, simulation, design of experiments…) that are necessary to design a robust POC. At the end of the module, students present conclusions drawn from their POC to the company which explain to students the next steps envisioned from their contribution.

The module is two years old : so far, the authors supervised twelve students split into four industrial projects. Feedback for both companies and students were collected, as well as the lectures and the final presentations. Based on these, we conducted a preliminary analysis that suggests that students experience the value of reflexive practices for engineering work during the module.

1 INTRODUCTION : FOSTERING REFLEXIVE PRACTICES IN PROJECT-BASED-LEARNING

The ability to take an external and critical look at one's professional activity has been regarded for years as crucial for engineers. This ability was coined by Schon [1] under the term of reflexive practices[1]. Recognising the criticality of reflexive practices, engineering education literature regularly calls for pedagogy that can encourage students to adopt a more reflexive attitude toward the work they are undertaking [3].

Fostering engineering students' reflexive attitude is often an objective of Project-Based Learning (thereafter PBL) approaches. PBL is an interesting approach as it confronts students with real open-ended problems where reflexive practices are particularly needed [1], [4]. However, reflexive practices are not naturally implemented, neither by students, nor by practising engineers. Therefore, teachers often impulse students' reflexive reasoning through specific assignments such as diaries, debates or reflexive questions on the journey followed during the project. These assignments often trigger original student reflections on topics he/she would have neglected otherwise [4].

Nevertheless, however good the reflection conducted by students, the question of whether they understood how to conduct reflexive practices remains open. Indeed, the literature highlights that conducting a complex engineering activity through PBL does not guarantee students' learning. Thus, attending a PBL design module is not enough as such to understand how to design [5].

More precisely, as reflexive attitudes in PBL are often driven by assignments given by teachers, one may wonder whether students really experience the value of reflexive practices for their future work. Indeed, the literature focuses more on assessing the reflexive skills mastered by students than assessing students' perception toward the value of reflexive practices [6]. Hence, our research question: how to make students experience the value of reflexive practices for an engineer in a Project-Based-Learning module ?

To answer this question, we conducted an exploratory case study based on a two-year-old teaching module of Mines Paris – PSL University, where students are asked by an industrial partner to design a Proof-of-Concept on an innovation subject.

Section 2 presents the methodology used to conduct the case study. Section 3 presents the teaching module of our case study. Section 4 explicits our findings. Section 5 displays our conclusive remarks on our research.

2 METHODOLOGY

We adopted an exploratory case study methodology to analyse how to make students experience the value of reflexive practices for engineers. The case chosen is the two-year-old module "Proof of Concept for a responsible industry" (thereafter POC module)

---

[1] Defining reflexive practices is a challenge for the literature and it is beyond our scope to provide a definitive answer. In this paper, reflexive practices include technical rationality, reflexion on action and reflexion in action as defined by Hatton and Smith [2]. We thank an anonymous reviewer for providing this reference.

in Mines Paris – PSL University, that we supervise. So far, we supervised 12 students split into 4 industrial projects. Our experience provides us with anecdotal evidence that students experienced the value of reflexive practices thanks to the POC module hence the choice of this module as a case study.

To conduct the case study, we collected as many evidence as possible to understand whether students and industrial partners highlight reflexive practices as valuable for engineers. We also gathered all the documents related to the POC module in order to identify the features of the module that helped students understand the value of reflexive practices for engineers. The data collected and the analytical approach are indicated in table 1.

Table 1. Data and data analysis of the case study

Data	Analytical approach to the data	Data gathering
Final presentations and company reactions	Assess whether students rely on reflexive practices during final presentation	Recorded (n=4/4)
Evaluation and debriefing of the POC module by students	Assess whether students highlight reflexive practices as a key aspect of the module	Questionnaire (n=12/12) Field notes
Evaluation and debriefing of the POC module by the company	Assess whether companies highlight reflexive practices as a key aspect of the module	Questionnaire (n=1/4) Field notes
Documents related to the POC module (lectures, flyers…)	Identify features of the POC module that may help the students understand the value of reflexive practices	All documents

The evaluation of the POC module by the students takes place through a questionnaire students fill at the end of the module. The questionnaire is composed of several quantitative questions such as *"Did you like the project that you were entrusted with?"* and of several open questions such as *"What were your expectations at the beginning of the module?"* The issue of reflexive practices is never directly raised; however, some questions make room for students to provide answers related to reflexive practices, for example "*Do you think that the POC module enable a better comprehension of what is an engineer ?*"

The debriefing of the POC module with students is an informal one-hour debate on the module. We also met the students after the POC module, in particular when they explain it to undergraduates. We included the informal exchanges we had with them on this occasion as an element of the debriefing.

The evaluation of the POC module by the companies is conducted through a questionnaire composed of six open questions. Four questions relate to the work conducted by the students on their specific projects. The last two questions relate more to engineering reflexive practices: "*Do you think that a teaching module* *dedicated to the design of a POC is important for the training of an engineering student and why?*" and "*Do you think that a teaching module dedicated to the design of a POC could be relevant for working engineers and why?*"

Our analytical approach to the data is to uncover whether students or industrial partners mention that reflexive practices as a key aspect of the POC module. As we do not raise the question of reflexive practices, a mention of theses from students or from companies would be considered as very informing.

3 CASE

This section presents the "Proof of Concept for a responsible industry" module as it was structured in 2021 and 2022 in the master engineering programme at Mines Paris – PSL University. Section 3.1 presents the module from a content perspective and section 3.2 exemplifies one project that took place in 2022.

3.1 Presentation of the POC module from a content perspective

In the POC module, industrial partners entrust groups of engineering students to design and implement a Proof-of-Concept (POC) to explore a particular innovation field the company is interested in. Students are split into small groups, typically three students per group, and work for eight weeks on their project.

To select the projects, the teaching team look for three requirements. First, the subject has to be linked with a current innovation project within the company. Second, the company must be willing to conduct an experiment of some sort on the innovation field. Third, the company should agree to host the students as interns and make them meet experts of the innovation field explored.

At the end of their eight-week project, students are asked to present their work to the company and to provide two deliverables. First, they must issue a grounded recommendation to the company concerning what Proof Of Concept is to be implemented to explore the innovation field. Second, students are asked to present the analysis of a limited experiment they conducted during their project. Thus, they are put in the position to analyse the results of an experiment. Generally, they cannot analyse the POC they recommend due to time and resource constraints. At the end of the presentation, the industrial supervisor comments on the work of the students.

Before starting their eight-week project, students follow two introductory courses[2] : one on production and logistic management and one on innovation management.

During the eight-week project, students participate in three interrelated learning activities. First, they work on their project as interns in the company during two and a half day per week. Second, students attend lectures and associated tutorials for a total of four hours per week. Third, each group of students have a one-hour meeting per week with two academic tutors. The organisation of a week is given by table 2[3]

[2] These two courses are not specific to the POC module, they are open to other engineering students.

[3] The shaded cells relates to slots dedicated to sport

Table 2. Organisation of a week during the POC Module

	Mo	Tu	We	Th	Fr
am	Project		Project	Coaching	Tutorial
pm	Project	Lecture	Project		Project

During the project, students are interns in the company: they work as an autonomous group that mimics an industrial project organisation. They receive supports both from their industrial supervisor that entrusted the project to them and from experts of the subject within the company.

The lectures focus on classical reasoning mobilised by engineers. In 2022, the lectures were the following : (i) Engineering Modelling ; (ii) Machine Learning ; (iii) Simulation ; (iv) Inferential Statistics ; (v) Design of Experiments ; (vi) Economic evaluation under uncertainty (vii) Risks associated with POC design. All the lectures are followed by a tutorial. The lectures and the tutorials are designed to show how classical pieces of engineering reasoning can be used to design a POC. Students are free to use or not these pieces of reasoning for their own project.

The coaching meeting is a favourable moment for students to present their work and to elaborate on what they need to do during the following week. The coaches are two academic tutors who belong to a lab where state-of-the-art research is conducted on POC and on POC design. Thus, the guidance of students is particularly well informed with insights on the usual pitfalls encountered by POC in industrial settings [7].

Presentation of the POC module with a project example : Improving glass wool stock management through image analysis. One of the 2022 subjects took place in an international company producing glass wool. The industrial setting of the subject was a leading plant of the company for the implementation of industry 4.0 technologies. In this plant, glass wool is stocked outside which leads to several stock management activities, one of which being regular inventories. The company has installed a 4D camera that is able to take pictures of the stock. The subjet given to the student was : "*How to improve stock management thanks to image analysis algorithms?*"

During the project, students tested, on real data provided by the company, several image analysis algorithms, mainly to count glass wool pallets. During their final presentation, they presented their best performing algorithm as well as all the research paths possible for the company to improve the algorithm. After their final presentation, the industrial partner highlighted : "*The subject enable an exploration of the expectations we have on image analysis technologies for industrial purposes, subject on which we have a lot of progress to make [in our company]*". (Industrial partner, Questionnaire, 2022).

4 RESULTS : EVIDENCE SUGGESTING THAT STUDENTS EXPERIENCE THE VALUE OF REFLEXIVE PRACTICES DURING THE POC MODULE

Several evidence suggests that students experience the value of reflexive practices for engineering work during the POC module. First, due to the innovative nature of the subject they tackled, students were confronted to open-ended problems for which companies were unable to indicate what students should do. Several students highlighted that these situations made them realise that a specific reflexive approach had to be implemented. For example, one student stated that "we quickly realised that, in our company, they did not know how to solve the problem they gave us. We had to set up our own method" (Student, Debriefing, 2021.) The idea that the innovative nature of the projects was the root cause for the need of reflexive approaches is well shared among the students : "The exploratory nature of the subjects calls for a permanent critical approach on what we are doing" (Student, Questionnaire, 2021). Some students even link their reflexive attitude to engineering practices : " I developed a critical approach to solve problems which now change the way I depict my missions [as an engineer]" (Student, questionnaire, 2022).

Second, students highlight that the weekly one-hour-long coaching sessions are moments to reflect upon their projects as well as key success factors. We received a lot of oral feedback from the students that indicate that coaching sessions were critical for the success of the project and 9 students out of 12 gave similar indications in the questionnaire. When digging into why students find the coaching session critical, the answers converge toward the following quote : "*Thanks to the project, we learn a lot of useful things as engineers and thanks to the coaching sessions we learn how to consider our subject with a different perspective*" (Student, Questionnaire, 2022). Therefore, it seems that students identify the coaching sessions as moments of reflection and found these moments useful for engineering work.

Third, the final presentations make students realise that other engineers conduct reflexive practices. Indeed, the final presentation is an opportunity for students to take part in discussions with other engineers. One example is provided in 2022 by a group that had to design a POC of a continuous inventory process. One of the main findings of the group was that there were different formulas that could be used to conduct such an inventory. As one of the students stated :"*Clearly, they [the company] had not realised that there were different formulas. The discussion [after the presentation] makes it clear that they need to reflect upon these formulas before implementing any continuous inventory process*" (Student 2022, debriefing)

Fourth, feedback from industrial partners also provides evidence that the POC module helps students realise the value of reflexive practices. According to the industrial partner, this understanding is achieved because the design of a POC leads the students to "*explicit the experiments conducted, the lessons learned and the recommendations derived from the experiments*" (Industrial Partner, Questionnaire, 2022). This feature of the POC module "*is probably even more interesting for engineers with 2-3 years of experiences of conducting industrial projects*" (Industrial Partner, Questionnaire, 2022).

Last but not least, through their final presentations, the students triggered reflexive practices of engineers of the company they were working with. For example, one presentation explicitly encourage the company to debate and agree on the mathematical formula that should be used to assess stock deviation (Students, Final

Presentation, 2022). Industrial partners admitted that this reflection was of critical importance for the project they were pursuing. Thus, students experienced the value of reflexive practices as they witnessed their importance for working engineers.

Thus converging evidence suggests that the POC module allows the students to experience the value of reflexive practices for an engineer.

5 CONCLUDING REMARKS

In this concept paper, we conducted a preliminary analysis of a two-year-old teaching module where students are asked by an industrial partner to design a Proof-of-Concept on an innovation subject. Our aim was to strengthen our feeling that the POC module helps students understand the interest of reflexive approach. We therefore gathered several evidence indicating that students experience the value of reflexive practices [1] for engineering work.

As a concluding remark, we would like to highlight that the question of the features of the POC module that make students experience the value of reflexive practices still have to be investigated. To do so, we would like to relate the features of the POC module to engineering education literature to see whether such features are reported to be linked with reflexive practices.

ABSTRACT

Molecular modeling is a chemistry tool that has been widely used in the last decades to mainly support the basic concepts of general chemistry and organic chemistry, in both undergraduate programs of basic sciences and some technological careers. Despite its use, except in some very specific cases, it has been extensively employed as illustrative examples of the chemical concepts that were being demonstrated. Despite the numerous existing applications to comprehend the phenomena behind the development of new materials and biomedicine, it is difficult to find a conceptual introduction of molecular modeling applied to specific problems on the modern engineeries within the undergraduate programs. In the present work, it will be shown the introduction and adaptation of molecular modeling concepts within a new optional course for students coming from materials engineering, chemical engineering and biomedicine engineeries. Different approaches to problem-based and small project-based learning are presented to encourage the scientific spirit of students using techniques of molecular modeling that had not been visited throughout their studies and, thus, to discover their potential appliacation in a more specialized context.

1 INTRODUCTION

Interdisciplinary teachings such as molecular modeling, which involves mathematics, physics, chemistry, computer science and biology, are still scarce both at high school and at the general College level [1]. However, it is observed a shy wave of change in the last decade due to easier access to powerfull desktop installed in the computer classrooms, as well as to a more accessible simulation software [2]. Indeed, subjects where the use of computer programs is predominantly present, such as molecular visualization, bioinformatics, molecular modeling, and computer simulations, are almost absent from high schools, and in the University are offered only to very specific science majors or as a complement to other disciplines, in the most advanced years [1]. However, there is some simple activities such as those devoted to introduce fundamental chemical concepts regarding molecular shape and atomic orbitals, which can be easily included in the curricula of secondary schools able to involve an students' profile with very little background in chemistry [3].

On the other hand, in the University it is common to find undergraduate physical chemistry programs integrating molecular modeling into their quantum mechanics curriculum [4]. Also, undergraduate life science programs such as the biochemistry [5], pharmaceutical [6], and medicinal chemistry [7, 8], among others, have been gradually emboiding most of the molecular modeling techniques to predic biological outcomes and elucidate details at atomistic level. Indeed, currently molecular modeling is being incorporated as an important part of the research in areas ranging from physics to chemistry to structural biology, as well as the drug design in the pharmaceutical industry.

Regarding undergraduate engineering programs molecular modeling usually is not explicitly included in the syllabus even though implicitly is present in many topics developed in the curricula. Altarawneh and Dlugogorski [9] show the importance of strategic applications of quantum chemistry in chemical industries and present an easy way to introduce chemical engineering students to illustrative case studies that deploy molecular modeling in the design of reactors and derivation of thermochemical functions. In fact, there are reported in the bibliography different experiences incorporating the molecular modeling into the chemical engineering curriculum with specialized curses presenting a comprehensive overview of the use of simulation techniques, including thermochemistry and reaction rate data, physisorption equilibria and diffusion rates, and transport properties [10]. Other initiatives were more in the way to build specialized front-end application to deal with quantum mechanical calculations exploring applications more focalized to the thermodynamic properties of molecules, thermochemistry of chemical reactions, and the optical and chemical properties of doped nanodiamonds [11].

In the present work a new optional course in molecular modeling of materials is offered to students coming from materials engineering, chemical engineering and biomedicine engineeries is shown as an ongoing project. Tuvi-Arad [12] presents three different models for including computational chemistry in the undergraduate program: the specialized course model, the augmented course model, and the islands of computations model. Here, an specialized course is the way chosen to incorporate the theoretical and practical concepts. Along the course several problem-based and small research project-based learning were conducted. Students participating in an undergraduate research (e.g., in a computational molecular modeling lab) have shown to be able to develop better novel and independent projects later [5]. The development of critical thinking and the communication of scientific ideas in oral and written formats that are expanded in these types of projects are essential to ensure that students evolve into a greater understanding of basic scientific knowledge and the research process. Currently the molecular modeling research/training is less dependent on ‘home-written’ programs than it used to be, existing a large number of well-written and well-supported open source packages available to the user. Thus, facilitating and shortening the initial learning curve. In fact, Allen [2] shows a succesfully experience using such software packages for teaching molecular modeling to non-specialists students in a relatively short time.

2 IMPLEMENTATION OVERVIEW

2.1 Material and Methods

The main practical challenges to develop this course lay on both the computing environment and the computational tools that are involved in the computation chemistry applications. Independently of the science branch in which the course should be inserted, the main challenge is to shift the minds of the student from an application’s-based environment (either *Windows* or *Apple*) to an intensive computing-based environment, i.e., *Linux*. Most students have never had contact with Linux Operating System (OS) and require building up the proper computing tools to emulate Linux OS within a Windows or Apple (*OS X*) environment. Two potential options may arise to achieve this goal, either building a dual mode configuration, with the inherent problematic of running two different and often incompatible, OS or building a virtual machine able to run in any given home-focused OS. In that regard, our university developed a universal web-based platform [13], which is a desktop virtualization solution developed from free software. This platform provides the user with a personal virtual desktop that runs on the remote server independently of the device (Windows, OS X, or Linux computer) from which the connection is made. Through this platform the students can emulate a Linux environment inside any personal platform that they may be using, either classroom desktops, personal laptops or even tablets.

Within this context, each virtual desktop contains all the Linux tools that the students will require to achieve the course goals. Moreover, their virtual machine allows an easy connection to our small computer cluster via ssh protocol (security shell connection [14]). The use of a computer cluster is a necessity in order to carry out simulations of actual meaning. One of the main drawbacks of computation chemistry, especially when performing Quantum Chemistry simulations (QM), is the necessity of using multiple computing threats to finish those simulations in acceptable time frames. Solving thousands of complex non-liniar equations at the time implies the need of huge amount of RAM memory and many CPUs working in concert to achieve calculations speeds suitable for acceptable time costs.

The computational tools used for the proper development of the course will be distributed between the virtual desktop used by the students as main terminal and the advanced programs used in the cluster. The virtual machines will have all the resources of *Debian GNU/Linux10*, which includes *Mozilla Firefox* for internet access and scientific tools such as *Python* scripting, *GNUplot* for results graphical plots, *jmol* [15] for visualizing chemical structures, and *VMD* [16] for analyzing simulated trajectories. In the computing cluster, students will find all the scientific programs and suits necessary to learn and explore the basic approaches used in computational chemistry. This pool includes computer programs to perform Quantum Chemistry (QM) calculations, which consist in *NWChem* program [17] and Molecular Mechanics (MM) based programs. For the latter case, *AMBER* suite is preferred, version 20 [18], because not only performs all kinds of simulations within MM approach but also allows performing hybrid QM/MM simulations.

2.2 Course development

The structure and contents of the course are organized on active learning and solving problems. Each lesson is based on learning and assimilating new concepts through solving practical problems or performing realistic simulations. While unfolding the contents of each chapter, the students are engaged to solve specific problems and exercises that illustrate each new explained concept and at the end of each part the students must solve a final realistic simulation problem organized as an individual directed work (hereafter “practice”) that applies the acquired knowledge to a practical exercise, which at the same time would constitute a part of their academic evaluation. The final grade will be averaged over all the accumulated of individual grades, complemented with an oral presentation of a chosen subject (commonly a review of a scientific article), performed in small groups of 2 or 3 people. This methodological approach allows a progressive and integrative acquisition of new concepts based on a global vision of the subject and a direct practical application into the academic fields from which the students come from, since this subject is a multidisciplinary class and the general field of molecular simulations is used in a great variety of scientific applications.

3 RESULTS AND DISCUSSION

3.1 Subject implementation

The overall structure of the course and the timeframe used for each section is listed in Table 1.

In the initial sessions of the first section the students are introduced and familiarized with Linux Operating system, its basic commands, and the use of scripting as programming tools and execution of simulations. At the end of this section, the students are required to solve practical applications by using scripting, all gathered in

Practice 1: *Introduction to Linux. Based on scripting programming*. Most of the focus lies on a practical approach, in which the students are engaged in applied challenges to be solved using the commands they are introduced. For instance, the students are tought to use bash scripting to manage different commands within real simulation environment, which allows for multiple solutions to solve the same problem.

Table 1. Course structure and the timeframe section

#	Section	Time[a]	Assessment[b]
1	Introduction to molecular modeling	12	P
2	Classic model: conformational studies of materials and proteins	12	P
3	Quantum model: heterogeneous & enzymatic catalysis studies	12	P
4	Applications. Advanced simulation of materials	22	PJ
5	Research papers. Real cases under study.	2	RO

[a] Time in hours; [b] P, Problem-based; PJ, Project-based; RO, Report & Oral exposition

In the second section, the classical model applied to chemical structures is presented, showing the computation of structural energies using a Classical Force Filed, followed by the definition of simulation concept and the two main kinds of simulations used within the framework of *Molecular Mechanics* (MM), *Molecular Dynamics* (MD) simulations and *Monte Carlo* (MC) simulations. It is also at this point where the students are introduced to visual tools that allow the representation and visualization of crystals, amorphous materials and proteins. The final activity of this chapter is summarized in Practice 2: *Structural study of a polymer, crystal and/or protein*. In this final practice the students are challaged to study the effect of several enviromental factors, such as ionic strength or temperature, over the conformational stability of an small protein using AMBER program (Fig. 1)

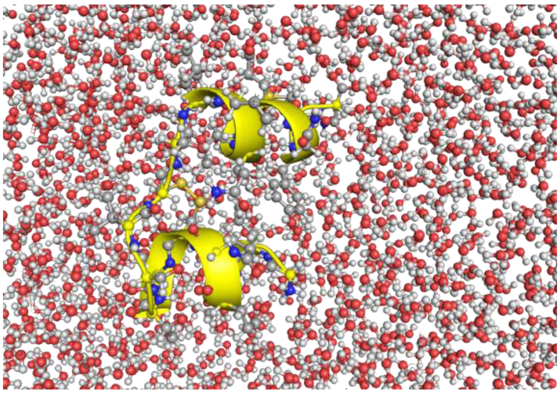

Fig. 1.- Human Insuline immersed in water filled box

In the third section of the course the students are presented with the challenges of modeling of thermodynamic properties, chemisorption on different materials and chemical reactions, which implies solving Schrödinger Equation. A quick review to its exact solution for the hydrogen atom is used to present the conundrum of setting the proper Hamiltonian in polyelectronic systems, leading to the exploration of the different quantum simulation techniques, going from Hartree-Fock based methodologies, their approximated solution through Semiempirical methods and finally the introduction to Density Functional Theory and its applications. This section is completely self-guided through different exercises of growing complexity starting with the atomic properties such as the atom multiplicity, solving the IR spectrum of some molecules, studying the geometry of organometallic complexes, and ending by obtaining the transition state of a reaction in gas phase. The chapter is closed by solving Practice 3. *Simulation of a heterogeneous and/or catalytic process* (Fig. 2).

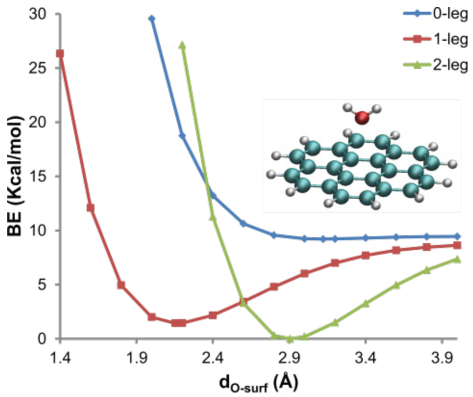

Fig. 2. - Chemisorption of water in graphene[19]

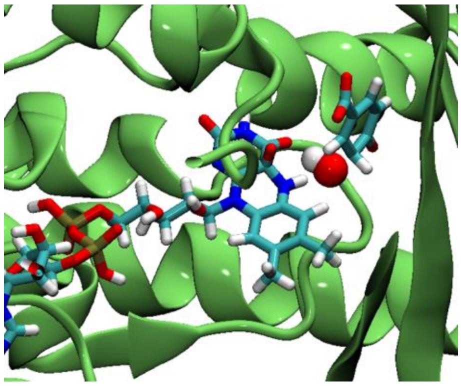

Fig. 3. - Oxygenation reactions catalysed by the enzyme p-hydroxybenzoate hydroxylase[20]

The fourth section of the course is divided in two different parts. A first section showing other computational tools used in the Biological and Material sciences, e.g., polymer and biopolymer simulations, enzyme catalysis (Fig. 3) and structural bioinformatics. This part is organized in demo-pills with all the material and files made available to the students, thus allowing a later reproducibility. Structural bioinformatics is emphasizing the techniques involved in homology modeling, fast threading (Fig. 4), and computational aided drug design. A second and last part, that revolves around solving a practical scientific case using the tools and techniques learnt throughout the course. This application is organized in a final simulation project (see section 3.2) that constitutes Practice 4.

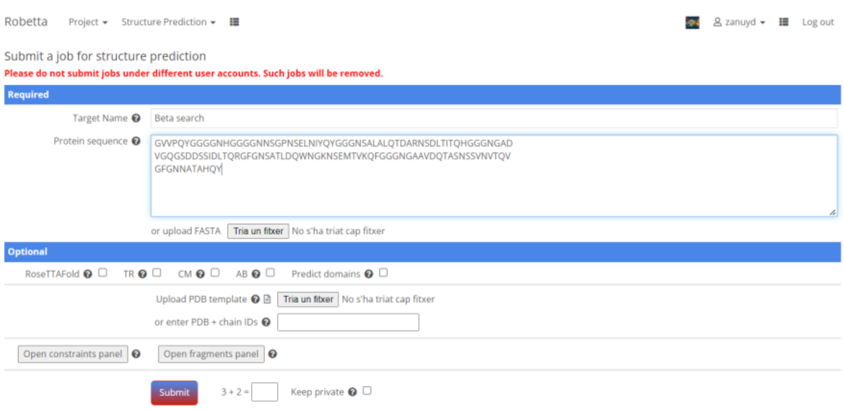

Fig. 4. - Online interface for Robetta project computations for fast threading.

The last section is devoted to studying different research works on molecular modeling, published in peer-reviewed journals, to complement the learning of those new methodologies not explored throughout the course. The students, organized in very small groups, choose a research project at the beginning of the course among several according to their own scientific interest. They try to understand the methodology used, the results obtained, as well as the conclusions reached by the authors of the article. On the last day, together with a report, it is exposed to the rest of the classmates, which allows a small debate to be opened about it.

3.2 Directed Learning Activity: Simulation Project

The final simulation project is the longest directed learning activity of the course and it is conducted after the students have gained most of the theorethical and practical concepts. Each student choses one topic among several projects (all with different development) and laying in different fields within molecular modeling, e.g., material science, structural biology, and bioinformatics. All the methodology to be used in this section has been acquired within the subject and the main difficulty developing the project is laying in the comprehension of the studied concepts. Usually, at this point the students get much involved in the topics, thus gaining a strong command of molecular modeling. Indeed, an improvement in critical thinking and a greater knowledge of the research process by students was observed at the end of the course, which was reflected in the work developed in Practice 4. *Advanced simulation of materials*.

3.3 Course Assessment

The subject has been conducted along three academic years involving a total amount of 29 students. One of the most difficult point that students have to face in this multidisciplinary course, beside of revive the basic buried concepts of chemistry and physics in the first years of the undegraduate program, is the missing unawareness on basic computational science. The student is very familiar with the visual informatics as common user but fails in the command and scripting languagues, which are necessary in this kind of simulation, where most of the applications are running in Linux OS. Thus, facing the Linux OS is one of the first challenges that the student has to deal with. The continous learning curve observed is mainly based in the computer lab experience, adquired along the subject development. Indeed, the subject assessment is trying to reinforce the working lab through proposing to the student different problems to be solved, as well as a small project that will be evaluated individually, coinciding with the five sections in which the subject is divided (see Table 1).

Finally, an equitable evaluation of the five sections of the subject is carried out. Considering this way, the part of individual development, both of the short problems at the end of each main topic (sections 1 to 3) and the application project (section 4). The assessment ends with the commentary in group on the research article (section 5). Spite of most of the developed work is evaluated independently, there is a common background in the problem description with a different problem development that would allow to the students to discuss and work in their own project at the same time that are working in group to obtain a final solution. Differences between their scientific background and origin (10 % students were in an Erasmus program) reinforced the collaborative work at the time that increased the group motivation.

We assessed the degree of satisfaction of our students using a enquiry that we specifically designed for this porpouse. The general level of satisfaction for this new class was between high or very high. Some students had some missgivings regarding the depth of the theoretical contents and suggested a more applied approach. However, this particular question becomes quite unfeseable due to the lack of background in statistical mechanics and quantum mechanics that they had from previous years. There is though consensus about both the utility of the applied examples and the direct applications practical of the newly accuaried knowledge. Throughout these three years most of the suggestions raised by our former students have been incorporated. However, it is really tough to only focus on practical problems when there are important lacks on their background.

4 SUMMARY AND ACKNOWLEDGMENTS

In this work the introduction of a multidisciplinary optional subject straddling different teaching programs of different engineering careers is presented. The whole subject is supported by short problems- and projects-based learning that the student carries out to complete their learning curve. The constant challenge designed to foster scientific discussions among them from different students backgrounds, working together to solve a problem, increases their motivation for the subject. As a result of these first three years has been the presentation at the end of the course of elaborate simulation projects with a high dose of independence, development of basic scientific knowledge and research process.

Istanbul Technical University - Istanbul, Turkiye

Conference Key Areas: Sustainability, Sustainable Development Goals, Engineering Skills
Keywords: 21st Century Skills, SDGs, CIPP, Challenge-Based Learning

ABSTRACT

Since learning, literacy, and life skills have become essential for individuals in the information age, the focus on education has shifted to preparation of students for the knowledge society. This is valid for all levels and spheres of education including but not limited to foreign language teaching in higher education. With this in mind, a new English for Academic Purposes (EAP) Course aiming to equip freshman level university students with necessary learning skills has been launched. A particular emphasis has been given to developing the students' English language skills so as to facilitate their communicative competence both in their academic and professional lives. The course adopts a challenge-based learning approach, which provides students with a meaningful framework for learning as it is based on solving real-world problems. In the course, the students work on real world challenges based on the 17 Sustainable Development Goals (SDGs) of the United Nations (UN) while using the learning skills (the four C's) of the 21st Century, namely critical thinking, creativity, collaboration, and communication. During the course, the students work together on the issues highlighted as challenges in United Nation's report on Turkey's state regarding the 17 SDGs, and offer solutions in groups in the form of poster presentations, academic papers and oral presentations. The course has been implemented since fall 2021. In this concept paper, the researchers will share their experiences and research plans about the evaluation of the course based on Stufflebeam's Context (C), Input (I), Process (P), Product (P) (CIPP) Evaluation Model.

1 INTRODUCTION

1.1 21st Century Skills

The integration of 21st century skills in education has changed the nature of teaching and learning to a large extent. The replacement of conventional teaching methods with a new focus on the essential skills of the information age has led to the emergence of new practices in teaching that aim at fostering student engagement. When literature in the field is examined, it is found that all levels of education give importance to learning, literacy and life skills in their curriculum.

Due to a surplus of information and the possibility of easy access, the 21st century is agreeably called the age of information and technology. The ease to reach information and the infinite sources to have knowledge about a particular subject may sound to the advantage of individuals and societies that aspire for progress, yet it should also be noted that analyzing, interpreting and evaluating this abundance of information is much more vital to make optimum use of it. Knowing how to use information rather than reaching it has become a required skill, thereby making the integration of 21st century skills into every sphere of life essential. Moreover, the changing conditions of the world, economic structures, and social dynamics must also be taken into account. As Voogt and Rublin (2010) also discuss in their paper, the nature of jobs are changing and young people are educated for the jobs that do not even exist today, which requires individuals to compete globally while working both individually and in groups (Jacobson-Lundaberg, 2016). It would not be wrong to argue that teaching 21st century skills to young people will prepare societies for a future they cannot fully grasp.

1.2 Higher Education and 21st Century Language Teaching

The first category of 21st century skills, learning skills, are adopted in language education for the sake of a more integrated approach to teaching in higher education. Fostering the interaction of students through group work, which necessitates collaboration and communication, as well as developing their oral and written competencies with individual assignments that require creative thinking and creativity, 4Cs-oriented language teaching responds to the needs of 21st century university students. The emphasis on 21st century skills in language education also reflects the premise that individuals express themselves through language and language learning plays a key role in "professional success" as it gives one insight about the presence of different cultures and global issues (Cruz & Orange, 2016, p.2). A comprehensive language education, which encompasses all aspects of 21st century skills will ultimately give university students from different backgrounds the chance to work collaboratively and have a sense of teamwork. This will in turn develop their communicative skills as they will feel more self-confident seeing that they can communicate with people in a non-native language. Feeling the need to listen attentively in order to understand, thinking critically to make sense of what is said and giving an appropriate response to continue the conversation will develop communicative skills like listening, respecting different ideas and having empathy. In other words, teaching the language of another culture will both necessitate and develop the use of 21st century skills.

1.3 21st Century Skills for Global Citizenship and Challenge-Based Learning (CBL)

An emphasis on 21st century skills in language education inevitably paves the way for the discussion of global issues in the classroom. Cruz and Orange argue that "21st century interdisciplinary themes" are used as subjects in language classrooms to develop academic language competency of students (2016, p.2). Discussing global problems as varied as and not limited to climate change, gender inequality, decent work, and sustainable energy both orally and in writing assignments gives students a new perspective to look at the global challenges countries are faced with contributing to their global citizenship competencies. In this respect, adopting challenge-based learning (CBL) as a pedagogical approach in language teaching in higher education makes it possible to engage students in real-life scenarios by using a secondary language to understand and discuss it.

Defining CBL as "extended problem-based learning", Baloian et al draw attention to its project-based aspect. In 21st century language classrooms, the attempts to foster students' collaborative and communicative skills as well as creativity through group projects become more meaningful when real life challenges are included as subject materials in courses. Similarly, Quieng et al argue that teaching 21st century skills to students enables them to be aware of global challenges, which will in turn help them endure difficult conditions and turn challenges into advantages (2015). With this objective in mind, language teaching with a challenge-based approach will equip students with necessary skills to respond to the needs of the era and fulfill the standards of the 21st century learning framework. A student who can think critically, communicate and collaborate in another language will also develop these skills further to conduct research, analyze and interpret information in the target language. Able to express themselves about social, economic and environmental issues in their native and non-native languages, students will also feel motivated to take active part in decision-making mechanisms, a skill which is formally defined as "civic engagement" and considered one of the liabilities of socially responsible universities of the 21st century world.

1.4 Challenge-Based Learning through Sustainable Development Goals (SDGs) in Higher Education

One way of applying challenge-based learning in higher education is discussing global issues in a systematic way with real-life scenarios as course materials. With this purpose in mind, the Sustainable Development Goals (SDGs) of the United Nations (UN), may be used as the context of lectures. Since their launch in 2015, the SDGs have been addressed in various settings such as strategic plans of institutions and companies, political agendas of policy makers, theoretical framework of many scientific studies and the curricula of educational institutions. The emphasis of the UN on active citizenship and inclusive societies has been adopted in education as the basis to raise a more conscious and responsible youth with a new understanding of their role as decision-makers and drivers of change. Sustainability studies envision that collective action and learned practices for a more sustainable world have a recreative power. Dlouha et al emphasize the necessity of implementing an understanding of individual competences through SDGs in higher education (2019). In language education, SDGs function as the intercultural context in which the students are expected to have an understanding of sustainability practices in different countries. Using the target language as a tool to have debates about global challenges, do research about sustainability solutions and write reflective papers to propose their suggestions are all examples of practices for sustainability education. Indeed, a sustainability-oriented course enables the instructor to carry challenge-based learning a step further by fostering self-learning and contributing to enhancement of students' civic participation.

Although sustainable development has remained on the agenda for engineering disciplines for a long time, the broadening of the concept in the form of Sustainable Development Goals to other disciplines in higher education is a relatively new form of implementation. This is doubled by the need of integration of 21st century skills and competencies into classes to cater for the requirements of the new era. To this end, this concept paper will evaluate a relatively new course aiming at improving engineering students' academic English skills through content focusing on SDGs and equipping students with 21st century learning skills. A particular curriculum evaluation methodology will be applied for the evaluation of the course and the paper will seek responses to the following research questions: (i) What is the context behind the implementation of the course? (ii) What forms of input are available for the course? (iii) What is the process used during the operation of the course?

2 EVALUATION FRAMEWORK

Ornstein and Hunkins define curriculum development as a process comprising not only planning, implementation, and evaluation, but also people, processes and procedures (2003). It entails a dynamic relationship between the objectives, content, learning-teaching process and assessment elements of the education program where a change in one of those components affects all dimensions in the system. Curriculum is developed by designing, implementing, evaluating and reorganizing educational programs based on a needs analysis or program evaluation study, which can be defined as the decision-making process regarding the effectiveness of the program in reaching the predetermined goals and objectives. Using models in evaluation guides the evaluator not only about the kind of data that will be collected, but also when, where, and how the data collection process will take place. Without an underlying theory, the evaluator will seem to be working in the dark and will not be able to attribute the results to the program.

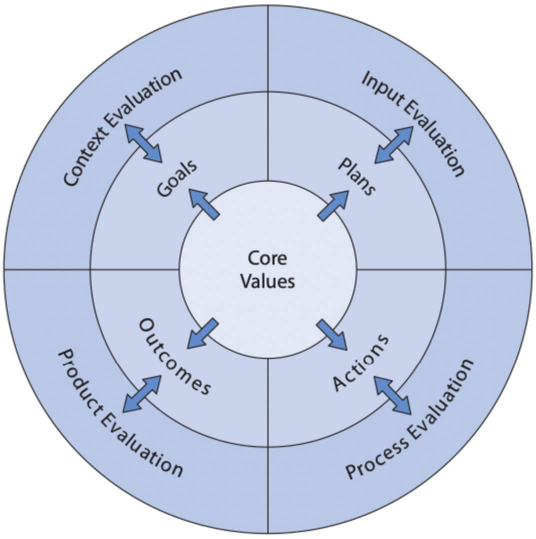

Figure 1. Key Components of the CIPP Evaluation Model and Associated Relationships with Programs (Stufflebeam & Coryn, 2014, p.318)

The evaluation model first developed by Stufflebeam, CIPP, which is an acronym for four types of evaluation: Context, Input, Process, and Product, was used during the design and evaluation of the course in this study. As depicted in Figure 1 above, while context evaluation aims to identify needs with the purpose of deciding on program goals, input evaluation is conducted to design plans involving the strategies and designs. In the process evaluation, shortcomings in a current program are explored and actions to revise implementation are taken, and product evaluation measures outcomes so as to decide about the revision or continuation of the program (Stufflebeam & Coryn, 2014). Moreover, as cited in Christie and Alkin (2013), the CIPP model defines evaluation as a cyclical practice, rather than a product, which needs to be based on a carefully designed, but flexible process.

In accordance with the CIPP methodology, the specific questions that the study seeks responses to are provided below:

Context	1. What are the needs of the 21st century engineering student? 2. What are the aims, goals, and objectives of the course aligned with the context dimension of the CIPP model?
Input	1. What are the resources and materials used in the course? 2. What strategies and activities have been used to address the needs of the students? 3. What forms of assessment have been implemented?
Process	1. To what extent are the planned activities carried out and is there a need for adjustments or revisions of the course? 2. How do the instructors perceive the course materials and teaching methods? 3. How is the teaching and learning process affected during the implementation of the course?

3 EVALUATION AND DISCUSSION

In accordance with the aforementioned evaluation model (Stufflebeam & Coryn, 2014), *English for Academic Purposes (EAP) through Global Goals Course*, which has been implemented at Istanbul Technical University (ITU) School of Foreign Languages (SFL) for two consecutive academic terms, will be evaluated elaborating on Context, Input and Process dimensions. The Product dimension of the CIPP model will be finalized after the complete set of data is collected as part of continuous quality improvement process.

3.1 Context

Regarding the context evaluation, firstly literature on sustainable engineering and the needs of the 21st century engineers was reviewed. Sustainability is a concept referring to a future that balances societal, environmental, and economic issues with the aim of achieving a higher standard of living. Hence, society, environment, culture, and economy are all interwoven components of sustainable development, which cannot be considered separately. Similarly, based on the report titled *Engineering for Sustainable Development: Delivering on the Sustainable Development Goals,* sustainable engineering adopts a multidisciplinary approach focusing on not only technical issues, but also social, political, and ethical ones while taking into account the whole system and the global context (UNESCO & ICEE, 2021). Thus, 21st century engineers have a critical role in solving global challenges related to such fields as energy, health care and environment. For this complex task, they need to adopt a multi-disciplinary approach while working in collaboration with culturally diverse teams, and develop complex communication skills. Consequently, curriculum and instruction in the 21st century integrates 21st century skills into core subjects and interdisciplinary themes, rather than focusing mostly on technical content. Based on the report of the American Association of Colleges for Teacher Education (AACTE) and the Partnership for 21st Century Skills, learning and innovation skills comprise critical thinking and problem solving, communication, collaboration, creativity and innovation, which are all to be constituent components of 21st century engineering curriculum (Greenhill, 2010).

Istanbul Technical University, which has a pioneering role in raising engineers in Turkey, is also one of the partners of the European Engineering Learning Innovation and Science Alliance (EELISA), which "is the first alliance of Higher Education Institutions (graduate engineering schools, technology universities and full-spectrum universities) from different countries in Europe. It offers high-quality programs and courses in line with the objectives of the alliance, thereby contributing to its mission to transform European higher education while strengthening links between engineering and society by re-inventing the 'European engineer'" (EELISA, 2022).

Moreover, in line with the mission of the University with its emphasis on contributing to a sustainable community, the School of Foreign Languages at ITU started to implement *EAP through Global Goals Course* for the first time in Fall 2021, so as to design language education conforming to the needs and priorities of engineering students. It is offered as a 3-credit EAP course aiming to develop students' English language skills through 21st century core skills or the 4Cs (Critical thinking, Communication, Collaboration, Creativity) and United Nations Sustainable Development Goals. As Mikhnenko and Absaliamova pointed out in their article, language education of engineers in the 21st century provides an open ground for "intellectualisation" (2018, p. 37). They argue that integrating language education with a special focus on EAP and ESP enables engineering students and specialists to develop basic skills that a professional needs such as creative and analytical thinking, communicating by using different languages and learning how to access information (2018). Not different from what Mikhnenko and Absaliamova suggest, the course at ITU also offers an academic and intellectual environment for the professionalization of engineering students. Among the objectives of the course are to enable students to express themselves using appropriate discourse strategies in written and spoken communication, to develop the 4 Cs (Critical thinking, Communication, Collaboration, Creativity) of 21st century Learning, which are core skills that the students will need in their academic and social lives, to enhance students' awareness regarding Sustainable Development Goals, to improve students' collaboration skills in multidisciplinary groups, and to develop associated academic practices and soft skills, such as goal-setting, self-reflection and time management.

3.2 Input

EAP through Global Goals Course has been taught online by 26 English language instructors to 999 first year students enrolled in various engineering departments since fall 2021. It has been offered as a compulsory course for students at a certain level of English proficiency. The textbook used in this course is licensed under the Creative Commons Attribution-Non-commercial 4.0 International License, and it is in line with the goals and objectives defined in the syllabus. To supplement the textbook to be used in the program for the first time and to better serve the goals of the course, a unit on problem-solution paper writing has been integrated. Moreover, creative/critical thinking, and teamwork skills of students have been enhanced through a case study unit. Sample problem-solution and case study papers have been created and shared with students. To provide the instructors with background information related with SDGs and 21st century skills and learning, lesson presentations have been shared. During the course, the students have the chance to improve not only their English language skills, but also 21st century learning skills while reading, listening and responding to texts about the SDGs.

Concerning the assessments, the students are to prepare poster presentations on two related SDGs, attracting attention of the audience and providing solutions to a problem.The students are expected to perform this task in pairs, in compliance with the focus of the 21st century skills on communication and collaboration. The students are also expected to write a problem-solution paper on one of the challenges in the report by Sachs et al (2021) regarding the implementation of the SDGs, which has enabled them to critically tackle real life problems of their own countries and propose solutions. To help them get acquainted with this kind of assessment, different from previously implemented formats, the students have been provided with sample problem-solution papers presenting the problem and suggesting alternative solutions. As final assessment, the students work in groups and write an essay analyzing a case scenario based on its relationship with the SDGs and deliver an oral presentation on it. As underlined in *A Core Inventory for General English (British Council/EAQUALS)*, using real life scenarios in language teaching enables the students to evaluate a particular situation using the target language and develop new perspectives by providing a “holistic setting” (North et al., 2015). Within this scope, this assessment has contributed to the students’ ability to work in teams as well as enhancing their critical thinking and communication skills contributing to their development of new perspectives. With regard to the input of the course, it is obvious that students have solution suggestions to global issues ranging from climate crisis, gender inequality, global hunger to water sanitation, education rights and innovative cities, indicating improvement in their awareness of the SDGs as a consequence of implementation of the course.

3.3 Process

As Stufflebeam emphasizes, the most foundational principle of the CIPP model is “not to prove, but to improve” (cited in Stufflebeam and Coryn 2014, p. 176). With an aim to develop the course, certain steps have been taken. For instance, since fall 2021, feedback on course materials and assessments has been collected from the instructors via an online platform. To collect feedback on course materials, the following two open-ended questions were asked: 1. What would you change in Unit XX next time you teach the Course? (pacing, videos, activities, supplementary materials, etc.?) 2. Would you like to add anything else? To collect feedback on assessments, the instructors were asked to write down their comments about each assessment’s guidelines and rubric. In addition, 30 minute informal discussions to share experiences, i. e. what went good or bad, or ask questions, suggest changes were held online.

As a result of the feedback collected and online meetings, it was observed that most of the instructors felt their students needed more input and context on SDGs before starting to work on their first assessment, i. e. poster presentation. Consequently, in spring 2022, each student was assigned one of the 17 SDGs and asked to present the details of the goals and their targets and conduct a student-led discussion, which also gave the students the chance to improve their communication skills. Moreover, most of the instructors agreed that in line with the course objectives, the problem-solution paper regarding the SDGs that remain as challenges for Turkey should be an oral assessment rather than a written one, which is considered as one of the steps to be taken for improving course implementation due to the expected focus of the course on spoken communication rather than written language production to better cater for the needs of engineering students.

The fact that the course was not delivered in person and all these assignments and presentations were carried out online contributed to another objective of the course as well. Delivering online presentations using digital tools, doing online research and preparing posters with the help of various multimedia tools obviously fostered the digital literacy skills of students, which are also among the 21st century skills. Students were expected to use their critical thinking and problem-solving skills to complete online tasks. Considering that companies are employing their workers through online exams and interviews, dissertations are presented online in academia, and the number of webinars, open access courses, workshops as well as certificate/degree programs is rapidly increasing, the online delivery of a challenge-based course has enabled students to simultaneously use various skills. Considering that a challenge-based course addresses social and cultural dynamics that lead to important transformations in societies, a language course through SDGs cannot be given regardless of the changes in technology and the acceleration of digitalization. As Gómez-Zermeño also argues, Education for Sustainable Development (ESD) cannot be “prescriptive” particularly in the age of digital learning, highlighting the potential of digital learning to facilitate “active knowledge co-creation and communities of practice” (p.579). Online delivery of the course, in this respect, contributes to the objectives of 21st century challenge-based courses to provide ample ground to share information and experiences as well as resources, inviting students and instructors to contemplate how knowledge is created.

4 CONCLUSION

This paper presents the evaluation of the course *EAP through Global Goals* in accordance with CIPP model elaborating on Context, Input and Process dimensions. It captures the background for multiple criteria in the context of CIPP providing insight and reference points for implementation. The integration of Sustainable Development Goals, 21st century learning skills and challenge-based learning in higher education undoubtedly underpins the essentials of engineering education in the knowledge society as indicated in the scope of the study. Despite information provided concerning constituents of the evaluation model in the current study, this is still a work in progress and is to be completed by the next step in which structured feedback will be collected from students. The results will then be used so as to fine-tune the content as well as assessment of the course. Sustainable Development Goals and 21st century citizenship are a critical consideration in accordance with the requirements of the current era and involve further exploration in various fields of higher education.

ABSTRACT

To help first-year students get accustomed to university, many universities organise intra- and extracurricular support initiatives. During the academic year, student support services at the Faculty of Engineering Technology at KU Leuven offer both course-specific activities as well as initiatives focusing on study career guidance and academic skills. Yet we notice that not all students find their way to these voluntary activities – even if they would benefit from the help.

The purpose of this study is (1) to understand how first-year engineering students perceive the student support services, and (2) to understand how we can reach

[1] *A. Van Dyck, annelies.vandyck1@kuleuven.be*

doi:10.5821/conference-9788412322262.1413

students who need the support, but do not find their way yet. This will further guide us in the development and communication of support activities.

A small-scale questionnaire was distributed among first-year engineering students, followed by two focus group discussions.

Our findings indicate that support needs are bigger at the start and end of the first semester. Crucial information such as how to study, and communication regarding support activities, should be served more than once, as first-year students still find it hard to filter out the right information. Students prefer course-specific Q&A sessions where they can hear questions of fellow students as well as the answers to those questions. A mentor for study career guidance is well appreciated. Tests and trial exams are important as triggers to start studying. We believe that these findings can inspire colleagues in other institutions.

1 INTRODUCTION

1.1 Student support activities

All first-year university students face a daunting task: besides getting accustomed at a new environment, with new friends, they also need to quickly adapt to the teaching methods and tempo at their new college [1]. Across the globe, universities are therefore seeking ways to accommodate their first-year students with support activities [1,2,3]. In Belgium, many of these activities are non-compulsory.

For specific studies, such as engineering technology, Belgian students are obliged to take a non-binding diagnostic math test before they can enroll. However, Belgian regulations stipulate an open enrollment system for most study areas including engineering technology, so the diagnostic test is low-stakes. As a result, many students start their engineering studies with underpreparedness for math [5].

Student support includes a rich variety of possible activities in response to local needs [6,7]. At the Faculty of Engineering Technology (FET) at KU Leuven, the support activities are arranged roughly into two categories: course-specific activities such as Q&A sessions and basic mathematical skill courses, and activities that surpass the course-specificity such as academic skills interventions and study career guidance. We will call the latter ‘non-course-specific support’.

FET is a multi-campus faculty. In this study, we focus on the student perception of both categories of student support activities at KU Leuven Campus De Nayer, one of the seven campuses of FET.

1.2 Student support activities at KU Leuven Campus De Nayer

At Campus De Nayer, students are divided into study groups of around 20 students who follow exercises and laboratory sessions together. Theory lectures and Q&A sessions are taken by all students at the same time, regardless of study group. Typical for the campus is the relatively high number of commuting students: 70% of first-year students in 2021-2022 travel over 10 km to the campus on a daily basis.

In Table 1, we describe the support activities that were offered to first-year students at Campus De Nayer in the first semester of academic year 2021-2022.

Table 1. First-year student support activities, KU Leuven Campus De Nayer (2021-2022)

Activity	Description
Course-specific activities in the first semester	
Q&A session	Voluntary group session. Students can ask questions about the course material. Each course offers at least two Q&A sessions per semester. Just before the first and second exam periods, an extra Q&A session takes place (‘Return Day’).
Tests	Compulsory tests in November that partially count in the exam score, depending on the result and the course.
Trial Exam	Voluntary non-binding test imitating an exam. Each course is represented with one question.
Basic mathematics skill courses	Voluntary mathematics support, consisting of a Massive Open Online Course (MOOC) and an online support trajectory on basic mathematics
Non-course-specific activities in the first semester	
Starters Days	Compulsory two-day activity at the start of the academic year. Campus life and practical tools are explained, PhD students show the link between their research and the courses, and first-year students have a chance to get to know each other.
LASSI Workshop	Compulsory test and workshop at the beginning of the semester. LASSI stands for Learning And Study Strategies Inventory. Topics include time management, study method, motivation, etc.
Workshop Time Management	Voluntary in-depth workshop following the LASSI workshop.
Workshop Efficient Study Methods	Voluntary in-depth workshop following the LASSI workshop.
Tutoring by staff	A mentor is assigned to each study group. The mentor helps with study-related questions, follow up on results, and is a coach for study-related questions. An individual mentor meeting is offered after the tests and after each exam period.
Tutoring by peers	Two higher-year students per study group help the first-year students get accustomed to university life and the campus.
Online modules	Online modules and training videos on study planning, fear of failure, procrastination, etc.

The goal of the study was two-fold: (1) Starting from the current support activities (both course-specific and non-course-specific), we wanted to know, from a student’s perspective, which are the essential building blocks. (2) Moreover, we were looking for inspiration on how we can reach students who need the support, but do not find their way to the current support activities.

2 METHODOLOGY

We used a mixed method, starting with a small-scale questionnaire to help us find the right qualitative questions. Subsequently, we ran two focus groups. As we were primarily looking for student perceptions, we relied on self-report data. Self-reports are subject to a number of biases, so insights should be interpreted with care.

2.1 Small-scale questionnaire

In the small-scale questionnaire (41 students; response rate = 42%), we explored three themes: (1) feeling of support at the beginning of the studies, (2) knowledge of and participation in support activities, and (3) support activity preference (ranking). The questionnaire was offered on a voluntary basis during a theory lecture, and was administered via PollEverywhere. The English translation to the questions in the questionnaire is listed in the Appendix.

2.2 Focus groups

Based on the questionnaire results, we explored emerging themes in more depth in the focus groups (n=10). We invited students from two study groups with different characteristics in order to have a good mix of students who attended the student support activities, and students who need the support but did not yet find their way. All students were invited to participate on a voluntary basis.

3 RESULTS

In this concept paper, we will focus on the insights that are most striking and that will guide us in rethinking student support and communication, based on student perception and self-reported needs.

3.1 Results of the questionnaire

Overall, students report they felt well-supported when starting their studies. As Fig. 1 shows, 69% of students felt supported to very supported at the start of their studies.

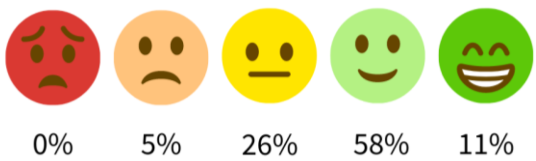

Fig. 1. First-year student response to the question how supported they felt in general at the beginning of their studies.

Table 2 shows that self-reported knowledge of the course-specific activities is high for most activities (known by 78%-95% of respondents), except for Return Day (49%). As for self-reported student attendance of these activities, we see a remarkably low reported attendance rate of Q&A sessions with respect to reported knowledge of the sessions. In the open-ended question on course-specific activities (no. 5 in Table 5), we found that 6 out of 18 students ask for ‘group Q&A sessions’.

Table 2. Percentage of students claiming to know or have participated in a selection of course-specific support activities.

Course-specific activity	Know by	Attended by
Q&A session Fundamentals of Math.	95%	63%
Q&A session Chemistry	80%	37%
Trial Exam	88%	76%
Tests	78%	78%
Return Day	49%	29%

Looking at the the non-course-specific activities (Table 3), we learn that the individual mentor meeting, which is part of the tutoring by staff, is well appreciated: it is best known and attended by students. Moreover, in the ranking question (no. 8 in Table 5), the individual mentor meeting came out as the top student preference.

Knowledge of both the compulsory LASSI-workshop and the Starters Days is low (known by 51% and 68%, respectively). In the open-ended question on non-course specific activities (no. 9 in Table 5), 3 out of 11 students reported the need for more communication regarding these activities, e.g. reminders.

Table 3. Percentage of students claiming to know or have participated in a selection of non-course-specific support activities.

Non-course-specific Activity	Know by	Attended by
Tutoring by staff: individual mentor meeting after the tests / first exam period	85%	61%
Starters Days	68%	56%
LASSI Workshop	51%	29%

3.2 Discussion of questionnaire results

The reported feeling of being well-supported at the start of the academic year stands out, in particular as it contrasts with the fact that that not all students find their way to student support activities. This raises the question how the perception of support evolved throughout the semester.

The spontaneous request for ‘group Q&A sessions’ is striking, since Q&A-sessions are organised in group by default. This suggests the need for a closer look into how these sessions are organised, and what students would need.

The high appreciation of the individual mentor meeting made us wonder if the same appreciation holds true for tutoring by staff in general and for the tutoring by peers.

As for the low reported knowledge and attendance rates for both the course-specific Return Day and the non-course-specific LASSI-workshop and Starter’s Days: we know from the attendance numbers that, contrary to what is reported by the students, most of them did attend these activities. Yet, only about half to a third of the students who participated in the questionnaire report that they have attended. This suggests that the activities themselves might be well-known, but their names are not. Moreover, we wanted to better understand why some students asked for more communication regarding non-course-specific activities specifically.

The questionnaire findings hence led to the following focus group questions:

- How did your feeling of being supported by the campus evolve during the first semester?
- In the first semester, what were reasons to go to / skip the Q&A sessions?
- Which non-course-specific activities were communicated well? Which were not communicated well? Why is that so?
- Which questions would you ask your mentor? Which would you ask your peer tutor?

Since one of the goals of the study was to look for inspiration on how to reach students who need the support, but do not find their way to the activities yet, we decided to add one more question to the focus group discussion :

- What, if anything, would make you start studying sooner?

3.3 Focus group insights

All students in the focus groups reported that the feeling of being supported persisted throughout the first semester.

The need for support decreases as the students become more familiar with the campus: *"The first time you come in a laboratory, you don't really know the teachers and you don't dare to ask a question. That is different in the last lab, when you know them and the barrier to ask questions is smaller."* However, the need for support increases again towards the end of the semester, as the first exam period comes closer. Several students report that they appreciated the information on how to deal with exam periods and the corresponding study blocks. As one student said: *"It's the first time that we have to study two weeks in a row without doing anything else."* This information should be given just in time: *"In the beginning of the semester, you don't think about the need to start studying in a few months and how you could do that."*

Yet, support can still be improved from student's point of view. Students from one focus group reported that they did not know how to study their course material. One student suggested to organize a session where all lecturers would indicate what is important and how they expect students to study, referring to similar activities in secondary school. This shows that the process of getting used to independent study is still in full swing.

Table 4 lists reasons to attend or skip voluntary Q&A sessions in the first semester. As mentioned before, Q&A sessions are organised in group, yet several respondents to the questionnaire spontaneously asked for 'group Q&A sessions'. When probed for the Q&A sessions, several students say they attend group Q&A sessions, even if they do not have any questions. Listening to the questions of fellow students – and the answers – helps them understand the course material better.

Yet, students report that in some Q&A sessions, questions are answered face to face rather than in group, so these sessions are not perceived as group sessions. Students consider this a missed opportunity: *"It's always interesting when you hear other people's questions, because then you think – Oh yeah, I did have the same question! But if you don't hear them, they can't help you. So I stopped attending those sessions."*

Students of both focus groups emphasized the need for good planning of the Q&A sessions. This is related to the relatively high number of commuting students at Campus De Nayer. As one student said: *"If the Q&A is planned at 8.15 am, I need to catch the train at 6.50 am and I have to get out of bed at 6 am, which I find hard. So I tell myself: it's just one question – why bother?"*

Table 4. Reasons (not) to attend the course-related Q&A sessions as claimed by students.

Reasons to attend	**Reasons not to attend**
Curiosity (very first Q&A session)	Too early / late in the day
To ask a question	No other activities planned before or after the session
To listen to questions of other students	No questions / haven't studied course yet
Difficult course (e.g. mathematics)	Questions are answered individually only

Students seem to be okay with the communication of non-course-specific activities in general. When asked for ways to improve, several students say they wish to receive information through multiple channels, e.g. not only a note in the digital learning environment, but also an e-mail, a calendar item and/or a mention during one of the lectures. This confirms the data from the questionnaire, which suggested the need for reminders. Students say they are swamped by information, and believe that multiple-channel communication will help them filter out the important messages.

As suggested by the questionnaire data, some activity names appeared to be lesser known than the activities themselves. This was confirmed in the focus groups where students said a few times that they did not remembered an activity, while when explained what it was, they admitted to have attended it. We believe this shows that activity names could be clearer. One activity should be referred to by one name only.

As for the interaction with their mentor (staff tutor), the focus groups confirmed the questionnaire findings as several students pointed out that they enjoy the interaction. Most students did not bring specific questions when they met individually with their mentor, yet they appreciated the information given about (trial) exam results, study tips, coaching, etc. One student reported that he checked his summaries with his mentor. The mentor has a direct impact on the wellbeing of the student: *"She encouraged me when my result wasn't good. She reassured me that there was still time, and gave tips."* Although students appreciate the individual meetings with their mentor, the mentor should also be a teaching assistant for their mentee group: *"In the first semester, we saw our mentor once or twice a week, so that we could ask* *questions in the classroom before the lecture would start. (…) This semester, we see her less often, which means we have less contact with her."*

In contrast, the relation with the peers is more ambiguous. Most students appreciate that they have access to a higher-year student to ask questions and claim that they would contact them if needed. However, for most students, the contact with their peers is limited to rare messages on social media (mostly from the part of the peer tutors). Yet, the peers are viewed as a role model: *"Every professor mentions in class that we have to start studying early, because it's a lot, it's difficult. But they say that everywhere. (…) So the effect is bigger when you hear it from a higher-year student, because they know it will backfire if you don't."*

Some students claim to have started studying early, but to have left their books as soon as they noticed that they could not keep up with everything. They decided to wait for the exam period, when they had more time to study. Most students refer to bad grades as the most reliable strategy to make them start studying in time. Without tests, it is hard to start. Several students asked for more tests during the semester, although others disagreed, saying they liked the tests as they are organised now because more tests would give them more stress.

One topic came out ad-lib in the focus group discussions. Students in both focus groups spontaneously mentioned the exam review moment, a week after the exams, when students can obtain feedback about their exam from the lecturer. This moment is viewed as valuable, but could be made more efficient. Following improvements were suggested: (1) communicate partial and mean exam results upfront, so that students who need only these results don't have to come to the review moment (leaving more time for other students); (2) hand out exams to 4-5 students at once; (3) organise an online exam review moment.

4 SUMMARY

Although first-year students have a lot to deal with in their first semester of university, the students in our study claim to feel well supported by the campus. Support needs of this group are bigger at the start and end of the first semester, due to the newness of university (October) and the first upcoming exams (December). Tests and trial exams are welcomed, as the students see bad results as the best trigger to start studying. They prefer Q&A sessions in group, to learn from the questions of other students. As for study career guidance, students appreciate the interaction with their mentors who serve as a go-to person for all study-related questions. Due to the newness of their studies and the information overload experienced, first-year students ask to be given information on specific support activities more than once. Activity names should be clear and unambiguous.

The transferability of these results to other campuses or study programs needs to be further researched. We believe it is worthwhile to do so, although a few specific findings might be related to specific campus demographics (e.g. the specific need for good planning of the Q&A sessions seems to be related to the high number of commuting students at KU Leuven Campus De Nayer).

APPENDIX

Table 5. Questions asked in the small-scale quantitative research

No.	Type	Question
1	Clickable image	Think back to the beginning of the first semester (October). How supported did you feel by our campus as you began your studies?
2	Multiple choice	Below is a list of different forms of course-specific support activities that the campus organises in the first semester. Indicate which ones you have already heard of.
3	Multiple choice	Below is a list of different forms of course-specific support activities that the campus organises in the first semester. Indicate which ones you have participated in.
4	Ranking	Rank the different forms of course-specific support activities for mathematics in the first semester. Put what you consider least valuable at the bottom, and most valuable at the top.
5	Open ended	According to you, what do we have to know if we want to improve the course-specific support activities of the first semester?
6	Multiple choice	Below is a list of other types of support that the campus organises in the first semester. Indicate which ones you have already heard of. (*)
7	Multiple choice	Below is a list of other forms of support that the campus organises in the first semester. Indicate which ones you have participated in. (*)
8	Ranking	Rank the different forms of non-course specific support. Put what you consider least valuable at the bottom, and most valuable at the top. (*)
9	Open ended	According to you, what do we have to know if we want to improve the course-specific support activities of the first semester?

(*) The tutoring by higher-year students was left out of the questionnaire list at this point. The reasons for this decision were (a) not to overload the list and (b) not to confuse students, as this form of tutoring is strictly speaking not offered by the campus staff but by students.

ABSTRACT

Spatial abilities are an important, and often overlooked, component of Science, Technology, Engineering and Mathematics (STEM) education with skills like spatial visualisation and mental rotation being important for technical professions such as engineering. Individual differences in spatial abilities have been reported throughout the years. Factors such as being female or having a low-socioeconomic status are linked with lower spatial abilities level. Spatial abilities training interventions have proven to be effective, with some showing improvements, not only in spatial abilities level, but also in the success and retention of students enrolled on STEM degree

[1] *M. Velho. E-mail: mariana.velho@tudublin.ie*

doi:10.5821/conference-9788412322262.1169

programmes, especially for women. In todays' technological society, STEM outreach activities are a common method to promote STEM for children, showing them role models in the area, and improving their self-efficacy, sense of belonging and motivation to follow careers in STEM. At the same time, the underrepresentation seen in the area (e.g., women; LGBTQ+ community; ethnic minorities; and other marginalised groups) needs to be addressed in order to enhance the inclusive environment of these fields. This concept paper discusses review work in relation to underrepresented groups and how future spatial abilities studies should consider integrating the knowledge from past spatial abilities studies into STEM outreach activities. This integration can make spatial training available to more people, revealing itself to be a useful tool in helping diminish underrepresentation in STEM.

1 INTRODUCTION

When considering a career path in STEM, different factors influence someone's decision to follow that path. Not everyone starts their career path from the same position and there is a lack of representation and role models in STEM fields (e.g., visually impaired people, women, ethnic minorities, LGBTQ+ community, low-socioeconomic status, etc.) [1] and being from an underrepresented group can deter someone from following a STEM career. Underrepresentation can lead to a lack of role models in the area – making people from underrepresented groups feel like they don't belong in STEM and particularly vulnerable to dropout of STEM programs [2].

When promoting STEM as a career path, the focus tends to be placed on building a sense of belonging and self-efficacy in the area. However, spatial abilities level [3] has been shown to be another extremely important and influencing aspect which has been identified as a sleeping giant – or a phantom menace – that helps identify and develop talent in STEM domains.

Spatial abilities training programs have proved to be effective not only in improving participants spatial abilities level but also in maintaining participants in STEM degrees, especially women [4]. However, these programs are usually implemented in classroom settings. STEM outreach activities and programs are a common way to showcase STEM career paths to a variety of audiences through different delivery methods, delivered in different environments and communicating a range of scientific disciplines.

Adapting spatial abilities training tasks into STEM outreach programs that are designed for a wider audience can make spatial abilities training more accessible, allowing more people benefit from it. This paper suggests how existing outreach programmes can be adapted to improve the starting position for underrepresented populations on their journey to a successful STEM career.

1.1 Spatial abilities, STEM education and individual differences

In our daily lives, when packing a suitcase, organising objects, exploring around a city, describing where a place is, or the relation between two objects, there is a set of skills common to these tasks: spatial abilities. Spatial abilities can be defined as the performance of tasks that require (a) the mental rotation of objects; (b) the ability to understand how objects appear in different positions (i.e., if we move and look to the object from different positions); and (c) the ability to conceptualize how objects relate to each other in space [5]. They have been shown to play an important role at least in 84 different careers [6] and having 3D spatial skills are critical to success in a variety of careers, including engineering [7]. Spatial abilities are also correlated with students' achievement in STEM domains [8] [9] [10] and can predict the likelihood of students pursuing, majoring, and persisting in STEM careers [8] [11] [12]. There is a strong relation between spatial abilities and STEM performance, at all levels of expertise, because spatial abilities either limit or enhance whether a person is able to perform the kinds of spatial thinking that seem to characterize STEM thinking [12].

Within spatial abilities, mental rotation exercises are among the cognitive tasks for which the largest gender differences, in favour of men, is found [13]. Factors that have been shown to influence gender differences are stereotyping, gender role identity, socioeconomic status, and strategy selection. However, it is important to state that the majority of past studies about gender differences in spatial abilities collected and focused on gender with a binary lens, or don't state clearly how sociodemographic data regarding gender was collected and analysed (e.g., non-binary data actually being collected but not included in the analysis since that data didn't fit in the study aim). Future studies should encourage a more inclusive change on how gender or sex is studied and reported, even if gender is not a main factor in the research and it is only for demographic reporting. A researcher that is not studying gender explicitly, still has an ethical and scientific obligation to describe the demographic characteristics of their sample so that other scientists can evaluate the representativeness, inclusivity, and generalizability of the research [14].

1.2 Past spatial training studies

Recent research findings indicate that spatial abilities aren't as immutable as many people may have been led to believe [15]. Meaning that spatial abilities aren't a static skill which we are born with and can't be improved. Spatial abilities are malleable, and some forms of training can even endure and transfer to other skills. This ability can be learned and trained, with an overall size effect of training of 0.47 standard deviations, according to a meta-analysis with the result of over 200 studies on spatial training [16]. Considering what was already stated about the role that spatial abilities play in STEM education and in following STEM careers, knowing that they are malleable, gives us a window of opportunity to put this knowledge into use and help keep underrepresented minorities in STEM paths by giving them the required training in the area. Students with lower spatial abilities levels will be therefore be better supported and reduce the likelihood of them dropping out of STEM paths.

Previous studies on spatial abilities training showed that besides improving students' spatial abilities performance, training one spatial ability construct can lead to improvements in other constructs not included in the intervention programme [17]. Besides, it showed that different activities, durations, modalities (paper-based, digital-bases, or both), environments (classroom setting or not), and pre- and post-test timings, are important variables to take into consideration when developing an intervention that aims to train and improve spatial abilities.

1.3 STEM outreach: a tool for accessible spatial training

STEM outreach can be considered "the act of delivering STEM content outside of the traditional student/teacher relationship to STEM stakeholders (students, parents, teachers, etc) in order to support and increase the understanding, awareness, and interest in STEM disciplines" [18]. It provides a unique platform to reach students of all grade levels and ages, using different delivery methods (lectures; active learning problem-based learning; workshops; camps & events) and communicating different scientific areas (e.g., biology; chemistry; engineering; physics).

However, the majority of STEM outreach activities are developed with the aim to communicate a scientific concept and making science fun and accessible to everyone. This means that usually the spatial abilities dimension, or the spatial ability level of the audience, is not taken into consideration when developing an activity. STEM outreach activities that can train or develop spatial dimensions usually do it "by accident". For example, in a STEM outreach activity developed to communicate and show the work engineers do, participants are required to model the engineering design process making blueprints of their cities and create replica models showing a block of their cities using all recyclable materials. Preparing a blueprint can make participants visualise and sketch their design and, by transferring the design from paper to three dimensions, they are making a connection from 2-D to 3-D promoting spatial thinking [19].

1.4 The importance of an intersectional framework

When taking into consideration the integration of spatial tasks into STEM outreach activities, underrepresented populations must be acknowledged, with the focus changing from reducing the bias to promoting inclusive behaviours [20]. In order to adapt these tasks, previous knowledge from past spatial abilities studies should be considered as well as the knowledge on how STEM outreach activities have been made more inclusive. For example, simple gestures such as looking to those tasks used in past spatial abilities training interventions, with sighted individuals, and adapt them with the use of textures (sandpaper; Braille; etc) or haptic screens, making them more suitable for sight-impaired individuals. Or, for example, by including scientists from these different underrepresented groups presenting the scientific concepts to the audience, making the majority of people feel included by seeing all those different role models.

Spatial abilities has an important role in following a STEM career and past spatial trainings have shown that they can help keeping people in STEM degrees. However, we can't think that training someone's spatial abilities is enough to motivate them to follow a career in STEM. When adapting and integrating this training to open them to more people we must do it considering all the factors that can play a role and might interfere with the positive results of spatial training. Looking at integrating spatial abilities training tasks within STEM outreach activities considering an intersectional framework that acknowledges that each person's individual characteristics (e.g., gender, race, physical ability) overlaps with one another and affects their status in the world is essential.

2. FUTURE DIRECTIONS

Considering the previous topics, and brief literature review, we can see that there is a line of study that should focus on how spatial abilities and STEM outreach activities interact, acknowledging from the beginning that when developing STEM outreach activities spatial abilities should be taken into consideration. This integration of spatial abilities into STEM outreach can prove to be a valuable tool in improving underrepresentation in STEM fields by getting STEM concepts and spatial training closer to a wider audience. The following suggestions should be considered in future studies that aim to look into spatial abilities and STEM outreach programmes:

- ⇒ A more inclusive collection and reporting of data regarding gender. Provide participants more response options, reflecting the present knowledge we have of gender being a spectrum. Even if analysing only binary data, all the data should be reported, acknowledging the existence of those responses and why they were deleted from analysis (e.g., not enough data);
- ⇒ Always aim at making the activity the most welcoming and engaging for everyone. When developing STEM outreach activities always have an intersectional framework in mind, taking into consideration all the different characteristics of your audience and if they are being considered by the activity being developed. When facilitating a STEM outreach activity, we can be previously aware of some characteristics of our target audience, or not, but that doesn't mean we shouldn't previously think about them. For example, if we know the age range of our audience we will prepare the activity to fit that age range. But why not also consider that the audience is as diverse as it can be? And, for example, include role models of scientists that come from underrepresented groups and work on the STEM area that is being communicated. This will already allow the children from your audience that come from these underrepresented groups to have contact with a role model in the area. Or, when developing activities that have characters (e.g., games; books; etc.) have characters that represent these groups and show as much inclusion and diversity in STEM as possible.

When designing an activity that aims to be engaging to everyone, spatial abilities level should be taken into consideration. With the current knowledge we have on the relation between spatial abilities and STEM education, we must acknowledge that according to the audience spatial ability level they might find the activity harder. Although, for example, asking teachers, or parents, to pass some spatial abilities pre-test to the audience we are engaging with would be the perfect scenario so we can be aware of our audience spatial ability level, and adapt our activity accordingly. However, this is most of the times not possible. This doesn't mean that at least thinking about how this can have an effect in facilitating the activity shouldn't be considered. We know from past studies how spatial abilities level relate to some factors such as gender and socioeconomic level, by knowing the audience demographics this can help us adapt the activities accordingly. Another possibility is, by keeping always in mind that spatial abilities might affect the engagement of the audience with the activity and if having multiple outreach sessions with the same audience is possible, start with simpler spatial tasks and adapt them as the audience finds them easy or difficult. Furthermore, usually big science centers or STEM outreach facilities have a pre-defined catalog of STEM outreach activities from where they choose which ones to use, mainly according to the audience age range.

However, these centers should start considering the spatial abilities factor and think if the cataloging of these activities should also be done according to the spatial abilities level that they might require (e.g., are some activities more appropriate to an audience with a lower spatial abilities level?). By having these cataloging done these science centers could ask teachers to pre-test the kids before bringing them to an activity or – if that is not possible – and considering they have the resources, having spatial tests on tables or laptops ready to be filled by the audience before starting the activity with almost instant results (e.g., use of software such as Qualtrics ®) and choose the activity to be done with that audience accordingly to those results.

SEFI UMBRELLA FOR TEACHING MATHEMATICS IN ENGINEERING

D. Velichová
Slovak University of Technology in Bratislava
Bratislava, Slovakia
https://orcid.org/0000-0001-9506-3570

Conference Key Areas: *Mathematics at the Heart of Engineering, Fostering Engineering Education Research*
Keywords: *SEFI Mathematics Special Interest Group, European programmes, didactic cooperation, mathematics in engineering, students' feedback*

ABSTRACT

Cooperation of mathematics teachers under the umbrella of SEFI Mathematics Special Interest Group (former and more proper - SEFI Mathematics Working Group) has brought many benefits and improvements of strategies adopted at various European technical universities for teaching mathematics courses. Many successful international research teams were formed during the group bi-annual seminars and SEFI annual conferences, which benefitted on grants awarded by the European commission that supported international programmes aimed to improvements in teaching/learning scenarios. Some information summarizing results and findings of 8 European projects accepted and supported in different European programme schemes (Socrates, Leonardo da Vinci, Erasmus) will be presented in a brief analysis about impact of these projects on the introduction of innovative teaching-learning scenarios of mathematics courses at the participating European technical universities. Paper will address several didactical problems revealed from students´ answers in didactical questionnaires as feedback and reactions from the "other side". The attitude of students as other actors in didactic situations who are encouraged to actively cooperate with teachers is often neglected when introducing various innovative teaching/learning methods, which are generally considered to be active.

1 INTRODUCTION

1.1 About SEFI MSIG

Special working groups were formed within SEFI organization at the very beginning of its establishment and operation in the European higher education and research area. Mathematics Working Group appeared among the first ones, and it has always belonged to the most active groups consisting of enthusiastic maths teachers engaged in teaching basic mathematics courses at higher technical institutions and universities in the majority of the European countries. Formed Steering Committee of the group organised various interesting activities for group members, while regularly held bi-annual seminars about engineering mathematics proved to be one of the most useful and enjoyable ones. Good tradition is kept until today, next year 2023 the 21st SEFI MSIG Seminar on Mathematics in Engineering will take place in Romania. Seminars serve as a free forum for exchange of best ideas, good examples and personal experience of maths practitioners gained in their mundane didactic life. Atmosphere at these seminars is traditionally very friendly, open and inspiring. The reason is probably the fact, though not very much optimistic, that mathematics courses generally do not belong to the most favourite parts of engineering study programmes anywhere. Very similar problems which lecturers face in their everyday practice form the fruitful platform for vivid discussions, stormy debates and enable the birth of many original ideas and non-traditional solutions leading to the continuous improvement of the used didactic methods and practices.

At the same time, such busy working environment creates fertile ground for the formation of stronger international cooperation between colleagues from various institutions and for the birth of research teams seeking to submit project proposal and obtain funding from European structures and funds.

In this paper, 8 international projects dealing with teaching mathematics courses to engineering students will be presented, while all project teams were formed, developed their project proposals and successfully defended project results under the SEFI umbrella. This environment therefore proves to be really very conducive to the development of engineering education and its constant direction towards future improvements, ambitious expectations and successful achievement of the goal to maintain “*Mathematics at the Heart of Engineering*”.

1.2 About projects

Among many research and educational programme schemes provided by the European Commission, e.g. Tempus, Phare, Grundtvig, Socrates, Minerva, Leonardo da Vinci, Comenius, Erasmus+ programme that is a funding scheme to support activities in education, training, youth and sport seems to be the most powerful and centralised action managed at the European level by the European Education and Culture Executive Agency (EACEA). Most of the recent educational programmes belong to this scheme under specific sub-classification as Stategic partnerships or Partnerships for cooperation. Programmes, we are going to analyse, will be presented as they were realised in the consecutive time sequence.

1. **EU Socrates programme project No. 90196-CP-1-2001-1-NO-Minerva-M**
   Xmath, years 2002 -2004, was coordinated by Hogskolen i Buskerud, Kongsberg, Norway and there were 6 partners cooperating – Universita Potificia Madrid, and Salamanca University from Spain, University in Kuopio, Finland, Munich software company from Germany, International Centre for Theoretical Physics in Trieste, Italy, and Slovak University of Technology in Bratislava, Slovakia. Project was aimed to explore the possibility of creating a database of mathematical modules available free on the Internet. Team of researchers was formed during SEFI conference and their cooperation was successfully fulfilled with development of one basic module on Differential Calculus, [1].
2. **Leonardo da Vinci programme project No. N/03/B/FF/165.011**
   dMath, years 2003 – 2006, coordinator: Hogskolen i Buskerud, Norway, was continuation and support of the previous project aimed to finalisation of the second module of Integral Calculus. There were also first trials to develop an on-line calculator (supported by Mathematica commercial software product) providing step-by-step calculations in a remote mode. This idea proved to be not very successful due to utilisation of an expensive software solution. Anyhow, both modules developed by means of innovative presentation of mathematical formulas using MathML coding in xml pages are still used as additional instructional materials for students at the participating universities, [1].
3. **Leonardo da Vinci programme project No. SK/06/B/F/PP-177436**
   EVLM – European Virtual Laboratory of Mathematics, years 2006 – 2008, coordinated by Slovak University of Technology in Bratislava was a very successful project that aimed to develop database of on-line electronic materials available on a freely accessible platform. 7 project partners were recruited among participants at the SEFI Mathematics Working group seminars: Paisii Hilendarski University of Plovdiv, Bulgaria, West Bohemian University in Plzeň, Czech Republic, Tulossilta Company from Tampere, Finland, Technical University in Miskolc, Hungary, University of Limerick, Ireland, Salamanca University in Spain, Coventry University from the United Kingdom. During 3 years of the project life a common EVLM portal was opened storing all developed materials in English, while all of these resources were translated and available in national languages of partners at their institutions. Portal is partially functioning at some of them even today, depending on the partner institutions interest and effort to keep the created materials available even after the necessary period at the end of the project, [2].
4. **Erazmus - Strategic Partnership project No. 2015-1-FI01-KA203-009044**
   Future Mathematics, years 2015 – 2018, coordinator: Tampere University of Applied Sciences, Finland. Three partners were - Polytechnic University in Madrid, Spain, Slovak University of Technology in Bratislava, Slovakia, and Technical University of Civil Engineering in Bucharest, Romania. Project was initiated to support modern-day teachers and students by providing a platform as well as resources for teaching and learning in digital form. Moodle environment was used at the platform, and the idea of step-by-step calculations available for students to

self-testing was realised by generated stack-exercises. Project fulfilled its aims to respond to the requirements of modern society and to make mathematics' learning and teaching more digitalized, effective and accessible, [3].

5. **Erazmus - Strategic Partnership project No. 2017-1-PT01-KA203-035866**
   DrIVE-MATH, years 2017 – 2020, coordinator: PTEI Porto, Portugal, was aimed to introduction of innovative active learning methods into the basic mathematics courses in engineering study programmes. Partners – Claude Bernard University, Lyon, France, Technical University in Chemnitz, Germany, Slovak University of Technology in Bratislava, Slovakia – introduced various learning scenarios in their educational practise, as eduScrum, Problem Based Learning, Individual Projects, Gamification, Jigsaw Puzzles, Interactive lectures, hands-on-techniques. Results were analysed and compared, while all gained good and bad experience was presented in Project book with didactic instructions and recommendations, [4].
6. **Erazmus - Strategic Partnership project No. 2017-1-PT01-KA203-035866**
   RULES_MATH, years 2017 – 2020, coordinated by Salamanca University, Spain was a huge project with many partners – Paisii Hilendarski University of Plovdiv, Bulgaria, Slovak University of Technology in Bratislava, Slovakia, Ankara Haci Bayram Veli University, Turkey, Czech Technical University in Prague, Czech Republic, Polytechnic Institute of Coimbra, Portugal, Technical University Dublin, Ireland, Technical University of Civil Engineering in Bucharest, Romania, Spanish National Research Council, Madrid, Spain. The main objective of the project was to develop assessment standards for a competencies-based teaching-learning system for mathematics in engineering education. Project team was based on partnership from several previous projects, while the main goal was to bring practical ideas how to assess knowledge gained after successful completion of basic maths courses focused on development of mathematical competencies – concept developed and elaborated at the SEFI Mathematics Special Interest Group seminars. [5].
7. **Erazmus+ Partnership for Cooperation,**
   Project No. 2021-1-RO01-KA220-HED-000032258
   DIGI STEM, years 2021 – 2024, is a new project coordinated by Tampere University of Applied Sciences, Finland, and bringing together for further cooperation partners cooperating in the previous successful project Future mathematics - Polytechnic University in Madrid, Spain, Slovak University of Technology in Bratislava, Slovakia, and Technical University of Civil Engineering in Bucharest, Romania. This new project is going to develop further ideas partially elaborated 3 years ago, and its main goal is to lay the foundations of digital pedagogy and summarise experience of the two-year long distance education with heavy utilisation of digital technologies in on-line or hybrid teaching and learning during the Covid-19 pandemic throughout the whole world. Project is aimed more theoretically, its primary goal is to provide fundamental guide to maths teachers on how to adapt teaching/learning strategies to the paradigm of the 21st century – digitalisation of all aspects of social life, not excluding education and knowledge acquisition in general [6].

8. **Erazmus+ Partnership for Cooperation**
   Project No. 2021-1-RO01-KA220-HED-000032258
   PYTHAGORAS, years 2022 –2025, coordinator: Lucian Blaga University of Sibiu, Romania, partners: Aalborg University, Denmark, Karlstad University, Sweden, Porto Polytechnic, Portugal, Slovak University of Technology in Bratislava, Slovakia, University dela Laguna, and EVM Spanish Consultancy Company, Tenerife, Canary Islands, Spain, Hellenic Mediterranean University, Heraklion, Crete, Greece. This ambitious project strives to develop policies that will make learning Mathematics more inclusive, efficient, enjoyable and real, connecting Mathematics teaching with real life cases linked to the students' fields of study. All project outcomes and activities will be tailored to address the prerequisites of the partner institutions for undergraduate students regarding their fundamental mathematics background and these perquisites will be checked from all aspects: mathematical content, mathematical processes, views about the nature of mathematics, and personal and academic characteristics of students & teachers. Project expected intellectual outputs and results include: Toolbox for teachers on Education for Sustainable Development, Learning scenarios and guide for gamifying online and hybrid mathematics education at university level, and An online and open access Precalculus Course (MOOC) in English, [7].

Brief analysis of the presented projects´ methodologies and strategies, including summary of their results and outcomes articulated in published reccommendations are presented in the following chapters.

2 METHODOLOGY

2.1 Long 20 years of transformation

Time interval of 20 years between the first and the last presented projects that are dealing with almost the same problems and issues indicates how conservative might be our educational systems and institutions on one hand, while it also reveals their authenticity, stability and persistence of verified values they are representing on the other hand. Long-lasting journey and endless efforts are necessary to establish changes in the traditional educational practises that have to be overcome in order to introduce visible changes in educational approaches and used methods.

While the first two – three projects solved during 2002 - 2008 present just minor insignificant attempts to utilise information and communication technologies and available software products appearing at the scene somehow also in education, projects currently approved in 2022 bring forward a serious research efforts to define, develop and use in pedagogical practise digital methodology and didactics. The worldwide Covid-19 pandemic lasting more than 2 years was one of the main reasons of the rapid and almost complete switch from the "steady on-site" to "experimental on-line" teaching at all levels of education systems. This unexpected situation fostered the urgent need of digitalisation of all aspects of educational processes, from delivery of information, communication between teachers and students, through practising theoretical knowledge and formative assessments up to the summative assessment and on-line examination solutions. Consequences of these fast changes reflected in the knowledge acquisition will be analysed in the currently solved projects [6], [7].

2.2 Project strategies

All referenced projects were aimed to introduce innovations into traditional university learning scenarios used for ages in mathematics courses – lectures for delivery of theoretical backgrounds, practicals for training solutions of related problems, oral or written examinations. Overall digitalisation of all social processes evoked legitimate attempts and efforts to rethink how mathematics is taught to engineering students. On one hand, ICT revolution enabled experimentation with different distance learning scenarios and enabled development of more versatile modes of instructional materials - on-line modules for self-study, stack exercises for step-by-step calculation training, electronic lecture notes available free on-line, didactic videos, animations, solved examples and applications as projects´ results.

On the other hand, these strategies were sometimes leading to even more passive behaviour of students than it was the case of traditional didactic situations, as learning was more personalised and depended on the involvement of students themselves and their inner motivation to study and acquire new knowledge. Teachers became more developers and authors of e-learning materials and moderators of the educational processes than their facilitators. Anyhow, this did not automatically led to activation of students, just the opposite. Teachers were often frustrated by the enourmous amount of work they had to put into developing innovative instructional materials, which was not adequately received by students, but led to their passive acceptance and even refusal to study all this materials as another hurdle they had to overcome in other to pass the exams successfully.

In all mentioned projects, research teams strived to receive feedback from both actors in the education process. Structured didactical questionnaires were used to perform opinion poll and to receive and analyse answers of respondents in realised didactic experiments at the partner universities. Cohorts of students were chosen on voluntary basis, sometimes there was an entire traditional Mathematics course transferred into a personalised distance learning module, or into a team work solving relevant applied problems by mathematical methods. Attempts to introduce active learning methods as eduScrum, Jigsaw puzzles and PBL methods were one of the most interesting, while the overall detailed analysis of the case studies was presented in articles published in educational journals and at the didactic conferences, see e.g. [8].

3 RESULTS

3.1 Statistical overviews

Most statistical data proving the first observations that “Less seems to be sometimes more” were obtained from the project *DrIVE-MATH*, [4]. Randomly chosen cohort of students in the basic course of Mathematics at the bachelor study engineering programmes participated in the experimental teaching strategy EduScrum. This method showed students a new way of work during tutorials, a teamwork in small groups of 4-5 students, which they rated very positively. The aim of the experiment was to find out the level of knowledge acquisition and to compare abilities of students to solve mathematical problems independently, or as a collective work in the small groups. Anonymous questionnaire answered by students after completion of the experiment gave researchers a good feedback and overview of their opinions, from which they could compare their attitudes towards different teaching methods applied.

It has to be stated that students with weaker knowledge benefited more from the team work as practised in the randomly formed small group. Very good students helped their classmates to receive better marks and took a greater part of the work on their shoulders. On the other hand, team represented one unit as all members were supposed to be equally responsible for their common achievements. This was often a strong motivation and driving force encouraging both - good students and not that good ones to do their best and contribute to the team final success.

It is up to the teachers how they will introduce this method into their teaching. Team of maths teachers in the project was enthusiastic and keen to implement new active learning scenarios in their teaching practise. They worked with enjoyment and this pleasurable attitude was naturally transferred also to their students. Preparatory work and development of necessary didactic materials is a quite time consuming activity. It requires a real devotion of teachers who should plan carefully all activities in advance, support students with enough learning instructional materials and to be ready to help them with advice in mostly unforeseen situations that might occur during the activities.

Positive aspects of eduScrum method: possible continuous assessment of students' knowledge during the whole semester, from separate parts of curricula consequently; method eduScrum taught students to work in the team, to be responsible for their solutions, to be responsible for the whole team as a unit, to lead a constructive discussion about problems and to understand better the problem solution. As students pointed out in the interview, team work helped to more than 75% of them to understand learned content better.

Negative aspects of eduScrum method: random distribution of students to working teams based on their friendship after the arrival to university study, not on base of knowledge level from mathematics; weaker students learned how to "grasp" problem and how to start to solve it, appreciated help from better students with solutions of their own problems and acquired more points in their "score" from particular topics thanks to better students in their team; better students were a bit "constrained" by weaker students, they had to explain to weaker students how to solve their problems in order to receive as much points as possible for their own score so they solved entirely also problems of other students, with the same points for everybody; they often received less points on their "score" for not correct solutions of problems solved by weak students, as they could receive provided they had solved the problems themselves and correctly, or in another constitution of the working team; better students were willing to work, later during the semester, in smaller groups (2 - 3 members) and they agreed on finding solutions of all given problems in the time limit.

In connection to general recommendation for future broad general implementation of eduSrum method in teaching mathematics to the engineering students at the bachelor or master study programs, we suggest the following few ideas in order to support development of the best students:

– to recognise in each course of mathematics at least 2-3 teams of excellent students and "train" them as excellent teams to solve practical problems in their respective technical professional subjects
– to support healthy competitiveness between these teams of excellent students
– to build common worksheets for team work with problems that could be solved by these excellent teams of students, analyse the overall results consecutively, and contribute thus to better education of future European engineers in mathematics
– to organize at least one competitive teamwork session between excellent student teams inorder to support their higher need
– to appreciate achieved results of all teams, regardless their composition to support and encourage students with weaker results
– to monitor and carefully record results of all students and give them due feedback.

In general, none of the surveys carried in the terminated 6 presented projects proved that the greater efforts by teachers to support students lead to their exceptionally better results and better motivation to learn.

4 SUMMARY AND ACKNOWLEDGMENTS

We believe that, given the current state of knowledge of students, their basic working and methodical skills necessary for the study work at universities and the new roles of teachers in the educational process, the goal of teachers will continue to be focused on the quality and not the quantity of students who complete the subject.

ORCID 0000-0002-0454-4924

Conference Key Areas: Fostering Engineering Education Research, Physics and Engineering Education

***Keywords**: Concept development, Conceptual understanding, Cultural-historical theory, Work analysis, Microengineering*

ABSTRACT

Concepts are a matter of importance for engineering education. Believed to be critical for developing expertise and engineering competence, conceptual knowledge has become a focus for research and training. Despite focusing on it, engineering graduates still often do not understand core concepts for their practice. With a few exceptions, most research concerning conceptual knowledge in engineering has been developed on assumptions of cognitive psychology, which have been subject to strong criticisms. One of these criticisms points out that mainstream approaches on concepts do not account for the socio-material conditions in which concepts are used and transformed. Some researchers in engineering education have moved beyond, taking a situative perspective. These studies have shown how, compared to training, knowledge in the practice is highly contextualized, depends on tools in which it is inscribed, and is distributed among collaborators. However, while stressing the socio-material dimension of conceptual knowledge and the differences in concept use between training and practice, the situative perspective does not account for the way in which conceptual knowledge develops. Alternatively, the cultural-historical theory of concepts offers an approach that overcomes the weaknesses of mainstream approaches while addressing the problem of development. Drawing on cultural-historical theory, this paper presents an ongoing research aimed at the study of concept development in microengineering teaching and practice. I will present the

martin.vergara@unine.ch

respective methodological approach—borrowed from a French tradition of work psychology—for studying concept development from interactions in work and teaching activities. Expected results and implications for engineering education will also be discussed.

1 INTRODUCTION

Concepts are central for all human activity. Whether we are talking about the everyday concepts we learn from our earliest childhood, or the complex concepts developed through years of scientific activity, they are deeply embedded in our experience. In these concepts we can find what has become meaningful for a community over time, what is important for its activity and what it accepts as true given the current state of knowledge. Beyond being a reflection of the past, since science and technology are ongoing activities, new concepts are developed to express new phenomena and communicate about them. Concepts are commonly shared within a community (e.g., professional, disciplinary, or practice communities) where they are useful for communication, collaboration, and understanding. They have been learned at some point, and they must be taught to newcomers so that they can master the activities performed by the community.

Learning the concepts that are important for living in society is one of the main tasks of the school. Likewise, the appropriation of the concepts that guide a qualified activity is at the core of post-secondary and professional education. However, it is a well-known fact that most conventional meanings, or concepts, are difficult to learn, even for adults and after several years of instruction. One of the most salient approaches to the study of this phenomenon in education is the research on Conceptual Change [e.g., 1, 2]. It studies the early representations held by learners and those held by experts, the changes they undergo, the mechanisms behind those changes, as well as the instructional strategies to promote them. From the early 1980s to the present, a growing body of research has studied conceptual change in diverse domains, from the natural sciences and mathematics to history and the social sciences. Today there is some agreement that concepts, being embedded in more or less coherent structures that have a certain explanatory capacity and functional value, change and evolve gradually. In their different versions, the difficult of conceptual change would be due to the interpretation of scientific knowledge in terms of previous knowledge [e.g., 3], to ontological miscategorization [e.g., 4], or to the initial lack of organization of sub-conceptual units [5].

Most researchers in conceptual change would recognize these days the importance of the contexts and situations in which concepts are formed and transformed. However, some sociocultural approaches have a addressed those criticisms in a radically different approach. Rejecting or de-emphasizing most cognitive assumptions, these researchers have moved towards a *participation metaphor of learning* [6]. These perspectives, move the cognitive level to the background, to understand learning as a situated and interactional process consisting of “taking part in” or “being part of” the discourses and social practices of scientific communities [7]. Examples of these approaches are the discursive approach of Roth [e.g., 8], the sociocultural approach of Säljö and colleagues [9], and Greeno's situative perspective [e.g., 10], which has also been used in research in engineering education as I will discuss in the next section.

2 CONCEPTUAL KNOWLEDGE IN ENGINEERING EDUCATION

In engineering education, concepts have also received important attention. According to Streveler et al. [11], engineers rely upon conceptual knowledge for their practice—including intuitive expectations, not just sophisticated models or physical prototypes. Therefore, conceptual knowledge is believed to be critical to develop expertise and engineering competence, becoming a focus for research and training [9, 10]. In spite of this attention, engineering graduates often "do not understand the foundational concepts of solid and fluid mechanics, physics, thermodynamics, digital logic" among other fields [13, p. 83]. Differences between engineering students and practicing engineers in conceptual understanding of core engineering concepts [14] and in their conceptions of engineering itself [13, 14] are also described. While they are widely used in the field, the notions of *concept* and *conceptual understanding*, are not satisfactorily understood [17].

Most research concerning concepts in the engineering education rests on assumptions from cognitive psychology. Conceptual understanding is referred to as the collection of concepts (i.e., pieces or clusters of knowledge), beliefs (i.e., propositional relationships between concepts), and mental models (i.e., groups of meaningfully related beliefs and concepts that allow people to explain phenomena and make predictions) [13]. Although the different branches on conceptual change that we have discussed before are known and have been brought to the field [e.g., 13, 18–20], there is still little research on conceptual change in engineering education from sociocultural approaches, as Brown and collaborators point out [21].

On the other hand, noticing that undergraduates and practicing engineers performances are very different—with students often outperforming practitioners in concept inventories [e.g., 14]—, some researchers have highlighted the context and activity dependency of conceptual understanding [20–25]. Consequently, they have paid more attention to the way in which the understanding and use of concepts vary across school and work. For example, Bornasal and collaborators use an ethnographic approach to study conceptual growth in transportation engineering work [25]. Taking a stand near the situative approach, they show how conceptual understanding development relies on contextual constraints, on negotiated meanings with others, and material resources "such as computer software, reference books, and calculators, to address problems associated with certain features of concepts" [25, p. 336]. Similarly, Barner and colleagues [20–22] use ethnography in structural engineering workplace and undergraduate structural engineering courses, describing how the use of heuristics, use of tools and conceptual representations differ in both between the two contexts.

These researches have confirmed the differences between training and practice engineering activities, and have deepen our understanding of the way in which conceptual knowledge is embedded in those contexts, distributed among people and the tools they use. However, beyond pointing out the differences, it is critical to advance towards the understanding of how participation in these activities progress and mastery on conceptual knowledge grows.

3 CONCEPT DEVELOPMENT IN CULTURAL-HISTORICAL TRADITION

Cultural-historical theory [28, 29], developed by Lev S. Vygotsky, addresses explicitly the problem of concept development. Schematically, four key ideas are fundamental to understand this approach. First, concepts are actual thinking processes, and not mental entities. Every time we use a concept, we are generalizing, i.e., treating a unique event as belonging to a class of events. However, we do not generalize by putting linguistic labels on events or objects. Concepts are not the *tools* by means of which we classify. On the contrary, that generalizations *occurs* in the concrete uses of language. Every time we use a concept, we are carrying out such a generalization.

Second, concepts are the basic units of verbal thinking: word meanings. However, what make them meaningful is not their place in the language system, but their concrete and specific function in social life. As concepts always fulfill a function for reasoning, understanding or communication, we derive the meaning of words from the way in which they are used in social situations. Thus, the meaning of the words we use in training and practice activities, will be inevitably attached to the functions they have in those activities.

Third, while concepts as conventional meanings have the stability of language and the social practices in which they are used, they change both microgenetically and ontogenetically. Microgenetically since, as was mentioned above, every time we use a concept we are generalizing in a particular way, in relation to the specific situations in which they occur. Ontogenetically, since the meaning of the words we use changes as our participation in a community changes. Although children and adults, as well as newcomers and old-time practitioners can use the same words and understand each other, but doing so they are actually performing different acts of thinking.

Finally, the development of concepts through life is initiated as actual socio-material relations. In other words, before being appropriated by the individual, concepts were actual relationships with others. These social situations in which we take part, exchanging with others, using their language and their tools, to fulfill certain purposes, are those that will be internalized. A critical aspect in relation to the last point is that, while our lives are full of social and material relationships, not all of them will become psychological functions. On the contrary, only those that are experienced as conflicting or emotionally charged, will initiate such a process [30].

As discussed, there is much more behind the external appearance of concepts. As noted by some researchers in engineering education, concepts are embedded in the contexts where they are used, distributed among people and tools. Furthermore, following cultural-historical theory, these concrete socio-material relations will develop into internalized concepts. Although learning and development will almost inevitably occur from social interactions, to initiate a specific developmental path that ends with a particular outcome within a given time frame—as is the goal of education as we know it—will require the acknowledgment of those specific interactions to reproduce them. However, the social and material nature of concepts remains hidden behind a static appearance. Going beyond description, this research seeks to shed light on the developmental paths that concepts follow from social, discursive and material relations, to be mastered by individuals (i.e., to become psychological processes) in the accomplishment of concrete functions. In the next section, I will present the methodological approach taken by this research.

4 A METHODOLOGICAL APPROACH TO STUDY CONCEPT DEVELOPMENT

Vygotsky did not preview a method for studying concept development from work activities. Building a theory of psychological development and believing that early childhood was the privileged age to study it, he did not even focus on adult development. However, as we have discussed, since social interactions are the source of development and work activities are one of the—if not the—most important activity we carry out as adults, then it is normal to look for development in this kind of activity.

Activity Clinic [31], a French tradition of work psychology drawing on Vygotsky's work, explores precisely development in work activities. It is primarily conceived as an interventionist methodology, aimed at supporting the development of collective capacities of organizations. Activity clinicians recognize that work activity exceeds what is visible. Work activity includes not only the practitioners (with their skills, knowledge, experiences, and preferences) and the specific tasks prescribed for them (as defined by documents, procedures, and structures). Additionally, in work activity these practitioners are always addressing to other individuals, whether they are partners, managers or customers, and, to do so, they make use of a set of collective resources historically developed. Furthermore, beyond the realized activity (i.e., what is actually performed and observable by its results), there is a set of unrealized possibilities:

> […] what workers don't do although they would like to, what they do without succeeding, what they abandon doing, what they think they would do under different conditions, or even what they do to avoid doing what is expected of them. [31, p. 58]

By means of different techniques, work psychologists in Activity Clinic structure dialogues with practitioners oriented to collectively analyze and improve their work activity. Of particular interest for us is the methodology *cross self-confrontation interviews*. In these interviews, activity clinicians co-analyze with practitioners their own practice. The outcomes of these analyses are used as tools to mobilize dialogue among the different levels of the organization and to promote change in it.

The methodology that interests us is implemented in different stages. Initially, practitioners interact with the researcher at the workplace, while the latter observes the activity of the former. The researcher, by means of their questions and comments, encourages practitioners to observe their own practice. In a later stage, workers are invited to engage in the research. Later, the researcher and the volunteer practitioners conform then the “associated research group,” which will collectively choose relevant sequences of work activity to analyze. These sequences are recorded and then co-analyzed, first, in simple self-confrontation (in which a practitioner and the research discuss their own activity) and later in cross self-confrontation (in which the practitioners are asked to comment on their own activity and react to the comments of a colleague). Finally, the researcher and the volunteers will select video clips from both the activities and the interviews highlighting critical aspects and conflicts of the job, to present and discuss with a wider audience, including the different levels of the organization.

While my research in principle does not concern an organizational intervention, Activity Clinic and, particularly, the dialogic framework of cross self-confrontation interviews features a suitable setting for the study of concept development [32]. As it was discussed in the previous section, the study of concepts should (1) go beyond the external, static appearance of concepts, (2) accounting for the contexts in which they are used and change and (3) highlighting the conflicting social relationships where their development begins.

As ethnographic approaches do, Activity Clinic observes the real activities carried out by practitioners, in the concrete context in which they occur. Going beyond what is visible in those activities, in self-confrontations, practitioners themselves are invited to explicit and make sense of their own activity and those of their colleagues activities. Furthermore, confronted to the different ways of performing and to the comments and questions of colleagues and the researcher, even simple statements they know and share with their professional community can be called into question. In the observation, analysis, and comparison of similar activities performed by different individuals, cross self-confrontations trigger comments and questions.

This dialogical activity puts practitioners in the spot and create structured conflicts in a way that requires them to “go beyond well-established knowledge to be able to convince both the researcher and their colleague” [32, p. 335]. In this way, the observations and comparisons of routine behaviors, combined with thoroughly structured discussions of convergences and discrepancies, what had been packed over time, becoming invisible even to experts, is retrieved and unfolded for analysis [32].

Following the described method, this research is taking place at a Swiss university in the domain of microengineering. It concerns both teaching and practice activities which constitute two different fields of study. On the one hand, I am studying the activities undertaken in a laboratory working on microengineering. In that context, I follow a group of engineers with different levels of experience collaborating on design, development and research projects that are led or supervised by them. On the other hand, I will study a course on mechanism design for second-year students run by the same team. In the course, both the teaching activities of the staff and the activities carried out by the students in a design project will be studied.

5 DISCUSSION

Concepts, conceptual thinking, and conceptual development are important phenomena for engineering education. Despite the attention they have received over the last decades, there is still a lot of work to do. As it has happened in psychology and education, the mainstream understanding of concepts has overlooked aspects that are critical for study them. As in psychology and education, sociocultural perspectives have also reached engineering education, highlighting the importance of the contexts and instruments to which knowledge is inextricably associated. We have arrived to the acknowledgment that the way students understand and use concepts in training is quite different from the way practicing engineers do it in real contexts. Bridging this gap, however, is still a pending task.

We know that engineers in their new professional contexts will learn what they need to learn *after a certain course of development*. However, although development and learning will inevitably occur over time as a result of the participation in social interactions, to produce an outcome deliberately in training, certain processes, particular designs, or the arrangement of certain conditions are required. We need, then, to shed light on how the development of the concepts that actually interest us occurs in real sociomaterial interaction, to reproduce them in training. In that vein, I suggest that engineering education can benefit from research conducted following the cultural-historical theory.

This research is aligned with the research that has been developed using ethnographic methods from situatives perspectives, and tries to push it one step further. Furthermore, the proposed method consistently follows the rationale behind the cultural-historical theory. Nevertheless, this approach is rather experimental and pioneer in engineering education. Therefore, careful and systematic empirical research is needed.

Although it could have taken place in any context, engineering practices and engineering education are exciting environments to conduct this research. On the one hand, well-known concepts, stabilized in the community and critical for the discipline are permanently at stake. This environment offers us the possibility to address in the context of their use, to examine their sociomaterial roots. On the other hand, stabilized activities taking place within a community of practice might be available to be conceptualized. While it is still very early in my research, some aspects have already emerged concerning both, the usual ways in which these engineers address mechanical concepts in designing and in teaching, and a very particular way of doing design, recognizable by them, yet not conceptualized.

It is important to notice that the way of doing things among different disciplines and subdisciplines, but also among communities of practitioners within them will differ. Therefore, at a certain level the results will also be idiosyncratic and the translation from one context to another will not be evident. If with the cultural-historical theory, we assume that human development is a process “historically rooted, socially shared and culturally shaped” [33, p. 45], then we have to accept that fact. However, by unveiling the particularities of concept development in different contexts we can make training practices more appropriate and, in the long run, account for the regularities of the phenomena that concern us.

For the sake of my argument, I have briefly discussed here some research approaches that have been important in educational psychology and engineering education. Articulating the notions of *concept* that underlie each of the different perspective, however, may require a finer treatment. The concept of concept held by different research traditions that often rest on different epistemological underpinnings, make of this and important and challenging task. The dialogue between disciplines and research traditions is, however, strongly necessary.

ABSTRACT

There is a growing urgency to incorporate sustainability in all facets of society to stay within the planetary boundaries. Higher education has a significant role by educating their students - our future work forces – with the knowledge and competences that are crucial for working with sustainability challenges. The development of sustainable technology thereby takes a significant place, pointing out the role of engineering education. This article presents the journey of integrating sustainability in the M.Sc programme Electronic System Design and Innovation at the Norwegian University of Science and Technology. We focus on three aspects of this journey. First, we present the approach used and the process stages for the integration of sustainability, which is a renewed version of a toolbox for integrating ecodesign in engineering studies. Secondly, we present how academic staff is involved throughout the integration process. To be able to succeed with incorporating sustainability into a study programme, it is important to engage and empower academic staff, since they have a central position through their responsibility for a study's central building blocks - the different courses. Lastly, we outline insights and experiences from the perspective of academic staff and the project team involved in the integration process. We conclude with how the approach used and the lessons learned can provide useful strategic and practical insights for other engineering programmes in their process of integrating sustainability and plans for future activities.

1 INTRODUCTION

1.1 Integrating sustainability in higher education curricula

This article presents insights and experiences from academic staff related to the integration process of sustainability in an electronic engineering programme. Through this work, we aim to contribute to the need for incorporating sustainability in all facets of society in order to stay within the planetary boundaries. Higher education has historically played a role in transforming societies, by educating decision-makers, leaders, entrepreneurs, and academics, and by serving the public good [1]. A growing number of universities gets engaged in incorporating and institutionalizing sustainable development (SD) into their education, research and outreach, and campus operations [2], [3]. The role of higher education is to educate and equip their students with the knowledge and competences that make a sustainable transition happen [1]. Growing pressure from industrial entities - asking for graduates with an engineering degree and the relevant skills to be able to handle SD - has become an important driver for higher engineering education to integrate SD in the curriculum [4].

1.2 Involving academic staff

Several researchers emphasize the importance of involving academic staff in the transformation towards education for SD [2]. This is related to the central role they have in curricular development and how to direct it more towards sustainability. However, literature also indicates that there is a strong need for support for educators that empower and involve them in the integration process [4]. In this article, we focus on academic staff involvement during the journey of integrating sustainability in the M.Sc engineering programme Electronics System Design and Innovation (Elsys) at the Norwegian University of Science and Technology (NTNU). We focus on how academic staff got involved and supported throughout the integration process of SD in the curriculum, and on experiences from involving academic staff seen from different perspectives. The results are part of a pilot project within the strategic initiative Technology Education of the Future at the university. The integration of competences for SD in all the university's future engineering and technology studies forms a significant component of this initiative.

2 METHODOLOGY

2.1 Pilot case: study programme Electronics Systems Design and Innovation

In this work we focus on a pilot case, the Elsys study programme that is currently integrating sustainability in its curriculum. The case provides empirical data as a foundation for gathering insights and experiences from academic staff on the integration process of sustainability in the M.Sc programme. The study program Elsys is a 5-year integrated Master's program within electronic engineering, with courses given mainly by the faculty at the Department of Electronic Systems at NTNU. Approximately 120 new students enroll in the program every year. Within the study program, the students can choose specializations within analog, digital and embedded design, signal processing, radio communication, nanoelectronics and photonics, and acoustics. Traditionally, the program has had a limited focus on sustainability. This may be linked to the past and current focus of the program and its associated academic community on fundamental and enabling technologies, and to a smaller degree on end products, thereby distancing the technology development from end users and society.

2.2 Toolkit for integrating sustainability in engineering education (ISE toolkit)

The *toolkit for integrating sustainability in engineering education* - shortly ISE toolkit - that is used in this work aims to support the integration process of sustainability in M.Sc programmes and has been applied in the Elsys study program. It is based on the EHE toolkit, a toolbox for integrating ecodesign in engineering studies [4] and has been updated, amongst other by including the UN Sustainable Development Goals (SDGs), and adapted to the context of the university. The new elements and adaptations of the toolkit have been tested throughout several stages of the development process and applied in the pilot case.

2.3 Data gathering and analysis

Students and academic staff have been involved in the integration process of sustainability in the pilot case, thereby applying the toolkit, its approach and elements. In order to gather insights and experiences on academic staff involvement, the project team gathered qualitative data, including a *questionnaire* that provides feedback from academic staff on specific steps of the integration process, *interviews* with academic staff that provide insights on opportunities and barriers for integrating sustainability in the curriculum, and *reflections* that offer insights from the project team on experiences from participants and facilitators during different stages and activities of the integration process. A thematic analysis has been used on the pilot case data to gather insights on how academic staff got involved and supported throughout the integration process of SD in the curriculum in practice, and on the experiences from involving academic staff seen from different perspectives.

3 RESULTS

3.1 Approach for integrating sustainability in M.Sc programmes

In this section we shortly present the ISE toolkit's approach for the integration of sustainability, the main process stages and the toolkit's main elements, before we present how the process took place in practice in the pilot case.

The aim of the ISE toolkit is to facilitate study programme management, academic staff and other stakeholders to integrate sustainability in the curriculum. It does this through *informing*, *motivating*, *inspiring* and *connecting* academic staff and other relevant stakeholders throughout the integration process, thereby supporting *collaborative learning* around SD and how it fits into the curriculum [4]. Moreover, the toolkit *combines a bottom-up with a top-down approach*, whereby initiatives and ideas from academic staff are warmly welcomed and get supported, whilst simultaneously engaging the head of department and other leadership positions in order to provide driving forces in the integration process.

The toolkit provides guidance in getting an overview of SD in the whole curriculum (*programme-driven approach*), as well as it offers the opportunity to look at specific courses and how sustainability fits in. It does this through dividing the work in different process stages, which can be represented in two main stages of the integration approach: 1) Mapping sustainability in study programme and 2) Opportunities for further integration.

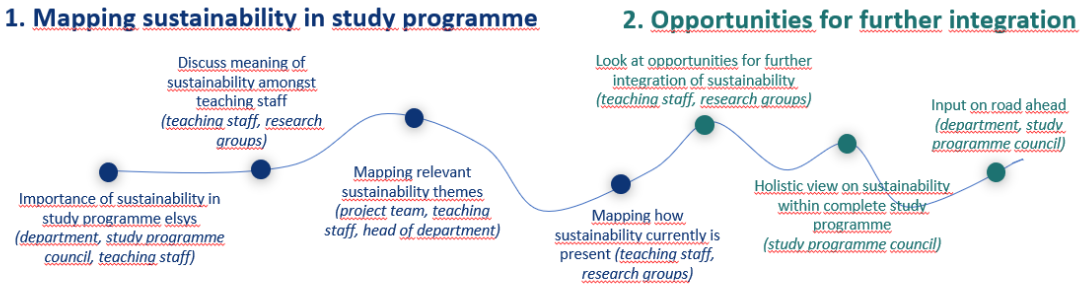

Fig. 1. The process stages of the integration of sustainability

Lastly, the toolkit brings together different pedagogical elements that are crucial in education, thereby combining knowledge on relevant *learning content* related to SD, *competences* for SD and student-active *teaching methods*. These elements are presented in the form of learning theme cards, competence cards, work sheets and guidelines for the integration process.

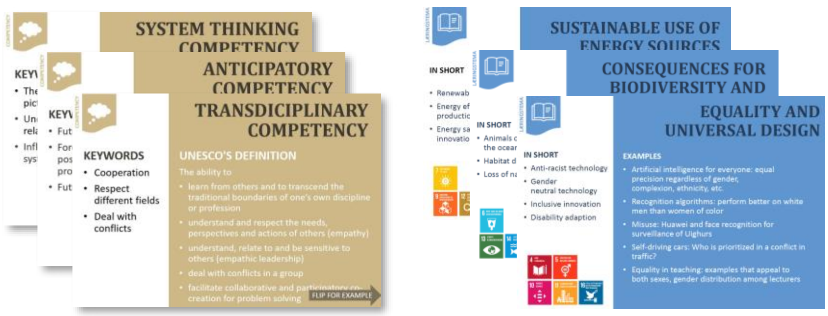

Fig. 2. Examples of the competence cards and the learning theme cards

3.2 Academic staff involvement in the integration process at Elsys

In this section, we present how academic staff at Elsys is involved throughout the integration process so far. To be able to succeed with incorporating sustainability into a curriculum, it is important to engage and empower academic staff, since they have a central position through their responsibility for a study's central building blocks: the courses that make up the curriculum. Creating an environment that values SD is thereby essential to create lasting changes and sustained educational improvements [5]. The academic staff have been, and will be, involved as active participants in completed and future workshops, training seminars and other activities. Fig. 3 presents a timeline of the activities in the pilot case.

Fig. 3. Timeline of activities involving academic staff

Thus far, one webinar and two workshops have been held in the period between the spring semester of 2021 and 2022. In the webinar, the staff were introduced to SD in higher education and asked to reflect upon the role of SD in electronic engineering. In the first workshop, the staff were asked to map the current status of integration of SD in the programme and identify opportunities for further integration. The second workshop focused on looking forward by making plans for integrating SD in specific courses, course groups and the whole study programme.

In preparation for both workshops, a smaller group of the staff has been invited to test versions of the workshops, allowing the project team to observe the staff, getting feedback and enabling improvements to be made. For example, the learning content and competence cards along with the webinar introducing education for SD came as a result from the first test workshop, where we realized that the staff's knowledge of SD was insufficient to complete the work sheets.

Lastly, between the first and second workshop, the staff were invited to sign up their courses as pilot courses for integration of SD, entailing that they were willing to make smaller changes to their courses to facilitate integration of SD and serving as exemplars for the rest of the staff by sharing their plans at the second workshop. In addition, any staff willing to start integrating SD into their courses have been promised support and extra resources in order to enact these changes.

3.3 Insights and experiences from the pilot case

In this section, we share insights and experiences on the integration process from the perspective of the academic staff and the project team. We frame the results in terms of how the toolkit's approach supports the integration of sustainability in the curriculum.

Inform: Based on the interviews with staff and reflections from the project team, the lack of knowledge on SD in education is found to be an obstacle, which gets supported in literature [6]. This came forward especially when staff tried to connect fundamental technology courses with its application in and impact on society and environment. This opened up for reflections from the staff on the role of their study program to society and is illustrated in the following quote: *"... there exists nearly no product today that doesn't have electronics in it, so it's a really important field for everything happening in society […]. So-called enabling technology".* In the pilot case, information has been shared with the staff on SD in higher education and electronics in general, the student perspective on the importance of SD, SD learning content relevant for electronic engineering and competences for SD. Information has been given through the webinar, workshop presentations and material, and in staff meetings not organized by this project. The importance of discussing and working actively with the shared information was mentioned by staff in the questionnaires to be indispensable in order to get a shared understanding, as well as to challenge and inspire each other.

Motivate: Based on the data from the questionnaires and interviews, the staff indicate that there is agreement on the importance of integrating SD in the curriculum. The following quote from a staff member exemplifies this: *"sustainability is important for all, it is good that we also started talking about it"*. However, when it comes to working with specific courses, several educators reacted that SD does not fit into their course, and pointed out other courses where it would fit better. Through exemplifying in the workshops and with pilot courses, we aimed at overcoming this hurdle. The mapping of and reflection on how SD already is present in the curriculum and different courses was mentioned by staff in the questionnaire to be a motivator for taking further steps. Simultaneously, further activity needed to be initiated by the project team and management, thereby pointing out the need for a change agent to lead the integration process forward. Next to that, we experienced that support from management, thereby emphasizing the importance of integrating SD in the curriculum, was important to motivate academic staff. It turned out to be difficult to stimulate them to join workshops related to SD, on top of other teaching and research activities. We encountered that we managed to motivate a part of the staff to actively get involved in the integration process of SD, whilst a group of the academic staff has not been triggered to join (yet).

Inspire: For changes to occur as a consequence of the information and motivation efforts, the staff needs to be inspired to take action, thereby facilitating a bottom-up approach driven by staff in addition to the top-down driven by management. Through the discussions at the first workshop and associated test workshop, statements were made that indicated one hindrance being a limited view by staff on how integrating SD in a course or a programme practically can be done. Simultaneously, while the staff can understand the context and importance of SD in education, they can lack inspiration and the awareness to take action. The following quote from one of the interviews illustrates this: *"... I think that the biggest challenge may be being conscious and thinking of it, and actually doing things for it as well. Because I don't think it's very difficult to implement more of it in my course".* The pilot courses and examples from other programmes aim to illustrate practical integrations of SD in education. These show that the choice of teaching methods is important for the activisation of students and SD competence development, and lower the barrier for action. We also aim to create awareness on the need for a programme-driven approach, in order to succeed in creating a holistic integration of SD, where courses build onto each other in order to meet the curriculum's intented learning outcomes. Through working collaboratively in workshops we intent for the staff to inspire and support their colleagues.

Connect: The main workshops have the goal of providing arenas for discussions and reflections on SD and the own teaching, and creating a shared understanding among the staff, thereby framing the structures of courses, curriculum and their own role as educators with a responsibility towards students and society. Based on the questionnaires and reflections, both the teaching staff and the project team experienced that these activities support collaborative learning on SD for the attendees. The test workshops offered us insights into how the workshop activies shaped these reflections, allowing us to make meaningful changes before inviting all academic staff.

However, in order for connections to be formed, as well as informing, motivating and inspiring the staff, participation in the process is important. A challenge we have seen is a lack of attendance at the workshops, with significantly less than half of invited staff joining some of the workshops, which reduces the effect of the ISE toolkit on the integration process. The underlying reason for an academic staff member to choose not to attend, can stem from a multitude of reasons. From the interviews and our own reflections from observing the staff, we have indications that a large group of the staff does not prioritize to integrate SD in their courses due to fear for the extra workload, a conviction that SD should be in a separate course rather than in their course, and/or a lack of believe that their field is relevant to SD. Understanding how to overcome these barriers is one of the most important goals moving forward.

4 CONCLUSION

Based on the pilot case, we believe the approach used and the lessons learned can provide useful strategic and practical insights for other engineering programmes in their process of integrating sustainability through involving academic staff. However, one should keep in mind that the ISE toolkit provides guidance for the start of this process, whilst the entire integration process runs over a longer period of time. Next to that, assigning someone for the role of a change agent to lead the process is crucial, together with support from management. All in all, it is the academic staff that makes a transition happen, whereby much effort goes to motivating and inspiring them.

Further steps related to the integration of SD in the curriculum of the Elsys study programme entail the further development and teaching of the pilot courses in 2022, taking up competences for SD in the intended learning outcomes of at least three course in the coming year, including SD in the intended learning outcomes of the study programme, and designing structures that allow courses to build on one another to reach these intended learning outcomes. The long-term goal is to have SD integrated in the complete study programme by 2025. Further development of the toolkit entails incorporating the lessons learned from the pilot case. Next to that, we aim to pilot the toolkit in another study programme before making it publicly available.

ABSTRACT

Challenge-based learning (CBL) offers students in engineering programmes an opportunity to develop communicative and collaborative skills, apply disciplinary knowledge and develop boundary-crossing competencies. Mono-disciplinary approaches to CBL are generally regarded too limited, but whether multi-disciplinary, interdisciplinary, or transdisciplinary approaches should be used is open to discussion. Often, these concepts are used interchangeably, but there are notable differences. In literature, knowledge integration is mostly mentioned to make a distinction, but because of difficulties in applying this concept to education, we focus on tangible differences in educational practices, related to learning objectives, assessment, and the design of challenges. The different forms of CBL are illustrated by three case-studies carried out at a research university in the Netherlands. We found similarities, but also some subtle differences between multi-, inter- and transdisciplinary approaches to CBL. Multidisciplinary CBL projects are relatively pre-structured, with an indication of the knowledge that is to be applied, deepened, or combined. Interdisciplinary CBL is more open-ended, with students made responsible for connecting their disciplinary backgrounds to the project and for integrating disciplinary perspectives. Transdisciplinary CBL focuses more on impact than on integrating disciplinary contributions. Challenges are open-ended from a content and stakeholder

doi:10.5821/conference-9788412322262.1176

perspective, while structure emerges in the interactions between students, teachers and stakeholders. Which form of CBL can best be employed in a course or programme is dependent on the intended learning objectives. Educators should be aware of trade-offs and of the specific teacher competences required to design and support these different forms of CBL.

1 INTRODUCTION

Challenge-based learning (CBL) is gaining popularity as an approach to engineering education. By working in groups on authentic, wicked problems of real-world stakeholders, students can develop transversal competencies and learn to apply disciplinary knowledge and skills in the analysis and solution of complex engineering problems [1] [2]. If supported well, students can also develop competencies to cross boundaries between academic cultures and disciplines [3]. Challenges, which are often related to Sustainable Development Goals, are complicated and require the involvement of several disciplines. Mono-disciplinary approaches to CBL are still used frequently [2], but the incorporation of different perspectives is generally considered to lead to richer and more creative ways of tacking societal challenges [1]. However, there is less consensus on whether multi-disciplinary [1] [2], interdisciplinary [4], or transdisciplinary [5] approaches are to be employed in challenge-based education. The terms are often used interchangeably, but on closer inspection there are notable differences. These relate, for instance, to how far students go beyond their disciplinary knowledge base, to knowledge integration, and to societal stakeholder involvement [6] [7]. In this paper we will explore how multi-, inter- and transdisciplinarity are different and how these differences show in challenge-based engineering education. The different approaches to CBL will be illustrated empirically by case-studies from a research university in the Netherlands.

2 CONCEPTUAL BACKGROUND

To distinguish between multi-, inter- and transdisciplinarity, education literature often refers to knowledge integration [6] [8]. In multidisciplinary projects students divide problems into components which they solve through disciplinary means, without any substantive integration of their approaches. The integration of disciplinary views and the arising of new, combined perspectives remain limited. In interdisciplinary projects, students do integrate knowledge from different academic disciplines. Transdisciplinary projects go a step further in integration, breaking down disciplinary boundaries and incorporating knowledge from ‘non-academic’ practioners and local stakeholders. In studies on interdisciplinary or transdisciplinary education it is noted that knowledge integration that pervades the whole process, from challenge definition and theoretical models to the choice of methods and proposed solutions. This integration complements processes of bringing in disciplinary insights, critical reflection and establishing the purpose of a project [6].

However, the concept of ‘knowledge integration’ is not without challenges. Pinpointing it empirically is difficult [9]. It is embedded in various activities of a complex problem-solving process and can often only be identified indirectly through reflections and explanations of participants [8]. Besides, the integration concept appears to assume a unification of models, approaches, etc., in a coherent whole. This oversimplifies the iterative, emergent and diverse ways in which fields of knowledge may interact in problem solving and learning processes. In these interactions, there may be all kinds of misfits, conflicts and incommensurabilities, especially when knowledge from engineering disciplines is being combined with that of social science, humanities and (non-academic) stakeholders. The process may then be better characterized as tinkering and bricolage [10] than as integration and synthesis. Given these complexities, disciplinary knowledge integration and the kind of novel combinations this entails may be beyond reach in student projects. Furthermore, interdisciplinary and transdisciplinary ways of working have their own models and approaches [11], which go beyond the integration of models and approaches of separate disciplines.

In this paper we will not focus on the somewhat elusive concept of knowledge integration to distinguish between multi-, inter- and transdisciplinary CBL, but look at differences in educational practices, showing for instance in learning objectives and problem-solving processes, to characterize these distinctions for educational purposes. Typical for *Multidisciplinary* CBL projects is that they start with the identification of the disciplines of participating students. Learning objectives are primarily related to the application and deepening of disciplinary knowledge in a complicated context and to the development of skills to collaborate and communicate with other fields of expertise. To be able to reach these objectives, decomposition of the challenge along disciplinary lines is important. Final products contain different disciplinary parts, which are aligned and aggregated in an overall solution. To avoid marginalization of certain participating disciplines, the challenges need to be designed or specified in such a way that all participants can reach their learning goals. This asks for careful alignment with involved stakeholders and limits the open-endedness of the challenges [12].

Alternatively, *Interdisciplinary* CBL projects start from more open-ended, unstructured, ‘real-world’ or wicked problems, which are more loosely coupled to the disciplines of participating students. Learning objectives are primarily related to collaborative teamwork and other transversal skills [4], less to the deepening of disciplinary knowledge. Students also learn to identify new knowledge they need for tackling the problem. Solutions may include of disciplinary parts, but students work actively on synthesizing or linking these. Stakeholders are involved as challenge owners, who bring in the problem, provide information and feedback, and to whom the solution is being presented or ‘sold’ [12]. Student teams act as problem solvers [13] and as interdisciplinary problem-solving goes beyond their disciplinary training, scaffolding by teachers is crucial [4].

In *transdisciplinary* CBL, an extra layer of complexity is being added. Stakeholders are seen as part of a heterogeneous learning community rather than as challenge owners. Challenges, processes and solutions are being co-created by students, teachers and (multiple) stakeholders [14]. The problem-solving process is focused on societal impact or transformation rather than on the application of academic models or techniques [7]. This implies that students' learning goals highlight the development of societal collaboration, communication, co-creation and other boundary-crossing skills. They also learn to deal productively with situated knowledge and input from non-academic sources [15]. Interdisciplinary scaffolds are being complemented by scaffolds targeting understanding and collaboration across academia-society boundaries [16]. Table 1 gives an overview of the different characteristics.

Table 1: Characteristics of multi-, inter-, and transdisciplinary educational practices.

	Multidisciplinary	*Interdisciplinary*	*Transdisciplinary*
Learning objectives	• application and deepening of disciplinary knowledge in a complex context • collaboration and communication with other disciplines	• identification and use of new knowledge from various academic sources • collaboration and teamwork across disciplines • transversal cognitive skills	• identification and use of new knowledge from academic and non-academic sources • collaboration and teamwork across disciplinary and societal borders • impact oriented skills
Challenge design	• relatively prestructured • carefully balanced disciplines	• open-ended • loosely coupled to participating disciplines	• open-ended and ambiguous • loosely coupled or not coupled to participating disciplines
Problem-solving	• decomposition along disciplinary lines • alignment and aggregation of disciplinary contributions	• synthesizing and linking disciplinary contributions	• bricolage of disciplinary and non-disciplinary contributions
Stakeholder involvement	• providing challenges that are carefully aligned with learning objectives	• providing challenges that are relevant for their practice • providing information and feedback on process and product	• providing challenges that are relevant for society • co-learning, co-creating, co-assessing

3 METHODOLOGY

To get a better understanding of how multi-, inter- and transdisciplinary approaches to CBL work in practice, they will be illustrated by three case-studies of educational modules, carried out at the University of Twente in the Netherlands. Table 2 gives an overview.

Table 2: Overview of cases

Approach	*Case*	*Involved Disciplines*	*Level*	*Kind of module*	*# ECs*
Multidisciplinary	Consumer products	Industrial Design, Mechanical Engineering, Industrial Engineering	Bachelor	Mandatory course	15
Interdisciplinary	Science to Society	Various technical and social sciences	Bachelor	Minor module	15
Transdisciplinary	Shaping Responsible Futures	Various technical and social sciences	Master	Extra-curricular programme	30

Data were collected through semi-structured interviews with module coordinators, teachers and participating students. Besides, study materials (such as project assignments and rubrics) and products of the challenge-based projects were collected. Educational prospectuses, course manuals and module pages hosted on the learning management system provided further sources. For this concept paper, a comparison was made on the basis of data on learning objectives, assessment, and design of CBL projects. These elements provide a first idea of the differences in educational practices.

4 RESULTS

In the description of the learning objectives of the three cases the terms multidisciplinarity and interdisciplinarity were used to a large extent interchangeably. The multidisciplinary module even talked about ‘interdisciplinary teams’, while the interdisciplinary and transdisciplinary modules used ‘multidisciplinary teams’ to describe student collaborations. However, there was a difference in the composition of student teams. In the multidisciplinary module ‘Consumer Products’, students from three bachelor programmes participated and each team included participants from these different backgrounds. In the interdisciplinary case ‘Science to Society’, which is part of a minor, the involved disciplines varied over the years and over the teams. Students self-enrolled in teams and were encouraged to mix gender, disciplines, etc. The extra-curricular transdisciplinary ‘Shaping Responsible Futures’ also included varying disciplines. However, as it was selective the coordinators could steer on heterogeneity of the influx. Students formed their own teams as long as these represented the disciplinary, gender, cultural variety. Learning to communicate and collaborate is these teams was a learning objective in all three cases.

When regarding the learning objectives of the cases there was clear overlap, but when looking more closely, two differences became apparent. First, in the multidisciplinary module the application and combination of disciplinary knowledge was much more specified (*Integrate and employ knowledge from different fields of expertise (like marketing, styling, CAD/CAM, intellectual property, packaging, production, supply chains, research methodology, etc.),* while the interdisciplinary and transdisciplinary modules left this open. The interdisciplinary and transdisciplinary cases dedicated seperate learning objectives to integrating knowledge and needs (*Composing requirements that integrate the needs of different stakeholders and different domains*) and to transcending disciplines (*Transcending disciplinary perspectives in creative, systemic and responsible designs*) respectively. A second difference was that the latter two more strongly emphasized stakeholder engagement. In the interdisciplinary case this was phrased as collaboration and communication with stakeholders, in the transdisciplinary case as boundary crossing (*Collaborating and communicating across disciplinary and social boundaries*).

.

When regarding the rubrics used to assess the final products of the CBL project there were also subtle differences between the cases. In the multidisciplinary project rubrics, the terms ‘coherence’, ‘multiple dependencies’ and ‘balance’ were used to describe how contributions of the three involved disciplines and of the sections in the report should be related. A high score, for instance, was for final reports in which “*the sections are very well balanced and of high value. A wide range of mutual dependencies and important consequences is correctly presented*.” In the interdisciplinary project, the student disciplines varied and it was up to the students to integrate their disciplinary contributions. According to the rubric, a good project ”*includes all the disciplines present in the group and integrates them optimally, using supporting literature*” and “*the most relevant requirements from various disciplines are present and nicely integrated into a coherent requirement specification,…*” Stakeholder interaction was also part of the assessment. The result should “*reflect frequent and clear collaboration with the target group and the problem provider*”. In the transdisciplinary case, a single point rubric was used to provide feedback on the final product. It stated that the presented innovative solution should be “*clear, well-argued, original, transdisciplinary, realistic, with potential to contribute to SDG, based on academic literature and other sources*”. There was no reference to the specific disciplinary contributions of the participating students. Extensive engagement with different kinds of stakeholders was also valued in the transdisciplinary assessment rubric.

When looking at the design of the challenges and the problem solving process, there were also differences. In the multidisciplinary case students went through specified stages of a product development cycle (*from portfolio analysis, via market research to the presentation of mock-ups and manufacturability*) to develop a consumer product. They interacted with a real-world customer and had autonomy to develop a solution within certain boundaries. In the interdisciplinary case, the challenge and process were more open-ended. Students could choose a challenge and a client based on their interests. The end product was a prototype of a product, which would be further developed in a subsequent module. The transdisciplinary case was even more open-ended, in terms of framing of the challenge, design process the form of the final product. Scaffolding was provided, but to a large extent the challenge and process were shaped along the way by students in interaction with teachers and stakeholders, inspired by ideas, models and theories brought in by the different participants. Stakeholders were approached as co-learners, sparring partners and as starting-points to connect to the broader societal field.

5 DISCUSSION AND CONCLUSION

In this paper we explored the differences between multidisciplinary, interdisciplinary and transdisciplinary ways of shaping challenge-based engineering education. Rather than taking the often employed but somewhat elusive concept of knowledge integration as a starting point for distinguishing between multidisciplinary, interdisciplinary and transdisciplinary CBL projects, we focused on differences in educational practices. These were exemplified in learning objectives, assessment rubrics and designs of challenges and CBL processes. We do not deny the relevance of knowledge integration, but approach it as embedded in multi-faceted, context-specific, social processes of learning and teaching rather than as the outcome of a more abstract process of disciplinary aggregation, synthesis, or transcendence.

In our study we found clear resemblances between multi-, inter- and transdisciplinary approaches to CBL, but also some notable differences. The challenges and CBL process in multidisciplinary projects were more pre-structured, by teachers and stakeholders, with a careful balance between the contributing disciplines. There was a clear view on which knowledge was to be applied, deepened, or combined, which was reflected in learning objectives and assessment rubrics. Interdisciplinary challenges were more open-ended, offered choice, and gave students the responsibility to link their disciplinary background to the project. Integration of disciplinary perspectives was expected and assessed. Transdisciplinary projects were open-ended from both a content and a stakeholder perspective, meaning that neither the framing of the challenge nor the stakeholder constellation were fully set beforehand. Structure emerged along the way in the interactions of students with teachers and stakeholders, and there was no obligation for students to apply 'their' discipline. The relevance of the output was valued over the disciplinary input. Learning objectives were formulated at a more abstract level and rubrics were open to tailored evaluation and feedback.

It may be tempting to regard transdisciplinary projects as the ultimate form of CBL, as they take on the most complex and ambiguous challenges, have the richest student-stakeholder interactions, and are most strongly impact-focused. However, challenges can also be approached in multidisciplinary and interdisciplinary fashions. It depends on the intended learning outcomes of the courses and programmes. Educators should be aware of trade-offs (what is won in open-endedness may be lost in disciplinary depth) and of the different teacher competences needed to design, organize and scaffold these different forms of CBL. Interdisciplinary and transdisciplinary CBL also require the teachers to cross boundaries and get out of their disciplinary comfort zones. Engineering programmes may consider to offer their students multi-, inter- as well transdisciplinary forms of CBL in their curriculum, in order to provide them with richer learning experiences needed to prepare for jobs as professionals or researchers in a complex society.

This paper offered an exploration and illustration of three different forms of challenge-based engineering education. This is meant as a first step. Further conceptualization of multi-, inter- and transdisciplinary education is needed. Also the empirical analysis is to dive deeper into the communalities and differences in educational practices and learning processes. What do student actually learn from these different kinds of CBL, how can they deal productively with the different kinds of knowledge and how can teachers effectively scaffold the more open-ended processes? These pressing questions ask for further research.

ABSTRACT

New theoretical perspectives on how engineers generate economic and social value have emerged from research on engineering practice, complementing the conventional entrepreneurship emphasis on innovation and start-up enterprises. This

doi:10.5821/conference-9788412322262.1342

research demonstrated, apparently for the first time, how most engineers generate significant economic value with limited if any opportunities for innovation, research and development in their work.

In the absence of appropriate theory, students acquire limited understanding on the contributions they will make to society as engineers. Observations from engineering practice provide a more compelling research-based narrative that could attract a more diverse student population, and help graduates secure well-paid employment.

Many engineering faculty share uneasy feelings that their students will rarely use the advanced mathematical analysis techniques taught in classes. Research explains how practice solving traditional textbook problems builds tacit knowledge that enables rapid technical decision-making in engineering practice. The research also provides insights on how typical engineering science research supports engineering practice.

We argue the benefits from widely disseminating the findings presented in this paper to help faculty staff and students better understand how they will contribute to our collective future. This can help overcome current significant engineering performance shortcomings in sustainability and productivity growth without major curriculum changes.

---

1 ENGINEERING PRACTICE AND ENGINEERING VALUE GENERATION

Research on engineering practice, the work of engineers, has provided a rich body of evidence for engineering educators over the last three decades. References cited in this paper provide reasonably comprehensive coverage of research published in recent decades. For example, among many other findings, this research demonstrates that the common notion that engineers are expert technical problem-solvers needs adjusting. While solving problems will always be part of engineering practice, expert engineers aim to avoid problems by adopting systematic organizational processes and compliance with standards.

Research helps to demonstrate three complementary types of engineering activity [1] and the career roles associated with them:

1. Interact physically with artefacts and tools, mostly individually, occasionally with others;
2. Interact cognitively with abstract objects and tools, concepts and ideas, mostly using information systems; and
3. Interact with people to plan, organise, collaborate in, and coordinate type 1) and 2) activity, also advocating for and securing required finance and material resources.

In this paper, our main focus is on professional engineers who mainly specialise in type 3 activity, with periods engaged in type 2 activity and occasional type 1 activity.

Technicians develop skills and expertise mainly for type 1 activity. Many also develop aptitudes and skills for type 2 activity to support their type 1 work, and for type 3 activity as supervisors.

Technologists mainly specialise in type 2 activity, often with knowledge acquired through type 1 activity. Examples include drafters, coders, network engineers, plant operators, air traffic controllers, designers, and many others.

As they transition from education focusing mainly type 2 activity to practice that requires mainly type 3 activity, professional engineers need to rapidly acquire skills and knowledge that receive little if any attention in formal education. Many companies provide highly developed infrastructure in the form of supervision, standards, systems and work processes that support competent performance by early career engineers.

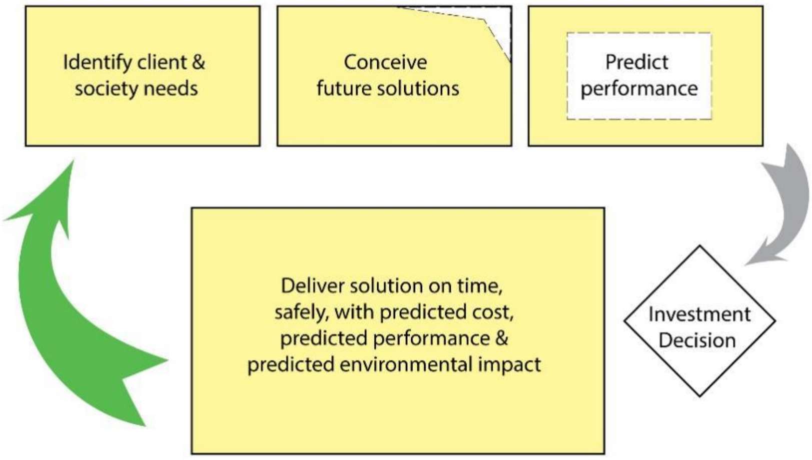

Figure 1: Sequence of engineering activities required for projects. Dashed areas in upper thread denote formal education focus [2].

Looking more closely at type 2 and type 3 activities that characterise the work of most professional engineers we see two threads shown in figure 1 [2, Ch3]. In the upper thread, engineers ascertain needs and requirements, and conceive solutions for clients in the form of engineering possibilities. They then define one or more favoured solutions and prepare plans, budgets and performance predictions to help investors raise sufficient finance. After an investment decision to proceed with the project, engineers organize procurement, delivery, implementation and operation of the required solution with the intention of meeting the anticipated performance predictions within financial and regulatory constraints. In performing this activity they acquire knowledge that improves their capacity for similar work in future, symbolised by the large arrow.

Innovation provides the principal conventional explanation for economic growth and value generation based on work by 20th century economists such as Joseph Schumpeter. This idea has led to the contemporary emphasis on entrepreneurship and start-up enterprise that often seem to attract far more interest and investment than much larger traditional firms. As a result, many educators have recently advocated entrepreneurship education for engineers.

However, both government data and ethnographic observations of engineers help to demonstrate that most engineering involves rather limited opportunities for innovation, research, and development. Nevertheless, most engineers aspire to innovative work with significant technical challenges. As one engineer exclaimed in an interview “the only two times in my entire career that I really enjoyed myself was when the client forgot to ask – has this been done before?”

In our research we observed that many engineers, perhaps most, have difficulty explaining how their work creates economic and social value [3]. This inspired a series of studies to understand how engineers generate significant economic and social value from routine activities that do not necessarily require innovation [4], complementing existing entrepreneurship models [5].

I. Engineers *create* value by differentiating products from competitors and producing plans and predictions that justify significant investment decisions to provide financial and material resources.
II. Engineers then *deliver* the potential value from these investments by engaging in highly disciplined collaborative activity. They coordinate performances by many other people, helping to ensure that original technical intentions are implemented with sufficient integrity. Mutations are inevitable as different people necessarily re-interpret technical intentions. For example, original designs are re-interpreted by construction and manufacturing firms to suit their particular expertise, along with financial, safety, environmental, regulatory and technical constraints.
III. Many engineers *protect* accumulated value through sustainment and maintenance activities. Maintaining a social licence to operate by active and supportive engagement with communities and regulatory agencies protects accumulated value created by ongoing investment in engineering operations. Investment in defence equipment provides assets that can deter or limit destructive activities by other people, again protecting accumulated value.

Reduced to the simplest possible terms, engineers generate value by conceiving and delivering artefacts that enable people to be more productive: to do more with less human effort, time, material resources, energy, uncertainty health risks, and environmental disturbances. This summary addresses sustainability as well: the need to enable the full scope of human existence while keeping well within the limits imposed by a finite planet Earth [6].

2 NEED FOR PERFORMANCE IMPROVEMENT

Historical engineering performances have been impressive in many ways, helping to emancipate and relieve billions of people from hardship, poverty and destitution. However, we now face existential threats because planet Earth cannot sustain the current rate of resource depletion, pollution and natural habitat destruction [e.g. 7].

Two significant engineering performance deficiencies compound these difficulties.

I. Most large engineering projects fail to achieve their financial objectives by a large margin and a significant proportion involve a complete write-off for investors [8, 9]. This data, available in confidence to most investors, continues to show further performance deterioration. Most projects fail because of collaboration weaknesses and overconfidence by project owners. Trevelyan [2] provides a detailed case study that illustrates how major projects can fail.

II. During the last two decades, most countries have reported significantly lower productivity growth than in the 20th century [10-12].[2] Productivity here refers to macro-economic indicators that measure the value of goods and services produced relative to labour, capital and material resources needed to produce them. This has led to stagnating or declining real incomes for many people and major political unrest in some countries. Productivity in low-income countries remains, on average, five times less than wealthy countries and this ratio has changed little in recent decades [13].

   As explained above, engineers significantly influence national productivity because productivity relies on infrastructure, tools and equipment conceived and implemented under the guidance of engineers. Yet, many engineers today do not understand the connections between their work and national productivity. Sustainability and addressing climate change rely significantly on reducing material and energy resources needed to provide goods and services, in other words, productivity improvement.

Understanding these engineering performance deficiencies can point out ways to improve engineering performances and hence sustainability.

3 INSIGHTS FROM RESEARCH FINDINGS

We argue here that applying engineering practice research findings in engineering schools could lead to significant engineering performance improvements. For example, improving the understanding by engineers on how to generate economic value could lead to improved value generation performances by engineers and productivity improvements.

We suggest that awareness on the links between engineering performances and financial outcomes has receded, as evidenced by our findings on engineers' awareness on economic value generation from their work performances. In the 1950s, this link was explicit in the definition of engineering adopted by the ASEE Grinter report [14]. Contemporary definitions of engineering make this link much less explicitly. For example, New Zealand engineers were asked to define engineering as part of a recent study by consultants to estimate the contribution of engineering

[2] See for example US Labor Productivity in Manufacturing: https://alfred.stlouisfed.org/series?seid=MPU9900063&utm_source=series_page&utm_medium=related_content&utm_term=related_resources&utm_campaign=alfred

towards that country's GDP [15]. None of the comprehensively reported engineers' responses mentioned the need for minimizing cost.

Therefore, we argue, educators have opportunities to rebuild awareness on the economic and social benefits arising from engineering and the need for performance improvements by drawing on the research we have referred to. We suggest there are three significant benefits.

3.1 Attracting more diverse student enrolment

It is well known that more women enrol in biomedical, chemical, and environmental engineering programmes [16] because they can readily appreciate the social benefits and applicability of disciplines that enact altruistic goals and values [e.g. 17, 18]. We suggest that providing a more compelling narrative for prospective students that explicitly engineering with its social and economic benefits in terms of enabling people to do more with less effort, resources, health risks and environmental disturbance may help to attract more women and students from diverse backgrounds into other engineering disciplines.

3.2 Improving graduates' career outcomes

We suggest that graduates who have a clear understanding on how their work creates economic value for firms and social value for communities are more likely to provide benefits for their employers. In the long run, these graduates may attract higher remuneration in recognition of the value they provide for their employers, in accordance with the marginal revenue productivity theory of wages in labour market economics [19].

3.3 Faculty motivation

Many engineering faculty staff experience identity conflicts and an unease that few students will ever directly apply the knowledge they acquire in engineering science and mathematics classes [20-23].

Recent work on how mathematics is used in engineering practice could provide reassurance. While it is true that engineers rarely apply the methods they learned in class directly, they often make instinctive decisions based on that knowledge. In other words, they acquire substantial tacit knowledge from solving numerous textbook problems which helps them make rapid strategic decisions that rely on knowledge of mathematics and engineering science [24]. Furthermore, many engineers rely on software that incorporates advanced techniques, often far beyond those learned in school, so they apply classroom knowledge indirectly, without necessarily being aware that they are doing so. That is the nature of tacit and embodied knowledge: it is knowledge that one is mostly unaware of [25].

Faculty staff can gain further reassurance by understanding that engineering science research builds knowledge that finds its way into practice through software, data libraries, standards and sometimes new technologies and products. All these contributions enable more accurate performance predictions, faster diagnoses and more reliable artefacts and materials, generating considerable value in the hands of engineers. Again, practicing engineers are not necessarily aware of all the knowledge embodied in the products and software they use in their work.

4 SUGGESTIONS FOR ACTION

Despite more than two decades in which graduated competencies have shaped engineering education, the gaps between education and practice remain, and graduates are surprised by the emphasis on type 3 activity when they start work [26]. While many would argue that education can never provide a complete preparation for practice, overcoming significant engineering performance deficiencies outlined in this paper requires urgent actions.

We first suggest that engineering schools help students learn from research-based explanations on how they will contribute economic and social value as engineers as outlined in this paper. This can help rebuild awareness on the critical nexus between technical engineering and economics [5]. This could be reinforced by helping faculty staff understand how their work contributes economic and social benefits, so that they can, in turn, better inform students on how their classroom learning will contribute to practice. Accordingly, we advocate substituting commonly repeated explanations with research-based explanations provided in this paper and the cited references.

For example, the common notion that ‘engineers are expert problem-solvers’ is only partly true, as explained above, and fails to distinguish engineers from many other occupations in which practitioners use their expertise to solve problems. We advocate using research-based explanations specific to engineering such as delivering artefacts and systems that enable other people to be more productive with less effort, time, materials, energy, health risks, uncertainty and environmental disturbance are specific to engineering.

We also suggest that engineering schools ensure that students are aware of significant contemporary engineering performance deficiencies as outlined in this paper. Students also need to know that they can contribute to performance improvements through their work, at the same time improving productivity and sustainability.

In engineering schools with entrepreneurship courses, we suggest complementing material on innovation and start-up businesses with explanations on how engineers also create social and economic value through routine, everyday engineering that does not involve innovation.

We further suggest that educators work at reducing the many misunderstandings on engineering practice that have arisen because there has historically been little understanding of practice among faculty staff. Trevelyan [2] lists around 100 such misunderstandings.

We suggest that engineering schools encourage collaborative pedagogies [e.g. 27] with known educational benefits in order to better prepare students for the collaborative type 3 activity that characterizes most engineering practice.

We suggest that all of these actions could be achieved without significant curriculum changes. The authors are happy to help engineering schools implement these suggestions.

5 ACKNOWLEDGEMENTS

The authors acknowledge contributions from hundreds of engineers who contributed their time for interviews and field observations in studies contributing to this paper. Conversations with Russell Korte informed parts of the argument.

ABSTRACT

One of the concerns in service mathematics courses, such as calculus for engineering, is students' interest in these studies. Research suggests that engineering undergraduates' lack of awareness about the importance of mathematics for their study success and for their careers contributes to their low motivation for mathematics. An approach to increasing student motivation is to take advantage of technological tools to provide students with more engaging learning experiences. Recent studies showed that augmented reality (AR) enhances student engagement, motivation, and knowledge retention. However, implementing AR can be challenging since it can be quite costly and technically complex. The current paper describes a case study in which an AR application was designed and developed using WebXR, in the context of a service mathematics course for teaching calculus. The AR content involves drawing of level curves and the visualization of a volcano and the flow of lava to support students' learning of directional derivatives. A pilot study was conducted to examine engineering undergraduates' perceptions of using AR for learning mathematics. Results show that students perceived using AR for learning math as enjoyable and motivating. Students reported that AR content adds value to their classes by making the mathematical concepts clearer and helping them apply what they have learned to real life. However, the AR content did not work well on all mobile phones and all versions of web browsers. Lessons learned from the design and development of AR using WebXR as well as recommendations for future studies are discussed in this paper.

1 INTRODUCTION

1.1 Service Mathematics in Higher Engineering Education

Mathematics is often service-taught by mathematicians to students who are not majoring in mathematics as a foundation for science, technology, and engineering in higher education. Research shows that engineering students' motivation to study mathematics is low and many perform poorly in service mathematics courses, despite the importance of mathematics for academic success and professional practice [1]. One of the reasons is that many engineering students do not perceive mathematics as their primary interest [2]. This leads to procrastination of tasks for learning. Another reason is that students are not aware of the importance of mathematics as the foundation of the subjects in their field of study, nor are they familiar with how mathematics is applied in their subject of interest [3].

At the Delft University of Technology, the Program of Innovation in Mathematics Education (PRIME, https://www.tudelft.nl/en/eemcs/the-faculty/departments/applied-mathematics/education/prime) was introduced in 2014 to redesign service mathematics courses. The goals of PRIME are to improve study results, enhance the connection between mathematics and engineering, and increase students’ active participation and motivation. Over the years, a number of innovative practices, such as pre-lecture videos, interactive quizzes and online exercises, have been introduced. To better meet the needs of engineering students, PRIME continues to examine ways in which various technologies (e.g., augmented reality) can be leveraged to enhance the teaching and learning of mathematics in higher engineering education.

1.2 Using AR to Support Learning of Mathematics

The technology of Augmented reality (AR) gives users the opportunity to see digital information superimposed onto the real world, and hence, offers a novel experience and interactivity with the learning content. Research on AR in education has been rising over the last 25 years and one of the trending topics is the use of mobile devices for deploying AR learning experiences [4]. In a recent systematic review on the use of AR for learning mathematics [5], AR was shown to be an effective tool for learning mathematics by increasing confidence and understanding, enhancing visualization, and making learning interactive across all educational levels. To date, research examining the effect of AR on mathematics learning in the context of higher education is relatively scarce.

In [6], a combination of 3D tools (i.e., augmented reality, virtual environments, and 3D printing) was used in the process of mathematics teaching and learning to enhance spatial visualization and orientation skills. The study showed that students in the experimental group who took the multivariable calculus course under the new methodology scored seven points higher than those in the control group. There was a 14% drop in the experimental group’s failure rate. Furthermore, the new methodology helps students to improve the way they described objects in space using mathematical language. In another study [7], AR content was integrated into the Mathematical Analysis class for electrotechnical engineering. Students in the study perceived the AR tool as a way to better understand and access knowledge. Moreover, they were curious and interested in the prospects of the software.

More recently, a “Vector AR3” app was developed as a means to shift from a theoretical approach to teaching math to an approach that focuses more on the application of the learning content [8]. While the app has won the International eLearning award 2020, the impact of the app on teaching and learning has yet to be evaluated due to Covid-19. The studies described in this section suggest the potential of AR to enhance mathematics teaching and learning. In order to reap the potential benefits of AR for mathematics education at universities, it is important to explore ways to ease the use of AR for the growing student population.

1.3 Current Study: Using WebXR to

Pitfalls of AR include accessibility and scalability. To address these pitfalls, the current study employs WebXR for the AR tool. Unlike mobile applications that require different codes for android and ios, WebXR allows the AR tool to be embedded into the learning management systems and can be deployed as a web application and accessed through a mobile browser [9]. Moreover, students will not be required to download an application through an app store via Google or Apple, bypassing the procedure of downloading and logging in. To our knowledge, very few studies have examined WebXR as an AR tool for teaching and learning math. The aim of the current study is to examine the feasibility of using WebXR to develop an AR tool for learning mathematics. The study consists of two parts: 1) designing and developing the AR tool, and 2) examining the usability of the AR tool.

2 DESIGN AND DEVELOPMENT

2.1 Designing the AR tool

When designing the AR tool, meetings were conducted between the developer, math lecturer, course coordinator, and educational researcher. During the meetings, the team members brainstormed ideas for the math topics and ways in which the AR tool can be implemented. The math lecturer proposed a math application question that was already covered in the existing math lecture as a task for the AR tool. Figure 1 illustrates the math application question. Two design features were proposed to deliver the math application in the AR tool:

1) Drawing level curves that will be transformed into a 3D volcano.
2) Visualizing lava flow as a connection to directional derivative.

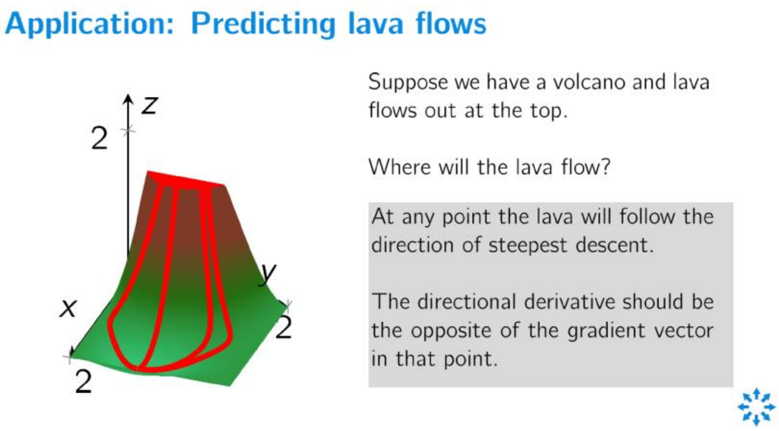

Figure 1. Mathematics application taught in the course

2.2 Developing the AR tool

Figure 2 illustrates the technical infrastructure of the AR tool. A web application that has been developed through a 3D JavaScript library, ThreeJs, was employed. This library enables developers to create 3D web applications using WebGL API, which supports WebXR to create AR content. The AR tool features an empty drawing screen where students can draw the outline and level curves of the 3D volcano by using touch input. The first shape that the student draws is an outline of how the 3D volcano should be shaped in general. This outline shape is used as a ground level to build the volcano geometry. To recreate an organic volcano formation from an outline, multiple points are scattered randomly inside this outline and Delaunay triangulation [10] is performed to create a triangulated mesh. From this point on, students can draw multiple level curves on top of the triangulated mesh which is used to calculate how the mesh should deform in height. The final step of generating a 3D volcano is by starting the AR view, where the tool will calculate the final shape of the 3D volcano by combining all drawn level curves and taking account of a set of parameters; Height, noise, crater size and crater depth. With AR view started, the 3D volcano is displayed in AR and following the camera movement. The volcano can be placed on any surface by pressing on the screen. With the volcano in place, the student can touch any volcano surface to start a lava flow trail. Gradient descent is used to calculate the path of the lava and is then projected on the volcano. With these features in place, the application is packaged and hosted online to be accessed through a browser.

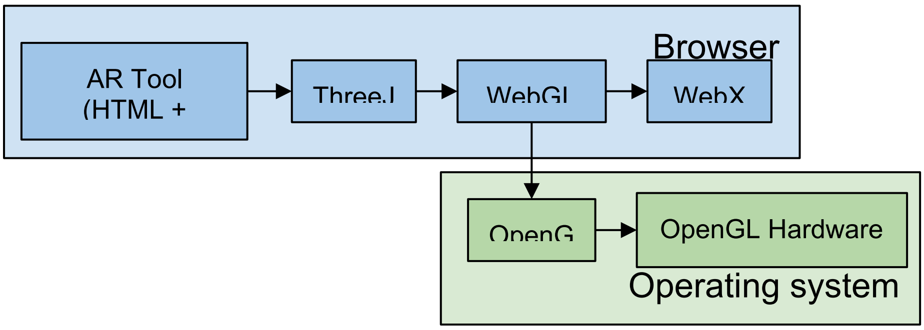

Figure 2. The technical infrastructure of the AR tool

3 PILOT STUDY

3.1 Method

The aim of the pilot study was to examine how students perceive the utility of the AR tool for learning math. Students taking Calculus I in Applied Earth Sciences were invited to take part in the pilot study. Nine students (four males and five females) participated in the pilot study. The average age of the students was 18.6 years old. Students were directed to a web link (https://sbayoumy.github.io/threejs-test/) that enabled them to use the AR tool on their mobile phones. In addition, students were provided with a set of questions to aid their exploration of the AR tool. Figure 3 illustrates an example of a volcano drawn and visualized using the AR tool.

After exploring the AR tool, students were asked to complete a survey consisting of 14 Likert-scale questions and three open-ended questions. The Likert-scale questions included 5 items measuring *student satisfaction* with the AR tool, 3 items measuring *engagement in learning* concerning whether the AR tool promotes active learning, 3 items measuring *enhancement of learning* addressing the question of whether the AR tool helps to enhance their understanding, and 3 items measuring the *extension of learning* concerning whether the AR tool helps to extend the learning of math to other contexts. The survey items were adapted from [11], [12], and [13]. Students were asked to respond to each item on a 5-point Likert scale from 1 (strong disagree) to 5 (strongly agree). The open-ended questions were used to gather students' perspectives on what they liked or disliked about the AR tool and how the AR tool supported their learning.

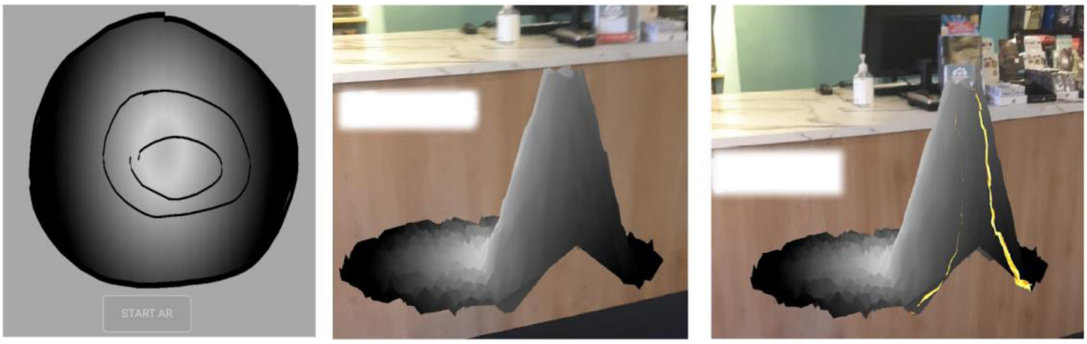

Figure 3. An example of a volcano drawn and visualized using the AR tool

3.2 Results

Table 1 provides an overview of students' satisfaction ratings of the AR tool. The results show that students generally agree that using the AR tool was enjoyable and entertaining. As for user-friendliness, students' ratings varied. This reflected the instability of the AR tool and the challenges of making the AR tool work on all mobile devices. Diverse ratings were obtained on the two items measuring satisfaction with the AR tool as a study tool and overall satisfaction with the AR tool.

Table 1. Students' satisfaction rating of the AR tool

	Strongly disagree	disagree	neutral	agree	Strongly agree
I was satisfied with the AR application as a study tool.	1	3	4	1	-
I found the AR application entertaining for me.	-	-	3	4	3
I enjoyed using the AR application.	-	-	1	7	1
I found the AR application user-friendly.	1	1	1	3	2
Overall, I am satisfied with the AR application.	-	3	1	3	1

Mean scores and standard deviations were obtained for engagement (*M*=3.79; *SD*=.67), enhancement (*M*=3.79; *SD*=.56), and extension of learning (*M*=3.93; *SD*=.49). The mean scores suggest that students were generally positive about how the AR tool can support their learning. For engagement in learning, almost all of the students (8 out of 9) agree or strongly agree that the AR tool motivates them to start learning and causes a passive to active behavioural shift. There was less agreement regarding whether the AR tool allows them to focus on the task with less distraction.

For enhancement of learning, students felt rather neutral about whether the AR tool allows them to demonstrate their understanding of learning better than other tools. Students mostly agree that the AR tool allows them to develop a better understanding of the learning content and makes it easier to understand concepts For extension of learning, three-quarters of the students (6 out of 8) agree or strongly agree that the AR tool creates opportunities for them to transfer learning to other contexts, creates a bridge between mathematics and engineering, and allows them to develop skills that they can use for their program of study.

When asked about what they liked most about using the AR tool and to what extent the AR tool contributes to their learning, students mentioned that the AR tool makes learning fun and helps them to apply what they have learned to a real-life context. They also found it helpful to be able to have a visualization of the mathematical functions learned in class. A student stated that being able to see how the math is being applied makes learning motivating. In addition, a student reasoned that if the AR tool can be implemented in a good way in the math exercise classes, it might give students an incentive to attend the classes. Some of the quotes from the students are shared below.

> *"It is very interactive. You can make your own volcano and then get your own equation."*

> *"It's fun to use and I understand the concept of level curves better with it, it helps visualize the whole thing."*

Through the survey, we also received feedback on what students disliked about the AR tool. The AR tool did not seem to work very well and did not run on different models of mobile phones. Students also experienced difficulties with the drawing tool. A student mentioned that the drawing tool was slow even when the wifi is good and another student was not able to get the drawing tool to work. The problems that students encountered when using the current AR tool could have influenced their satisfaction and engagement in learning. This can be reflected in the quote below.

> *"It doesn't work very well yet, which makes it frustrating to use. This would make me distracted from my learning*."

4 DISCUSSIONS AND CONCLUSION

The results of the pilot study show that the AR tool has the potential to enhance learning of math for applications and facilitate student engagement. Students were positive about using the AR tool to learn math. However, challenges remain with the technical deployment and design of the AR tool. As identified in a scoping review of augmented reality in K-12 and higher education [13], technical thresholds and design considerations are major limitations in studies examining the effect of AR on learning. Technical malfunctions and problems may lead to student frustrations when using the app and reduce learning effectiveness.

Developing the AR tool with WebXR is a compromise for the lack of support of the WebXR API in a set of browser versions. However, the current state of the WebXR API and its features are yet to be fully supported on existing browsers or standardized in the WebKit platform (see https://caniuse.com/webx for a list of supported browsers). Therefore, developing cross-platform web applications involve risks around having to implement specific solutions for different browsers and devices. It is crucial for future iterations of the AR tool to take the technical thresholds into account and explore ways to mitigate these risks.

One of the strengths of the current study is the participation of the math instructors in the design of the AR learning content. Therefore, the AR tool is complementary to the learning content in the ongoing mathematics course. As demonstrated by the results of the pilot study, students perceived the learning content as helpful, particularly the visualization of the math concepts that were taught in class. Estapa and Nadolny [15] reasoned that the benefits to manipulate, visualize and use authentic contexts make AR a natural fit for mathematics instruction. Despite the small sample size in the pilot study, the results suggest that implementing AR in the math course could potentially have a positive impact on student motivation. Given that learning performance was not measured in the pilot study, it is not clear if and how the AR tool increases math knowledge. To better understand the effects of AR on learning, there is a need to use multiple metrics (both quantitative and qualitative on motivation and learning effectiveness) [16]. Also, future research with a bigger sample size and using randomized controlled trials is needed to further investigate the effect of scalable AR tools on learning mathematics, student engagement, and motivation.

In conclusion, our study demonstrates the benefits of involving teachers and students in the design and development of an AR tool using WebXR for teaching and learning math. The math instructor plays a critical role in ensuring that the content of the AR tool is meaningful for the students. Similarly, students' perceptions and feedback that we have gathered in the pilot study will inform the future iterations of the current AR tool.

5 ACKNOWLEDGMENTS

The authors would like to thank Dennis den Ouden-van der Horst and Beryl van Gelderen for the mathematics input in the design of the AR solution and implementation of the study, Winnie Dao for data collection, Job Vlak for initiating the educational innovation, and the students who participated in the pilot study.

ABSTRACT

In tertiary mathematics education for engineers (hereafter called service mathematics education, SME), there is a long-lasting controversy on what and how to teach. The goal of SME is to provide a base for engineering-specific courses and to develop mathematical competencies needed for academic success and professional practice. A leading question in engineering education is how to take mathematical competencies into account when designing content. Mathematical competencies are employed to understand, judge, do, and use mathematics in a variety of mathematical contexts and situations in which mathematics could play a role [1]. Although mathematical competencies have been introduced for about two decades, Alpers [2] noted that research in engineering higher education had focused chiefly on the *modelling* competency and less on other competencies. By means of a scoping review, the current study aims to examine how mathematical competencies are investigated in higher education research. The main research question is “To what extent and in what ways have mathematical competencies been examined in higher engineering education research?” Papers were retrieved and qualitatively reviewed using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. A systematic search yielded 166 records, of which, 65 unique records were relevant to engineering education and screened for eligibility. A synthesis of 23 studies reviewed showed that *problem-solving* and *modelling* were the most investigated mathematical competencies and were often investigated together or with other mathematical competencies. The inconsistencies in the terminologies used suggest a need for clearer conceptualizations to advance research and inform practice on mathematical competencies.

1 INTRODUCTION

1.1 Service Mathematics in Higher Engineering Education

Mathematics is an essential discipline for many professions, and therefore, also in higher education [3]. In Science, Technology, Engineering and Mathematics (STEM) education this is even more the case since mathematics provides the basis and language for physics and engineering specific courses students need to complete. On the other side, mathematics is also viewed as a means to teach students to think analytically, to model and to solve problems in their fields [4]. Mathematics education for non-mathematics students (or major) is usually referred to as service mathematics education (SME), since the subject is being taught as a service to other disciplines and their programmes. The main challenge in this education is to tackle the question of what subjects to teach, in what depth, in how much detail, at what level, and with how much connection to applications. One way to deal with these challenges is to adapt the framework of mathematical competencies to the context of SME for engineers.

1.2 Mathematical Competencies

In 2000, the KOM (Competencies and the Learning of Mathematics) project was initiated in Denmark in response to various challenges in mathematics education at all levels. According to Niss [5], mathematical competence is defined as:

> "someone's insightful readiness to act appropriately in response to all kinds of mathematical challenges pertaining to given situations."

Eight mathematical competencies were identified that built the edifice to achieving mathematical competence. A mathematical competency is someone's insightful readiness to act appropriately in response to a specific sort of mathematical challenge in given situations. These eight mathematical competencies are grouped into two categories. The first one consists of four competencies involving posing and answering questions in and through mathematics. The second category consists of four competencies involving handling the language, constructs and tools of mathematics (for an overview, see [1] and [5]). The level of competence is defined in terms of (1) degree of coverage: to what extent does an individual possess this competency; (2) radius of action: represents the range and variety of different contexts and situations in which the individual can successfully activate the competency; (3) technical level: level and degree of sophistication of the concepts, theories, and methods an individual can bring to bear when exercising the competency [5].

Deeken et al. [6] have shown the need for instructors to consider the problems first-year students encounter after transitioning from secondary school to university. For example, *mathematical representations* are used and presented differently in terminology, presentations, and mathematical evidence. In general, if the competencies are addressed in the curriculum, e.g., in Sweden [7], secondary education focuses on communicating the right solutions. However, university curricula focus on rigorous deductive argumentations and formal proofs requiring advanced *mathematical thinking* (one of the competencies). Consequently, new first-year students must adapt to a new academic learning environment concerning the learning of mathematical competencies in SME. Besides the challenges regarding the transition from secondary- to university education, mathematical competencies could potentially foster transfer from SME to engineering. As SME could support a characterisation of mathematics and mathematical competencies which address the variety of perspectives in different disciplines [4]. It would be of immense value to employ mathematical competencies at various educational levels, and especially in SME, to foster mastery and transfer of mathematics.

1.3 Current Study

Given the potential of mathematical competencies to guide the design and evaluation of SMEs, there is a need to better understand how mathematical competencies are being examined in higher engineering research. We first searched for review studies on mathematical competencies. However, we found that only a limited number of reviews have been conducted. This seems to suggest a gap in the field in synthesising research knowledge about how mathematical competencies have been employed. The current study attempts to fill this gap by performing a scoping review on how mathematical competencies have been studied in higher engineering education. Results of the scoping review will inform the field on the current state of mathematical competencies research in higher engineering education and provide insights into potential research directions.

2 METHODOLOGY

2.1 Identifying Research Question and Relevant Papers

According to Arksey and O'Malley [8], a scoping review typically consists of five steps: identifying research questions, identifying relevant studies, selecting studies, charting the data, and summarising the results. Our main research question is: "To what extent and in what ways have the eight mathematical competencies been examined in higher engineering education research?". Accordingly, the following sub research questions were formulated to guide the reviewing process:

- What is the current state of research on mathematical competencies?
- Which mathematical competencies were researched in the studies?
- How are mathematical competencies being employed in higher engineering education?

We first conducted searches across two databases (i.e., Scopus and Web of Science) to obtain relevant papers in February 2022. Each search string consisted of three categories of key words: 1) one mathematical competency (i.e., think*, reason*, model*, represent*, problem* solv*, handl* symbol* formal*), 2) a general term (i.e., math* competenc*) to limit the search to studies related to mathematical competence or competencies, and 3) educational level (i.e., higher education, tertiary, and universit*) to limit the search to studies conducted in higher education. We did not include two of the eight mathematical competencies (i.e., communicating in, with, and about mathematics, and making use of aids and tools) as they were relatively more difficult to assess [9]. In March 2022, two discipline-related journals, European Journal of Engineering Education and International Journal of Mathematical Education in Science and Technology, were searched using the same method. Along with a snowball search, 166 papers were identified in total.

2.2 Selecting Papers and Synthesising of Data

Results from the searches were uploaded to an intelligent systematic review software (rayyan.ai) that aided the selection and reviewing of the papers. We selected only papers that mentioned engineering by selecting the keyword “engineering”. After removing duplicates, 65 unique records were identified and screened by two independent researchers. 23 papers met the four main inclusion criteria and were included in the review: 1) relevant to SME, 2) mentioned mathematical competencies or mathematical competence, 3) were written in English, and 4) had full text retrieved. All selected papers were read in detail to extract information addressing the sub research questions.

3 RESULTS

3.1 Current State of Research on Mathematical Competencies

The 23 included papers consisted of journal articles (*n*= 12), conference papers (*n*= 10), and a book chapter (*n*= 1). The first paper was published in 2002, but the rest of the publishing activity was concentrated between 2011 and 2021 (see Figure 1). The reviewed studies were conducted in 14 different countries whereas the country was not specified in four papers. Figure 2 illustrates that most of the relevant research is in European countries. Regarding the type of tertiary education institution, universities were the most prominent (*n*= 15), followed by institutes (*n*= 3) and academies (*n*= 1). Five papers did not provide information about the type of institution. The information suggests a growing interest in mathematical competencies over the last decade at the tertiary level. While the main research activities are in European universities, there is also a developing interest across education institutions worldwide.

Research in the corpus was diverse, comprising empirical studies (*n*= 12), theoretical/conceptual papers (*n*= 5), reports on programme/instruction implementation (*n*= 4), and literature reviews (*n*= 2). Within the group of empirical papers, nine quantitative (*n*= 7 descriptive and *n*= 2 correlational) and three qualitative studies (*n*= 2 case studies and *n*= 1 narrative) were identified. Most papers focused on 1st year engineering students (*n*= 10), whereas several papers did not specify the students’ year level (*n*= 6). Out of the 23 papers, 13 provided information about the type of engineering programme. The studies were conducted in a diverse set of engineering programmes, including chemical and civil engineering. Of which, the highest number of studies were conducted in Electrical, Electronic, and Technology engineering (*n*= 10), and Mechanic and Materials engineering (*n*= 6).

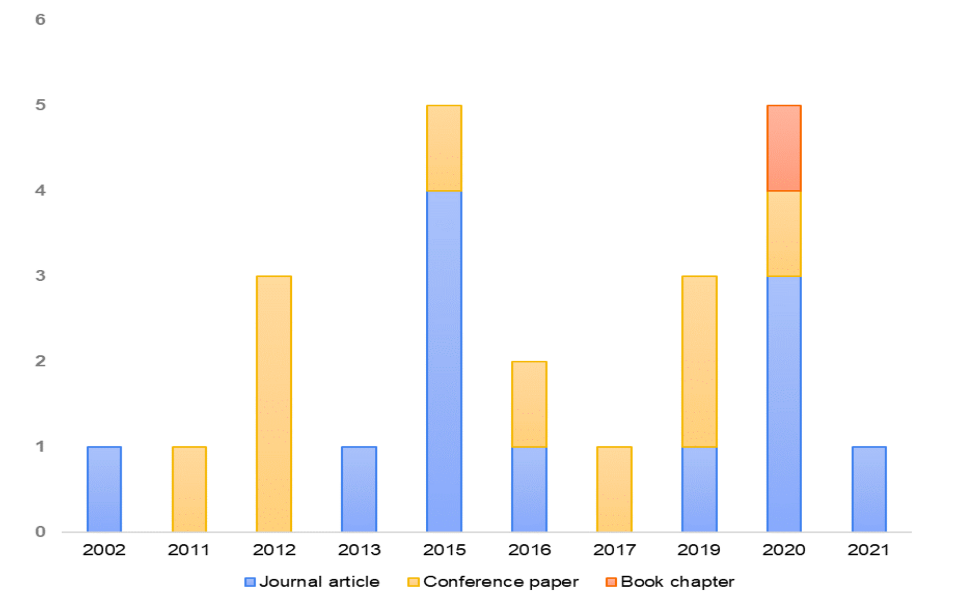

Fig. 1. Distribution of publication's number across the years

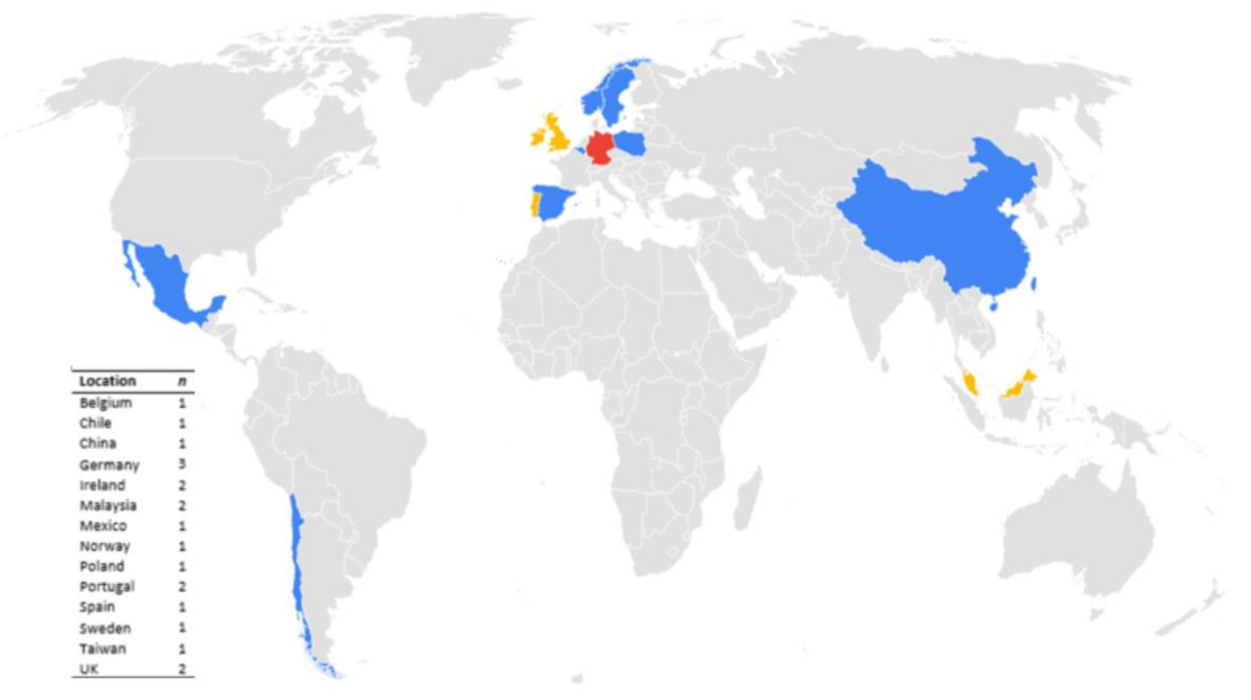

Fig. 2. Geographical locations of the reviewed papers

3.2 Mathematical Competencies Investigated in Engineering Education

A matrix table was used to map the terms employed to describe the concept of mathematical competencies and the specific mathematical competencies investigated in the papers. As shown in Table 2, two mathematical competencies, namely *posing* - and *solving problems* (C3) and *modelling* (C4), were the most investigated mathematical competencies. Not only were the two mathematical competencies individually investigated by the highest number of studies, but the two mathematical competencies were also frequently investigated together [10] and alongside other mathematical competencies [11]. There were no studies that explicitly investigated *representing math entities* (C5). Six studies (26%) investigated more than one mathematical competency (i.e., mixed). The investigation of more than one mathematical competency in a study suggests the interconnectedness of certain mathematical competencies.

Many studies did not use the term "mathematical competencies" when referring to a specific mathematical competency. For instance, *mathematical modelling* was referred to as skills [12] and competence [13]. Table 1 shows the diverse set of terms used in the studies. Our review showed that six studies (26%) mentioned the term "mathematical competencies" according to Niss's [1] definition, while four studies used the term "mathematical competencies" but did not mention the framework by Niss. The term "competenc(ies)" was also often used with other terms, for example competence, skill, and literacy. Therefore, indicating a lack of consistency or clear definition for the terms used in mathematical competencies research.

Table 2. Mathematical competencies and terminologies used

	C2	C3	C4	all eight	mixed	general	Not specified

3.3 Approaches in which Mathematical Competencies were Employed

For our third research question, we examined how mathematical competencies were investigated and organised the studies according to similar approaches. Table 3 provides an overview of the identified approaches to studying mathematical competencies. We first identified whether the mathematical competencies were investigated in a course context. Successively, we looked at teaching practices and student preparedness for math education.

The studies in the category of “in a course context” were further organised into three subcategories. The first subcategory consists of three studies investigating assessment and how an assessment tool measured a certain mathematical competency [14], [25], [26]. For example, in Kortemeyer & Biehler [14], student-expert-solutions were used as a tool to analyse students’ *problem-solving* process. Another subcategory consists of studies exploring how tasks can be designed to develop mathematical competencies [15], [16], [17]. Alpers [15] provided examples of tasks to illustrate how *mathematical reasoning* can be used to set up a curriculum for a practice-oriented study course in mechanical engineering. Jaworski [16],[17] also provided a clear example of how an inquiry-based task helps develop the eight mathematical competencies.

The largest subcategory comprises studies that examine various teaching practices [9], [10], [11], [13], [18], [19], [20], [28]. The teaching practices were briefly described in Table 3. Several studies examined the use of technological tools to promote the teaching and development of mathematical competencies. Lakoma [18] highlighted the need to use technology to teach mathematics. Other studies examined the use of technology to assess or teach mathematical competencies (e.g., video lessons in Caridade & Rasteiro [9] and wiki in Hennig et al. [19]. There is also a strong focus on enhancing teaching practices for *mathematical modelling* [10], [11], [13], [20]. The teaching practices investigated in the studies provide insights into how mathematical competencies can be used to better develop courses and activities to enhance SME.

Among the seven studies in which mathematical competencies were not investigated in a course context, five studies examine students’ preparedness for higher engineering education using “general” mathematical competency test in relation to basic math knowledge and skills. Two studies investigated the relationship between specific mathematical competencies and other thinking skills: 1) *mathematical modelling* and *creating thinking* [12] and 2) complex word *problem solvin*g and spatial, verbal, numerical, and general *reasoning* abilities [21]. The studies in this category suggest that examining students’ level of preparedness or state of competence is an emerging area of research focus.

Table 3. Overview of approaches investigating "mathematical competencies"

Approaches	Paper and short description	Course name
In a course context

4 DISCUSSION AND CONCLUSION

The objective of the review is to examine how mathematical competencies are being investigated in higher engineering education where mathematics is typically taught as a service subject. Addressing Research Question 1, this scoping review yielded 23 papers with studies conducted across 14 countries employing a diverse set of methodological approaches. The results are aligned with Niss et al.'s [32] finding on the conceptualization of competencies in mathematics education research. When naming mathematical mastery, the terminologies used are highly diverse. Without a deeper analysis, it is not clear whether the different terms refer to the same concept nor whether the same term was used but are referring to different constructs.

Despite the presence of terminological issues, the studies in this review suggest a shift towards symmetry in adopting the definitions provided by Niss [1]. A common definition would help to advance research and inform practice on mathematical competencies. Educators and researchers can build on each other's work by employing a similar definition and use the eight mathematical competencies from Niss as a starting point. Another way to move forward is to empower math educators in embracing and owning the notions of mathematical competencies [32]. By doing so, educators can better develop teaching materials and approaches to foster mathematical competencies.

For Research Question 2, this review found that research has focused on the investigation of two specific mathematical competencies, *modelling* and *problem solving*, either independently or combined in the same research context. An explanation could be that these two competencies play a central role in the education of future engineers [33]. However, this finding suggests the need for future research to examine how other mathematical competencies can be individually supported within service-mathematics courses for engineering students.

Furthermore, the analysis indicates that studies often investigate a combination of three or more individual mathematical competencies either as independent or interdependent concepts, e.g., [10]. This observation might be related to the fact that teaching methods and learning materials rarely address isolated mathematical competencies in authentic educational settings. In this case, Niss et al.'s [32] recommendation for more empirical research on the interconnectedness among individual competencies is highly relevant.

In relation to Research Question 3, the studies reviewed show an emerging interest in the abovementioned connection in the level of task analysis, e.g., [17]. Future research could investigate the relevance of different competency combinations at the level of various service-mathematics courses or engineering programmes, e.g., [15] and [16]. Moreover, Lakoma [18] and Pedersen et al. [34] suggest that there is a need to examine how development of mathematical competencies can be supported by various technologies given that digital technologies are becoming a commonplace at school and at work. An example of course design, using mathematical competencies linked to digital technologies and workplace contexts is the concept of Techno-mathematical Literacies by Van der Wal et al. [35].

The current scoping review had some limitations. First, only two major databases were used, so the search was not exhaustive. To gain a more in-depth understanding of mathematical competencies research in higher engineering education, a more systematic review of studies will be much needed. Nonetheless, the current scoping review acts as a precursor for future systematic review and raises potential questions and areas for research.

Secondly, the scoping review did not look at the dimensions for specifying and measuring progress in mathematical competencies. Future reviews could consider examining dimensions for a more thorough investigation of the literature on mathematical competencies. The goal of defining and researching mathematical competencies in SME is to support course and curriculum design based on competencies. This review shows that the field is not at that point yet with substantial research findings to guide the design of SME.

As an extension to the current scoping review, our future work will include investigating lecturers' perspectives on developing mathematical competencies in service mathematics courses. To conclude, the scoping review provides a contemporary understanding of the trend of mathematical competencies research in SME and adds to the emerging research field of competence-based course and curriculum design by identifying the gaps in research between the definition of competencies, their interconnectedness, and their assessment.

ABSTRACT

ALCAEUS is a voluntary evaluation scheme developed by the Spanish agency ACPUA, designed to provide visibility to institutions and centers that demonstrate commitment and contribute to the achievement of the UN Sustainable Development Goals (SDGs) / 2030 Agenda. It is a pioneering international external evaluation program within the European Higher Education Area, open to faculties and schools that have successfully undergone an IQAS certification review (institutional accreditation). The ALCAEUS pilot program was carried out last year and two Engineering Schools (Escuela de Ingeniería y Arquitectura and Escuela Politécnica Superior) of the University of Zaragoza (Spain) participated in it. The evaluation was based on a site visit conducted by an international review team. The two schools demonstrated a firm commitment to SDGs and were awarded a 2030 Agenda quality label valid for 6 years.

1. INTRODUCTION

1.1 Origins of the ALCAEUS program: INQAAHE project

The program ALCAEUS arises from the participation of the Aragon Agency for Quality Assurance and Strategic Foresight in Higher Education (*Agencia de Calidad y Prospectiva Universitaria de Aragón*, ACPUA) –full member of ENQA and registered in EQAR– in the project 'Making connections between the Institutional Evaluation and the Sustainable Development Goals. Empowering stakeholders for quality enhancement'. This capacity-building project was awarded by the International Network for Quality Assurance Agencies in Higher Education (INQAAHE) and coordinated by the Higher Education Quality Agency of Andorra (*Agència de Qualitat de l´ensenyament superior d'Andorra* AQUA). It lasted one year (until May 2019) and involved the main stakeholders in higher education and sustainability in Andorra and Aragón.

The main objective of the project was to align quality assurance in higher education with the SDGs and to empower stakeholders in university systems. Through participatory processes of joint reflection and diagnostic analysis, a 'Proposal of indicators to embed the Sustainable Development Goals into Institutional Quality Assessment' was published in 2019 [1].

1.2 Aim of the ALCAEUS program

The main objective of the 2030 certification of centers and/or universities awarded through the ALCAEUS program is to give visibility to the efforts that institutions are making to meet the SDGs set out in the United Nations 2030 Agenda.

The ALCAEUS program contains an international assessment protocol that measures the degree of commitment to the SDGs, approved by ACPUA's Commission for Assessment, Certification, and Accreditation (CECA) on 17th July 2020. The process involves a verification and review process and awards points that correspond to four possible levels of certification [2].

2. METHODOLOGY

2.1 Program schedule

The ALCAEUS Programme was launched during the academic year 2020/2021 on a pilot basis. Those centers of the University System of Aragon that had obtained institutional accreditation during the academic year 2018/2019 voluntarily applied for this program. For this purpose, the announcement of 9th October 2020 was published by the Director of the ACPUA, which called upon the centers of the Aragon University System to participate in the pilot assessment for the certification of their degree of commitment to the SDGs.

After the deadline for submission of applications, no further 2030 certification processes of centers and universities under the ALCAEUS program were allowed to be launched until the pilot evaluation was completed and a meta-evaluation process of the pilot program was carried out, which included the results of the evaluation, as well as the opinion of the participants in the process (evaluated and evaluators).

Following the ALCAEUS evaluation protocol, at the proposal of the CECA, the Director of the ACPUA appointed on 14th December 2020 the expert evaluators of the visiting panel, who carried out online visits (due to the situation created by the COVID-19 pandemic) to both the Escuela Politécnica Superior (EPS) –on 17th and 18th December 2020– and the Escuela de Ingeniería y Arquitectura (EINA) –on 11th and 12th March 2021–. Both centers belong to the University of Zaragoza and base their strategy on the 2030 Agenda, taking as a starting point the recommendations of the UN Sustainable Development Solutions Network [3].

The panel of experts issued the relevant visit report which, together with the evaluation documentation, was submitted to ACPUA’s Subcommittee for Thematic Evaluations (SETE) and Subcommittee for the Evaluation of Centres (SEC). The latter committee issued the corresponding report proposal, which was sent to the centers so that they could make any allegations regarding the content of the report and any proposals for improvement of the program that they considered appropriate.

In their letters of allegations, the centers, properly understanding the characteristics and objectives of a pilot program such as this one, included and integrated reasoned contributions for the interpretation and improvement of the ALCAEUS program. For this reason, the aforementioned letters were sent to the ECSC (the technical committee responsible for ACPUA's evaluation methodologies and programs), which unanimously approved the final reports.

2.2 Evaluation protocol

The evaluation is based on several criteria, which are structured in six dimensions referred to aspects such as the strategy of the center, resources, transparency, Internal Quality Assurance System, teaching programs, and staff. Each dimension includes several criteria, which in turn, are broken down into several guidelines. For each guideline, criterion, and dimension a maximum score can be obtained, in such a way that the maximum total score adds up to 100. Table 1 shows all the dimensions and their criteria.

Table 1. Dimensions and evaluation criteria

Dimension	%	Criterion	%
1. Strategy, partnerships and recognition	20	1.1. Commitment and strategy of the centre	40
		1.2. Partnerships	40
		1.3. Internal and external recognition	20
2. Transparency and accountability	20	2.1. Public information	100
3. Internal Quality Assurance System	15	3.1. Processes and quality strategy	50
		3.2. Staff responsible for the Internal Quality Assurance System	50
4a. Programmes (for faculties, schools and	25	4.a.1. Development of policy frameworks	10
		4.a.2. Student-centered learning. Competencies	30

educational establishments)		4.a.3. Student-centered learning. Theoretical learning opportunities	30
		4.a.4. Student-centred learning. Practical learning opportunities	30
4b. Research projects	25	4.b.1. Objectives	40
		4.b.2. Planning of activities	30
		4.b.3. Outcomes	30
5. Staff	15	5.1. Heads of teaching provision/research activity	34
		5.2. Teaching and research staff	33
		5.3. Administrative and support staff	33
6. Founding and Resources	15	6.1. Administrative and support staff	60
		6.2. Resources	40

Before the visit of the external evaluation panel, each participant center prepares a self-assessment report about all of these dimensions/criteria and guidelines, providing evidence and setting a range of four levels for each criterion: A (fully implemented), B (sufficiently implemented), C (insufficiently implemented), and D (not implemented).

The final score obtained by each center leads to a final Certification level for teaching or research centers:

- Level 0 – No certificate. Score: 0-24 → Emerging commitment to 2030 Agenda.
- Level 1 – BRONZE. Score: 25-49 → On route to the 2030 Agenda
- Level 2 – SILVER. Score: 50-74 → Strong commitment to the 2030 Agenda
- Level 3 – GOLD. Score: 75-100 → Flagship and international reference center.

3. RESULTS

The ALCAEUS program is intended to enhance the motivation of university centers to implement the 2030 Agenda in all their activities. For this reason, at this stage of development of the program, the main results to be shown here are not so much those related to the level obtained by each center, but rather the strengths and weaknesses of the certification program concerning the aforementioned goal that have been identified in the pilot program.

The preparation of the self-report and the development of the visit of the external evaluation panel by the centers required them to develop a reflective and contextualization process about the multiple activities carried out, which in turn allowed them to identify points of improvement and to discover areas of untapped work. Both centers, when issuing their report on allegations and suggestions for the meta-evaluation, indicated that –although the certification mostly included dimensions, criteria, and guidelines appropriate for its purpose– some criteria and guidelines related to aspects on which centers lacked autonomy of action did not allow an adequate assessment of their true commitment to the SDGs.

Both centers also drew attention to the fact that a center's commitment to the SDGs does not reside solely in its teaching or quality areas, but rather that it must constitute an indispensable part of its own "metabolism", extending to its activity and the management of its infrastructures. This rationale implied that the actions of the centers aimed at reducing their environmental impact and activities aimed at a healthier campus, which directly affect several SDGs (viz. SDGs #3, #6, #7, #12, #13, #14, and #15), should also be taken into consideration. Hence, both centers suggested that the environmental management of the center/campus and the actions aimed at improving the quality of life on campus should be incorporated into the certificate as additional dimensions to be assessed.

After the contributions of the centers, the meta-analysis was carried out through different forums, among which the meeting conducted on 11th March 2022 may be highlighted. Various stakeholders, including the Director and technicians of ACPUA, Directors and Deputy Directors of Quality and Sustainability of the two centers involved (EINA and EPS), the external evaluation panel, as well as the Vice-Chancellors of Academic Policy and Infrastructures and Sustainability of the University of Zaragoza, in addition to various Secretarial Directors of those Vice-Chancellors, participated in the session.

Finally, it should be noted that both University of Zaragoza centers (EINA and EPS) obtained the ‘Level 2’ certificate, accrediting their “Strong commitment to the 2030 Agenda”.

Fig. 1. ALCAEUS seal

This ALCAEUS as an evaluation protocol of the Agenda 2030 is a pioneering programme in the field of quality assurance within the European Higher Education Area, as recognised by ENQA: “The planel commends ACPUA for developing ALCAEUS as a pioneering evaluation scheme focused on the UN Sustainable Development Goals, which aims to enhance the social dimension of higher education in Aragon” [4]

4. SUMMARY AND ACKNOWLEDGMENTS

The ALCAEUS pilot program proposed by ACPUA to certify and make visible the degree of commitment of university centers to the 2030 Agenda and the SDGs has been developed with the participation of two centers of the University of Zaragoza. The process, based on the contributions of both parties (evaluated centers –EINA and EPS– and the Agency –ACPUA–) has resulted in the final configuration of a certification that may be regarded as a powerful tool to encourage university centers to implement a strong and effective commitment to sustainability.

Keywords: *professional influencing skills, leadership skills, self-management practices, peer networking, continous learning*

ABSTRACT

Professional working life skills have become an essential part of the engineering skillset in recent years. However, it seems that basic engineering education does not sufficiently provide the students with these skills. The Finnish Association of Academic Engineers and Architects (TEK) established a new kind of peer forum to develop these skills of its younger members. The forum consists of workshops, assignments, and peer dialogues over a four-month time period The forum's approach leans on a dialogic, experiential and reflective way of learning enabling the participants to further build their personal influencing practices; investigate their professional relationships; experiment changes in their self-management practices; and share their experiences in peer groups. Since 2017, over 900 young TEK members have participated. The aim of this study in progress is to make an overview to the experienced impacts of the forum and scrutinize the forum's influence mechanisms in a more detailed way. The data was collected through an inquiry to all participants. The study indicates that the forum has been most influential in supporting the participants to become more aware of their professional influence, to build capabilities to change their personal and social practices, and to enhance their professional networks. The most significant impact element has been various peer discussions and dialogues. As a conclusion the study highlights the needs and interests of young professionals to develop the essential working life skills.

1 INTRODUCTION

Professional working life skills have become an essential part of engineering skillset. The general change of working life to dynamically evolving VUCA (Volatility, Uncertainty, Complexity and Ambiquity) environment and the new forms of organizing require more advanced competences in communication, collaboration, personal and professional influencing as well as in change and development from all professionals including engineers [1,2]. However, it seems that basic engineering education provides the students insufficiently with these skills [3].

As a part of the service offering to its younger members TEK (Association of Academic Engineers and Architects in Finland) initiated a new peer forum to support the development of personal and professional influencing skills of freshly graduated academic engineers. The aim of this study is to make an overview of the experienced and perceived impacts of the forum, and highlight the influence mechanisms of the forum in more detailed way. The research questions are: *1) What have been the experienced impacts from the Young Professionals' Forum? 2) What have been the most essential elements of the forum on behalf of the impacts?*

2 YOUNG PROFESSIONALS' FORUM (YPF)

TEK (The Association of Academic Engineers and Architects in Finland) has some 77000 members of which 20000 are student members. TEK along with most of the professional associations in Finland has suffered a declining number of members during the past decade. After graduation, a growing number of student members has discontinued their memberships. To respond this negative trend TEK has renewed its strategy and started to develop services and activity models that would better serve the needs of its younger members. The new strategy has been successful and TEK has been able to turn the trend to positive. The Young Professionals' Forum (YPF) has been one of these responses. However, an even more fundamental motivation for the forum has been to support the young engineers to develop their essential working life skills in their early careers.

As leadership teachers we (the authors) were invited to develop the pilot version of the forum. The pilot version was arranged in 2017 with 50 participants. The positive feedback encouraged to continue the service. Since 2017 the forum has been arranged fifteen times for over 900 participants. In practice the forum is four-month long training process consisting of four three-hour workshops, three personal assignments, and three peer group meetings between the workshops. Next the pedagogical foundation and practical design of the YPF will be presented more in detail.

2.1 Pedagogical foundation

The pedagogical foundation of the forum is based on constructivist and experiential learning with dialogic, reflective, reflexive, and even critical undertones [4,5]. Improving personal influencing skills and practices in a sustainable way is a highly personal process as we all have a unique growth history, personalities, strengths and developmental needs, learning abilities, and professional contexts. Influencing skills are grounded on our views of social reality, our values, our past experiences, and our routinized habits and practices. Thus, improving personal influencing skills in a sustained way requires *1) willingness to scrutinize the prevalent personal beliefs, principles and values, influencing requirements within own professional context, and current personal and social practices, 2) getting experience of improvement steps in personal practices and reflecting on the experiences, and 3) to repeat the new practices long enough to routinize them.*

The additional elements of the learning process are processuality, contextuality, and a facilitative way of instructing. *Prcocessuality* refers to the duration and rhythm of the process as well as the integration, iteration and reciprocity of different program elements, themes, and concepts. *Contextuality* refers to the connection to each participants own professional and personal life context as well as to the temporary learning community formed in the forum. *A facilitative way of instructing* means that the role of the instructors is to engage the participants in an active conversational process and sharing right from the start; to enable allowing, trusting, and open atmosphere; to provide the participants with appropriate concepts and theories; and to maintain adequate structure of the process.

2.2 Practical application – forum design and delivery

The forum has been arranged mainly in the Helsinki area where the majority of TEK members live but few times also in other major Finnish cities. Due to COVID19 pandemia the forum was turned to online mode, which at first was worrying as the forum's concept leans heavily on living face-to-face conversations. Despite our worries the online forum seemed to serve its purpose relatively well. The online mode enabled participants to join more easily from distant locations. All in all the number of single forum participants has varied from 30 up to one hundred.

Basically the Young Professionals' Forum is a four-month long personal and social learning process consisting of four three-hour workshops, three individual assignments and three peer group meetings between the workshops. The aims of the forum are to *1) support newly graduated engineers to develop their personal professional influence and self-management, 2) strengthen participants' ability to build and develop their professional relationships and interaction, 3) build practices and commitment for continuous development as an interactor and influencer,* and *4) enable participants to build and strengthen their professional identities further*.

The forum is strongly participant-focused and is planned to create a holistic learning process, in which different elements build on each other. The participants are requested to investigate and scrutinize their current working practices, professional relationships, leadership thinking and preassumptions, interview their collaboration partners and ask personal feedback, and experience small step changes in their professional practices. These experiences are discussed and shared in the workshops, in which appropriate concepts and supportive tools are also introduced by the facilitators. Furthermore, in the beginning of the process the participants are divided into peer groups which aims to serve as support groups throughout the whole process. The peer groups meet between the workshops and share the assignment experiences as well as discuss the topics that are relevant for the group.

The participants are asked to document their assignments but they are allowed choose the level and accuracy of the documentation as the purpose is most of all to serve the personal learning. Documentation through writing allows the participants to reflect on the experiences in a profound way. The assignments build on each other forming a holistic review of the personal state of the art situation. The final report forms a reference point for assessement of personal development and thus, at its best serves as a reflective framework for further development.

3 METHODOLOGY

An online inquiry was sent to 740 former YPF participants. 123 responded to the questionnaire. The questionnaire contained five background questions, ten scale (quantitative) questions, and three open (qualitative) questions. The inquiry aimed at charting the initial participation motivation and expectations, the experienced and perceived impacts, the most influential elements of the forum, and the hidden potential of the forum. The qualitative data was analyzed following the guidelines of qualitative content analysis.

4 FINDINGS

The findings are divided into three sections. First the background of the respondents is summarized. Second the expressed impacts and usefulness of the forum are presented based on the questionnaire data. Finally, the impact factors of the YPF are presented based on the open questions of the inquiry.

4.1 Background of the respondents

The YPF has been arranged fifteen times from 2017 on. There were respondents quite evenly from all the years the forum has been arranged. The YPF participants represent in practice all possible industries and engineering fields as the TEK is an association for all academic engineers and architects. The YPF is directed to freshly graduated professionals (less than five years from the graduation) thus the vast majority of them fit to age range from 25 to 35. During the forum 90% of the respondents were in specialist roles and 10% in managerial roles.

To gain learning benefits from the forum based heavily on the participants’ own activity requiring to use of their free time to the workshops and assignments, and daring to share their personal thoughts and experiences with others. The respondents were asked how the overall way of working suited to them (“*The way the forum was organised was successful for me”).* 68% of the respondents expressed that the way of working suited to them well or very well. For 17% the way of working was ok, and for 15% less suitable. Furthemore, the respondents were also asked to evaluate how pleased they were on their personal way of working and participating (“*I am happy with how I got to participate and work during the forum”)*. 65% of the respondents expressed that they were pleased or very pleased how they managed to work and participate to the YPF process.

4.2 Learning experiences and outcomes

The learning outcomes and experienced impacts were scrutinized through scale questions, in which the respondents were asked to assess positive claims concerning the forum with a scale from one to five (1=not at all, 2=little, 3=somewhat, 4=significantly, 5=very significantly). The first claim was about the overall usefulness of the forum: "*The forum was useful to me".* Two thirds of the respondents expressed that the forum was significantly or very significantly useful for them. 23% felt that the it was somewhat useful, and 13% felt that the forum was just little useful for them. None felt that the participation was useless.

The Figure 1 illustrates how strongly the forum was experienced to contribute to the development of respondents' *self-management practices, professional influencing, continuous personal development, career advancement,* and *professional identity*. Improvement of practices both personal and social as well as the respective skills, and personal developmental practices were the core aims of the forum.

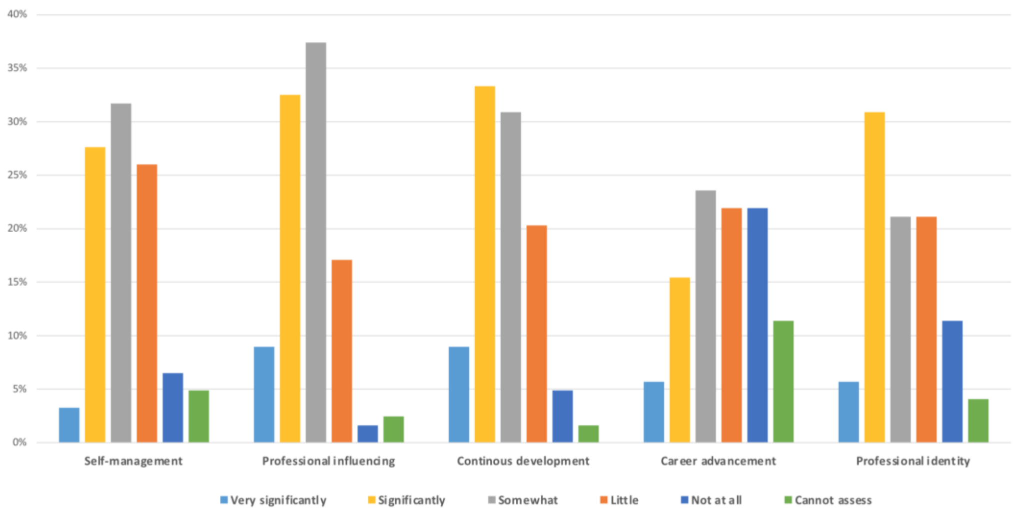

Figure 1. Expressed and experienced YPF impacts 2017-22

It seems that the forum has been successful in promoting the skills and practices which were the actual topics of the forum – *self-management, professional influencing, continuous development*. Based on the questionnaire data the strongest impact was indicated on the professional influencing skills and practices as almost 80% of the respondents experienced significant, very significant or at least some impacts on their professional influencing skills and practices ("*The forum supported me in developing my own professional interaction and influence")*. The mildest impact was experienced on the career advancement. However, the career advancement was not in the actual focus of the forum. An interesting result is that the participation was experienced to strengthen the professional identity quite clearly despite the fact that the focus of the discussions and the whole forum was in social aspects of the engineering profession and practice, not in actual professional content. Almost 60% of the respondents felt that there was a significant or very significant impact on professional identity ("*Participating in the forum has strengthened my professional identity").*

All in all, the forum seemed to be a meaningful experience to the majority of the participants both personally and professionally. In the end of the inquiry the respondents were asked to assess how strongly would they recommend the forum to their colleagues and friends. The scale was from one to ten in which one represented the absolute no and ten absolute yes. The average was 7,9 when 79% of the respondents gave 7 or higher.

5 IMPACT FACTORS

The second topic we investigated was what factors of the forum were experienced as the most essential from a personal learning point of view. The respondents were asked to assess the impact factors with an open question in the inquiry: "*The forum consisted of workshops, personal assignments and peer group meetings, which formed a process that lasted about four months. What elements and components of the forum did you find most important for your own learning and benefit? Why*?" There were 66 responses to the question.The responses were categorized by the mentioned impact factors. Four categories were formed: *peer discussions, workshops, assignments,* and *the process as a whole*.

5.1 Peer groups

The vast number (over 80%) of the responses mentioned the peer discussions and peer groups as the most essential impact element of the forum. The peer group meetings between the workshops were mentioned to enable deeper conversations in which personal questions and experiences were shared in a safe environment. An important realisation mentioned was that all others had the similar questions and worries and that sharing those with others is meaningful as one respondent described: "*Peer group discussions helped me to realize that all have work related challenges and worries, and sharing those with others is fruitful. Our group met on free time which supported to build open and trusting connection within the group"*.

The peer meetings and sharing were mentioned to be essential forums and sessions for personal reflection and meaning making. The interactive and social reflection helped the respondents to clarify and expand their own thinking – why do I think like this? What are other possible ways of interpreting and thinking? Social reflections were experienced to be much more fruitful than just thinking and reflecting alone as one respondent described: *"Through peer discussions you got many view points and perspectives and not just your own. In peer discusssions we generated a lot of new ideas and insights".*

The peer groups were formed randomly and people did not know each other beforehand. Nevertheless, there were multiple comments on how the peer group was experienced as a safe and trusting environment to share personal thoughts and experiences, and discuss even uncertainties and worries as one respondent commented: *"Peer meetings between the workshops were very fruitful. The group* *formed a safe and trusting place to talk and share personal experiences"*. For most the peer group seemed to form trustful and helping relationship context which supported sense making, reflection, and personal development in a meaningful way. There were groups that continued to meet also after the forum.

An important aspect was also to hear and get practical tips about the methods and practices, and also share your own experiences. The peer group sessions and sharing was mentioned to support to develop professional self-confidence further. All in all the realization that I am not alone with all these questions seemed to ease the personal pressures to perform excellently all the time.

5.2 Workshops

The second impact factor mentioned was the workshops. The most forums had four three-hour workshops in the evening time from 5 pm to 8 pm. The workshops were participatory, including sections of lecturing, group discussions and exercises in pairs. The workshops were mentioned to form important moments for personal thinking and reflection. The most comments concerning the workshops were about the group discussions but the theoretical and conceptual content and introduced practices were also mentioned as value adding elements: *"The best for me were the practices and concepts presented in the workshops as well as the sharing of ideas"*. Some also mentioned the coaching exercises in pairs as an impactful course element. For some the workshop discussions remained vague compared to the discussions in the peer group. Before the Covid, the workshops set-up was face-to-face which enabled the participant to network and continue their discussions also during the breaks. In online time this opportunity was cut off. The online workshops were experienced as beneficial, however, three-hour intensive sessions after online workday was considered rather tiring and demanding by many participants.

5.3 Assignments

The personal assignments that were done between the workshops formed the third impact factor category mentioned by the respondents. There were three assignments altogether, which were connected to each other in a way that formed an integrated whole. Fourteen respondents mentioned the assignments as an essential element from their personal learning point of view. The most connected the assignments and various reflection discussions together as an impact factor: *"Assignments and peer discussions were important. Through these it was possible the process, think, and develop the issues further".* The assignments enabled the participants to analyze and document their current situation, practices, thinking, relationships and work context, and later on in the workshops and peer discussions they were able to give deeper meanings and develop their thinking further. It was also mentioned that through the assignments, the participants produced a valuable documentation for themselves concerning their own development and practices.

5.4 The process as a whole

The fifth impact factor category mentioned by the respondents was the process as a whole. There were ten responses concerning the integrated and co-constituted impact of all the elements. One respondent described the impact very illustratively: *"I think that the most important from the learning point of view was the process as a whole. In the workshop the ideas and concepts were introduced and discussed which supported the accomplishment of the following assignment. Then the thoughts and insights from the assignment were shared with others in peer group meeting. The discussion continued in the following workshop and the ideas were shared cross the peer groups."* Most of those who mentioned the forum as a whole to be the essential impact factor highlighted the integration and collective influence of different forum elements. There was only one respondent who stated boldly that he "*experienced the whole forum more or less as a waste of time".*

6 DISCUSSION

This study is a work in progress. The YPF has been deemed a success by both the organizer TEK and the vast majority of the participants. Our data collection is still ongoing and this paper represents our first attempts to understand why and how the forum has been influential. According to our study, the participants in the YPF felt it enhanced their self-management practices, professional influencing, continuous personal development, and professional identity. It seems that the forum manages to produce impact on the essential working life and personal influencing skills in a sustained way.

The participants highlighted the peer discussions and opportunities to share their experiences, thoughts and insights as the most important part of the forum. Also the workshops and personal assignments got mentions as meaningful measures to support personal growth. Some participants saw that the process as a whole was what made it impactful. We argue that without the organized and facilitated process and individual analysis, and conceptual input the peer discussions would not have been so impactful. In our view, the experiences and impactfulness is most of all built through the confluence of different process elements.

The findings highlight strongly the social aspects of the learning process. One of our further directions in deepening our analysis is to look the forum as a "*temporary community of practice of learning*". This would allow us to tap into the processual, dynamic and relational aspects of the learning process. In building a better understanding of how and why the forum was experienced impactful, we strive to contribute on how to help engineers better their collaboration, influencing, and personal development skills. To be sure, there are multiple ways to achieve these goals. However, we hope our experience will shed light on what kinds of interventions might work, and thus, provide additional understanding and concepts to (engineering) educators what makes soft skills development impactful.

ABSTRACT

In the fall of 2019, the research club changING started as an outreach program in the Cluster of Excellence SE^{2}A. While the cluster deals with interdisciplinary research topics to explore technologies for sustainable and environmentally friendly aviation, the associated research club offers students from the 10th grade onwards the opportunity to gain insights into engineering. The target group here is primarily young women, who are heavily underrepresented in this career field. The research club is experience-oriented and offers high school students the opportunity to explore engineering, its systems, technologies, applications, and social and cultural significance by participating in different projects at various engineering institutes in the Cluster. During their four years of participation in the club, which is voluntary, students are challenged to discover, create, construct, and solve problems. In the process, students learn different engineering concepts and skills. Currently, three batches (75 highschool students) actively participate in the program, accompanied by engineering Bachelor students who serve as mentors. This paper presents the

doi:10.5821/conference-9788412322262.1397

structure of the research club which is based primarily on theories of the emergence and development of individual interests and self-efficacy expectations. A well-known model depicting the development of individual interests is the four-phase model. This model is considered the basis for the structure of the research club program. In this paper, the most important factors in the set-up of the research club and the expected results as well as the many lessons learned are presented.

1 INTRODUCTION

In recent years, numerous initiatives have been developed to promote interest and understanding of technology. The everyday life and the social contacts of young people are increasingly characterized by technical devices. However, young people are usually not actively engaged with technology as such, as they are neither concerned with materials nor with the functionalities or the original use of the devices, as various interest studies show [1]. This discrepancy between a life in the midst of technology and simultaneous technology remoteness in terms of interest and understanding has various causes, which have been investigated in the studies on technology socialization [2]. Since October 2019, the research club has therefore been pursuing, among other things, the goal of promoting young people's interest in technology and science and providing insights into the professional field of engineers. In the next sections the conceptual framework is presented followed by the methodological approach and structure of the research club.

2 CONCEPTUAL FRAMEWORK

2.1 Emergence of Individual Interests

An overview of current theories of interest can be found in the review article by Renninger and Hidi [3]. In their review article, they define the characteristics of interest and emphasize that these are the characteristics that a majority of scientists in this field would agree with. Accordingly, interest is a motivational variable that meets five criteria points [3]. According to Krapp [4], interest occurs when the distinguished -cognitive, affective, and value-related components are experienced.

2.2 Development of Individual Interests

A well-known model that depicts the development of individual interests is the four-phase model by Hidi and Renninger [3]. It describes the first phase of interest development as triggered situational interest. The triggered situational interest can then move into the second phase, the maintained situational interest. The third phase can develop from the second phase and is characterized as emerging individual interest. The fourth phase is a well-developed individual interest. Each of these four phases is connected with certain affects, more or less pronounced knowledge of the subject and the value estimation of its content, i.e. the cognitive, affective and value-related components of interest. These components describe a form of cumulative interest development, provided that this process is externally supported and maintained. Without external support, any phase of interest development can break off prematurely, with interest regressing to the level of an earlier phase or disappearing altogether.

2.3 Self-Efficacy

Closely linked to the experience of competence, which is set as a basic need for interest development, is the self-efficacy expectation [6]. Self-efficacy expectations are defined as "beliefs in one's capabilities to organize and execute courses of action required to produce given attainments" [6]. The term self-efficacy beliefs refers to one's confidence in one's competence to initiate and complete even difficult actions. The belief that one is capable of organizing and executing certain behaviors or achieving certain goals influences one's choice of future activities, efforts, and perseverance.

2.4 Gender Roles and Career Choice

Studies show that the lack of personal contact with people in the engineering sciences and the lack of role models are among the most important reasons why so few female high school graduates choose to study engineering. In addition, many young women are afraid of confirming negative stereotypes [7].

From the point of view of developmental and learning psychology, career choice is not an isolated event, but a developmental process that is prepared by experiences during childhood. During this process, vocational interests, judgments about occupations, and expectations regarding the compatibility of an occupation with personal prerequisites and life plans are formed. Priorities are also formed, such as those expressed in Gottfredson's [8] postulated compatibility of an occupation with the criteria of "gender type", "social prestige" and "personal interest".

It is undisputed that career choice is significantly influenced by gender. Herzog et al [9] writes: "Professions have a face in which traits of social prestige and gender difference are drawn, which is why different professions are open to a girl than to a boy". According to Gottfredson [8], the public presentation of gender roles actually forms the most important occupational choice criterion. The choice of a gender-untypical profession therefore requires a great deal of self-confidence and a great willingness to compromise. Accordingly, Gottfredson emphasizes how important it is in today's society not to further reinforce the limitations in the self-perception of young people as well as in their perception of the professional world, but to keep the spectrum of acceptable professions open and to raise awareness of inappropriate processes of limitation.

3 SETTING UP THE RESEARCH CLUB STRUCTURE BASED ON THE CONCEPTUAL FRAMEOWRK

Evaluation studies [2] point out the importance of support programs in connection with situational interests, but at the same time show that such initiatives are not sufficient for the development of individual interests. For this, continuous offers are necessary from childhood until beyond the career decision. Our research clubchangING therefore offers regular meetings so that the development of individual interests can be ensured.

German as well as international studies [10] have shown that practical work and the production of a product with reference to the use in everyday life have an interest-promoting effect, whereby the latter is particularly motivating. For girls in particular, it is also important to deal with the social contexts of technology. Some studies [7] could prove a positive influence of technology lessons on the career choice.

The structure of the research club is based primarily on theories of the emergence and development of individual interests and self-efficacy expectations. The 4 phase model is considered as the basis for building the program of the research club. In Table 1, we show the most important factors in building the research club and the expected outcomes.

Table 1. Important Factors and the expected outcomes during the 4 years participation.

Factor/year	**1st year**	**2nd year**	**3rd and 4th year.**
Main goal and expected change.	**Generating initial interest**: According to [3], interest occurs when the different components - cognitive, emotional and value - are experienced.	**Increase interest and self-efficacy**. Interest development so-called Basic Needs that contribute to the stabilization of situational interests (cf. [3]): experience of competence, self-determination (or autonomy) and social inclusion.	**Development of own intrinsic interest** through individual projects PjBL. Impact of PjBL on **self-efficacy**. Competency expectations and the 4 sources of self-efficacy. [7]
Main Meeting type	Institute visits, basic skills, experiments, expert meetings	Same as 1st year. As well as working on self-directed projects in a MakerSpace.	Institute Projects: Students work on an authentic, real-world problem. Allows for different focus and processing methods.
Main parameters studied (measured impact)	Acceptance. Initial interest. Subgroup differences.	Change of attitude towards engineering. Increase in interest and self-efficacy.	Behavior change. Intrinsic interest and self-efficacy, study and career choice intention.

By participating in the research club, students in the 10th grade and above can experience the different facets of engineering. They can start in 10th or 11th grade and meet regularly once every two weeks. Mentoring and possible projects and workshops are offered through 13th grade. The groups are either all-girls groups or mixed groups.

In the research club, participants have the opportunity to interact socially with other technically interested young people while exploring the University and other facilities of the Cluster of Excellence SE^{2}A and experiencing research projects. Through the different meetings throughout the 4 years the participants gain background knowledge on the topics being researched in the participating institutes, including visiting the laboratories and assisting with experimentation. They thereby get an idea of what engineers do, get a chance to ask their own research questions and gain access to tools that facilitate their project work; they may visit areas of special interest and receive assistance from experts. Adding to that, the students are accompanied by experienced mentors and get to meet potential role models. The mentors are mechanical engineering students, preferably female, and accompany the groups during the 4-year program. Beforehand, the mentors are trained by an educational psychologist (training in mentoring tasks and gender-specific language use). This is a very important success factor, especially in the recruitment of female students [7].

3.1 Recruiting participants for changING – Lessons learned

One of the main goals of the research club is to attract talented and interested high school students. However, the marginalized minority, girls and students from low socioeconomic backgrounds should also be reached and supported.

As a strategy for attracting students, measures taken include the following: Physics teachers at schools are contacted to organize a visit so that mentors can introduce the research club directly to the youth in the classroom. Youth centers are also contacted and students form different socioeconomic backgrounds get the chance to join the club. Conventional means such as newspaper articles and social media are also used. The variety of channels ensures that a very large number of young people in the region learn about this research club and get the chance to join. The students are also offered to have their participation in the research club noted in their school reports in the form of an after school activity.

4 SUMMARY

The main objective of the changING research club is to support high school students to think seriously about engineering as a career and to increase the likelihood that talented youth will consider the possibility of pursuing a career in engineering.

Furthermore, it is important to support girls to think seriously about engineering as their career field, making it easier for them to consider engineering as a career option, since the social aspects of technology and engineering are explained and shown.

The participants are being interviewed at different points through their participation at the club and the participants' interests, self-efficacy expectations and career aspirations are surveyed, differences between subgroups are identified and presumed correlations between the variables are substantiated. In order to be able to derive factors that help to formulate measures for action, it will be investigated whether and to what extent participation in the research club influences the students' relationship to engineering and technology. Using the accompanying study to document the progression of the students' career decision-making over time as well as during their school years, it becomes possible to identify and map the influences that shaped their sense of purpose in the profession.

ABSTRACT

The transition of students from high school to university is a changing and complicated stage. It is during the initial phase when most drop-outs from engineering degrees occur. There are several reasons for this, however, the most highlighted ones are: i) the mismatch between the students knowledge level after finishing high school and the initial level required by the university degrees; and ii) the lack of a habit and constancy of study on the part of the students.

The proposed project aims to design specific tools to improve academic performance in the initial phase of the Degree in Industrial Technologies imparted at ESEIAAT by addressing the two problems mentioned before. In light of this, the measures adopted to solve these points will be tackled separately and properly explained in the following two blocks: block I) Initial level acces, block II) Monitoring of self-learning. Finally, an assessment of the strategies followed will be carried out in a final phase, block III) Integration project.

doi:10.5821/conference-9788412322262.1110

1 INTRODUCTION

1.1 State of the art

The academic performance of students can be considered a key factor when analysing the quality of higher education [1]. The academic failure is on average 30% in the engineering degrees at ESEIAAT during the first years, with an accumulation of dropouts between the 1st and 2nd years. Once this phase is overcome, there is a certain stability in academic behaviour and also a notable improvement in academic performance. In addition, the dropout rate is significantly reduced to a value below 10%.

In [2], [3] and [4], there are several studies that try to determine the factors that affect the academic performance of students during these first years, in order to determine possible actions to prevent dropout, increase motivation and so, improving overall academic performance.

Of the many factors that trigger poor performance in engineering, the following points can be highlighted:

- Lack of understanding of basic concepts and even lack of preparation for the subjects taken in the initial phase, depending on the education received in secondary school.
- Difference between the learning methodology used in high school and the techniques used by university professors.
- Lack of study habits and therefore difficulties in planning autonomous learning.
- Memoristic learing habits that lead to difficulties in reasoning and extrapolating concepts when solving different problems.

Taking these factors as the basis for the deficiencies of the students, a series of tools have been desinged in order to improve these statements and therefore the academic performance of the students of ESEIAAT.

1.2 Objectives

The main aim of this project is to improve the academic performance in the initial phase of the degree in Engineering in Industrial Techonologies at ESEIAAT. To do so, the specific objectives are listed below:

- To ensure that students are able to detect their own lack of the necessary knowledge to start the engineering degree with a solid foundation. In addition, if necessary, to motivate them to carry out a series of actions in order to obtain the level required **before the start of the course**.
- Provide them with a weekly plan with all the tasks, both evaluative and autonomous learning, of the five subjects **during the first term of the initial phase**. In addition to accompanying them with a follow-up during this period.
- Assessment of the measures taken to prevent the student academic failure **during the second term of the initial phase** of the degree.
- To improve the horizontal coordination of subjects of the initial phase thereby providing a smoother change.

2 METHODOLOGY

The project has been definied by means of three main blocks which are divided into different tools integrated into the initial phase of the degree:

I. The development and implementation of tools designed to be used by future students just before access to the university degree.
II. A weekly tool for organisation, coordination and management of time as well as autonomous work during the first term of the initial phase of the degree.
III. An evaluative project within the subject called Industrial Technologies that encompasses the lectures taught during the first term of the initial phase of the degree. This project is carried out during the second term of the initial phase of the degree, thus assessing the competences aacquired.

The tools used in each block will be explained in more detail below.

2.1 Block I: Initial level access

The first block consists of a phase prior to the beginning of the course to ensure that students start the degree with a solid foundation from high school and with an adequate level to successfully overcome the initial phase.

In this block, two type of tools will be defined; one tool to assess the initial level of the students before starting the degree and another tool, for those students who require it, to acquire the necessary basic knowledge.

2.1.1 Initial level quizzes

Quizzes for each subject have been developed based on a selection of multiple-choice and true or false questions provided by each coordinator. These quizzes enable to check the level of the students before starting the course, both personally and on the part the teaching staff.

Each question have only one correct answer. In the case of a wrong answer, a feedback appears at the end of the test showing the correct answers as well as how the problem should be solved in some of the questions.

Once the student has completed the quiz, a global feedback appears (see Figure 1), so that the future student is aware of his/her level and be able to prepare for the beginning of the academic course.

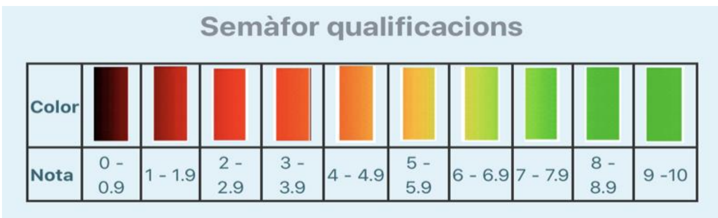

Fig. 1. Global feedback: traffic light of ratings

2.1.2 Entry level retraining support material

A web page has been designed for each of the subjects imparted during the first term of the initial phase of the degree in Industrial Technologies Engineering; Physics I, Chemistry I, Algebra, Calculus I and Graphic Expression. In which, with an agile, didactic and homogeneous format, support material of the lectures is presented to help students aquire the level required to successfully pass the initial phase. There is support material related to the content to consult during the academic period.

Below are listed the links to each of the support websites for the different subjects:

- **Algebra:** https://sites.google.com/upc.edu/greti-algebra
- **Calculus I:** https://sites.google.com/upc.edu/greti-calcul
- **Physics I**: https://sites.google.com/upc.edu/greti-fisica
- **Chemistry I:** https://sites.google.com/upc.edu/greti-quimica
- **Graphic expression I:** https://sites.google.com/upc.edu/greti-expressio-grafica

The support websites have been designed with a common structure to facilitate and speed up browsing. The structure consists of:

- Introduction and information about the current subject (see Figure 2). The contact details of the coordinators as well as the other professors.

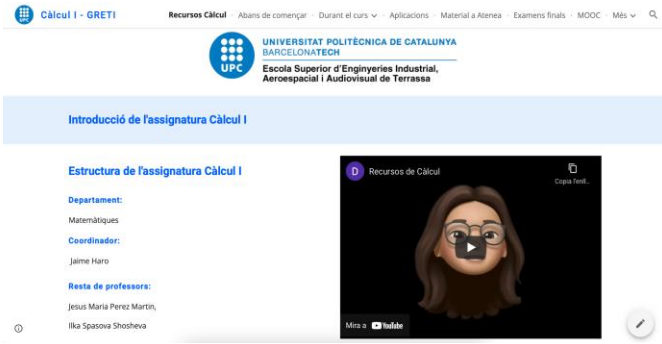

Fig. 2. Virtual assistant of the support website in Calculus I

- Support material to consolidate high school concepts prior to the beginning of the academic period separated in different sections. Within each thematic section, there are: short videos (5 – 10 minutes), teaching notes and many examples related to the lecture as well as practical applications.

- Thematic support modules for a better understanding of the content of the lectures imparted during the academic period (see Figure 3). Within each thematic module, there are: short videos (5 – 10 minutes) and some activities.

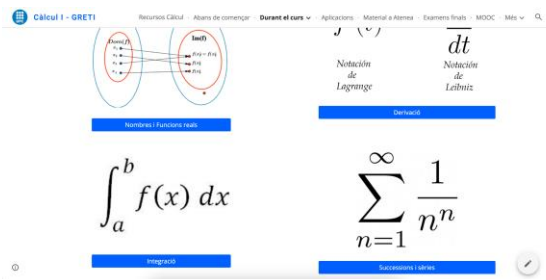

Fig. 3. Thematic modules of the content imparted during the academic period of the Calculus I support website

2.2 Block II: Monitoring of self-learning

The application of the second block takes place during the school period of the first quarter of the initial phase of the degree. This block seeks to consolidate the perseverance on the part of the students when it comes to autonomous learning.

Three types of tools will also be defined; a planning tool so that the student has the calendar of weekly tasks, exams, deliveries and number of hours of autonomous work or study scheduled for each of the subjects the first year of university career, another that will allow counting the number of weekly hours of dedication and finally a dossier that includes the proposed activities of autonomous learning by the teaching staff.

2.2.1 Weekly task planning template

A template has been developed and coordinated transversally (Figure 4), with the weekly tasks throughout the semester, of the 5 subjects that are part of the first engineering year. This template is made available to students on the first day of class to help them in the autonomous work of monitoring each subject.

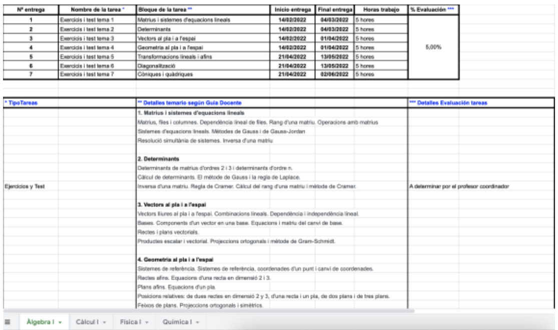

Fig. 4. Weekly task organization template

With this tool, the student can know in advance the dedication that each subject requires weekly in order to be able to keep a good study agenda that allows them to organize themselves and pass the subjects.Additionally, depending on the circumstances and availability of hours of the student, it can allow him to decide what magnitude of subjects he can tackle and correctly select his dedication.

2.2.2 Weekly autonomous learning hours log form

A link is sent to the student, at the end of each week and by means of a message through the forum that he receives with an SMS on his mobile, reminding him to fill out a form with the information corresponding to the hours of dedication (see Figure 5).

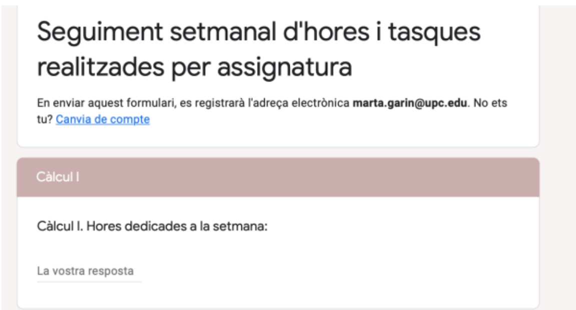

Fig. 5. Dedication hours registration form

Once the academic period of the first semester has finished, a graph has been made of the correlation between the average number of hours dedicated each week by the students based on the final grades obtained by them. It must be taken into account that factors other than the dedication in hours itself come into play, in such a way that it is not necessary to reach a firm conclusion. After a few generations, increasing the number of samples of the population, it will be possible to adjust to a more real scenario.

Below (see Figure 6) is the correlation between the average number of hours dedicated each week by a specific student and the final grade obtained by said student. From the linear regression equation, the future student could estimate the final grade for the subject based on the hours spent per week.

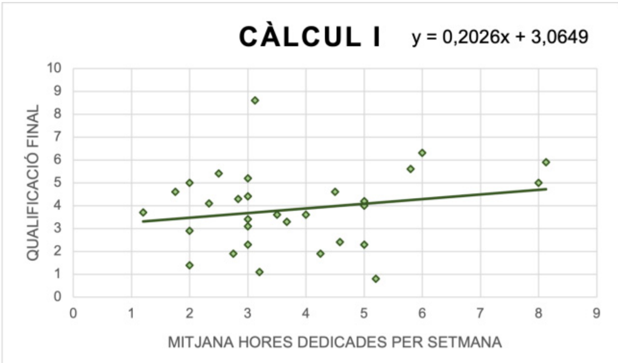

Fig. 6. Correlation between the time record and the final grades obtained

2.2.3 Autonomous learning dossier (Figure 7)

This tool consists of a compilation of the self-learning activities proposed by the professors during the academic period. In this way, students have in an ordered way a serie of activities which summarise the content of the lecutres. In addition, a transversal agreement has been reached with the coordinators of the subjects so that the delivery of these activities is worth 5% of the final mark.

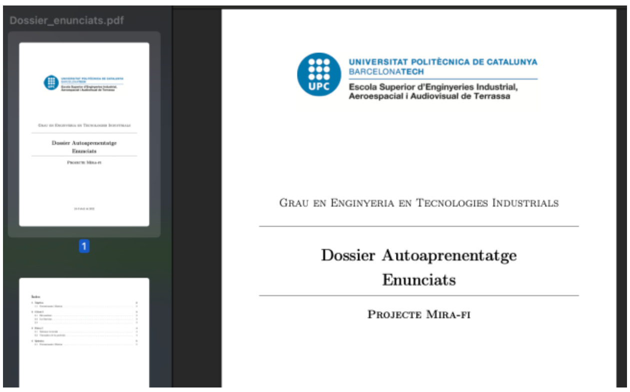

Fig. 7. Dossier of autonomous learning tasks

2.3 Block III: Integration project

This final block is the third phase of the project. It takes place during the second term of the initial phase in order to continue with the monitoring of the academic performance of the students. It consists of the **Integration Project**, carried out within the subject of Industrial Technologies.

The main objective is to evaluate the understanding of all subjects previously coursed through the creatin of a transversal project. The subjects that can not be assessed within the project itself have been integrated by means of a *Scape Room (Figure 8)*.

To carry out this project, students are divided into groups to encourage teamwork and motivate students with practical applications of engineering.

Fig. 8. Integration project website

3 RESULTS

The different tools designed for the implementation of the project are summarized below:

- **Database with personalized questions for each subject** of the first semester of the initial phase. From it, the questionnaires are generated that allow determining the level of access of the student.
- **Web page with support material** so that new students can acquire the necessary level to successfully follow the first semester of the initial phase.
- **Template for planning and managing autonomous work** that allows the student to have at the beginning of the course an organized and coordinated vision of the different tasks on a weekly basis for the block of subjects to be studied.
- **Registration form of the hours dedicated by the student to each subject weekly and real measurement of the work** required by the teaching staff to the students of the subjects of the first semester of the initial phase. Once the semester is over, it has been possible to graph a correlation between the average number of hours dedicated each week by the students based on the final grades obtained.
- **Autonomous learning dossier** that compiles a series of activities proposed by the teaching staff with the aim of consolidating a record in the self-learning of students.

- **Integration project made up of a series of enigmas** related to each of the subjects of the first semester of the initial phase for the evaluation of the skills taught in said subjects.
- **Homogenization of the teaching/learning methodologies** used in the different initial phase subjects.

4 CONCLUSIONS

The tools designed address the main problems detected in students who access an engineering course for the first time and their implementation gradually allows:

- Generate a study habit and encourage student involvement in their autonomous learning process.
- Improve student self-management and self-planning of their weekly study time.
- Improve overall academic performance.
- Increase student satisfaction/motivation.

5 SUMMARY AND ACKNOWLEDGMENTS

This project would not have been possible without the altruistic and rigorous collaboration of all the coordinators of the ESEIAAT's first-year Industrial Technology Engineering courses (Rafel Amer, Jose Antonio Diego, Jorge Macanás, Jaume Haro and Francisco Hernández) and of the fellows who have collaborated on it (Patricia Vela and Marta Sunyer), as well as the continuous support received from the Center through the sub-directorate of innovation (Marcel Macarulla).

ABSTRACT

The present work depicts the development of an experimental equipment that reveals compressible fluid dynamics, while collecting data from an incompressible flow like water in an open-channel. It consists of an extensive theoretical framework followed by a practical analysis, the aim of which was to trigger the hydraulic jump, both normal and oblique, in order to illustrate its hydro-gasdynamic analogy with a shock wave, occurring in supersonic compressible flows.

The assembly, called "water table", arises from the necessity of economical alternatives to expensive supersonic wind tunnels in the experimental study of compressible flows. Thus, a canal based on a Laval nozzle was constructed where water flow could experiment a hydraulic jump. Through its visual and experimental perception, fellow interested could more easily understand the physics and engineering behind this phenomenon.

Multiple design alternatives were evaluated considering environmental, economic, functional and aesthetic factors. A low-cost implementation was critical in the design process. The measurements revealed that the geometry of the nozzle and the wedges designed as obstacles to cause obliquity were the most influential elements in the formation of a hydraulic jump in the set-up. Regarding the experimental variables, the upstream and downstream

heights had the highest relevance. Therefore, their manipulation and analysis could lead to further educational investigations.

This research is a step forward to support students in the understanding of compressible flow principles by providing an in-house experimental set-up. The equipment is an opportunity of carrying out lab measurements, which certainly guides to a major commitment in the field.

1 INTRODUCTION

1.1 Scope

The experimental study of compressible flow dynamics has been of growing interest since the 1940s, for both experts and students of fluid mechanics due to its learning difficulty, since this type of flow is not very common and easy to visually detect. Unfortunately, its experimental simulation presents the disadvantage of requiring expensive equipment such as a supersonic wind tunnel that not all universities can afford[1-5]. Therefore, the main goal of this paper is to describe the design, manufacture and experimentation of an equipment that illustrates the hydro-gasdynamic analogy between the shock wave, compressible flow characteristic, and the hydraulic jump. From the set-up students can collect data while experimenting with water easily and economically.

The purpose of this work is not only to show the evidence of theoretical formulas throughout an experimental modelling, but also to develop it by means of an inexpensive and easy-to-manufacture experimental assembly. Hence, it demonstates support for students' knowledge of compressible flow principles and, as a result, the physics and engineering education major engagement.

1.2 Theoretical context

The objective of the theoretical context is to elucidate the analogy between the dimensionless Mach (Ma) and Froude (Fr) numbers because they are both based in describing the fluid velocity, compressible and incompressible flow, respectively.

An extensive explanation of the theoretical development could be detailed and followed by fellow interested, but it is not the purpose of this short concept paper and it can be found in many fluid mechanics books[7]. In preference, the most relevant formulas are going to be presented.

On the basis of Bernoulli's equation applied between the stagnation state and a generic point of a reservoir open to the atmosphere of fluid depth connected to a hydraulic canal, the dimensionless Froude number (Fr) can be defined as:

$$Fr = \frac{v}{\sqrt{gH}} \tag{1}$$

Where v is the velocity, g gravity and H the height of the generic point. If an analogous analysis is carried out on a streamtube of compressible flow like air, where the steady-state conservation of energy equation is applied, and it is compared to the previous one according to an incompressible flow, a certain similarity between the ratios of velocities arises. At this point, the first analogy between Mach (Ma) and Froude numbers is revelead, if the hydraulic current is seen as a hypothetical gas flow of $\gamma = 2$. Consequently, both dimensionless numbers can be equally estimated[8].

$$Ma \cong Fr = \sqrt{2\left(\frac{H_0}{H} - 1\right)} \tag{2}$$

Additionally, Mach number is defined by using the sound speed (a) and the fluid velocity (u):

$$Ma = \frac{u}{a} \tag{3}$$

From the equations of perfect gas, isentropic flow and the continuity equation results the hydro-gasdynamic analogy for the ratio of the throat area and the local area in a diffuser of compressible flow. From the following formula, A denotes the surface and the superscript "$*$" represents sonic conditions[7].

$$\frac{A}{A^*} = \frac{1}{Ma}\left[\frac{2}{3}\left(1 + \frac{1}{2}Ma^2\right)\right]^{3/2} \tag{4}$$

Furthermore, the analogy between bidimensional supersonic compressible flow and supercritical incompressible flow can be studied. A shock wave can form an oblique angle when the oncoming flow collides with an obstacle, like a wede of angle 2θ. Under particular conditions for an incompressible flow, the analogous oblique hydraulic jump arises[2,3,6-8]. Thus, the following equation outlines the mathematical relation between their variables. It may be considered that β is the angle between the shock wave and the incident supersonic current, subindex 1 refers to supersonic flow and δ is the angle between the hydraulic jump and the oncoming flow.

$$\theta = \delta - tan^{-1}\left[\frac{2tan\delta}{-1 + \left(1 + 8{Fr_1}^2 sin^2\delta\right)^{\frac{1}{2}}}\right] \tag{5}$$

2 METHODOLOGY

To begin with the experimental set-up building process and analysis, a deep study and evaluation of design alternatives, materials and dimensions was carried out. The first 3D design incorporated two reservoirs (upstream and downstream) and the noteworthy water canal that followed a Laval's nozzle criteria.

The next step was the definition of different materials and configurations of the initial 3D designed model. The alternative called "A" consisted of two prefabricated plastic reservoirs and the water canal printed in 3D, made of polylactic acid (PLA). Whereas "B" was made up of methacrylate and "C" of stainless steel. All of them were evaluated following the weighted sum technique, marking each alternative according to the Saaty scale and a variety of criteria (see Table 1).

Criterion	**Weight (%)**	**Alternatives**		
		A	**B**	**C**
Environmental impact	20	8	5	6
Cost	35	9	4	4
Functionality	30	5	8	8
Aesthetic finish	15	7	9	8
Weighted score		**7.30**	6.15	6.20

Table 1. Weighted sum evaluation

As it is denoted in the resulting weighted scores, alternative “A” was the one developed for the experiment. In addition to the three main components aforementioned, three wedges were also printed in 3D and tacked on to cause obliquity.

According to Figure 1 Left), the hydraulic flow of the final experimental set-up starts in a water pump, from which it reaches the upstream reservoir through valves and pipes. Across the nozzle throat, the flow accelerates achieving first the critical state and finally the supercritical one. Then, the hydraulic jump makes the water return to its slow subcritical regime. From the mentioned figure also should be noticed the main variables of the work, which should be emphasized by students when recreating the experiment. There are two independent variables: e, the width of the throat, and b, the width of the nozzle’s diffusing part. The width of the throat was adjusted from 0.07 m to 0.03 m in steps of 0.01 m by means of two adjustable plates. Each of these widths generated a specific Froude number, which could be analytically obtained through the measured heights (dependent variables) H_0 and H, shown previously in equation (2). Finally, b was used to fix the point of the nozzle’s diffusing ending part, right after the hydraulic jump occurred.

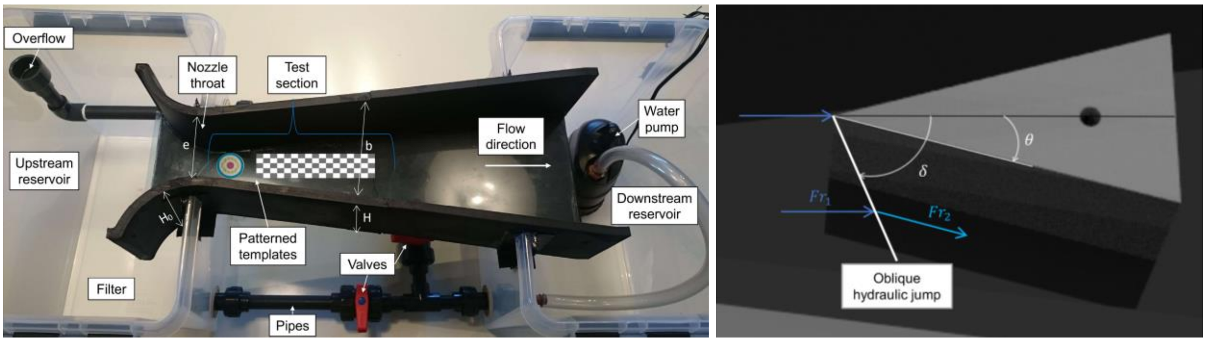

Figure 1. Left) Experimental set-up design and variables; Right) Wedges design and variables

Moreover, the wedges of angles 7.5°, 15° and 20° were of height 0.04m and length 0.08m. The independent variables of the second stage of the experiment are also the widths e and b, by adding the angle of the wedges θ. Hence, the angle of the oblique hydraulic jump δ caused in each case is the dependent variable (see Figure 1 Right)).

3 RESULTS

3.1 Normal hydraulic jump

For each of the fixed five widths of the nozzle’s throat, two Froude numbers were calculated from equations (1) and (2), respectively. In addition, theoretical and experimental values of A/A* were obtained through equation (4) (see Table 2).

e (m)	Ma=Fr (eq 2)	Fr (eq 1)	Relative error (%)	A/A* (eq 4)	A/A* (b/e)	Relative error (%)
0.07	1.593	1.482	6.96	1.168	1.214	3.84
0.06	1.558	1.242	20.27	1.151	1.417	18.78
0.05	1.420	1.035	27.12	1.091	1.700	35.82
0.04	1.183	0.763	35.47	1.020	2.125	52.02
0.03	1.085	0.528	51.38	1.005	2.833	64.56

Table 2. Mach and Froude numbers results

If the results are observed, it can be seen that Froude numbers from equation (1) are greater than one only for nozzle throat widths above 0.04 m, which indicates the experimental formation of a hydraulic jump for this range of width values. This result is consistent with the fact that the error between the results from both equations increases when the width decreases, from a 7% ($e = 0.07$ m) to a 51% ($e = 0.03$ m).

3.2 Oblique hydraulic jump

According to the fact that the best results were obtained from the throat widths of 0.07m, 0.06m and 0.05m, the second stage of the experiment was conducted to measure nine cases, and in five of them was possible to see experimentally an angle δ of the oblique hydraulic jump. Heights H_0 and H were also measured in order to obtain Froude numbers (through equation (2)) and consecutively theoretical δ values from equation (5), calculated by using MAPLE™ program[9]. Analogous to the behaviour of compressible flow, it occurs a detached shock wave (DS). This means that under these conditions, angle θ and Froude number, a δ value between 0 and 90° does not exist.

e (m)	θ (º)	Fr (eq 2)	δ (measured) (º)	δ (eq 5) (º)	Relative error (%)
0.07	7.5	1.573	63	51.07	23.36
0.06	7.5	1.536	50	52.93	5.54
	15	1.434	72	DS	-
0.05	7.5	1.408	58	63.81	9.11
	15	1.336	54	DS	-

Table 3. Angles δ results

3.3 Photo tracking

Photo tracking was utilised as means to physically capture the hydraulic jump. Figure 2 Left) shows an example of it when the width of the throat is 0.05 m and Figure 2 Right) depicts an oblique hydraulic jump, which corresponds to a throat width of 0.07 m and a wedge of 7.5°.

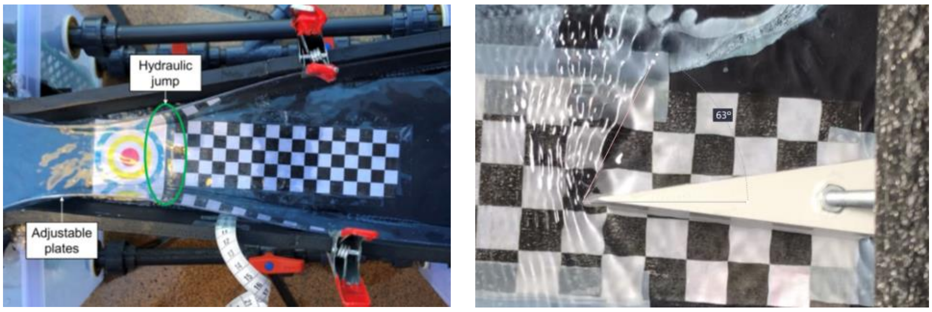

Figure 2. Left) Photographic capture of a hydraulic jump; Right) Photographic capture of obliquity

4 DISCUSSION AND CONCLUSION

From the theoretical study and experimental data obtained, it is concluded that under the suitable boundary and geometrical conditions, a compressible flow in a water table can be modelled by students on hydro-gasdynamic analogy.

The fact that an undular jump was visually detected and that the results were in agreement with the theoretical framework is outstanding. It adds even more value to this work the low cost of the constructed experimental set-up presented in this paper, being of 329 € (around 369 $), which is orders of magnitude less than a supersonic wind tunnel[6]. Thus, the set-up is easily reusable and inexpensive for fluid physics education.

Regarding the experiment itself, when the angle of the nozzle is higher, making its width smaller, the probability of what it could be called "stall" becomes higher, and this phenomenon can produce alterations in the flow path[10]. From the nozzle geometry designed in this experimental study, the theory confirms the presence of a “two-dimensional stall” for widths values lower than 0.05 m, which would justify the high error values. Hence, a plausible explanation is that hydraulic jump occurs for wide widths, whereas stall can appear as a restriction for narrow widths. Then, it is of interest for a future investigation to design a nozzle of higher experimental widths, to try to reduce this phenomenon and better visualise the hydraulic jump[11].

Finally, this study has found the cause-and-effect relationship between the results obtained and their meaning, which brings a sense of fulfilment. One of the major lessons learned is that despite the difficulties encountered and low budget invested, the presented work proves valuable. From the point of view of a fluid mechanics student, who has carried out the experiment, I believe that it is more illustrative and formative to physically see results with theoretical background rather than memorising random formulas. Therefore, it could be included in physics and engineering bachelors as a laboratory practice so that more students could gain the same enriching learning and engagement, and carry on with the proposals for future research in the field[12].

ABSTRACT

The European Universities Initiative (EUI) promotes European values and identity and aims to revolutionise the quality and competitiveness of European Higher Education. As part of this effort, the University Network for Innovation, Technology and Engineering (Unite!) is working on developing a Joint Program (JP) offer with embedded mobility and flexibility. To achieve this goal, we present in this paper the major challenges in implementing Flexible Study Pathways (FSP) at a transnational level identified in a survey conducted at the seven partner Universities of Unite!.

The most desirable forms of flexibility regarding content of course/program were Elective Courses outside the domain and inside the degree of specialisation. Main difficulties identified by partners are related to academic calendars, time cost to organise FSP, legal matters, program agendas and ensuring the achievement of learning outcomes.

The results of this analysis show possible directions for the development of a European degree, which will require effective communication and stakeholder coordination and engagement.

1. INTRODUCTION

European Universities are key players in the establishment of a more resilient, progressive and thriving European Higher Education and Research, particularly by facilitating the implementation of Joint Programmes, pooling capacity and resources, and ultimately, to work together towards a joint European Degree.

The University Network for Innovation, Technology and Engineering (Unite!) [1] was one of the first 17 transnational alliances funded in the context of the European Universities Initiative [2] by the EU in 2019. Within this context, Unite! is working on developing Joint Programmes with embedded mobility and flexibility, allowing for students to develop individualised professional profiles, co-creating their learning. As part of this effort, and together with other European University Alliances, Unite! has published a Joint Position paper on the European Degree [3], collectively signalling the possible implementation bottlenecks, as well as pointing out some measures to ensure its success. These ideas are aligned with the step-by-step approach towards the Joint European Degree, as suggested by the European Commission [4]: exploring the scope, benefit and feasibility of a joint European degree as well as mapping obstacles and key enablers to foster joint study programmes and establishing European criteria for creating a joint European Degree.

Accordingly, this work aims to identify most desirable types of flexibility and major difficulties in achieving higher degrees of flexibility at a transnational level, discussing them as possible obstacles in implementing Joint Programmes.

2. METHODOLOGY

Information was collected through a survey [5] designed to cover four major topics: (i) the FSP forms, already present in Unite! Universities, as perceived by respondents; (ii) the most desirable forms of flexibility; (iii) the perceived difficulties to achieve higher levels of flexibility; (iv) the factors that can facilitate the implementation of greater flexibility. Accordingly, and considering this publication's objective, this work focuses mainly in sections (ii) and (iii). The survey included closed and open questions, which allowed for both quantitative and qualitative data analysis, thus increasing the questionnaire's robustness and completeness.

The targeted sample of respondents for the survey included informed directors, coordinators, student representatives, administrators and the like (target A); professors, students and administrators randomly selected (target B). About 20 to 30 surveys were sent per target (A and B) and per partner. The aim was to collect at least 15 answers from each partner university. Data were collected from October 2020 to January 2021. The collected answers were sorted by (i) Type of Participant and by (ii) University. Regarding the distribution by type of participant, respondents were classified into four major categories departing from a previous set of options (see parenthesis): Study Programme's Responsibles (Mobility Office Staff; Study Programme Scientific/Academic Coordinator/Manager), Students (Student at decision level/Student representative/Student delegate), Professors (Joint programme Faculty/Teacher/Lecturer) and Others (Quality Assurance of Study Programmes Faculty or Staff; Other).

3. RESULTS

A total of 112 answers from all partners were received. Figure 1 shows the distribution of respondents according to (a) Type of Participant and (b) University:

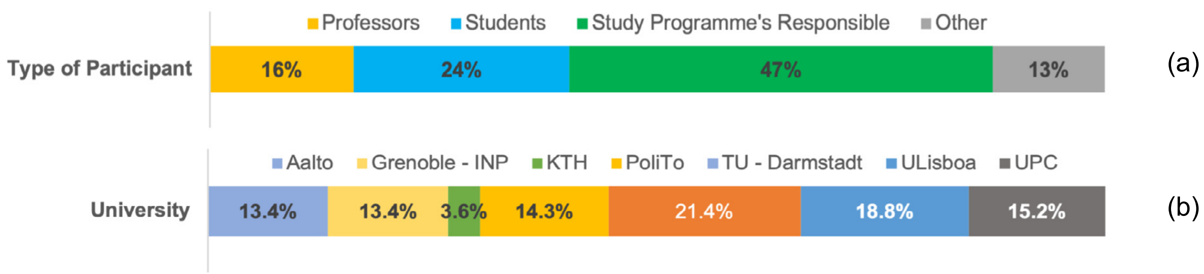

Fig. 1. Distribution of respondents (%) by (a) Type of Participant (b) University

The survey required respondents to choose the most desirable forms of flexibility from a closed list, with a possibility of indicating other options not included in the short list. The distribution of answers given on the most desirable forms of flexibility regarding content of course/program (%) is shown below in Fig. 2 by (a) Type of Participant (b) University:

	Type of Participants				Universities						
	Professors	Students	Study Programme's Responsible	Other	Aalto University	Grenoble - INP	KTH	Politecnico di Torino	TU - Darmstadt	ULisboa	UPC
a) Elective courses outside the domain	83.3%	77.8%	64.2%	85.7%	86.7%	80.0%	75.0%	68.8%	62.5%	85.7%	58.8%
b) Elective courses inside the domain	72.2%	63.0%	83.0%	85.7%	86.7%	46.7%	75.0%	87.5%	83.3%	76.2%	76.5%
c) Minors	38.9%	40.7%	43.4%	64.3%	86.7%	46.7%	50.0%	12.5%	29.2%	61.9%	35.3%
d) Alternative courses (same topic)	44.4%	51.9%	49.1%	28.6%	40.0%	40.0%	0.0%	56.3%	54.2%	66.7%	23.5%
e) Assignments and subject choices	66.7%	48.1%	37.7%	14.3%	46.7%	53.3%	50.0%	37.5%	33.3%	47.6%	35.3%
f) Supplemental courses	50.0%	44.4%	62.3%	42.9%	40.0%	80.0%	25.0%	31.3%	62.5%	71.4%	35.3%
Total of Participants	18	27	53	14	15	15	4	16	24	21	17

(a) (b)

Fig. 2. Distribution of answers given on the most desirable forms of flexibility regarding content of course/program (%) by (a) Type of Participant (b) University

The desirable forms of flexibility regarding content of course/program were flagged if reported by around 60% or more of the respondents. Elective Courses both inside and outside the domain (options *a)* and *b)*) are predominant and evenly distributed (around half the type of participants and Universities prefer outside the domain flexibility, whereas the other half favours having options inside the specialisation).

Considering these desirable forms of flexibility, the partners were asked what were the major obstacles to the implementation of FSP, and were given a series of possible reasons. The answers are synthesised below in Fig. 3:

	Type of Participants				Universities						
	Professors	Students	Study Programme's Responsible	Other	Aalto University	Grenoble - INP	KTH	Politecnico di Torino	TU - Darmstadt	ULisboa	UPC
a) University policy	38.9%	59.3%	41.5%	14.3%	46.7%	46.7%	50.0%	43.8%	29.2%	42.9%	47.1%
b) Legal matters (e.g, quality assurance in higher education)	38.9%	33.3%	60.4%	50.0%	40.0%	33.3%	50.0%	62.5%	41.7%	52.4%	64.7%
c) Programs agendas	44.4%	40.7%	49.1%	35.7%	53.3%	66.7%	100.0%	37.5%	33.3%	19.0%	58.8%

(a) (b)

Fig. 3. Distribution of answers given on the main difficulties in implementing the Flexible Study Pathways (%) by (a) Type of Participant (b) University

The obstacles were flagged if referred by around 60% of the respondents. They are mostly associated with two types of difficulties: practical issues (academic calendars, legal matters, time cost to implement higher levels of flexibility) and content of courses/programmes (program agendas and ensuring the achievement of learning outcomes). Regarding practical issues, it might be worth putting the effort into harmonising academic calendars in order to allow timely adjustments between partners. Regarding legal constraints, collected data indicate that further research needs to be done to identify the restrictions at the local and national level. For instance, in the case of ULisboa, these issues are often connected with the existence of a national accreditation agency and requirements imposed by professional orders.

The present study shows that the path towards FSP will demand effective communication and stakeholder coordination to overcome the practical and administrative issues, as well as the development of a common European Higher Education framework that ensures strong and coherent scientific and pedagogical offerings. Strong and consistent engagement from decision makers to provide flexible options that better prepare students for existing and future challenges will have to address policy-relevant issues such as coordination, articulation and transfer policies, as well as legislative and regulatory matters.

The development of innovative approaches to teaching and learning specifically targets the creation of Unite! Joint Programmes with integrated flexible study pathways and embedded mobility [5], expanding beyond the traditional dual and double-degree ideology. It is clear that it will be necessary to deepen the present analysis of data in order to properly design specific measures, eventually bycross-checking the most desirable forms of flexibility with the expected difficulties, thus establishing a potential correlation between them, in order to draw more accurate conclusions regarding both anticipated difficulties and possible solutions for identified roadblocks, paving the way towards a European Degree.

ABSTRACT

This short paper describes the first prototyping of a self-evaluation process of Curriculum Agility at a Faculty of Technology in Sweden. The process comprises guided, semi-structured, individual interviews at different organisational levels within the faculty, a joint narrative based on those interviews, prioritizing development strategies per level, and jointly mapping them on importance and implementation time. The self-evaluation is part of and based on the research on the principles of Curriculum Agility. The results show the interplay in timely curriculum change for futureproof engineering education between the teaching staff, the systems and the people who control the systems. The self-evaluation brings together the different perspectives and perceptions within the faculty and gives insight in how those affect

the willingness towards and occurrence of curriculum development. This work in progress indicates how doing such a qualitative self-evaluation paves the road for transparent strategic dialogues on a holistic level about what to give attention and organize differently.

1 INTRODUCTION

1.1 Transforming the engineering curriculum in a timely manner

For a higher education institution (HEI), having Curriculum Agility means "*to be responsive to changes in societal, industrial, and student characteristics and needs, by proactively adapting relevant organisational structures, learning outcomes, learning activities, and assessments in a timely manner*" [1][2]. The pandemic in the past two years has shown how much flexibility and responsiveness can be required of all educational organizational structures within a short amount of time. But Curriculum Agility is particularly important to engineering education, which for a few decades now is said to need to adopt to the fast changes in technology and society [3]. Certain engineering disciplines indicate that part of what they teach their students will have already become obsolete only a few years after graduation [4]. That means that the body of knowledge and skills that is taught in the curriculum needs to be adjusted accordingly and timely.

Another reason why Curriculum Agility is important is the increasingly diverse student population at the HEIs [5] as a result of globalisation, inclusivity, and accessibility. It makes personalisation of the learning ever more important for students to be able to go successfully, and at a desirable pace, through their program of choice. And those adjustment lie both on pedagogic principles of flexible education in pace, place, and time, as well as a flexibility in learning content. Furthermore, it prompts revisions of the traditional ways of teaching. For example, the perceived usefulness and willingness to co-create the education with students themselves is growing [6].

A fourth reason for Curriculum Agility is that engineering education is changing due to changing ethical perspectives [7], which change the intentions and approaches of the engineering profession. There is a growing understanding that engineers of the future work from within a social context and carry responsibility towards sustainability [8]. That inserts an added complexity to their work and asks for a shift in competencies that engineering students need to learn [9].

All these reasons together make the actually needed curriculum changes to be of an innovative or even transformative kind [10]. The engineering curriculum needs agility, to be able to grow with and towards what is happening in the outside world. But changing a curriculum has become a wicked problem, as it is nested within the contemporary organisational structures, policies, and legislation of HEIs. Many different stakeholders are involved who all have their own needs, constraints, politics and traditions.

2 METHODOLOGY

2.1 The Principles of Curriculum Agility

This research is part of an ongoing research project that started in 2018. What it takes to be able to work towards Curriculum Agility has been captured in nine principles by a diverse group of engineering educators from all over the world, in a series of so far eight, focus-group type, co-creative workshops during different conferences and seminars on engineering education [1] [2]. The widespread input of the participants has so far resulted in a more inclusive and less normative approach to what timely curriculum transformations are envisioned and desirable. The principles were sought to be in that line of thinking, and applicable in international settings under different circumstances. The set of principles as used is listed in the first column in table 1. The principles were divided in three areas. The principles on Curriculum Vision and Strategy looked at the proactive adaptability vision and which stakeholders involved in order to make that vision come true. Secondly, the principles on Curriculum Quality and Provision looked for the space for innovation within the existing structures while safeguarding the quality and conserving that which remains valuable in the transformations. Thirdly, the principles on Curriculum Design and Research deal with the changed design of the more agile curriculum and the pedagogical and didactic competency needed to make it successful.

2.2 The role of this sub-research in the whole process

The currently ongoing step in the workshop series is to provide universities with a self-evaluation method on the 9 principles of Curriculum Agility. Both the principles and the self-evaluation tool are developed through continuous prototyping. This sub-research was the first prototyping activity for the self-evaluation and served as input and inspiration for an upcoming co-creative workshop day in June 2022 on the self-evaluation. The main questions to answer in the Curriculum Agility narrative were: How are we doing at this moment? What enablers and barriers are present in our situation? And what do we want to grow towards? The richness and practicality of the resulting data of this trial was of interest for the ongoing research.

2.3 Method (describe briefly what reviewer 1 wants to see)

A choice was made for a qualitative, narrative approach to scanning the engineering Faculty of a Northern Swedish university on their Curriculum Agility. Because the concept is still relatively unknown and covers different aspects of the curriculum from organisation and management to course content, a guided process was picked, in which the interviewer informed the respondents as well as questioned them. Multiple levels within the organisation were included, i.e. Faculty, department, program, and course level. Respondents were first interviewed alone, and then invited for dialogue and strategizing together with the other respondents. This way the resulting narrative would be a multi-perspective mapping of their Curriculum Agility, and one they all agreed on.

The interviews were semi-structured, 60-120 minutes each, with 4 respondents from different levels within the university (faculty management, departmental director of education, head of program, and the latter two also functioning as senior lecturers). For each principle, respondents talked about the perceived strategic importance at their own and other levels, how much it was happening already, including examples, and which enablers and barriers were present. Short narratives were written based on the interviews. In a separate session, the respondents were asked to map desirable priorities that came out of the interviews on scales of must-have to would-be-nice-to-have, and (very) short-term to (very) long-term implementation. Next, their input was grouped and labelled in one visual overview, showing the different and similar viewpoints at the different levels. That was the basis for the final joint strategic session, in which the respondents were asked to discuss, group, prioritize and (re)position the strategic development points for increasing the curriculum agility of their faculty, and tweak on the narratives.

3 RESULTS

3.1 Summarizing the narrative

The set-up of first individual and later group discussions resulted in honest, modest, and insightful narratives which increased transparency throughout the organisational layers. It extends beyond the scope of this paper to show the depth of the acquired Curriculum Agility narratives. In table 1, brief summaries of each principle's narrative can be found.

Table 1. Narrative summaries for each of the Principles of Curriculum Agility (based on the principles as described in [1] and [2]).

Curriculum Vision & Strategy		
1	Educational Innovation: Towards Agility	Although for the faculty there is no literal vision of being agile towards changes in society and technology, at each level the respondents do feel it is an aspiration of their faculty. At this point, a more generic quality system for change and improvement is the focus. The willingness to change is different at the different levels, time is the biggest barrier.
2	Management Approach: Change Culture	Ensuring and maintaining a culture rather than a "one-person engagement" for change is deemed very difficult by all respondents. Teaming up over different departments, collaborating, and supporting initiatives are mentioned as facilitators. Barriers are the big cultural differences between departments, especially in collaboration with other faculties.
3	Stakeholder Involvement: Co-creation	Involving external stakeholders has suffered greatly during the pandemic, but interaction with industry and students is still happening at certain places. Internal stakeholders are not usually co-created with but are part of a quality system based on feedback, adaptation, and approval processes. It doesn't always result in the desired engagement.
Curriculum Quality & Provision		
4	Legislation and Policy: Reframing the Rules	Finding the space for innovation in between the rules is most feasible for the program director who is also involved in teaching. That double role creates opportunities for agile curriculum changes. Faculty managers also report some room for manoeuvring. Apart from that, the rules are indicated by all respondents to rather have a perceived change-inhibiting effect on teaching staff in general, particularly at department level.
5	Organization and Governance: Responsive Administration	The people working at the faculty can empower the systems that are used, up to a certain level. Finances are both a facilitator and a barrier, because of the faculty-budgets structure. Responsiveness often depends on the (pedagogic or contextual) understanding of what, how and why change needs to happen, and that can be a barrier.

6	Decision Making Process: Accommodating Implementation	Curriculum and course approval procedures have been directed at quality control, which sometimes collides with the aspired trust-culture. Informal leadership and delegated decision-making make more direct decisions possible, with some co-creation happening there. Timeframes are perceived long, 1.5year for bigger changes, half a year for smaller changes, and problematized mostly to the level of detail required at those deadlines.
Curriculum Design & Research		
7	Programme and Course Design: Dynamic Content and Flexible Education	Holistic learning goals bear the challenge of translating them into examination. There are wishes for more variable examination formats. Courses are mainly made flexible on content by using project education. Programs differ in level of flexibility for the students and internationalisation. In new courses or programs, difficulty is perceived in students choosing them, needed to break even and in maintaining progression through the years.
8	Pedagogy and Didactics: Scholarship of Teaching and Learning	There is a lot of facilitation of SoTL possible, with funds for visiting courses, conferences, and a meriting system in place at the university. Teaching is put on equal terms with research by the faculty. In the departments the enthusiasm for pedagogic development varies highly. Pedagogic development is facilitated for those who are willing and open. There is quite a bit of traditional teaching going on, despite efforts on incorporating inclusivity, sustainability, and active + project-based learning.
9	Learning Spaces: Flexible Solutions	Blended and hybrid social, physical, and digital learning environments are used, especially since the pandemic, and funds are available for more development. The pedagogic side of using these resources is still in its children's shoes. GDPR hinders.

The strategic mapping of Curriculum Agility priorities within the faculty resulted in increased insights in and agreement on issues within the faculty, which need attention. Outcomes varied from on short notice letting teaching staff know it is not that hard to change course or program plans (related to principle 4), and to provide (more structural) support for them (principle 1 and 7), to long-term building of a more unfluctuating positive teaching culture (part of principle 8). Also long-term was the wish for involvement of students and administration in curricular development work as co-creators instead of evaluators (coming from principle 6 and 3).

4 CONCLUSION

The chosen self-evaluation method proved to result in a multi-level understanding of the Curriculum Agility of the Faculty of Technology, as was intended. The dialogue provided by the method was highly appreciated by the respondents. In a follow-up, it would be interesting to include student level as well as higher management (at university level) in the process. Selecting respondents should of course be done in a way that gives the broadest information possible. To that avail, multiple same-level respondents could be considered as well, as much as resources permit.

Importantly, during the mapping process, the principles were all confirmed in their importance by the respondents, who had not been involved in formulating them. There was a natural flow from one principle to the other in the interviews and group discussions, but the grouping of the principles can be reconsidered. However, this first prototype of a self-evaluation of Curriculum Agility gave practical indicators per principle and forms a solid basis for a Curriculum Agility mapping method to increase the understanding of how capable engineering education is to adopt to the fast-changing future, and what is necessary and desirable to work on.

ABSTRACT

The future of engineering education does not depend only on the curricula designed by universities, but increasingly on the needs of society and the complex requirements of Industry 4.0. Now there is an urgent need to work on an educational approach based on the close collaboration of three stakeholders: the university, which facilitates authentic learning opportunities for students and professionals and ensures the quality of learning outcomes; the industry, which establishes the skill sets and competencies it requires of its workforce; and finally, governments and professional associations, which can influence, provide global collaboration frameworks to support transformation and funding for reskilling, upskilling, as well as institutional responses. This study presents an analysis and comparison of the engineering skills "eco-system" that considers not only the technical education in

[1] *Corresponding Author P. Caratozzolo*

pcaratozzolo@tec.mx

doi:10.5821/conference-9788412322262.1291

response to the Fourth Industrial Revolution, but also the problem-solving needs of society and the human factors that shape the transition to the labour market in global contexts.

1 INTRODUCTION

According to the recommendations of international educational organisations in their recent reports, the new curricular programs for engineering education should arise from a collaborative dialogue between academia and industry, based on a multicultural, sustainable, and socially oriented perspective. Examples are the reports of the World Economic Forum (WEF) [1] for general skills, and the Sky 4.0 Project [2] for specific skills. The review of the international literature shows how higher education institutions are beginning to incorporate the lessons learned during the COVID-19 crisis and to implement the most successful strategies, to end the state of educational contingency and move towards achieving the objectives education planned for 2030 [3]. From this review it became evident a gap has formed between Higher Education Institutions (HEI) from different regions of the world, related to the economies of the institutions, the level of digital transformation, and their technological infrastructures [4]. In this communication, we present the preliminary findings of the ongoing project in which Glasgow Caledonian University and Tecnologico de Monterrey collaborate on their institutional practices, programs, and initiatives in engineering, for the promotion and development of the new skill sets required by Industry 4.0. A desktop-based analysis and comparison of the policies and practices in the two countries/universities that have shaped current approaches to such skills development -the eco-system- and the impact that these are having on teaching, learning, and assessment approaches are presented.

2 ENGINEERING SKILLS “ECO-SYSTEMS”

2.1 The case of Scotland

Glasgow Caledonian University (GCU) is a modern university with a long history of providing education for professionals from Scotland, the rest of the UK and internationally. Its new strategy (Strategy 2030) clearly responds to these future demands through a key priority area around employability and skills, and also through its graduate attributes that influence all programme design and delivery with the updated attributes introducing ‘Systems Thinking’ as a new attribute, and centring learner agency. This new strategy is underpinned by the UN SDGs and is a continuation of previous educational practices to create globally competent graduates. The skills agenda eco-system for Scotland is reflected in Figure 1, where a combination of UK, Scotland-specific and industry influences the future skills requirements. To give examples of educational approaches that develop transversal skills and positive outcomes in engineering, the students are offered international mobility experiences, including Collaborative Online International Learning (COIL). Whilst international mobility dropped during the pandemic, it has recovered strongly for this academic year 2021-2022, with a similar pattern being seen for year-in-industry placements. Additionally, in another module shared across many programmes, students in teams self-define a future-driven community-focused problem aligned to UN SDGs and design an appropriate solution to this. Such student-centred learning is a growing feature of programmes. Also, GCU is the largest provider of Graduate Apprenticeships (GAs) in Scotland – these are degree-level apprentices in which students gain the required professional competences through university studies and workplace experience to a standard co-designed with industry [5]. Positively, GAs provides opportunities for those who want to up-skill themselves as much as for those starting their careers and produce industry-ready graduates. Importantly, 90% of graduates from all Engineering programmes are in employment or further study after 15 months, with 80% of those in employment in high-skilled graduate jobs.

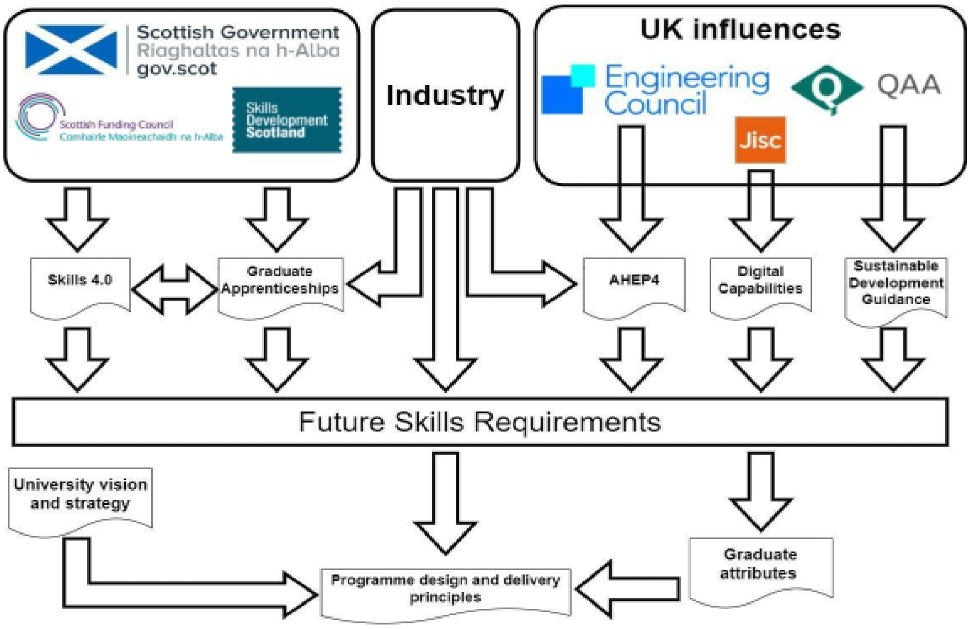

Figure 1: Skills eco-system influence engineering programmes in Scotland [Skills 4.0 defines the set of meta-skills for Industry 4.0; AHEP4: Accreditation of Higher Education Programmes 4th edition]

The strategic drive to enhance employability and meta-skills across the faculty is reflected in a Royal Academy of Engineering funded Visiting Professorship focused on preparing students for work in innovation-driven workplaces of the future. Considering technical skills, existing programmes emphasised digital and computer-based design and modelling, as well as systems approaches. Future curriculum transformation is underway with new modules with a focus on digital twins, predictive maintenance, and robotics, as well as new postgraduate programmes recognising the role of data science in engineering. Additionally, defining and implementing an Industry 4.0 Skills Taxonomy would better structure future enhancements in skills development.

2.2 The Case of Mexico

Tecnologico de Monterrey (TEC) is within the first 26 positions in the 2022 QS World Employability Ranking and the Top #1 university in Latin America [6], hence the interest to study the strategies that TEC has designed to be successful in terms of employability. The fundamental mission of the TEC is to train professionals and postgraduates with levels of excellence in the different areas of knowledge through specific educational programs and policies, to promote in students the development of an entrepreneurial and innovative spirit, responsible leadership, honesty, respect for the dignity of the human person, the preservation of the ecology and the appreciation of the historical-cultural values of the community and the country. TEC governs its programs by the Accreditation Board for Engineering and Technology (ABET). Currently, the process of globalisation of the world economy has had an impact on engineering education in four events: rapid technological change; the emergence of a new techno-industrial paradigm (Industry 4.0); the emergence of information technologies; and the worldwide institutionalisation of academic and professional accreditation systems. Faced with these demands, TEC decided in 2015 to progressively begin the implementation of a new educational model with four fundamental pillars: 1) Inspiring teachers, with great preparation; 2) Flexibility with hybrid or fully distance courses to enable learning anywhere; 3) Memorable Experience, with comprehensive physical, cultural, mental and sports development programs; and 4) Challenge Based Learning (CBL) where all courses are designed through a challenge resolution scheme, not problems or projects. These challenges are driven by real-world situations and for this approach to succeed, then the educational model in the design of the challenges involves not only the faculty but also training partners (Companies, industries, civil associations, non-governmental, municipal, or federal authorities, etc). The new paradigm must then be characterised by active learning, centred on the student that solves real challenges [7]. Active learning with the educational model with the CBL didactic technique is the fundamental basis of Socially Oriented Education, that is, developing skills based on the current need, whether labour or social problems [8].

3 METHODOLOGY

The study was designed considering the 2021 report in which the WEF brought together the ideas of ministers of education and labour, chief executive officers, chief human resource officers, chief learning officers, online learning providers and key industry skills experts, to propose a new framework for a global skills taxonomy based on ESCO (European Skills, Competences and Occupations) studies and aligned with the Occupational Information Network (O*NET) framework [1]. The report identifies that the successful adoption of this taxonomy is dependent on both institutional policy and practice. A comparative study focused on the strategies followed by the two universities -TEC and GCU- is being carried out during 2022. Strategies around fostering contemporary and lifelong skills in engineering are being compared: the description of skills frameworks, the how and by whom they were shaped, as well as how institutional policies supported these skills. The taxonomy used in this work integrates additional new skills and emerging attitudes related to the Fourth Industrial Revolution:

- Global Citizenship
- Socially Oriented and Multicultural Perspective
- Challenge-Based Learning

4 DISCUSSION AND FUTURE WORK

Similarities between the two universities include partnership with industry; approaches being influenced by the main industry sectors in the economy; responding to societal challenges (alignment to UN SDGs); and the desire to develop relevant meta- and technical Industry 4.0 skills.

Moreover, at both institutions, the partnership between university, employers and Professional Engineering Institutes nurtures professional engineers through work-based assignments that link module content and the workplace, as well as ongoing reflection.

Additionally, COIL opportunities at both GCU and TEC develop intercultural competencies, international perspectives, and ethical sensitivities, which are essential to develop as responsible global citizens. Companies value these skills as graduates have a more holistic understanding of synergy between engineering and business.

Furthermore, the inclusion of challenges and experiences that are socially oriented and focused on the UN SDGs allow for the robust development of skills (socially conscience and empathy; openness and resilience; creativity and sense-making) which are essential for obtaining jobs that meet the expectations of future engineers.

Some differences in approaches to skills development emerged: particularly the CBL approach present throughout the TEC curriculum allows for dynamic and ongoing engagement with industry, while at GCU it is generally a hybrid approach of project-based and more traditional technical modules. Another difference detected is that the national/government policy in Mexico does not have as much influence in defining the political agenda, so TEC had to develop its own framework, while GCU is being strongly influenced by educational policies at the national level.

The analysis also determined that the Skills Taxonomy, as outlined in [1], at both institutions was being defined. Future work includes the final stages of the study to analyse strategies that respond to the current concern of companies: what are the reasons for the difficulties in finding competent talent within each country? The analysis will focus on the circumstances that relate the difficulty of companies to find talent and the following shortcomings of engineering graduates: soft skills, digital skills, knowledge, and mastery of languages other than their native one, work experience and interpersonal skills.

5 ACKNOWLEDGMENT

ABSTRACT

This paper summarizes the results obtained in a project conceived to improve remote and face-to-face teaching of Calculus in the fields of industrial and biomedical engineering. The project consists of developing teaching videos that treat key topics of Calculus subject through some engineering problems at a first level university course. We focus on achieving the goal of learning by setting it in the approach and solution of a subject, making it more experiential. This type of practice should be the central focus of activities inside and outside the classroom. In this way we will be able to consolidate the students' mathematical skills, but at the same time acquire other skills that will be vital for their professional and personal development. The evaluation process must be formative, as the assessment should provide teacher-student

doi:10.5821/conference-9788412322262.1399

feedback in order to adjust teaching or learning based on the information received. We propose two main types of activities: Production of audiovisual material for the improvement of teaching and completion of Wiris questionnaires for self-assessment. The didactic video is very useful in class and has a motivating intention because rather than transmitting exhaustive and systematized information on the subject, it aims to open questions, raise problems, arise the interest of students, disturb and generate a participatory dynamic. With the elaboration of these videos, we promote that students be able to understand through specific problems and with the help of graphic material, a specific problem and then move on to the abstraction of more general situations.

1 INTRODUCTION

The health events of recent years, together with the growth of social networks and video platforms, have represented a revolution in the educational system. The world has evolved from the traditional education system to the online classroom system. Video conference rooms and platforms that offer live streaming for education have acquired the relevant role that the market was requiring. A clear example can be found in the Spanish platform Edpuzzle, which has revolutionized the world of education through video. Educational videos currently represent a very important part of higher education, providing an important tool to capture the attention of students. The effective use of video as an educational tool is enhanced when teachers consider different elements as how to maximize student engagement with video and how to promote active learning from video, see [1] and the references therein for an in-depth discussion of the topic.

In the present paper we present the material developed under a project that has been carried out in the Barcelona East School of Engineering by a group of professors teaching in the initial level courses. When the pandemic interrupted our lives, teachers had to make a 180º turn in their way of teaching. Most of the members of the group offered virtual classes through GoogleMeet using Ipads for transmission, others recorded their classes on videos and we created a YouTube channel to communicate with the students (Canal Càlcul). The generated material is open access in the ZonaVideo UPC. A subsequent analysis made us see that one-hour class through a screen or videos of more than 20 minutes may not be as effective as initially thought, which is consistent with the results presented in [2]. Our interest in capturing the attention of students and creating materials that can be used in any situation led us to consider creating videos of no more than 5' that introduce a topic through a problem of interest to them. This material has been complemented with brief scripts, videos of problems in Cristal Board and online tests to monitor if the objectives have been achieved. The materials produced will be available in open format at UPC Video Zone.

2 METHODOLOGY

The objective we want to achieve is attract the attention of student and raise their interest in studying and expanding their knowledge in each of the topics that make up the Calculus course. It is a standard first year course in any of the engineering careers.

The topics to be developed are function representation, continuity, derivability, Taylor polynomials and Riemann integration. Our approach has been to think of an object or concept that could be present in each of the videos and that would serve as a common thread for the presentation of the problem. Once the concept was chosen, we scripted the video and, with the collaboration of the Caminstech center, we produced the material. On the other hand, we use the support provided by CristalBoard to solve problems associated with each of the videos, as well as a small pdf of about 4 pages each that expands on the topic and includes some historical notes. Finally, self-assessment tests have been developed using the WIRIS software on the ATENEA platform of the UPC. The developed materials have been produced in Catalan and English, since part of our students take the subject in that last language. To give agility to the presentation of the videos we thought of animations with music and not in videos in which some teacher gives the explanation. Our goal is to give lightness to the presentation and get closer to the way of doing the students.

The object chosen as the initial thread was the Heaviside function. This function is an unknown element for students that comes from high school or cycles, so it can rise the curiosity of students. In addition, the Heaviside feature is largely present in the themes that we wanted to develop and that could be introduced as a real problem.

3 RESULTS

The results of the developed Project are classified into 3 typologies.

3.1 Videos

We have designed, scripted and produced 5 videos of no more than 5 minutes in which one of the topics of the Calculus subject is introduced through a problem of technological interest as explained in the Methodology section. In the following table we summarize the characteristics of the videos.

Table 1. Video futures

Video Name	Theme	Problem	Media
Turn on and off with mathematics!	Continuity	Turn on a light	Heaviside function
Displacement, intensity and velocity with mathematics!	Function representation and changes	Signals changes	Translation and dilation of functions
Turn on and off immediately with mathematics!	Derivability	Instantaneous changes	Delta function
Approximating functions with mathematics!	Taylor Polynomials	How a calculator works	Polynomials

Discharge of a capacitor with mathematics!	Riemann integration	Discharge of a capacitor	Antiderivatives

3.2 Complementary short text

To complement the information of the videos we have developed an explanatory text associated with each of the videos of no more than 4 pages in which the information contained in the videos is expanded and a small historical note of a character related to the topic in question is added, if it exists.

Table 2. Complementary material futures

Title	**Historic note**
Heaviside function	Oliver Heaviside
Functions transformations	Generic on functions
Delta Dirac function	Paul Adrien Maurice Dirac
Taylor Polynomials	Brook Taylor
Riemann integration	Georg Friedrich Bernhard Riemann

3.3 Test evaluation

The evaluation process must be transparent and formative. Transparency refers to the fact that the evaluation criteria must be public and known to the students from the first day of the course. And they must also be formative, since the assessment must provide teacher-student feedback, to be able to adjust teaching or learning based on the information received.

Figure 1. Example of a question

ABSTRACT

The learning styles of engineering students have evolved over the years with the advent of technology-enhanced education. Educators have also changed their teaching styles to incorporate student-centric pedagogy and educational technology. While the COVID-19 pandemic proliferated online teaching worldwide, often forcing educators to conceptualize and convert face-to-face teaching materials to online learning modules, Ansys academic endeavours have also pivoted to support educators and digital learning. This paper highlights the Ansys Education Resources, aimed at helping undergraduate materials and simulation-based design educators teach and inspire students. These are also perfect for students and self-learners who are looking to complement classroom content. Moreover, these help professors in assigning supplemental homework or capstone projects.

The resources, of which 80% are openly accessed, are categorized as lectures, case studies, micro-projects, exercises, etc., and make the educators' job easier in inspiring and engaging the students' digital learning process throughout the undergraduate curricula. Solutions to exercises and projects are restricted to educators with current Granta EduPack product licenses. In developing these resources, the content developers consider different teaching and learning styles with special emphasis on project-based learning and incorporating questions that inspire students to consider societal impact and ethical choices. Some resources are purposely prepared for discussions and debates.

The impact of these resources is measured through qualitative questions-answers in user group meetings, periodical surveys, and quantitative performance (such as download numbers) of the website repositories.

1 INTRODUCTION

1.1 Learning Styles of Students and Teaching Styles of Professors in Engineering

Students learn in diverse ways, depending on their own learning styles, but also depending on the discipline of study. The teachers should be adapting to such learning styles by designing appropriate teaching resources and picking up the appropriate style to instruct a specific group of students. The learning styles of engineering students have often been described as visual [1, 2, 3]; however, with the advent of digital communication systems, students lean on receiving information via digital media, with the ability of interacting with such material in different ways. In undergraduate engineering education, however, little has changed in classroom teaching to inspire students with these evolving learning preferences until the Coronavirus pandemic in 2020. Within a couple of weeks, sometimes even shorter, universities and colleges worldwide had to transfer in-person classes to remote teaching, often to live online classes or video-based asynchronous learning. Online flipped classrooms where students studied on their own and then joined live online discussions proliferated. However, the effort was more of a reactive response than a thoughtful, pro-active approach.

1.2. Teaching Resources for Visual, Interactive and Digital Learning

Preparing visually attractive, interactive, engaging teaching resources in digital format is not easy. For more than 10 years, the Education Division of Granta Design in the UK has been preparing such resources to help the teachers that will inspire materials education. Since 2019, after its acquisition by Ansys, this team expanded and are also engaged in preparing resources for simulation-based design and other engineering disciplines. This paper presents a few of those examples with relationships to how students can learn and how professors can teach in digital mode, using such resources, without losing interactivity or engagement in a virtual or an in-person classroom.

2 METHODOLOGY

2.1 First, Make it Visual

It is no secret that a picture speaks a thousand words. When Dr. Mike Ashby, a professor at the University of Cambridge and co-founder of Granta Design, Ltd. started working on such resources, visual appeal to engineering students, through appropriate animated slides, was one of the primary concerns. Resources were made where an educator would simply use one slide to describe a complex phenomenon, a concept, or seed a debate in the classroom.

2.2 Second, Make it Interactive

Sets of interactive learning resources were prepared for students in Adobe Flash, which have recently been changed into interactive PowerPoint slideshows that students could easily play with and learn from, and thus be inspired to learn more.

2.3 Third, Make it Thought-Provoking and Engaging

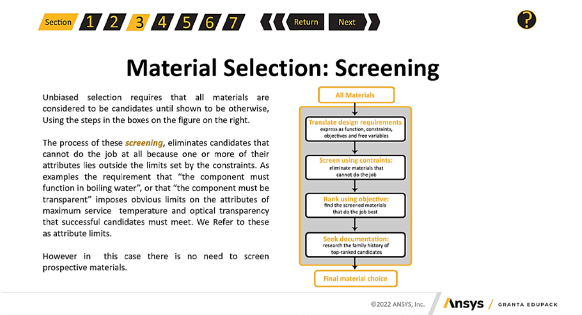
Today's students are well informed and genuinely want to contribute to the sustainability of earth and consequently to the 17 Sustainable Development Goals that the United Nations has set forth in Agenda 2030. The resources have embedded examples that provoke such conversations and engage the students.

2.4 Fourth, Make it a Package to Help in Teaching

We know from analytics that professors extensively use lecture notes, quizzes, exercises, micro-projects, case study-based projects, etc., to help students learn. So, the team has prepared teaching packages exclusively for professors, providing solutions to the exercises, quizzes and microprojects that the students cannot access. This helps new teachers and experienced professors alike to spend less time in creating examples and frees up more time to prepare for teaching.

3 RESULTS

3.1 Visually Engaging and Interactive Resources: An Example



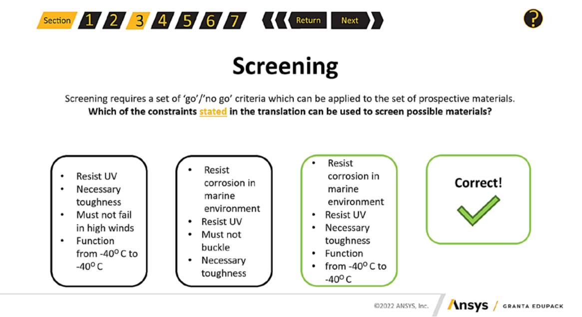


Fig.1 Students can click a box to assess knowledge *Fig. 2 The test takes to right or wrong answer*

3.2 Complete Teaching Packages

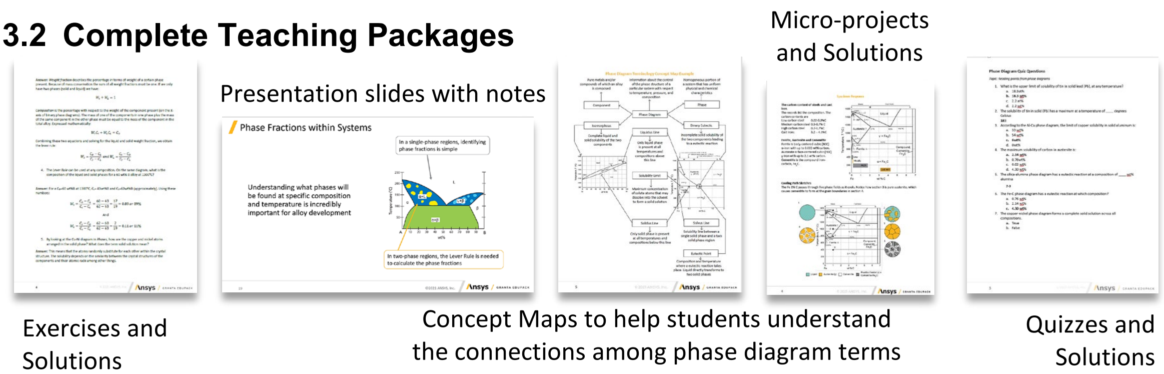

Fig. 3 A complete introductory teaching resource package contains lecture notes, micro-projects, concept maps and exercises besides other components.

3.3 Measure of Success: Quantitative

The team measured the likability and usage of every resource on the website [4]. Among the unrestricted access resources, visually appealing, active learning-inducing infographics had highest download of 11957 in the 2-year period examined, followed by booklets, such as Material Property Data for Engineering Materials, with 10460 downloads. All interactive examples and advanced industrial case studies (often used for final or capstone projects) had high download numbers, around 7000-8000, with the Industrial Case Study on Automotive Door Panel having the highest amongst those (8289).

3.4 Measure of Success: Qualitative

The team held a number of Users Group Meetings (UGMs) and surveys to know the usage of the resources and ways to make those better. From these UGMs, it was clear that professors were keen on using the, so called, advanced case studies, whereas the students preferred engaging, interactive, colourful documents. In recent years, there is an increase in requests for sustainability related resources that also include societal impacts from materials sourcing, product manufacturing, design, supply chain management and reuse of products.

4 SUMMARY AND ACKNOWLEDGMENTS

Addressing students' learning styles during teaching, thus adapting to a teaching style that engages students is essential. Today's students, especially those who study engineering, are digitally savvy and environmentally and socially conscious. A variety of teaching resources show that addressing all of these is possible through thoughtfully crafted, visually and interactively engaging and scientifically accurate resources that, based on the content, can be used for teaching and learning.

ABSTRACT

Universities have the challenge and responsibility to society to train good professionals. Moreover, they must adapt to current demands. They must do so not only by improving the contents of the different degree programs but also by incorporating new programs and activities that help students develop soft skills, teamwork, connections between the university and real life, making them the best professionals and excellent citizens.

To this end, in 2014, the UPV launched a program called Design Factory to channel and frame initiatives carried out by students to develop their prototypes and participate in student competitions.

The program facilitates the creation of interdisciplinary learning communities in which students are committed to their goals, their teams, and the university. The program's spirit is to encourage learning in an eminently practical way. Students have to lead the projects, attract and select candidates, manage a budget, carry out their activities and try to achieve their goals, which involves many soft skills.

For the program's operation, the university provides a team including management, technical and administrative staff, facilities, and economic endowment to the teams to carry out their activities. Funds are distributed in terms of the quality proposal, impact on the university, and results from the previous edition.

More than 2,000 students participate in more than 60 engaged teams whose coordinators show high satisfaction with their roles in the current academic year.

1 INTRODUCTION

1.1. UPV Design Factory

Since 2014, the Universitat Politècnica de València (UPV) has been promoting projects managed by students with the tutoring and support of professors.

The students motivated the creation of this program, asking for support to participate in specific championships such as Formula Student, in which students are responsible for designing and building an F1 prototype for a students competition.

Later in 2018, the UPV the Design Factory Program was officially approved, describing it as a training program that aims to support the extracurricular activities carried out by the university's students. These activities are characterized by contributing to the student's comprehensive development and facilitating the acquisition of transversal skills, self-learning, and new teaching-learning methodologies that promote training based on practice and integration of students in the university community from a broad perspective.

In 2020, with previous years' experience, the UPV approved the Rules for the Design Factory Program, which includes the operating guidelines. The regulations include the functioning of the groups to focus on the objective, that is, students learning by doing.

1.2. Design Factory promotes student learning

Aalto University (Finland) was the pioneer in promoting design factory groups in higher education.

The origin was creating an ideal working environment for students to develop their projects autonomously, with the collaboration of researchers and professionals.

This model of work teams has been exported to other universities, and after several years of experience, it can be affirmed that they contribute to improving students' learning and provide them with skills that often have no place in the curricula of the bachelor's degrees [1].

These skills developed are often called cross-curricular learning outcomes and undoubtedly have great importance in graduates' employability at the end of their studies [2]; we can highlight the development of skills related to teamwork and leadership, among others. On the other hand, belonging to these teams forces students to work in interdisciplinary, competitive, and complex environments, which leads to the development of skills that employers demand and are necessary for entrepreneurship [3,4,5].

For all these reasons, belonging to a Design Factory team will significantly impact the graduates' professional life development.

2. OPERATION OF THE PROGRAMM

The program's direction promotes that the students decide the topic, the project, and, if case, the competition they wish to participate in. The regulations require interdisciplinary teams, with a minimum number of members and a professor tutor who can supervise and help in the work they develop. The fact is that projects are complex and often require the help of multiple professors, which makes learning more valuable.

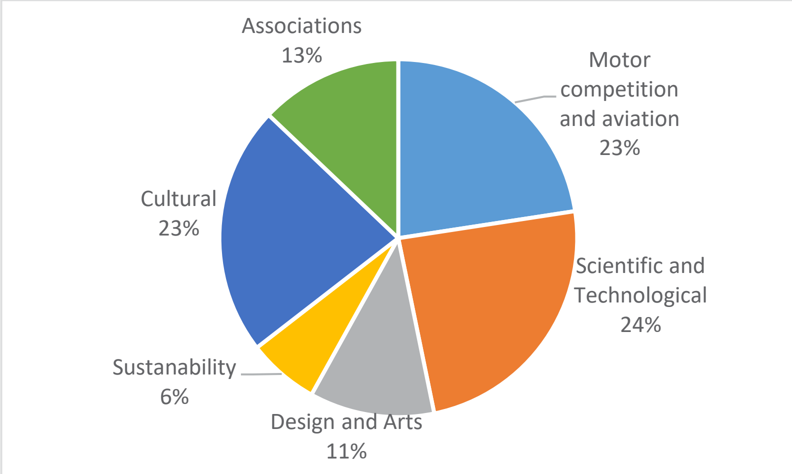
Two calls for funding are made per year, coinciding with the beginning of the course and the year. However, every year, projects are becoming more and more complex, consequently needing more budget, so teams need to seek sponsors to help cover the expenses of their projects, getting good partners. Collaborations can be both economic and in kind. These sponsors can also become partners of the university in different ways.

Each team has a lead captain who is the interlocutor with the program's direction. However, most complex teams usually have several coordinators who assume the direction of communication, management, design, and construction tasks.

3. RESULTS

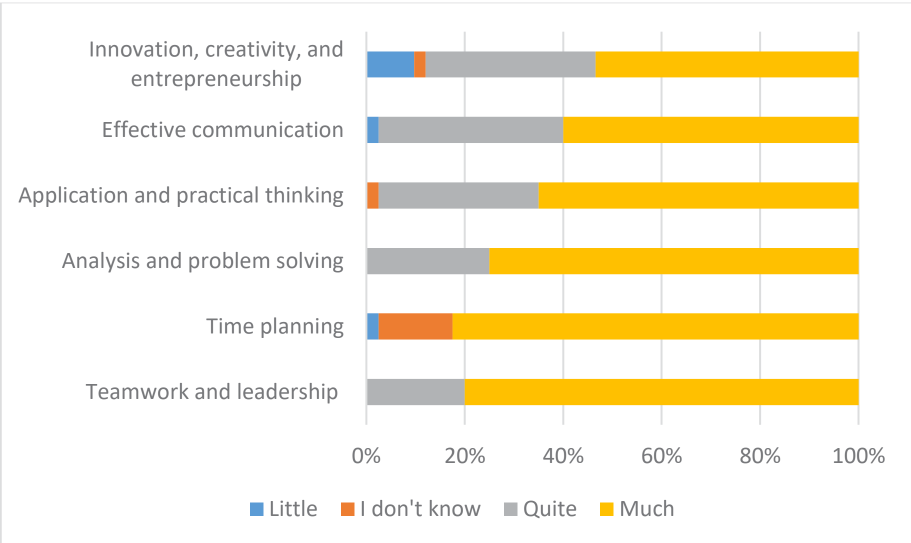
The most immediate successful result is the number of teams enrolled in the program and that has increased from 18 in the 2017-2018 academic year to 62 in the 2021-2022 academic year, distributed in the following categories:

Fig. 1. Design Factory Teams in the 2021-22 academic year by category



In addition, in a recent survey sent to students about their experience leading the team, they answered regarding the soft skills that they considered had developed more, the following:

Fig. 2. Soft skills developed by students' perception



Furthermore, 87.5% of team coordinators believe that being part of a team improves their readiness to enter the job market, and 72.5% of the coordinators consider their expectations met.

Lastly, the answer to whether they would recommend students join a Design Factory Team was 100 % positive.

4. CONCLUSION

There are many benefits to belonging to a Design Factory team, despite the challenge of making it compatible with formal learning. Students can put their knowledge into practice, improve their soft skills, interact with peers from other disciplines, and participate in events and competitions with other students, providing them with a well-rounded education.

ABSTRACT

The advantages of including technological tools, for example dynamic graphing software, into the teaching and learning of technical subjects have long been recognised. Using such tools effectively in the classroom is at least partially constrained by the teacher's knowledge and skills. Any teaching team benefits from skills diversity and always has, however, in recent years the skills needed for effective use of the tools available are becoming more numerous and more varied. Using a range of tools for assessment, rather than for in-class teaching and learning, demands an extra burden of care. Using an example from our own recent experience we illustrate the need for skills diversity in teams teaching and raise questions related to traditional assessment in mathematics.

1 INTRODUCTION

The value of technological tools for the learning and teaching of mathematics has long been recognised, from early computer algebra systems to today's powerful visualisation and computational packages. Over the past two decades such tools have gone from fringe elements of the classroom to being core features. GeoGebra, for example, is an excellent package to use in vector calculus as it requires no coding experience on the part of students or teacher and contributes valuable 3-dimensional visualisation. In specifically engineering contexts another example is LTspice simulating software, which lets the user model the behaviour of simple and

[1] *Corresponding Author*

t.s.craig@utwente.nl

doi:10.5821/conference-9788412322262.1224

complex (analog) circuits. Programming languages specific to engineering, such as MATLAB, are also widely used.

Many examples can be found in practice and in the academic literature on using these tools in the classroom for active teaching and learning purposes, yet far fewer examples can be found of them being used in assessment. Mathematics exams continue overwhelmingly to be closed book, written individually in a secure environment, without access to electronic devices. The reasons for not including digital tools in an exam are many and varied. For example, do we wish to assess whether our students can solve integrals by hand, or visualise and draw surfaces and curves without technological help? Additionally, tools that require access to the internet have inherent security concerns.

So why did we choose to carry out a technology mediated exam? The pandemic experience, forcing us to shift into uncomfortable spaces and to accept hitherto unacceptable options, also forced us to look at how we assessed in a new light. In the case of vector calculus we came to recognise that access to graphing software, powerful calculators and many reference materials could be seen as a boon.

This short paper forms part of documenting a larger project of exploring the design journey of shifting from traditional assessment to technology-mediated assessment in vector calculus. Elsewhere [1,2,7] we have discussed design principles, consequences for pedagogy and comparison of student results.This paper contributes to the conversation on team teaching in mathematics, highlighting the need for explicit roles to be filled by the team members. We provide context of the technology-mediated assessment project, discuss certain aspects of team teaching with special emphasis on roles, then analyse our practice in terms of roles and team teaching practice.

2 CONTEXT

Our vector calculus course runs February-April. In March/April 2020 and again in 2021 we were forced to have our vector calculus exams written remotely, at home, necessarily open book. Despite the challenges we experienced we recognised the value of allowing students to use the many powerful tools available to them. We were forced into a position of setting questions that assessed for higher order skills and conceptual understanding instead of falling back on questions that were more procedural or relied on memory. We have written about this elsewhere [1,2].

There are distinct disadvantages to the mode we were forced to accept in 2020 and 2021, primarily security. Now, in 2022, we are returning to writing the exams under secure circumstances but aim to retain the best aspects of the previous two years. Before the pandemic students wrote the exam without a calculator or notes. Now we allow a formula sheet, a graphical calculator and use of a Chromebook virtual environment including access to GeoGebra, Symbolab and course slides. GeoGebra is 2d and 3d graphing software and Symbolab is a powerful online calculator.

3 TEAM TEACHING

3.1 Team teaching roles and phases

[3] observe that the complexities of higher education are increasingly making team teaching a necessity rather than a choice. For example blended learning (in which learning activities are a blend of online and face to face) requires a teaching team with a variety of roles and skills [4] and interdisciplinary and multidisciplinary programmes require teachers to work in teams [5] to “collaboratively design courses that allow for the integration of various disciplines” [5: p. 198].

Clear roles for the members of the team are important [4,5]. [4] warn that failing to clarify roles incurs a “risk of assuming a perceived understanding around expectations” [4: p. 869] which can impact teaching practices. The role of leader within the team is of particular importance [4,5] although that role can rotate within the team [6]. Members of the team assume roles appropriate to their knowledge and skills and to the needs of the pedagogic environment. Beyond the roles of the teaching team, [4] observe that the students themselves adopt roles, such as active contributor, observer and evolving expert.

[5] outline three phases of collaborative course design, which are “preparation (phase 1: planning), teaching (phase 2: enactment) and evaluation (phase 3: reflection).” (p. 198) They advise that in phase 1 pedagogic needs must be prioritised over practical decisions and in phase 2 adaptation to the needs of the students must be possible. Our short paper contributes to the reflection phase of our design project.

3.2 Our team roles and practice

Our team was made up of the first author, a co-teacher and a member of the university’s e-assessment group. The first author assumed the leadership role. She was responsible for setting the exam, facilitating communication within the team and ensuring that the students were well informed about the assessment with opportunity to practise the skills required. The second member of the team co-taught on the course and advised on exam design. The third member of the team was an e-assessment specialist. He managed the Chromebook environment and liaised with the technical team and exam venue management.

Our team teaching practice [4] began a year before the exam with the formation of the team, planning, and booking use of the university Chromebooks. During the enactment phase the two teachers on the team incorporated use of the digital tools into the teaching and learning resources. They designed the exam questions, aiming for assessment of conceptual understanding and higher order thinking skills, and “stress tested” them using the digital tools. On several occasions the whole team met to consider the design of the virtual environment. The first author and the e-assessment specialist communicated with technical staff and venue management.

The three key activities were exam design, technical set up and communication. These three activities were performed competently, thoughtfully and timeously. Nothing should have gone wrong and yet something almost did.

3.3 A flaw in the system

The second author was a student taking the vector calculus course. Through active engagement with the digital tools he took on the impromptu role of evolving expert [4] and became aware of characteristics of the tools which had implications for the security aspect of the exam. He familiarised himself with the full extent of the weaknesses in the system and devised a plan for closing the security holes. He informed the first author of the situation and thereafter the virtual environment was redesigned to make it more secure.

Both Symbolab and Geogebra allow users to work remotely in groups with one another, which would jeopardise the security of the exam. GeoGebra furthermore has the option of uploading documents into one's profile, thereby creating inequitable open book environments. We must be clear about calling certain features of the tools we had chosen to use “weaknesses”. These are not weaknesses of the packages overall, they are rather an impediment to secure, individually-written exams.

The exam proceeded without a hitch. After the exam the second author remained in the exam venue, testing the security of the virtual environment in a variety of ways.

We are now in phase 3 (reflection) of the design process, which includes reflecting on what went wrong and how we could have avoided it. We are reminded of [4]'s warning that roles should be clarified to avoid perceived expectations. The teachers implicitly assumed all technical considerations to be in the purview of the e-assessment specialist, yet he (quite accurately) did not consider testing for security flaws in the digital tools to be part of his mandate. The exam itself was “stress tested” for use in the planned virtual environment, yet the environment itself was merely approved for looking as the team expected it to look; it was not stress tested for flaws or weaknesses.

In hindsight we recognise that what was missing from the team was someone with the role of stress testing the virtual environment, having both the technical skills to do so and close familiarity with the digital tools themselves. How this gap in the team might have been avoided would have been to explicitly identify the roles needing to be filled and to ensure that the team could fill those roles. A scenario planning brainstorming session early in the project would have been valuable.

4 CONCLUSION

Many higher education environments require the skills of more than simply one lecturer with a whiteboard, such as blended learning [4], interdisciplinary modules [5] and technology mediated assessment. Team teaching (or team working) [3] is called for in such cases. With the ubiquity of digital teaching and learning resources and tools, the recent increase in remote learning and a diverse student body, all embedded in a world facing local and global challenges, we suggest that not only is team teaching of vital importance, but the team should be carefully constructed to embody the diversity of skills required.

We have found the framing of "roles" useful for analysing our practice and how it (almost) failed. We suggest that, upon embarking on a team taught project, an explicit effort is made to identify all necessary roles and to ensure the needs of those roles can be met by the team. This could perhaps be achieved by a scenario-planning brainstorming session. Everyone on the team needs to be aware of their roles to avoid perceived understanding of expectations.

5 SUMMARY AND ACKNOWLEDGMENTS

Better informed on how to proceed with team teaching we are left with some fundamental questions. Should we even be shifting towards technology-mediated assessment given inherent security concerns? Should we only use software designed for assessment purposes in that case? Should we be assessing "securely" at all, that is, should we rather assess mathematical proficiency using groupwork or take home assignments? These are all questions informing our work as we aim to problematize and improve assessment in vector calculus.

In closing we observe that our contribution answers the call of [4] to include students as co-authors and co-researchers in the scholarship of teaching and learning. We gratefully acknowledge Tugce Akkaya and Amanuel Gecer for their invaluable contributions to this project. For further information on this project, including comparison of results, we direct the reader to [1], [2] and [7].

ABSTRACT

Despite numerous research studies that have examined why women are underrepresented in engineering education programmes, the phenomenon is still not fully understood, and no effective general solutions have been found. In this context, analysing women's experiences in engineering education can provide insights regarding the evolution of the students' learning strategies and socialization processes as well as contextual factors that influence their choice to persist in or leave their courses. This paper explores the pertinence of enhancing phenomenological analyses conducted in engineering education research by incorporating sociological perspectives, drawing on sociological studies that explore the relationship between gender, STEM education and persistence in STEM courses. The aim is to contribute to building a conceptual framework that, on the one hand, captures lived experience in engineering education and, on the other hand, analyses the social settings around engineering itself, i.e., the objectively significant circumstances, that condition female students' attitudes, behaviours, and expectations towards persisting or not in engineering courses. Conclusions suggest the conceptual framework around *subjectively meaningful experiences,* proposed by Alfred Schutz, who followed the phenomenological school of thought initiated by Edmund Husserl, might be useful in understanding not only (a) the representations

of the subjective social world for women in engineering education (that induces feelings of identification, security, symbolic values, and ultimately social actions), but also (b) the intersubjective social system that structures daily life, legitimizes behavioural patterns, assigns roles, and defines group membership along education in engineering. Expanding engineering education researchers' conceptions of phenomenology, to consider more of the structural issues that influence women's experiences and choices, can help generate increasingly meaningful research findings.

1 INTRODUCTION

Researchers have identified the social cultural masculinization construct in Science Technology, Engineering and Mathematics (STEM) fields as a prominent barrier, discouraging women from choosing any of these career paths [1, 2]. Although a variety of theoretical and methodological frameworks have been used to explore those factors and, of course, to elucidate how to reduce them [3, 4], enrolment data in STEM courses continue to reflect an unbalanced representation of women, particularly in engineering fields of study, where men represented 74% of new entrants in engineering, manufacturing and construction on average across OECD countries in 2019 [5][2].

Investigation about the underrepresentation of women in STEM fields has grown, to focus not only on factors or influences related to context and historical research of gender inequity in education (e.g., sexist institutional environments, gender imbalance in the profession, cultural barriers and lack of support), but also to study women's lived experiences throughout STEM education programmes [1, 6, 7].

In this context, the objective of this paper is to contribute toward eventually building a conceptual framework in engineering education research (EER) by now introducing the phenomenological sociology approach developed by Alfred Schutz. The Schultz approach can be helpful in the development of an analytical framework that captures the subjective interpretation of the students who elaborate a body of beliefs, values, and norms from their daily life experience in engineering education, as well as the social structural constraints reflected in such experiences. This means that together, they create and continually re-create a system of social values, and that structure, in turn, curtails their choices.

2 METHODOLOGY

Several researchers [2, 6, 8, 9] have encouraged increased use of theoretical frameworks in engineering education scholarship to foster a professional field that is more inclusive and diverse. In this sense, it is relevant to develop conceptual

[2] Also retrieved from the publication's website with additional information https://www.compareyourcountry.org/education-at-a-glance-2021/en/3//default/all/OAVG

approaches that address women's lived experiences in the male-dominated world of engineering [1,7–11].

Understanding how students experience their introduction to the world of engineering makes it necessary to build a conceptual framework that allows returning to the people who elaborate (enact and create) their social environment from daily life, attributing subjective meanings to it. In that sense, phenomenology as a research method explores the essence of a phenomenon by focusing on the perspective from those who have experienced it [12]. This approach is helpful to gain a deeper understanding of the meaning of everyday experiences of women in engineering education.

This paper uses a 'scholarship of integration' approach as defined by Boyer [17] to identify methodologies and prior research that can inform our upcoming study regarding the underrepresentation of women in STEM, a topic that has been researched from a broad variety of fields of knowledge, particularly psychology and education. Drawing on sociological studies that explore the relationship between gender, STEM education, and persistence in STEM courses, the aim is to explore the pertinence of enhancing phenomenological analyses in engineering education research by incorporating a sociological approach. Below, we review recent phenomenological studies conducted within EER; later we provide background on Alfred Schutz's sociological approach of phenomenology to, finally, explore some research performed with other methodologies, where Schutz's conceptual framework happens to be also helpful to interpret their findings and results.

3 DISCUSSION

Dryburgh [1] was a pioneer in conducting research on women's experiences in engineering who used a vast variety of qualitative methods. Based on Erving Goffman's theory of symbolic interactionism and the concepts of the presentation of self, Dryburgh's conclusions stated that women engineers must show competency in the field, in addition to enacting masculine norms of attitudes and interactions. Furthermore, the educational phase constitutes a learning path, through socialization processes to manage the masculine culture into which they are entering, a competence that requires extra effort beyond what is asked to men. Dryburgh concluded that women's adaptation to masculine culture includes denial of sexism, a condition that keep hiding obstacles for women may face in engineering.

Later, in 2012, Charity-Leeke [7] conducted research on women in engineering using phenomenological analysis to find meanings of the sociocultural systems that help women succeed or that challenge them as engineers. With a sample of nine participants, her analyses generated 5 categories: gender roles and sociocultural influences; context-based learning; gender relationships; work and family; essence of women as engineer. Her main findings, similar to Dryburgh's [1], show that women in engineering seek to prove their knowledge and improve their self-confidence as part of their socialization process.

More recently, Rodriguez et al. [10] conducted phenomenological research, with a sample of 17 undergraduate students, exploring the role of religious beliefs in shaping STEM identity in Latina college students. Results show that both elements reinforce each other, but also that intersectionality of multiple “marginalized” identities may be essential to sustaining students’ interest in STEM context as ways to examine and redefine their cultural values. Likewise, Morton and Parsons [9] explored the influence of a racial and gendered identity in STEM, using the Phenomenological Variant Ecological Systems Theory to better understand 10 undergraduate black women’s perception of race and gender in STEM. Conclusions indicate that the identity as ‘black women’ is in fact a positive and protective factor for their STEM engagement and persistence.

Phenomenological research approaches have become more popular in EER, and methodological toolkits have been published to increase understanding and applied knowledge of the phenomenology. An example in 2022 has been provided by Tomko et al. [11] who developed a methodological roadmap for phenomenologically based interviewing in engineering education.

However, some of the main criticisms of phenomenology are that it tends to ignore the structural context where the phenomena happen (leading, erroneously, to an overestimation of individuals’ agency) and that commonly results are based on small samples of participants (typically fewer than 30 people). To address such problems, we propose using the theoretical and methodological frameworks based on Schutz’s postulates of an intersubjective social world. These frameworks are intend to help distil the subjective interpretation of social action, to better understand the meaning that individuals attribute to objectively significant circumstances and use to guide their behaviour and ‘projects’ [13,14].

With regard the sample size, it is worth mentioning that this paper is framed as part of a broader project, initiated at Technological University Dublin in 2014, by Professor Shannon Chance with the support of Professor Brian Bowe [8], which currently has a longitudinal data set, comprised of 72 interviews, that represents a valuable resource for phenomenological analysis helpful to generate an understanding of the lived experiences of women who chose to study engineering.

Main concepts of the social phenomenology of Alfred Schutz

In the mid 1940s the sociologist Alfred Schutz [13] revived the phenomenological tradition of Edmund Husserl [15] in an effort to incorporate social characteristics in the understanding of the meaning structure in the world of daily life. This daily reality is presented to individuals and groups as a shared world. Schutz’s phenomenological sociology made possible the transition from Husserl’s theory of a ‘conscious individual’ to a new theory about the subject acting in society [16]. Schutz provided new conceptual tools to define the social structure of the world of daily life where we, as subjects, share a language, i.e., a series of signs, that help us understand others and be understood, emphasising the concept of the intersubjective world.

Using the concept of *subjectively meaningful experiences,* Schutz [13] argued that people elaborate a body of beliefs, values, and norms to help themselves understand their reality; these form a representation of their world and work together as a system of meanings that structure daily life, legitimize social relations, and help people assign roles. The system also induces feelings of identification, security, norms, and symbolic values within individuals, ultimately influencing their social actions. This postulate is helpful for understanding socialization processes that define the sign systems used by engineering students, conditioning their behavioural patterns and how they create membership groups.

In line with Schutz's concept, Eisenhart and Allen [19] reported that the socio-cultural system in STEM education, mainly in engineering and computing, constantly plays out in various types of exclusions that adversely affect many young women of colour. These include unequal opportunity structures, negative discourses and stereotypes, and interactions that marginalise certain groups of people. As a result, although a woman might have interest, ambitions, or the ability to pursue STEM fields, her socio-cultural system might carry expectancies that hinder her sustained engagement. Moreover, according to Dancy et al. [20], often members of privileged group of students in STEM education (white men) are unaware of how race and gender affect students' experiences as STEM majors. Exclusionary factors are frequently invisible to those not affected by them.

Increasing diversity in STEM education requires not only understanding how students experience membership but, also subjectively, how the group to which they belong plays a role in the formation of the sense of self held by individuals. This sense of self informs the adoption of behaviours of the group, demands certain norms to be respected and expectations to be fulfilled.

Schutz's system of meanings also explains how individuals make sense of and understand, organise, or order their experiences of time. Schutz [13] argues that 'memories' are established and shared by members of a group because the intersubjective world of everyday life was there before them, and it will continue to exist after they leave. The 'future' provides a common frame of reference for the projection of individual actions. Thus, the system of meanings links individuals to both the past and the future – linking them to their predecessors' and successors' sense of belonging to the group. In this way, the community transcends the finitude of its individual members.

That aspect surfaced in research by Smith et al. [18] who, referencing the concept of social capital (i.e., resources obtained from relationships), found that students' social networks are key factors influencing their persistence in engineering through the provision of support and information. Smith's team therefore suggested that women and underrepresented and minoritized students should be encouraged to participate in sectorial organizations at very early stages of their majors. Likewise, Turnbull et al. [2] identified factors explaining why female students are underrepresented in physics (while in the life sciences women are more equally represented). They stated that "individuals who begin their life with more capital, be that through inheritance or immediate exposure to the dominant culture, will be more able to gain personal and social advantages" (p5).

4 CONCLUSIONS

A group's culture, represented as symbolic systems, can be characterised as a set of objectified values. These objectified values are continually defined and redefined by the group, as members work to make sense of their lives, so that they can apprehend and transmit ideas. The symbolic system does not represent a permanent and intact code, but rather a constantly changing construction reinterpreted by individuals who adjust concepts to reflect new daily life experiences. In this sense, Schutz's conceptual frame might be appropriate in the exploration that retrieves the voice of women who, during their time at university, have also experienced the metamorphosis of engineering education.

Although engineering education is the result of a cultural elaboration, it has a subjective meaning for those who experience it, and therefore phenomenology is a pertinent method to analyse and interpretate qualitative data about the everyday experiences of women. Explanation of the social world demands understanding what the social world means to the people within it, and what meaning people assign to their actions within it. In that frame, phenomenology contributes with a useful methodology, but the approach used in EER can be further enhanced by incorporating more sociological perspectives in the lineage of Schutz [14] and Husserl [15]. Using sociological perspectives can expand the research produced within EER to consider structural aspects of the shared experience that using phenomenology alone has tended to overlook.

ABSTRACT

Multidisciplinary Engineering Education (MEE) is a specialist department at the University of Sheffield, dedicated to the practical teaching of all the University's engineering students. To deliver this, MEE has a unique building comprising workshops, study spaces, and most importantly 16 laboratories offering a spectrum of lab activities to a population of approximately 4000 students.

Effectively managing our resources (staff, equipment, lab space) is challenging due to the heavy demand of student numbers, but an effective approach allows at-scale teaching while ensuring the institutional vision of teaching excellence.

This paper presents the approaches used to optimise the "Cantilever Truss" activity, taking place in the MEE Structures Lab. Over the last 5 years, several key stakeholders helped develop this activity's efficiency and scalability which include academics, technicians, MEE's timetabling manager and teaching assistants.

The key factors in developing the activity were; tuning the learning outcomes for transferability across 3 major courses, optimising the activity tasks for constructive alignment, cross-departmental timetable management, and specialised training for the teaching assistants.

The improvements are measured by several teaching design parameters (teaching hours, student numbers, lab "up-time", cross-disciplinarity), and considered alongside information gathered from teacher reflection forms as well as informal student feedback. This paper discusses how the approaches used have yielded value in optimisation and improvement, before suggesting general elements that could be useful 'take-aways' for different contexts and institutions.

1 INTRODUCTION

The Faculty of Engineering at the University of Sheffield attracts hundreds of new students every year. With an increasing student population, large lecture theatres hosting up to 400 students make at-scale lecturing possible. However, it is not economically viable to have sufficiently large laboratories to support at-scale *practical* teaching. For example, one of the larger teaching labs for engineering at Sheffield (Structures Lab) has an actual capacity of 40 students. The labs (16 in total) are all housed in a state-of-the-art specialist department, Multidisciplinary Engineering Education (MEE) which is dedicated to practical teaching [1]. The limitation on lab capacity is overcome by repetition so that lab activities get delivered repeatedly until all the students in a given cohort have worked through them. For example, with a 200-student cohort, it would take 5 sessions for the cohort to complete one activity. To scale up this process, it is essential to optimise the use of resources (i.e., increase student numbers, minimise staff hours, maximise lab space and equipment usage) [2] while introducing appropriate quality control measures to ensure teaching excellence [3]. In particular, this study presents the gradual actions taken over 5 years to scale up the "Cantilever Truss" lab, focusing on three areas of intervention: the lab activity, timetable/resource management, and quality control.

2 METHODOLOGY

2.1 Teaching Activity

The "Cantilever Truss" lab teaches students (first year, first semester) the basics of load paths and load distribution within a simple truss structure. The optimisation process of this lab was guided by the constructive alignment philosophy [4] thus ensuring that all intended learning outcomes (ILOs) were catered for in the teaching/learning activities (TLAs). With this in mind, ILOs and TLAs were finely tuned, and the redundant or ineffective elements were removed. "To demonstrate the Principle of Superposition, as applied to forces and deflections of linear systems" was one of the original ILOs in 2017. However, a review of the programme material showed that students would not cover “deflection of elastic members” in lectures before the time the lab was scheduled. Dropping the “deflection” component of this ILO ensured better alignment between lab and lecturing material. This also meant students would not need to take deflection measurements, resulting in a significant reduction in the session time. To further reduce session time and to support student engagement, highly repetitive elements of the TLA were dropped. For example, the number of times students applied a load and took internal force readings was halved (from 10 to 5 repetitions) while still gathering a sufficient dataset to draw analogue conclusions. The optimised session time was pursued over the years via trial and reflection. ILOs deemed as low value (“Use a spreadsheet to collect data”) were also removed to focus on the core theoretical ILOs (“Qualitatively determine the distribution of internal forces in a truss structure”). In addition, online digital learning (pre-lab activities including a mandatory quiz) was employed to ensure that students arrived well prepared for more efficient working.

Once the TLA was sufficiently streamlined for Civil and Structural Engineers, it was advertised cross-departmentally. Due to the large overlap of basic concepts across several disciplines, the Mechanical, Aerospace, and General Engineering Departments each decided to include this TLA within their programmes.

2.2 Management

Since MEE opened in 2015 it has served across departments and disciplines in the engineering faculty. Initially, individual departments would dictate MEE weekly lab slots (a slot is “Monday p.m.” or “Thursday a.m.” for example) which often resulted in clashes or having to run the same activity over consecutive weeks, inefficiently. This, in turn, meant that lab time was largely spent being idle or setting up/taking down rather than teaching. To make labs more efficient, in 2021 MEE started timetabling the weekly lab slots for all departments, based on which of the MEE labs each department would primarily use. This averted potential clashes and allowed all departments to use the same lab within a *single* week, greatly minimising downtime.

2.3 Quality Control

The delivery of at-scale teaching in MEE hinges upon Graduate Teaching Assistants (GTAs), which make teaching high numbers of students possible with limited academic staff. To ensure excellence in teaching is retained despite the cyclical turnover of the employed GTAs, a new GTA training system was introduced in 2018 [5]. This training method supports GTAs ongoing pedagogical development and provides lab-relevant technical training.

3 RESULTS

Table 1 shows key data regarding the delivery of the Cantilever Truss lab over the last 5 years and their projection for the future.

Table 1. Teaching Delivery Data for the Cantilever Truss Lab

Year	Number of Modules	Teaching		Sessions		Teaching time (hr)	Lab usage (%)	Timetabled number of students	Students taught per-hour
		weeks	days	Number of	duration (hr:mm)				
2017	1	2	2	3	3:00	9	56	180	20
2018	1	2	3	5	2:00	10	42	120	12
2019	3	2	5	16	1:30	24	60	640	26
2020*	4	2	8	44	1:15	55	86	880	16
2021	5	1	5	23	1:30	34.5	86	920	26
Future	≥5	1	5	28	1:15	35	88	1120	32

* In 2020, due to the COVID-19 pandemic, the lab capacity was reduced to 20 students.

The optimisation of the TLA allowed for more than halving the session duration. Observing students suggested that this intervention was pedagogically effective as shorter sessions promoted students' focus and engagement. On the other hand, overly-short sessions (2020/21) caused the slower groups to struggle to complete all TLAs, potentially impacting students' achievement of the ILOs.

The centralised timetabling management was instrumental to the broader incorporation of the activity in different programmes (5 modules) as well as to the improved utilisation of the lab space. In 2021, 23 Cantilever Truss lab sessions were taught in just 5 days of a single week, maximising the teaching time (86% of the total weekly slot time was used) and minimising set-up and downtime.

In addition, the number of students taught increased more than fivefold (180 to 920) while the number of students per academic hour increased by 30% (20 to 26). This suggests that the implemented strategies were highly effective at scaling up teaching, with a secondary benefit to the usage efficiency of staff time. The drawback of having more students is the increased teaching load on staff. This was mitigated by employing more GTAs per session (up to 4). The introduction of a professionalising GTA training allowed staff to delegate teaching delivery without impacting its quality.

In the future, to accommodate a growing student population, this lab activity could be further streamlined and potentially delivered to over 1100 students in a week.

4 CONCLUSIONS

The Cantilever truss lab represents a 5-year process to scale up practical engineering teaching using lab activities. Some elements herein implemented for the Structures Lab will be employed by other MEE labs in the future.

- Teaching activity: minimising redundancy and promoting engagement.
- Management: streamline timetabling to maximise lab usage.
- Quality control: increase skilled teaching capacity by employing and training GTAs.

The philosophy underpinning such elements could be transposed to different contexts and used as a guideline also by other institutions aiming to develop their lab teaching.

ABSTRACT

Use of a wide array of teaching practices and strategies has been shown to improve students' conceptual understanding, appeal to a diverse set of students, and preparation for engineering work. Adaptability theory provides a lens for understanding changes instructors make and can be useful for conceptualizing faculty development going forward. How an instructor's adaptability plays out in the face of new demands lies in the complexity of the courses they teach. Course complexity refers to both the extent of the array of teaching practices/strategies used in a course and the challenge to implement those practices/strategies. The purpose of this paper is to begin to examine what information is embedded in syllabi that may be used to quantify complexity via a Course Complexity Typology. This work is a case study of a single instructor-course pairing and their course syllabi from multiple semesters.

1 INTRODUCTION

The use of a wide array of teaching practices and strategies (WATPS) has long been promoted as a means of improving student learning, including diverse learners, and preparing the next generation workforce [1-3]. Meantime, the COVID-19 pandemic shutdowns and long-term response forced instructors to adapt to the crisis as instruction moved from in-person to remote to modified-in-person delivery. This work is part of a larger project to investigate the long-term impact of events, such as the pandemic, on engineering instructors' employment of a WATPS through the development of a typology for course complexity. The purpose of this short paper is to begin to examine how syllabi may be used to reveal changes in and the extent to which a WATPS are employed by engineering instructors prior to and during the COVID-19 pandemic.

Adaptability is the theoretical framing of this study. It is novel in its focus on external motivators and therefore differs from traditional change models utilized in engineering education. Adaptability is defined as "the effectiveness of an individual's response to new demands resulting from the novel and often ill-defined problems created by uncertainty, complexity, and rapid changes in the work situation" [4, p. 3]. In this study, the external motivator for change was the COVID-19 pandemic.

Course (class) complexity accounts for the extent to which a WATPS are used in a course. The course complexity typology also considers the level of challenge for an instructor to implement each teaching practice or strategy. Practices are a focus as teaching quality is dependent on the teacher's beliefs, knowledge, and practices [5]. Practices can be directly accounted for via artifact measures such as syllabi and learning management software.

One assessment of college teaching is the Teaching Practices Inventory (TPI) [6]. The TPI provided insight into practices that might be captured from syllabi including course information (learning goals), supporting materials (e.g., notes, videos, readings), assignments (nature and frequency), other (student choice, reflection, diagnostics).

2 METHOD

Case Study Methodology

A case study approach was utilized in this research as it allowed for a deep dive into a single participant's experience [7]. The unit of analysis for the case was an instructor-class pairing, meaning one instructor and one class they taught.

Participants & Setting

The setting for this study is a College of Engineering at a research intensive university in the United States. The instructor-class case was selected based on the instructor teaching the same class over a period of time including pre-COVID, initial COVID-shutdown, and sustained COVID impact on instruction.

Data Collection & Analysis

Class syllabi were collected for all undergraduate engineering classes taught in the period of Fall 2019 (pre-COVID) through Spring 2022. Fall (Fa) typically occurs mid-

August to mid-December and Spring (Sp) occurs mid-January to mid-May. Analysis of the syllabi was conducted by two researchers. The TPI [6] inspired coding scheme consisted of five categories: (1) Class Descriptors; (2) Student Collaboration; (3) Communication of Student Performance; (4) Opportunities to Learn; and (5) Learning Supports for Students. Within each category, at least three codes were utilized to try to capture aspects of complexity change.

3 RESULTS

Course Descriptors

For the case selected, the instructor taught a lower division required engineering class each semester from Fall 2019 through Spring 2021. A total of five syllabi were collected; these included two from Spring 2021 (original and revised for the COVID shutdown). The class was a lecture/lab class. The addition of a second section (offering) in Fall 2020 expanded the enrolment and teaching assistant support for the instructor. The delivery mode for this class was in-person (Fall 2019 and Spring 2020 prior to COVID shutdown), asynchronous (Spring 2020 COVID shutdown), in-person (Fall 2020), and online synchronous (Spring 2021).

The learning objectives were reworded in Spring 2020; however, these changes did not imply a change in learning expectations. The number of Accrediation Board for Engineering and Technology (ABET) 1-7 outcomes addressed by the course dropped from four Fall 2019 (Fa19) to three Fall 2020 (Fa20) to two Spring 2021 (Sp21), retaining problem formulation (STEM content) and experimentation and losing teaming and learning strategies use. The only integration of the learning objectives through the class activities was related to the technical content.

Student Collaboration

Student Collaboration are activities that require students to work with each other including in teams and/or groups and in and out of class. Across all syllabi, there was no indication of teamwork activities and no out of class group assignments. In-class group assignments that pertained to the labs were present on the Fa19 and Spring 2020 (Sp20) syllabi but were absent as of the Spring 2020 Covid-revision (Sp20rev) syllabi and never re-appeared.

Communication of Student Performance

Communication of Student Performance includes the transparency of student expectations and grading criteria, student access to their performance in the course, and provision of feedback. Across all time periods, there was no change in the articulation of a grading scheme, how the course grade letter was assigned, or in how academic integrity was described (standard language with course specific consequences for violations). The number of grading penalties and leniencies (typical grade deductions on assignments) increased across the data collection period. In Fall 2019, there were three instances of grading penalties which increased to six on the Sp20 and Sp20rev syllabi. Grading penalties reached a total of seven on the Fa20 and Sp21 syllabi. Leniencies followed a similar pattern increasing from one on the Fa19 syllabus to two on the Sp20 and Sp20rev syllabi to four on the Fa20 and Sp21 syllabi. Prior to Fall 2020, there was no indication that feedback would be shared with students. Starting in Fall 2020 and into Spring 2021, an indicator of feedback (posting of exam averages) was present.

Opportunities to Learn

Opportunities to learn are indicated by both the frequency and variety of assignments and the contribution these opportunities made to the class grade. The frequency of assignments (weekly), variety of assignments (homework, lab work), and the graded components (homework, quizzes, lab work, class participation) remained the same across all syllabi. Homework became a larger contributor to the class grade (reflecting a reduced number of quizzes) during the COVID shutdown (Sp20rev). The change in the homework and quiz contribution to the class grade remained thereafter.

Learning Supports for Students

Learning Supports for Students are focused on the ways that an instructor provided guidance to students for learning and includes items such as class schedule, available personal supports (e.g., for mental health) and learning supports (e.g., for writing), technology that supports learning, and means of communication (Table 1).

Table 1. Summary of Learning Supports for Students

Coded Dimension	**Summary of Indicators**
Class Schedule	• Topic-list (Fa19–Sp20) • Meeting time based (Fa20)
Personal Supports	• Mental Health resources added (Fa20–Sp21)
Learning Supports	None
Assignment Descriptions	Format and submission logistics
Expectations	• Note on effort (Sp20–Spr21) • Note on classroom culture (Sp21)
Justifications	Links required presentation of work to professional practice (Sp20-Sp20rev)
Office Hours	• Location change: in-person (Fa19–Sp20) to web-conferencing (Sp20rev-Sp21) • Hours increased: 5 (Fa19) to 15 (Sp21)
Student Communication	Email (all semesters); discouraging email through the learning management system (LMS) (Sp21)
Instructor Communication	• Quiz topic announcements (Sp20rev) • Delivery mode updates (Sp21)
Technology	• LMS (Fa19-Sp21) • Web-conferencing (Sp20rev–Sp21) • Clickers and Plagiarism detection added (Fa20-Sp21)

4 SUMMARY

Course descriptors overall appeared to indicate a reduction in course complexity as links to teaming (ABET 5) and learning strategy use (ABET 7) are removed from the syllabus. But in fact, their removal was a better reflection of what was actually being taught in the class. Development of students' teaming skills and learning strategies were not found within any of the syllabi. Student collaboration was reduced due to the elimination of group assignments; however, this reflects the impact of having to teach remotely.

Communication of Student Performance in terms of penalties and leniencies adds complexity to assignment grading but detracts from students' learning as it focuses students' attention less on learning and more on points. There is a tension here in the provision of leniencies which promote a feeling of fairness in the class and penalties which force compliance and assimilation that some students might not understand and promotes a feel that grading is arbitrary.

Opportunities to learn were consistent from week to week (e.g., homework, labs) but perhaps limited in variety which limits the kind of learning objectives that can be integrated.

There are several artifacts related to COVID seen within the Learning Supports for Students that may indicate an increase in course complexity. Technology use increased overall and appeared to have a ripple effect on the number of office hours which were conducted via web-conferencing starting in Fall 2020. This increase in hours allowed students more access to the instructional team. The level of transparency of course expectations and justifications were found to be unstable as they were only sometimes present. Justifications disappeared in Fall 2020 while at the same time leniencies and penalties further increased. The removal of justifications may indicate that the instructor became increasingly focused on managing student behaviours during COVID versus connecting course practices to the overall bigger picture of engineering practice.

Overall, the current work outlined was helpful in identifying indicators of a WATPS that could be gleamed from a syllabus. The challenge ahead is to connect the highly nuanced class changes that can be gleaned from a series of syllabi to the literature on effective teaching practices and strategies. Mapping these changes will lead to a robust course complexity typology.

ABSTRACT

Heuristics, metaheuristics and matheuristics are quantitative techniques that can be used to solve complex combinatorial optimisation problems for many engineering applications (industry, logistics, supply chain, scheduling, services, etc.). The course Quantitative Methods of Industrial Process Management II from the Master's Degree in Industrial Engineering of the Technical University of Catalonia addresses such topic. The course is organised into 3 session typologies: (1) master classes, where lecturers provide students the theoretical concepts; (2) practical classes, where students solve small-size problems based on real cases; and (3) competitive project, which is the core of the evaluation. On this regard, a real-based combinatorial optimisation problem is provided and, in 3-member groups, students have to develop an ad hoc (meta/math/hiper)heuristic, based on the theory concepts, and code it with standard language (Python, Java, C++, etc.). For the evaluation, each group solves 10 exam-instances of the problem. The qualification is based on the result achieved by each group for each instance in comparison with a minimum quality threshold, defined by the lecturers, and the results of the other groups. In this manner, students learn very complex concepts in a friendly but competitive environment, which invites them to work hard on the application of theory concepts into a problem close to those they will find in their professional career. Students' assessments show an increase in their performance and interest regarding the course.

1 INTRODUCTION

In last years, university education is using innovative methodologies to improve students' understanding, reasoning capacity or skills for problem-solving [1]. In particular, future engineers are expected to deal with multidisciplinary problems, requiring cross-curricular capacities [2]. Project Based Learning (PBL) is gaining attention [3]. Students adopt an active role, while addressing real-based motivating projects [4]. PBL has been adopted in many courses [5]; often using a gaming environment to ease integration [6]. However, implementing PBL in Spain is not straightforward, mainly due to administrative and curriculum barriers [7].

This paper presents an application of PBL into the course Quantitative Methods of Industrial Process Management II (MQ2), taught at the Master's Degree in Industrial Engineering (MUEI) of the Technical University of Catalonia (UPC). It is a 4.5 ECTS course, compulsory for the Industrial Organisation branch students of MUEI and optional for the other branches. Every semester, around 40 students are enrolled.

1.1 Learning objectives and competencies

In MQ2, students learn to model and solve industrial organisation and management problems with exact and heuristic procedures. The learning objectives are:

- To model and solve classical combinatorial optimisation problems using exact and heuristic procedures.
- To develop ad hoc solving procedures for non-standard problems.

In addition, the competencies worked in the course include:

- Transversal. Group working.
- Basic. To develop ideas, in a research context.
- Basic. To apply concepts learnt into new and multidisciplinary contexts.
- Specific. To develop and apply analytic methods for decision making.

1.2 Teaching methodology

This course is based on PBL to favour learning of objectives and competencies [3]. There are 3 session typologies:

- In <u>master classes</u>, lecturers introduce the theoretical concepts of the course, using illustrative examples to ease understanding.
- In <u>practical classes</u>, lecturers guide students in applying theory concepts to solve small-size problems, encouraging critical reasoning.
- In <u>competitive project</u>, students develop an ad hoc heuristic to solve a real-based industrial organisation problem in 3-member groups (Section 2).

MQ2 has 7 modules: (1) mathematical programming, (2) combinatorial optimization, (3) heuristics, (4) enumerative searching procedures, (5) neighbourhood exploration algorithms, (6) matheuristics and hiperheuristics, and (7) real-based applications.

The final mark is calculated according to the competitive project (80%), as detailed in Section 2, deliveries during the practical classes (10%) and an exam to evaluate whether students have understood the practices or not (10%).

2 METHODOLOGY

The core of MQ2 is the competitive project. At the beginning of the semester, a real-based combinatorial optimization problem is proposed to students. The problem is enough complex to lead to a very high amount of feasible solutions, although only one (or a reduced set) is optimal. Over the course, students develop an ad hoc (meta/math/hiper)heuristic, based on the class concepts, and code it with standard language (Python, Java, C++, etc.). Examples of problems are: (a) assignment of boats to quays and containers to port locations or (b) path in a warehouse to pick up products for pallets to be sent to supermarkets.

Together with the problem statement, a set of test-instances is provided to students, each one representing a different combination of parameters of the problem, that can be used for testing purposes. The format of the instances and the results returned by the heuristics is defined beforehand and students adapt their codes accordingly. In addition, the results of the objective function obtained by a simple heuristic, developed by the lecturers, is also provided for the test-instances. This value represents the minimum quality threshold that will be considered acceptable for the evaluation. Finally, a testing programme is also provided to ensure the objective function is properly calculated, the results format is correct and avoid unnecessary mistakes during the evaluation.

The day of the evaluation, a set of 10 new exam-instances is provided to students (with the standard format). Using identical school computers, students launch their codes and solve the 10 instances in a maximum time of 5 minutes per instance. After 50 minutes, the results together with the code and a report, explaining the heuristic developed, must be delivered.

The evaluation of the competitive project is calculated based on the report (20%) and the average mark for the 10 exam-instances (80%), where each instance mark is:

- If the solution is better than the minimum quality threshold, the mark is 10 for the group getting the best solution and 7 for the worst (overcoming the threshold). A linear progression is considered for intermediate groups.
- If the solution is worse than the minimum quality threshold, the mark is 0.

The competitive environment forces students not to share their findings (ex.: strategies for developing heuristics), while being in a friendly-gaming environment.

In order to evaluate the perception of this activity by students, the students' satisfaction surveys carried out by the university are reviewed. At the end of each semester students can optionally give their opinion about the courses through an online university platform, logically anonymously and without the intervention of lecturers. These surveys are answered at the end of the lecturing period and before the exams period, to avoid the final marks influence the answers. The survey includes a quantitative assessment where students evaluate, on a 1-5 scale, lecturers and courses; and a quantitative assessment where they can express their opinion in a short text.

3 RESULTS

The evaluation of this activity is complex, since it was implemented during a Masters curriculum modification (September 2015), without the possibility of considering control and experimental groups. In addition, some sources of information are not available for all the semesters. Despite these limitations, Table 1 summarises the performance for some indicators before and after the competitive project, gathered from students' satisfaction surveys. Since surveys are optional, a variable number of answers is obtained each semester. However, approximately 30-40% of students answer the survey, i.e. around 12-16 students each semester. Before the competitive project here assessed, the course contents were the same and the teaching methodology was also based on master and practical classes, but the evaluation was done through traditional exams.

Table 1. Course performance before and after the competitive project

Indicator	Before	After	Variation
I1. Students' interest on the course (1-5 scale)	3.59	3.85	+7.2%
I2. Students' satisfaction on the course (1-5 scale)	3.52	3.44	-2.4%
I3. Students' average final mark (0-10 scale)	6.14	7.51	+22.3%
I4. Students abandoning the course (%)	9.9%	1.5%	-84.4%

The indicators I1 and I2 are compiled from students' surveys, carried out at the end of each semester. As observed, the interest on the course has significantly increased (+7.2%), although the satisfaction has slightly diminished (-2.4%). Examining the comments section in students' surveys, the main reason for not being more satisfied is that the competitive project requires from programming skills that many students do not have. Efforts are currently being made to address this issue. On the other hand, indicators I3 and I4 are calculated from the results of students after the course evaluation. As observed, the average mark has notably improved (+22.3%). This indicator is not robust since it compares two different evaluation methods, but assuming the course responsible has remained the same person, the rigorousness can be considered similar. Under this assumption, a notable increase in students' performance has been accomplished. Indeed, indicator I4 shows a very relevant diminution of abandonments and, through the comments section of students' surveys, a much higher dedication can be deduced.

4 CONCLUSION

This paper shows an example of PBL to teach complex engineering concepts, such as advanced quantitative methods to solve combinatorial optimisation problems (course MQ2). In general terms, the evaluation of PBL implementation is positive. Students invest more time to understand and apply the course contents and they show a higher interest. However, some limitations in the requisites to accomplish the competitive project still need to be addressed.

ABSTRACT

The smooth transition of students from secondary education to university study is seen as a factor of student retention and achievement. This is especially important in the case of students from non-traditional backgrounds who may lack the social capital that could help ease their transition. Peer transition mentoring is one of the

[1] *Corresponding Author*

S.B. Economides

s.economides@ucl.ac.uk

doi:10.5821/conference-9788412322262.1381

tools universities use to enhance the experience of new students. This study examines how the transition mentoring scheme of a highly selective institution (UCL) could be modified to cater for the students of a new EQF level 3 engineering preparatory programme (Foundation Engineering) which is aimed exclusively at students from under-represented groups. The transition mentoring scheme needs to address two practical obstacles: the lack of peer mentors with knowledge of the needs of the non-traditional student demographic and the physical distance between the main campus, where the peer mentors are located, and the off-campus location of the preparatory programme. A Students as Partners approach is implemented to examine the transition mentors' perceptions of their role. Semi- structured interviews with 16 current and former transition mentors were conducted to investigate the experiences of peer mentors and to establish their training needs. The paper concludes with practical guidance on best practice for organising and managing training for students mentoring peers from non-traditional backgrounds.

1 INTRODUCTION

1.1 Background

Peer mentoring transition schemes are used in higher education to help new students transition from secondary education to university life. It has been shown [1] that transition support is beneficial to students from underrepresented groups in STEM education, such as first-generation students, women and ethnic minorities, who would otherwise find it difficult to adapt to university life due to disengagement or the lack of social capital that would enable them to navigate successfully the early steps into higher education.

The authors' institution, a research-intensive, highly selective, large, multidisciplinary university, has in place a peer mentoring transition scheme. Paid "transition buddies" are assigned to every new student. The features of the scheme are given in Fig. 1. In recent years the scheme has been delivered online only, due to COVID-19.

Training	Structure	Resources
• One day training • Awareness of the role • Emphasis on boundaries and how to avoid problems	• 10 mentees per mentor • The scheme runs for the first term • Weekly meetings with the group at a time and place arranged by the university • Schedule of topics to be covered at the meetings	• Moodle page where all mentoring materials are stored • Booklet with addresses etc. • Q&A with Senior Mentors hafway through the scheme.

Figure 1: Features of the current transition mentoring scheme

UCL will offer an Engineering Foundation Year Programme (EFY) from the 2023-24 academic year. This is a one-year preparatory programme at level 3 of the European Qualifications Framework for students from underrepresented groups who have not achieved the normal entry requirements for an engineering degree. Its aim is to prepare students for study by improving their academic skills and subject knowledge. Although Foundation programmes are offered by many universities in the UK, this is the first time UCL is offering it in any discipline. Admission is based on socio-economic criteria such as family income, personal circumstances etc. The current peer mentorship programme does not consider the needs of the specific cohort nor does it reflect the way the EFY will be realised: There is an opportunity to redesign the peer mentoring scheme to better serve EFY students.

In existing literature the emphasis is on the mentees and the benefits of transition mentorship. There is less discussion of the experience of the peer mentors, raising the question of how peer mentors experience their role and how this could inform the redesign of the mentorship scheme.

2 METHODOLOGY

A students-as-partners (SaP) approach was employed [2]. Student and staff partnership for co-inquiry, co-creation and co-design is a pedagogical approach that has gained traction in recent years. It was chosen because it can give voice to the concerns and needs of student mentors and can lead to the design of processes that will address those concerns and needs [3]. The team comprised three undergraduate students who had previously worked as peer mentors and one postgraduate student carrying out research in engineering education. Two academic staff members acted as coordinators and advisors. Administrative and support staff were also consulted as necessary.

A case study approach was used for data collection. Sixteen semi- structured interviews with current peer mentors were carried out by the student-partners. This helped narrow the gap between interviewer and interviewed and enabled the participants to be open and critical of their experience. The aim of the interviews was to understand the participants' experience of peer mentoring, their thoughts on the training they received and their awareness of the EFY demographic. A thematic analysis helped identify areas for improvement.

3 RESULTS

The results of the study are somewhat limited due to the relatively small number of participants and the fact that the mentor experiences relate to a different demographic than the one expected at the EFY. Despite these limitations there are some strong themes emerging:

- *Participation*: Mentee participation was low, exacerbated by the online format. *"A lot of the mentees [are] so caught up with their university experience, they don't actually like to come to sessions". "The good thing about online meetings was it was so flexible". "Because it's online they don't open the camera and microphone. It's just like I am talking with my computer".*
- *Topics discussed:* Mentees were possibly discouraged by the group setting to discuss personal issues. *"Most commonly the sort of stuff I would hear would be very admin related not so much about their background […] but sometimes we would have one on one conversations and that's where I really got to hear […] their story".*
- *Format and content relevance:* Most mentors believed that the format was too rigid *"UCL had prepared all those leaflets for us but they didn't match my mentees' needs, for instance, I had to talk about London in so many meetings […] and all the mentees I had were from London.[…] I could go a bit faster, but still the mentees lost interest.". " It would have been really nice if we had discussed more about the actual course more things about that". "I didn't like that plan that much because I don't think it would be a good way to [address] mentees needs, like, it's quite kind of a one way instruction".*
- *What content should be like*: *"I prefer listening to previous transition mentor's experiences, I would like to look into personal experiences, rather than*

general instructions". "[I would prefer] instructions for us to develop our approach ourselves rather than telling us".

- *Support:* More input from experienced mentors and from each other was expected. *"I think maybe we could [talk] with past mentors every week". "I didn't have a senior mentor myself, to be honest, I didn't have someone to go to, one person. I knew there were some senior mentors in general, but not a specific person". "It would be nice to have some activities with other mentors regularly, to get to know each other and exchange ideas".*
- *Boundaries*: There were mixed feelings although friendship was seen as a positive benefit of mentoring. *"The boundary between mentors and friends is hard to control". "It's a quite good experience 'cause we can make friends with [the mentees]".*
- *Knowledge of non-traditional students:* There was no awareness of DEI issues in higher education. Only one mentor considered mentee background: *"I wish I had more demographic information about my mentees".*

Based on these themes, the recommendations for the scheme are given in (Fig. 2). The main features are:

- *Attendance*: Personal or one-to-two mentors. Embed mentoring activities to the teaching timetable. Start with face to face and let participants make their own further arrangements.
- *Match mentors to mentees*: The literature [5] indicates that mentoring schemes are more effective when mentors and mentees have similar backgrounds. This may not always be the case, so dditional training needs to be offered to mentors.
- *Flexible content:* Guide mentors to adapt the mentorship content to the needs of their mentees.
- *Support and community building*: Ensure staff/ senior mentors are available for ongoing support. Organise events where mentors can meet other mentors informally and exchange ideas.

Training	**Structure**	**Resources**
• Two or more days training • Awareness of underrepresented demographics • Being non-judgemental • How to nurture friendships • Setting boundaries and avoiding problems • Social events with other mentors	• One- two mentees per mentor • Run scheme for the whole year • Weekly meetings scheduled in teaching timetable on first term • Guidelines on topics to be covered, but flexibility to adapt • Social events for mentors and mentees • Allocated senior mentor	• Moodle page where all mentoring materials are stored • Booklet with addresses etc. • Training handbook • Staff check-ins with mentees to ensure support and smooth running

Figure 2: Features of the proposed transition mentoring scheme

4 CONCLUSIONS

Student-partners helped shape the future peer mentorship programme of the Faculty. The outcomes of the research will be implemented in the new Foundation programme and will help train new peer mentors, helping them better understand the importance of their role and supporting in the formation of long-term partnerships with the mentees, that could go beyond the mandated mentorship activities [4].

By implementing a students-as-partners approach the academic team were able to understand the student experience better. The approach also helped foster commitment, a sense of belonging and shared responsibility of the future of the scheme. At the same time, the practitioners underwent a personal journey of acceptance of the partnership as a power-sharing process with uncertain outcomes as opposed to a guided experience with known outcomes [5].

Further work needs to be carried out to assess the effectiveness of the peer mentorhips once the scheme is implemented in the EFY cohort. The experiences of peer mentors and mentees of the old and new programme will also need to be compared to those from other universities with peer mentoring schemes, with a view to further refining the scheme.

ABSTRACT

The project 'Strengthening reflection in technical higher education programs' is a response to the need for well-trained reflective science and engineering professionals and the subsequent question of teachers about how reflection can be designed and embedded in a meaningful way, especially in technical study programs. Within this project, eight technical education teams from two Dutch universities of applied sciences are working on improving the use of reflection in their

curriculum. Among other things, teachers are professionalized in their guidance skills, to improve the guidance of reflective activities of their students. One of the research activities within the project involved a questionnaire to gain insight into: 1) the extent to which engineering students have an inclination and need for self-reflection, 2) the reflection level that engineering students reach according to their own judgement, and 3) how engineering students value (guidance of) current reflection activities in their study program.

In the short (concept) paper we will address some main findings of this questionnaire based on data of 843 first- to fourth-year students from eight technical study programs. Amongst others, results indicate - contrary to some other research findings - that engineering students acknowledge the importance of being able to reflect as a future professional. However, they seem relatively less satisfied with currently provided guidance regarding reflection in their study programs. Also, most often employed reflection activities (i.e., reflection reports) are generally perceived least useful. Results give further direction to optimize activities and teacher guidance regarding reflection within higher (technical) education programs.

1 INTRODUCTION

1.1 Background

Within the current labor market there is a growing need for technically trained professionals. To function well within this labor market, young professionals should be able to critically react to often fast changing (knowledge) developments [1]. More specifically, there is an ongoing demand for technically trained students who are capable of reflective thinking in addition to their domain-specific specialism.

Though reflection as a means to foster students' personal and professional development and the importance of incorporating it as essential part of the curriculum is generally acknowledged [2], schools and teachers also experience difficulties regarding effective implementation of reflection in their programs [3]. Also, related research has shown that especially engineering students not always recognize the added value of reflection and the written format that is often used to incorporate reflection does not fit this technical target group [4].

The project 'Strengthening reflection in technical higher education programs' addresses these issues; eight technical programs from two Dutch institutes for higher education are working together with a project team for the duration of two school years on an improved vision and curriculum regarding the incorporation of reflection in their programs. In addition, efforts are made to improve reflection activities for students and professionalize teachers regarding the necessary guidance skills in order to help their students develop essential reflection skills.

1.2 Current study

As part of the project, a questionnaire was administered to gain insight into 1) the extent to which engineering students have an inclination and need for self-reflection, 2) the reflection level that engineering students reach according to their own judgement, and 3) how engineering students value (guidance of) current reflection activities in their study program. The first two parts are beyond the scope of this article; this paper focuses on the third part of the questionnaire.

2 METHODOLOGY

2.1 Participants

Participants came from two universities of applied sciences in the Netherlands. They were first- to fourth-year students divided over eight different technical study programmes. Initially, a total of 944 students participated in this study. Students who gave no permission for using their data or who did not finish the questionnaire were not included in analyses. This resulted in a final sample of 843 students (M_{age} = 19.9 years; 545 males, 298 females).

2.2 Materials

The part of the questionnaire that aimed to gain insight into the current situation regarding (guidance of) reflection activities consisted of different question types. A first set of items displayed various predefined reflection activities, aiming to provide insight into how often particular reflection activities are currently employed and to what extent those are considered meaningful by the students. These items were complemented with two open ended questions to determine examples of reflection activities that are perceived meaningful and less meaningful and reasons why they are considered to be meaningful or less meaningful. These questions were followed by seven statements focussing on perceived guidance related to reflection. A final set of five statements addressed the added value of reflection (activities).

2.3 Procedure

Prior to the distribution of the questionnaire, the questionnaire was pilot tested among engineering students who did not participate in the study to determine whether questions and items were clearly formulated. The final questionnaire was administered during a regular class whenever possible. When this turned out not to be feasible, the questionnaire was distributed by a teacher (known by the students) via email or another communication channel with a reminder being sent after a week. At the start of the questionnaire, students had to sign an informed consent, containing information regarding the goal of the research, their voluntary participation, and processing of their data.

3 RESULTS

3.1 (Perceived usefulnes of) currently employed reflection activities

Table 1 provides an overview of the extent to which predefined reflection activities are currently employed within the technical study programmes.

Table 1. Mean scores and standard deviations for currently employed reflection activities (1 = never; 5 = very often)

Reflection activity	M	SD
Reflection reports	3.34	.92
Reflection assignments	3.10	.95
Reflection conversations	-	-
Classroom	2.63	.97
With study career coaches	3.01	.84
With teachers	2.48	.91
With (group of) fellow student(s)	2.96	1.02
Pitches / presentations	2.36	1.05
Other	1.60	1.07

Table 2 presents an overview of the top 5 reflection activities that were most often indicated by engineering students as least meaningful.

Table 2. Frequencies of least meaningful reflection activities

Reflection activity	Frequency
Reflection reports	19.2%
Specific reflection assignments (e.g. games)	12.6%
Pitches/presentations	12.3%
Group conversations (in-class)	11.2%
Specific reflection assignments (personality/talents tests)	8.4%

Reasons why *reflection reports* are perceived least meaningful can be categorized as *only providing socially desirable responses / "fill-in-the-blank assignments"*, *waist of time / taking too much time*, and *no new learning involved / repetitive activities*.

Table 3 presents an overview of the top 5 reflection activities that were most often indicated by engineering students as most meaningful.

Table 3. Frequencies of most meaningful reflection activities

Reflection activity	Frequency
(1-to-1) conversation (with study coach)	19.5%
Specific assignment (other/track specific)	11.8%
Group conversation (project)	10.2%
Group conversation (unspecified/other)	7.2%
Reflection reports	6.5%

Reasons why *(1-to-1) conversations (with study coach)* are perceived most meaningful can be categorized as *gaining more insight from others or being/others held up a mirror, provides opportunities for improvement, provides insight in functioning, tailored towards the person himself/herself.*

3.2 Currently provided guidance

Table 4 presents an overview of statements related to received guidance regarding reflection and provides insight into the extent to which students agree with these statements.

Table 4. Means and standard deviations related to guidance (1 = fully disagree; 5 = fully agree).

Statement	M	SD
I receive clear instruction on what reflection entails	3.33	.89
I receive clear instruction on *how* to reflect	3.11	.94

I receive guidance from my teachers during my reflection proces	2.97	.97
I receive guidance from my teachers that helps me a step forward during my reflection process	2.99	.93
My teachers serve as a role model when it comes to how I should reflect	2.52	.99
I receive feedback from my teachers on my reflection	3.21	1.11
I receive feedback from my fellow students on my reflection	2.69	1.10
I receive clear instruction on what reflection entails	3.33	.89

3.3 Perceived added value of reflection

Table 5 presents an overview of statements related to perceived added value of reflection in general and provides insight into the extent to which students agree with these statements.

Table 5. Means and standard deviations related to guidance (1 = fully disagree; 5 = fully agree).

Statement	M	SD
I think it is important to be able to reflect as a future professional/worker	4.16	.63
I think reflection is an important skill to learn during my program	3.79	.82
When I'm given the task to reflect, it's about things that are important to me	3.46	.87
When I'm given the task to reflect, a connection is made to meaningful (practical) experiences	3.28	.90
When I'm given the task to reflect, I can see the added value of it	3.35	.91

3.4 Concluding considerations

Results indicate that engineering students do acknowledge the importance of being able to reflect as a future professional, apparent from a relatively high score on its corresponding statement. However, when considering the educational context, most often employed reflection activities (i.e., reflection reports) are generally perceived least meaningful. Also, mean scores regarding guidance can be interpreted as relatively low; students seem relatively less satisfied with currently provided guidance regarding reflection in their study programs. On the other hand, reflective conversations with study coaches are most often indicated as most meaningful. This emphasizes the importance of the teacher role in guiding students' reflections, but also indicates that there is room to further improve that guidance. Among other things, these improvements can be about being a role model and providing appropriate feedback as a teacher.

4 ACKNOWLEDGMENTS

doi:10.5821/conference-9788412322262.1289

ABSTRACT

The renewal of engineering education requires an education that is more affected by students' circumstances which, if known, will help to guide them into the future. It is about channelling the students towards learning, taking into account the factors related to the acquisition of knowledge and how they can share this knowledge with the teachers. The specific aim of the current study was to examine what it means for students to transition from secondary school to university and introduce changes to reduce the failures it generates.

The causes of low grades in the initial phase of university are analysed; subsequently some remedies are included. First, to gather information, student surveys and interview activities, led by an expert, were conducted. Subsequently, compensatory actions were organized by experts, for students and teachers.

The surveys were designed to provide a self-assessment of new students regarding dedication and performance, and were given to those who failed the first important exam, capturing how they experienced university entrance and their first failure. They point to some personal causes of low performance: time organization deficiencies, impediments to devoting themselves to continuous study, and difficulties to adapt. Half believe their dedication merits better learnings and marks, and stress the difficulties associated with an insufficient level of secondary education and with the types of exams.

This study, encompassed within the framework of the activities dedicated to educational improvement at UPC, highlights the need to implement guidance and accompaniment actions devoted to first-year students.

1. INTRODUCTION

We address a widespread phenomenon among engineering students in the first year of university, although with differences depending on the competences, degrees and higher education systems concerned. Many students who begin engineering studies do not pass some subjects, others pass hardly any of them, and some leave, at the end of the academic year, or before. The abandonment of university studies wastes tens of millions of euros of public and/or private spending in universities and also frustrates the personal expectations of more than a third of Spanish university students. Spanish universities record high gross rates of global abandonment ranging from 37% to 50% [1]. Only a small percentage of students easily complete the initial phase during the academic year of their admission. The current project analyses this problem and tries to improve the situation. Failed subjects can negatively affect students in relation to their initial perception of university [2] and also their motivation to learn.

2 METHODOLOGY

Many teachers in many universities have thought about solutions to the problem. They have offered all students, free of charge, ways of achieving greater "inclusion": tutorial plans, seminars, adaptations of curricular workloads, recordings, multimedia materials or environments with virtual reinforcements to facilitate comprehension, online self-assessment tests, flexible consultation schedules. But the problem remains.

At the Barcelona School of Agri-Food and Biosystems Engineering (EEABB) at UPC-Barcelona Tech, actions such as those described in the previous paragraph did not work for mathematics and chemistry, or did not work sufficiently. Due to the failure of so many initiatives of this nature, our group of teachers have now considered some forms more closely related to the accompaniment of students [3] and/or to specific features of the motivation of first-year students [4]. This is the "Mind the Gap" project. In particular, we have adopted a change in perspective and in the investigation of students suffering from the problem (or who at least appear to be candidates), what they think of themselves, the causes of the problem most attributable to themselves and, on the other hand, how they feel. In mathematics, the project is linked to one topic of the Special Interest Group in Mathematics (MSIG - SEFI): the activation of the students to ensure that they participate more in the learning process.

To this end, after the first major exams, and once the results were known, we addressed the students who had not passed them. In the 2019/20, 2020/21 and 2021/22 academic years, a survey was conducted with defined themes and closed and open questions. The response rate was sufficiently satisfactory, between 35% and 70% in different circumstances, for populations of between 80 and 100 students. The students were interviewed, looking for answers to questions concerning the issues described in the paragraph above: how they perceive their first academic failure, what level of demand they had in their way of working, and so on.

Students were asked the following questions, on qualitative more than quantitative aspects.

1. Do you think you have followed the subject?
2. What do you think about the knowledge you had when you got to university?
3. And about your learning capacity?
4. What dedication do you think you gave to the subject?
5. What was your weekly assignment of hours to the subject, in absolute terms?
6. And in relation to the other subjects?
7. What do you think about the relationship between dedication and results?
8.How do you value the virtual materials, based on their utility for study?
9.How do you value the interest of the different classes?
10. Have you used personal aid or external material resources such as private classes or classes in a training school outside the university?
11.Could you point to two topics that proved particularly difficult?
12. What was your mark in the exam?
13. What do you think your final mark will be?
14. With the experience you now have of the subject, what do you think you should improve?
15. Have you had personal situations making it difficult for you to follow the subject?

The desire to change the students’ vision led teachers to ask for psychological and pedagogical information, about students’ human traits, social forms and their attitudes, to help them discover the basics of the problem. The support was structured as a six-hour training activity conducted by an expert. Issues such as motivation, time management, adaptability, commitment, involvement and awareness emerged, focusing on specific points. The assessment was positive. Reflection and debate on the role of the teacher arose, taking into account how current students arrive. The key role of the initial phase was emphasized, as it is the time when the student needs to form a link with the studies, and the importance of using tools to strengthen the student’s commitment.

3 RESULTS AND IMPROVEMENT ACTIONS

In question 5, on weekly dedication to the subject, almost all the respondents answered two hours, one third of what ECTS credits require. In question 14, "With the experience you now have of the subject, what do you think you should improve?", the most common answers were: regularity in dedication (58%), organization of time (57%), motivation (45%), study technique (40%), prior knowledge (31%). According to surveys, the features that students see as low-performance causes are mostly personal: lack of organization of their time (non-continuous dedication) and problems in adapting to the university (their dedication does not correspond to enough learning or high enough marks). There are also more academic causes, notably the types of assessment and a deficient level of secondary education. This last response could encourage action to be taken in secondary education, but that has not been considered in this project as it is internal to the university.

First, actions were elaborated that would allow direct action on the roots of the problem, helping student persistence. This was done, above all, not in classical training fields (adhering to an academic aspect of training on the specific topics involved), but in more closely accompanying elements linked to positions, characteristics, customs and practices rooted in the students themselves.

The affected students took sessions in the field of psychological and pedagogical skills with the aim of altering their way of working and guiding them towards successful behaviours, with advice for a good first year at university, especially offering learning techniques to overcome organizational shortcomings. This was done with a free eight-hour workshop entitled “How to Improve My Academic and Personal Performance,” which was well received by the attendees and found to be helpful. From this area, also follow-up, attention and help sessions were opened, with a view to welcoming new students, and extended throughout the first semester. Learning assistants (more experienced students) were also integrated, as these can help to overcome some limitations that are commonly experienced when integrating far-reaching actions into long courses [5].

By way of conclusion, the project has led to greater awareness of the problem among the entire group. It has been seen that there are important extra-academic factors for failure, that students need support actions to overcome this type of difficulty and that it is important that the university transmits this support.

Keywords: *challenge-based learning; hackathon; creativity; participatory learning; digital education*

ABSTRACT

After the stop caused by the pandemic, the University of Trento and its newly born FabLab reopened the doors to DigiEduHack (https://digieduhack.com/en/), the decentralized hackathon dedicated to the most pressing challenges of digital and innovative education. More than 30 multidisciplinary students have ventured into the design of innovative learning tools to meet the challenge thrown at them: prototyping educational board games; multimedia artefacts and installations at the intersection of big data, art and technology; co-designing festivals in a combination of art, science and fun; laboratory images to be presented in the classroom. In this short paper, as a case study one, we will outline the DigiEduHack initiative, focusing on the potential of a challenge-based approach in stimulating and strengthening introspection, creative thinking and talent's expression. Supported by a set of qualitative data collected before and after the event, this work reports an education case study and shows the progress and preliminary reflections of the students and educators involved.

1 INTRODUCTION

1.1 Challenge-based learning

The Challenged Based Learning approach (CBL) found fruitful context at the University of Trento that is open to innovating teaching and learning, is embedded in a dynamic innovation ecosystem and is pushed to spread out stakeholders' networks. The pedagogy of CBL can be inscribed in the constructivism perspective

doi:10.5821/conference-9788412322262.1259

where students are the main characters of their learning process: they identify, analyse, and design a solution that solves a real-world issue (Tecnologico de Monterrey, 2015). Due to the fact that students approach complex problems, the learning experience is multidisciplinary, it includes stakeholders' perspectives, and it aims to collaboratively find a sustainable solution (Kohn Rådberg et al. 2018). Professors are facilitators and help teams in the process of building guiding questions, gathering the right information, processing data, presenting solutions, and eventually executing the outcomes. Improving soft skills, self-reflection, and stimulating talent expression are another important asset of the CBL approach.

1.2 Hackathon

In the context of CBL, hackathons are one of the most widely used formats. They are highly engaging, limited-time competitions in which participants, divided into groups, design and develop a solution in the form of an idea or artefact to a proposed challenge. Rosell, Kumar and Shepherd (2014) identify four constitutive attributes of hackathons: (i) focus on activity caused by the limited nature of time and space, (ii) novelty in both *doing* (creating something that did not exist before) and *knowing* (learning something new) dimensions, (iii) collaboration stimulated by time constraint, and (iv) reward that can act as an incentive for participation and productivity. Given their attributes, they represent a subclass of the so-called Innovation Contests: competition of innovators who use their skills, experiences and creativity to provide a solution for a particular contest challenge defined by an organizer (Bullinger and Moeslein, 2010).

2 CASE STUDY

2.1 DigiEduHAck at the University of Trento

The UniTrento Fablab joined DigiEduhack, the international initiative of the European Institute of Innovation and Technology (EIT), for the third consecutive year, as part of the European Union Digital Education Action Plan that takes place worldwide on the same dates. As stated by their website, "DigiEduHack is a global movement dedicated to solving the toughest digital education challenges organisations face today, which is manifested in a 24-hour hackathon taking place simultaneously in major cities around the world." (DigiEduHack, n.d.).

After the virtual edition of last year, the third edition of the local DigiEduHack challenge, organized by the Department of Information Engineering and Computer Science - DISI in collaboration with SOI (School of Innovation) and HIT (Hub Innovazione Trentino), in the framework of the Boogie-U project (Boosting Innovation and Entrepreneurship through European Universities) returned again on 9th and 10th November 2021 at the University of Trento. Students applied in order to participate in this optional initiative.

More than 30 students with different backgrounds have tried their hand at designing innovative learning tools to meet the challenge launched by the organizers: prototyping educational board games; multimedia artefacts, installations at the intersection of big data, art, and technology; festivals able to combine art, science, and fun; laboratory activities to be conducted in the classroom.

The five competing teams co-designed tools and activities, with the support of mentors from the SOI, HIT and the two FabLabs of the University of Trento and the University of Bolzano.

For the second, consecutive, year the winning team from the Trento edition also won in the global competition, this time with the project Hachi (https://digieduhack.com/en/solutions/hachi), an application for smartphones and tablets that can facilitate the understanding of abstract concepts thanks to augmented reality (AR).

2.2 DigiEduHack survey methodology

CBL, as a new model of learning, requires new assessment tools that monitor the self-reflection capabilities and soft skills acquisition process. Specifically, reflective learning tools can support this assessment through the process of remembering acts and events and then exploring why things went a certain way, and finally, taking possible actions for further experiences. In this context, we provided an online 15-question survey through which we explored, in three parts, the quality of the learning experience, the level of awareness about students' soft skills and the follow-up of the ideas developed during the hackathon. The soft skills' awareness was measured through the use of the IMI scale (Intrinsic Motivation Inventory), a multidimensional measurement device intended to assess participants' subjective experience (Ryan and Deci, 2000). The instrument assesses participants Interest/Enjoyment, Effort/Importance, Perceived Competence, Relatedness. In Paragraph 4, we discuss the main findings for each part of the survey. 12 out of 30 students answered the questionnaire.

3 FINDINGS

Analysing the results of the questionnaires, we found out that most of the participants (75%) judged the contribution of the mentors as really useful and 25% as useful. During the hackathon they succeeded in boosting team working leveraging two types of personal assets: expertise and charisma. Mentors have indeed been associated by some participants with the word "passion" and their presence has been labelled as "tangible and inspiring". These findings further underline the positive role model embodied by mentors during hackathons (Nandi and Madernach, 2016). More in details, students also evaluated in a positive way:

- the teamwork, the cooperation and collaboration among students coming from different disciplinary backgrounds;
- the friendly competition vibes;
- the creativity shown by every group;
- the positive and playful learning atmosphere – still remaining serious and challenging.

In fact, also from the IMI scale, most of the students found the activity pleasant but also empowering, due to the collaborational aspects with their team and the feeling of competence given by their work mixed with the guidance received by the mentors. They felt challenged, but not under-challenged, during the activity and this leaded to a full commitment to the task they were performing, “losing track of time”.

With regard to what could be improved in the future, suggestions were mainly related to the event duration and its expected outcome. Despite time constraint being a key factor in hackathons, participants would have preferred to have at least 24 full hours for solving the proposed challenge, which means starting earlier in the morning or/and staying overnight. Moreover, they would have appreciated more precise indications on what the expected outcome should have been (e.g. tangible vs intangible artefacts), even using real examples of previous hackathons.

4 CONCLUSIONS

This short paper illustrates some results of the DigieduHack initiative, as an education case study. In designing the activity we focussed on creating a participatory learning experience for the participants. Our goal was to provide students with the tools to reflect upon their soft skills, strengthen creative thinking and best express their own potential.

This result was achieved by mixing the topic of the challenge, apparently very stimulating for them, but also the support given by the mentors during the challenge. The informal - but challenging - climate made students feel challenged but also empowered by the results they managed to obtain, perhaps initially unexpected even for them given the limited time available. Reading their feedback in the questionnaires was very helpful for the research team, also in view of future events with this format. We believe that this combination has been successful in stimulating their creativity but at the same time increasing their awareness about the abilities and the results they can obtain.

5 ACKNOWLEGMENTS

The researchers wish to acknowledge some colleagues that have been instrumental in developing the DigiEduHack event in our University:

- the FabLab UniTrento and all its staff for the space and the great effort and contribution;
- HIT - Hub Innovazione Trentino;
- SOI - School of Innovation;
- Boogie-U project funded by HEI Innovate;
- ECIU (European Consortium of Innovative Universities) for the research on CBL;
- all the mentors and students who participated.

ABSTRACT

Year after year, a crowd of students from the Universitat Politècnica de València (UPV), a polytechnic university in Valencia (Spain) with over 30,000 students, are encouraged to start their own business projects. Since 1992, IDEAS UPV, the Entrepreneurial service at UPV, has been mentoring entrepreneurs. Up till now, IDEAS UPV has helped in the generation of close to 1000 new businesses with a survival rate of over 60% in five years.

In 2012, IDEAS UPV introduced new mentoring and tutorship activities for students by the creation of a business incubator within the university campus. StartUPV is currently a 5-year startup incubation programme and an entrepreneurial ecosystem with more than 300 startups and more than 50 million euros of overall private investment

StartUPV programme is divided into three different stages: (i) STAND UP, in which startups define a business model and complete a validation process; (ii) START UP, in which startups achieve a targeted market share and build their company management team; and (iii) SCALE UP, in which startups achieve maturity and scale to other international markets.

As university students and their startups face different needs in every step of the programme, different approaches for mentoring and tutorship are applied in every stage. For instance, a startup in the first stage is mentored in business modelling or market segmentation, while a scale up requires a more specific mentorship in dealing with corporates and venture capital. These different approaches are analysed in this work including the main findings of the 10 years of this programme.

1 INTRODUCTION

Universities are sources of talent in which their students are prepared to face the challenges of society. In addition to being trained in technical knowledge, the reality of the labor and professional markets shows that students must also be trained in transversal key skills in entrepreneurship [1]. It is for this reason that universities encourage and evaluate competencies such as teamwork, resilience and leadership. Moreover, these skills are vital for the creation of new companies.

In 1992, the Universitat Politècnica de València introduced IDEAS UPV, an advisory service for entrepreneurs from all the university community. Although initially only the first phases of the entrepreneurial process were covered, different factors such as the role of university in its regional ecosystem and the need for startups to stay close to the university have resulted in the creation of comprehensive university entrepreneurial ecosystems.

StartUPV is an entrepreneurial university ecosystem and a 5-year startup incubator programme managed by IDEAS UPV. Since its creation, more than 300 startups have gone through this programme that covers all stages of the entrepreneurial process. This paper presents the main initiatives carried out in each of these stages.

2 ACTIVITIES AND SERVICES IN THE PROGRAMME

Table 1 shows a review of activities and services in every stage of the StartUPV programme.

Table 1. Main activities and services of StartUPV in every stage of the entrepreneurial process

Stage	**Preincubation**	**Stand Up**	**Start Up**	**Scale Up**
Main users	*Students*	*Young entrepreneurs*	*Entrepreneurs*	*Business people*
Team	*Entrepreneur*	*Founding team, Assignment of roles*	*Complete a balanced team*	*Expansion of the team, new management*
Duration	*While they are students*	*1 year*	*1 year*	*Up to 3 years*
Innovation	*TRL 1-3, Idea*	*TRL 4-6, proof of concept*	*TRL 7-8, MVP*	*TRL 9, whole product*
Space	*School*	*Coworking*	*Private office*	*Custom space*
Main activities	*Business Opportunity detection, Mastering a technology, Starting a Business Model*	*Identify customer pain, Beachhead market, market strategy, Customer value proposition, competitive advantage, develop coherent set of assumptions*	*"Getting out of the building", Defining MVPs, Validation process, Customer development*	*"Cross the chasm", Expand to new (international) markets, Introducing new products and services, Getting investment*
Main supporting	*Mentoring, team building, hackathons, inspirational talks, business idea competitions*	*Mentoring, trainings on Marketing and Financials, Prototyping, funding, pitch competitions*	*Mentoring, trainings on validation, funding, intellectual property*	*Mentoring, Inverstor's Day, trainings on specific topics*

Although each cohort of startups is selected thinking of similar levels, then each startup advances at a different pace. For this reason, StartUPV programme allows the most advanced startups to go at a faster pace while the others can be properly assessed too.

2.1 Preincubation stage

This pre-stage is mainly designed for students who have a business idea. The university offers inspiring talks and hackathons to encourage entrepreneurial vocations and a team building platform to find possible cofounders in the project. The main mentoring activities are focused on defining a business model [2] and to acquire a correct understanding of the market needs, and whether the entrepreneur has or can access the technical knowledge required by the entrepreneurial project. Each of the university schools incorporates a space for its entrepreneurs.

2.2 Stand Up stage

This stage is designed for those students and graduates who decide to focus on creating a business project. At this stage, mentoring focuses on establishing and quantifying the key elements of a business model, such as the beachhead market [3] and the value proposition. In addition, the teams work on formulating hypotheses. Startups are incubated in a coworking space to facilitate synergies.

2.3 Start Up stage

In this stage, startups validate their business model through a validation process in which MVPs [4], prototypes and experiments are created, which in some cases can generate patents and other elements of intellectual protection. In addition, lean startup methodologies such as customer development are used for problem-solution fit and product-market fit. Startups are incubated for a year in a private office.

2.4 Scale Up stage

In this last stage, startups stop being startups to become successful companies. Instead of focusing on validating a business model, these companies carry out activities to expand and scale the project in various markets. For this reason, mentoring is focused on internationalization, market expansion and investment. This stage lasts up to three years in which the university provides a personalized space for the company.

3 CONCLUSIONS

For 10 years, StartUPV has been assessing startups built by students and graduates from the Universitat Politècnica de València according to the stages described in this short paper. More than 300 startups have been incubated in this ecosystem and these projects have achieved more than 50 million euros of overall private investment.

ABSTRACT

Although phenomenographic research approach has been widely used by education researchers to investigate students' learning, little attention has been paid to the relationship between a pedagogical approach adopted by teachers and students' learning outcomes, particularly in engineering education. This experimental study proposes integrating variation theory as a pedagogical approach to a face-to-face classroom environment for teaching complex engineering contents and adapting a phenomenographic approach to evaluate students' learning outcomes. The teachers who participated in the experimental group incorporated the variation theory in their teaching process. In contrast, the teachers in the control group, being ignorant of the variation theory, taught the same content to achieve the same specific learning outcome. Drawing on data from students' written responses both from experimental and control groups, this article illustrates how teachers implemented variation theory in the classroom and its impacts on student learning. The implementation of variation theory was confirmed by classroom observation, and the variation in understanding the topic was emerged from students' written responses and interview data through phenomenographic analysis. The findings indicate that teachers informed by variation theory use variation and invariance that creates necessary conditions for learning. This study demonstrates how, by incorporating variation theory, a faculty member designed different pedagogical approaches, which helps students conceptualize complex engineering topics more systematically than those who do not discern variation. The study concludes with theoretical, empirical, and pedagogic implications for teacher education in engineering.

1 INTRODUCTION

1.1 Rationale for implementing variation theory

Engineering education deals with complex engineering concepts that require diverse levels of teaching and learning methods [1]. For students to demonstrate such concepts, a few teaching methods are considered effective, such as face-to-face classroom teaching and project-based or problem-based learning [2]. However, the ability of these teaching and learning methods to set up the right conditions for learning is not clear yet. In this connection, the variation framework of teaching [3] claims that students learn to the extent to which the necessary conditions of learning are met. However, the theory has not been applied in engineering education. This research aims to explore the effectiveness of incorporating the variation framework into teaching engineering content.

1.2 Rationale for adopting phenomenography

Investigating 'how students learn' is often raised as an area of interest by academics. Over the last few decades, a substantial amount of research has explored students' conceptions of learning in different fields of education, adopting a phenomenographic approach. In engineering education, teachers and students need to deal with real-world practical problems that demand an appropriate 'object of learning' to be discerned by the students, and a phenomenographic approach is required to comprehend this discernment [4]. However, why and how students' conceptions of such problems vary is often surprisingly ignored by researchers, particularly in engineering education. This study fills this void by seeking answers to the following research question that guides the adaptation of variance and invariance in teaching engineering content.

Does the application of the variation framework in teaching engineering content enhance students' learning?

2 METHODOLOGY

2.1 Research Settings

The following flow chart (see Fig. 1) represents the steps involved in setting the research environment.

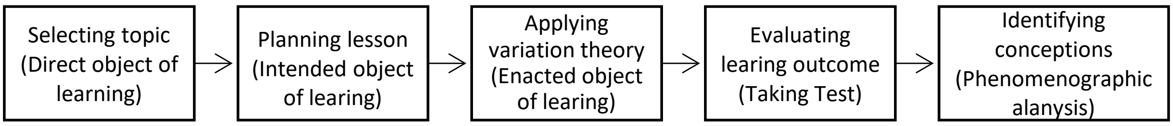

Fig. 1. Steps involved in this research settings

Two university teachers with more than five years of teaching experience participated voluntarily in this study. One of them is the third author of this study. Each of them developed their lesson plan independently to deliver the same *direct object of learning (content)*. The teacher in the experimental group, being aware of the variation theory, developed the lesson plan considering the relationship between students' learning and teaching patterns of variation and invariance. Whereas the teacher in the experimental group, having no knowledge about the variation theory, developed the lesson plan in traditional method.

2.2 Participants

63 third-year students (37 from the experimental group and 26 from the control group) enrolled in the *Industrial Quality Control* Course and two teachers from the mechanical engineering department of a teaching-oriented private university in Bangladesh participated in this study, where one of them applied the variation theory, and the other teacher taught the same topic adopting a traditional teaching method.

2.3 Lesson Planning

Three critical aspects of the phenomenon were identified, and four conditions were constructed to allow students to experience variation in those aspects as part of the lesson plan (see Table 1). The term 'critical aspect' was taken from Pang's research [5].

Table 1: Variation of different knowledge levels required to learn the lesson

	Critical Aspect 1	Critical Aspect 2	Critical Aspect 3	Intended object of learning
Conditions	Mean and Control Limits	Issue of Central Tendency/ Accuracy	Issue of Variance/ Precision	Level of Understanding the complexity
A	V	I	I	Evaluate Components related to Control Charts
B	I	V	I	Judge the Sample Acceptance/ Rejection
C	I	V	V	Complex Scenario Analysis
D	I	V	I	

Note. V = variation; I = invariance

2.4 Data collection

The two groups of students mentioned above were given the same written question (shown below) in two phases. In the first phase, teacher X taught the topic to the control group without using variation theory, and students had 30 minutes to respond. In the second phase, teacher Y used variation theory to teach the same topic to the experimental group. The students were asked to answer the identical question to assess how the variation theory had influenced their knowledge of the topic (learning objective).

<u>Question on Industrial Quality Control</u>

A quality control inspector at the Fun Fizz soft drink company has taken three samples with four observations each of the volume of bottles filled. The inspector collects the data on a regular basis. If the standard deviation of the bottling operation is 3 ml and 3 standard deviation limits for the 250 ml bottling operation are prescribed by the quality inspector, the control chart variables can be constructed with the sampled data. Assume you are the quality assurance manager of the company and are supposed to report to the operation manager to take any action you think is required. Comprehend the production line quality conformance for the data of 2 days as shown in Table 2 (please comment on each day's production operation separately). Justify your comments.

Table 2: Volumes of the sample bottles collected during Day 1 and Day 2 on different shifts of Morning, Noon, and Evening are as follows.

Sample / Observation	*Day 1*			*Day 2*		
	Morning	*Noon*	*Evening*	*Morning*	*Noon*	*Evening*
1	*249*	*251*	*250*	*239*	*253.5*	*256*
2	*250*	*252*	*252*	*243*	*251*	*256.5*
3	*246*	*249*	*253*	*239*	*252*	*256.5*
4	*249*	*249*	*251*	*246*	*252.5*	*256*
Sample Mean	*248.5*	*250.25*	*251.5*	*241.75*	*252.25*	*256.25*
Sample Range	*4*	*3*	*3*	*7*	*2.5*	*0.5*

Data Analysis

A phenomenographic data analysis technique was adopted to explore the extent to which the *intended object of learning* varied [6]. All the responses were combined into a "pool of meaning," and distinctions were made between qualitatively different explanations to form the category of the responses. Four categories of the object of study were emerged from the data. To arrive at the final categories, the following question was utilized as a guide:

How does 'quality of a production line' be understood by the students?

3 RESULTS

3.1 Comparison of learning outcomes

When exploring students' understanding of factors affecting industrial quality control, four qualitatively distinct ways of understanding the direct object of learning were identified.

A. Quality of production line can be expressed with control charts
B. Quality of production line can be rationalized for sample acceptance/rejection
C. Quality of production line can be explored by the offset from the mean
D. Quality of production line can be explored by the outlying variety of samples

Table 3. Distribution of the Conceptions for the Written Task

	Experimental Group (37 students) (Variation theory applied)		Control Group (26 students) (Variation theory NOT applied)	
Conception	Occurrences	%	Occurrences	%
A	34	91.9	22	84.6
B	30	81.1	16	61.5
C	34	91.9	1	3.9
D	36	97.3	1	3.9

3.2 Effect of variation theory on student learning

Table 3 shows how students in the experimental and control group understood *production line quality control* through the use of the presence and absence of variation theory in the classroom. The majority of students in the experimental group were able to recognize all four aspects of the phenomenon taught using variation theory. The students in the control group were able to understand the lower-order concepts A and B (85.6% and 61.5%), but they were unable to comprehend the higher-order concepts C and D (around 4% for each). In conclusion, this research confirms that variation theory has a better ability to create necessary learning conditions and thus has brought a positive impact on student learning in engineering education.

4 SUMMARY AND ACKNOWLEDGMENTS

This research investigates a novel phenomenon: using variation theory in engineering education and analysing its impact on student learning using phenomenographic principle. This short paper reports evidence of how, by incorporating variation theory, a faculty member designed different pedagogical approaches that ranges from less sophisticated (A to B) to higher (C to D), which facilitates students conceptualizing complex engineering topics more systematically than those who do not discern variation. An extended version of this article is expected to appear in future publications.

The authors are grateful to the Islamic University of Technology (IUT), for financial support to their contribution to this research. Research Grant number: REASP/IUT-RSG/2021/OL/07/009.

ABSTRACT

Challenge-Based Learning has become specifically popular in higher engineering education. CBL addresses the key characteristics of future engineering programs by embracing authentic, active learning, offering choice in problem-solving and learning practices as well as enabling training in interdisciplinary teamwork and decision-

[1] *Corresponding Author: K Helker k.helker@tue.nl*

doi:10.5821/conference-9788412322262.1256

making. This responds to the desire of many students for a sense of meaning in their education. Just as with many other educational innovations, we see a large variety of many different initiatives under the CBL label which is why much research is being conducted on the characteristics of CBL implementation. But the goal for researching different characteristics of CBL experiments is to, in the long run, understand whether CBL influences student learning, and in which way, since prior research suggests positive effects of such active learning approaches. In this short paper we present a framework for capturing the prerequisites, context, process and outcomes of student learning in Challenge-Based Learning. We take a close look at CBL as an educational concept in contrast to the prior ways in which student learning has been described. We put forward a heuristic analytical framework that will allow researchers and educators to capture the different aspects of the CBL process and context that could guide further education innovation and research to foster student learning gain in CBL.

1 INTRODUCTION

Higher education institutions worldwide have implemented Challenge-Based Learning (CBL) as a response to calls for more future- and student-oriented education. While CBL puts students at the center of the teaching and learning processes, most CBL research has focused on CBL design characteristics and has not yet systematically integrated existing research on student learning. This short paper therefore presents a framework for capturing the prerequisites, context, process and outcomes of student learning in Challenge-Based Learning.

2 THE FUTURE OF ENGINEERING EDUCATION

Today's societal, political, and economic changes in the world yield numerous challenges that are often complex, open-ended, and ill-defined [1] and call for competencies, often referred to as 21st-century skills, that go beyond workers' traditional tasks and responsibilities. This is specifically true for future engineers, who need to possess a T- or Π-shaped profile, mastering in-depth disciplinary knowledge as well as broader professional skills that will allow them to develop technical solutions to current problems.

These requirements are also presenting new challenges for engineering education, as traditional teaching approaches focusing on transmission of knowledge have started to lose their functionality [2]. Thus, many educational practitioners have strived to create modern and powerful learning environments that allow for students' distributed and co-operative learning through social interactions in representative authentic, real life contexts that have a personal meaning for them.

3 CHALLENGE-BASED LEARNING

One relatively new approach, that has become specifically popular in higher engineering education is Challenge-Based Learning (CBL). CBL aims at creating "a learning experience where the learning takes places through the identification, analysis and design of a solution to a sociotechnical problem. The learning experience is typically multidisciplinary, takes place in an international context and aims to find a collaboratively developed solution, which is environmentally, socially and economically sustainable." [3, p.4]. In order to achieve these aims, CBL usually involves open-ended challenges or problems from real-world practice that require students to work in interdisciplinary teams. The uncertainty that naturally arises in such authentic project work is expected to trigger students' self-regulation and motivation as students can make sense of their education [4]. Apart from students' improved technical and problem-solving skills as well as a deeper understanding of disciplinary knowledge [5], students in CBL settings are also expected to interact in real-world settings, acquire knowledge and develop skills they can apply to respond to any kind of complex problems in the future, such as self-awareness, self-leadership, teamwork, and an entrepreneurial mindset [6].

Given these advantages of combining experience, cognition, and behaviour, CBL has become especially popular in higher engineering education with a large variety of approaches that are being adapted to and shaped by different contexts, needs and learning objectives [7, 5, 8]. Whether the advantages of students' active involvement in their learning that have been shown in prior research [9] also apply to student learning in CBL however is not clear, as the two fields have not yet been systematically integrated. In the following, we therefore suggest a framework for capturing the prerequisites, context, process, and outcomes of student learning in CBL.

4 STUDENT LEARNING IN CHALLENGE-BASED LEARNING

The framework for capturing student learning in CBL can be seen in Figure 1. We will present the parts in the following, starting from the core of the framework, students' learning patterns, before turning to students' learning outcomes, and finally personal and contextual factors specific of CBL environments.

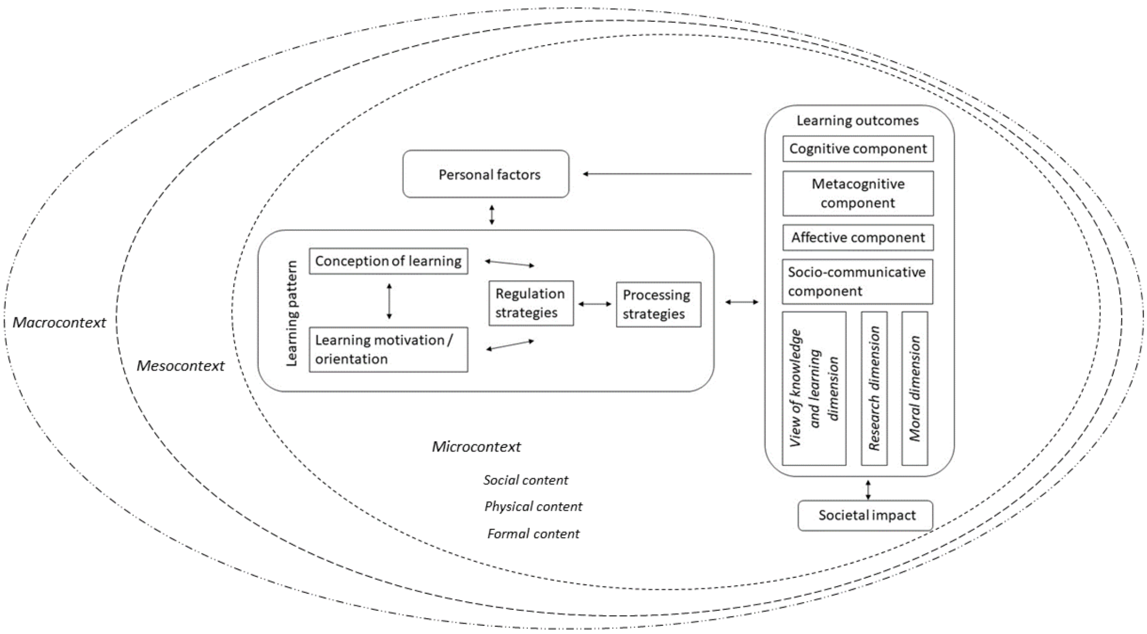

Fig. 1. Student learning in Challenge-Based Learning

4.1 Student learning patterns

A student's learning pattern has been conceptualised in prior research as "a coherent whole of learning activities that learners usually employ, their beliefs about learning and their learning motivation" [10]. These comprise students' cognitive processing strategies (what activities students employ to process subject matter), metacognitive regulation strategies (students' activities to plan, monitor, and evaluate learning processes), (metacognitive) conceptions of learning (students' views and beliefs about learning), and students' learning motivations and orientations (students' aims and goals). These strategies then result in four different learning patterns, i.e., reproduction-directed learning, meaning-directed learning, application-directed learning, and undirected learning [10]. Whether students' employ more or less beneficial learning patterns affects students' learning outcomes and is affected by students' personal and contextual factors, all of which will be described in the following.

4.2 Student learning outcomes

For describing the variety of student learning outcomes in CBL, we draw on Vermunt and colleagues' framework of learning gains in higher education, referring to "students' change in knowledge, skills, attitudes, and values that may occur during higher education across disciplines" [11]. This change may refer to the cognitive, metacognitive, affective, and socio-communicative components and three dimensions (view of knowledge and learning, research attitude, and moral reasoning) of learning gains. In CBL, specific emphasis lies on the socio-communicative component with students developing a professional identity, creative/ innovative and entrepreneurial thinking. Specifically important are the discussions of the cognitive component of student learning gains, as the specific contexts of CBL will allow for a large variety of learning outcomes. Further outcomes of students' work and learning in CBL, are that their solution or product developed in response to the challenge may have a societal impact, which may again affect student motivation and perceived usefulness of the CBL process [12].

4.3 Personal factors

Personal factors that affect student learning are usually described to be age, personal background, prior knowledge, educational experience, and epistemological stance. In our framework, we assume that students' experience with interdisciplinary and collaborative work in general and with CBL specifically, as well as their sense of responsibility for their learning and ability to deal with uncertainty affect them developing more or less beneficial learning patterns.

4.4 Contextual factors

The interplay between students' personal factors and learning patterns, leading to specific learning outcomes can be assumed to be affected by numerous contextual factors. Using a framework of context in higher education by Wosnitza and Beltman [13], these factors can be structured on three levels, namely the microlevel (i.e., the course level context), the mesolevel (i.e., the institutional level), and the macrolevel (i.e., the wider societal, local, national, international context). Each of these levels of context holds different content, namely the social content (e.g., the peers, coaches, teachers, external stakeholders the student interacts with, the frequency of meetings with them, the group atmosphere), the physical content (e.g., learning resources and space available for learners, learning technology), and the formal content (e.g., open-endedness of challenge, assessment/ feedback/ reflection methods, scaffolding on the microlevel, curriculum, institutional and departmental vision of CBL on the mesolevel, and global themes guiding the challenges on the macrolevel).

5 CONCLUSION

While some research has already emerged exploring various aspects of CBL implementation, not enough insights have been gathered about whether and how CBL influences student learning. As a first step, we therefore presented a heuristic analytical framework of student learning in CBL. This will allow researchers and educators to systematically relate the different aspects of the CBL process and context in future education innovation and research. Specifically focusing on the different levels and various content of the CBL context, such as student (interdisciplinary) team work in CBL, will allow for understanding how CBL can foster beneficial student learning patterns and outcomes and what configuration of CBL elements constitutes the most powerful pedagogy for educating future engineers.

ABSTRACT

This paper describes the development of a mini-module focused on sustainability and timber engineering as a component of a strategic partnership designed to broaden Transnational Education, increase staff/student mobility, and further develop industry and community links within two universities. Edinburgh Napier University (ENU) draws students from around the world and is internationally recognised for timber construction and wood science. The New Model Institute for Technology and Engineering (NMITE) is a new higher education provider in England pioneering an innovative approach to engineering education integrating business, engineering, the liberal arts, and professional skills. ENU and NMITE leveraged these strengths to develop a strategic partnership that brings together staff, students, industry, and the community for opportunities that create impact beyond traditional learning approaches. This can be seen through the development of a Sustainability Enrichment Week hosted by NMITE's Centre for Advanced Timber Technology (CATT) and attended by ENU Master's in Environmental Sustainability students. Students investigated interfaces between buildings, humans, and nature through experiential learning based around the construction of the CATT building, which has been developed as a Living Lab. Each day featured activities aligned to identified learning outcomes and was themed around one of five sustainability competencies: systems thinking, values thinking, strategic thinking, future thinking, and collaboration. The Sustainability Enrichment Week also served as a trial for a short course soon to be offered as part of a Timber Technology, Engineering, and Design programme. This project could be a model for other universities seeking to create similar strategic partnerships and learning experiences.

1 INTRODUCTION

Universities have long recognised the value of strategic partnerships that can help achieve institutional goals such as strengthening links to industry, adding value to programmes through additional talent and resources, and increasing knowledge exchange, all of which can ultimately lead to new student recruitment markets and therefore additional revenue streams. However, it is often hard for administrators to find space within traditional programme structures to add these kinds of activities, and while academic staff may see the value in these initiatives, they may not have the time to embed them within their existing modules. What can be done to overcome these challenges to creating strategic partnerships?

The purpose of this paper is to show how the development of a short course or mini-module can provide the opportunity to build relationships with industry and the community, to focus on broader or more holistic themes that may help students tie together their academic knowledge and experiences, to provide staff and students at different institutions the chance to collaborate in new ways, and to trial innovative pedagogies and technologies.

2 CONTEXT AND LITERATURE REVIEW

Over the past two years, an educational alliance has emerged between Edinburgh Napier University (ENU) and the New Model Institute for Technology and Engineering (NMITE) located in Hereford, England. Given the track record of ENU in timber construction and wood science research, the relationship is centred on co-developing a timber technology, engineering and design educational programme aligned with the NMITE integrated and challenge-based learning ethos. ENU and NMITE aim to leverage these roles and institutional strengths to develop a mutually beneficial strategic partnership that brings together staff, students, industry, and the community to create impact beyond traditional learning approaches. Besides creating learning opportunities for students and staff, this alliance also has the potential to create financial and reputational advantages to both institutions. One of the actions taken to strengthen this partnership has been the development of a Sustainability Enrichment Week for students in ENU's MSc Environmental Sustainability programme hosted in Hereford by NMITE's Centre for Advanced Timber Technology (CATT).

The theme of Sustainability was chosen not only because of its intrinsic importance; it was also a theme that unites the mission of the the CATT (to promote innovations in timber technology and engineering that lead to sustainable construction) with content in the ENU programme, which contains modules such as water and waste management and building energy performance. The Sustainability theme was also broad enough that it enabled interaction with several companies and organizations that might not ordinarily consider partnering with an engineering programme, leading to new potential avenues of engagement and support for both universities. Additionally, Sustainability could easily be linked to the modules in NMITE's Master's in Integrated Engineering (MEng), meaning that learning experiences could be developed that benefited students from both NMITE and ENU and could be delivered collaboratively with faculty from both institutions.

Rationale for development of this themed mini-module rests in recent scholarship in several areas. Firstly, using sustainability as a theme can bring students and staff from different backgrounds together for a common goal [1]. Indeed, learning about sustainability in a way that is not dependent on specific technical knowledge and that speaks to integrated, interdisciplinary solutions will be increasingly important in both engineering education and for achieving breakthroughs in sustainability. Secondly, given that Scotland and England have two different higher educational systems, this experience can fall under the umbrella of Transnational Education. Research on students who engaged in short-term study abroad has shown that even these brief experiences can be effective at achieving higher-order learning outcomes [2]. Thirdly, more effective industry and community engagement can be fostered even through these short, intensive sessions [3]. Fourthly, faculty who are involved in these types of short-term study activities have viewed them as a professional development opportunity due to the difference from the roles they play and interactions they typically have in a confined classroom setting [4]. Finally, while there is not as much research about these types of non-graded enrichments weeks that sit outside the proscribed curriculum, there is anecdotal evidence to show that students find these opportunities a valuable part of their educational programmes [5].

Based on this research, several aims of the Sustainability Enrichment Week were articulated to address the needs and expectations of a variety of stakeholders:

1. To enhance knowledge exchange between institutions via ENU's School for Engineering and the Built Environment and NMITE's Centre for Advanced Timber Technology, and between each institution's industry and community partners;
2. To provide a template for further staff/student mobility that enhances learning opportunities for both groups;
3. To promote, develop, and further deploy NMITE's interdisciplinary and experiential pedagogy that is an innovation in engineering education;
4. To create learning opportunities that bring together people from diverse backgrounds, bridging international as well as urban/rural divides;
5. To contribute to efforts that advocate for socially and globally responsible and responsive engineering.

2.1 Determining Student Outcomes

After agreeing upon aims of the Sustainability Enrichment Week, it was necessary to determine what outcomes could be most beneficial and desirable to students registering on this extracurricular module. An informal review of the modules in ENU's MSc Environmental Sustainability revealed that they contain rigorous content in specific subject areas like waste, water, energy, and construction, but it was less clear how the modules worked together coherently to result in a holistic professional approach to and understanding of environmental sustainability. Since NMITE's curricular approach is based on learning taxonomies that culminate in synthesis (tying together knowledge) and phronesis (whether or not knowledge or action is wise or valuable), it became clear that the enrichment week activities should focus on professional competencies in sustainability that stretch across and beyond technical disciplines to encompass these higher-order concerns.

Therefore, it was decided that the outcomes of the enrichment week would be to develop skills in the five sustainability competencies as promulgated by Arizona State University's School of Sustainability: systems thinking, values thinking, strategic thinking, future thinking, and collaboration [6]. Each day in the week was to focus on one of these competencies as a learning outcome, and contain a variety of interdisciplinary, experiential activities to support that learning.

2.2 Determining Module Activities

The construction of the Centre for Advanced Timber Technology building allowed for a specific case study through which to frame the week's activities. The building is a 2,500m^2 purpose-built educational facility that reflects the NMITE pedagogical approach and combines it with the capability to service the needs of the growing timber engineering industrial sector. On this basis the building is a "Living Lab" creating the necessary conditions for research to be undertaken on the building itself and the innovations created within it. Formed as a hybrid structure combing cross laminated timber, glue laminated timber, closed panel timber systems and steel braced and portalised frames, the building is measured and monitored utilising sensors and digital technologies acting as an ongoing educational toolkit. Since construction was being completed in spring 2022, this building site enabled the sustainability enrichment week to focus on the interfaces between buildings, humans, and nature. It also provided real-world experience and engagement with timber and monitoring technologies, construction management, and place-based learning.

For instance, in a day themed around the outcome of Systems Thinking, activities included: an introduction to the Living Lab building monitoring system; a tour of the CATT building construction site with its project manager; a lunch and learn session with the Sustainability Lead of the construction company; a workshop on environmental impacts within construction supply chains, and a seminar to reflect on the variety of systems involved in products, buildings, and communities.

This combination of learning, doing, exploring, and reflecting allowed for a multidimensional perspective on the systems thinking outcome, and showcased how systems thinking is required by real-world professionals in authentic situations. These activities also had a dual purpose: not only did they help achieve the aims of the sustainability enrichment week, but they also served as a testing ground for some of the content in NMITE's Timber Technology, Engineering, and Design course now in development.

3 RESULTS

Some uncertainty surrounded the initial development of the Sustainability Enrichment Week: it was unclear if and how students would respond to the opportunity, or if administrators and industry/community partners would be supportive. Additionally, there was little time for planning since the idea was developed in mid-February 2022 and executed in mid-May 2022. However initial conversations with various stakeholders were uniformly positive, and 6 staff from ENU and 6 from NMITE participated in various activities, with 8 companies and organizations outside the universities also being involved.

15 students attended the enrichment week, and these represented diverse demographic backgrounds. Some of the students had never before been to England, and most had never been to rural parts of the country. This group engaged with a cohort of NMITE's MEng students, which created another opportunity for students from both rural and urban and local and international backgrounds to interact.

Students were asked to fill out a pre-survey and a post-survey in order to elicit a comparison between their existing understanding of the sustainability competencies and their understanding after engaging in the week's activities. 8 students completed the pre-survey and 9 students completed the post-survey; in both cases they rated their own knowledge on a scale of 1 being the lowest and 5 being the highest. Table 1 provides averaged results from the surveys which indicate that knowledge increased across all 5 competency areas:

Question	**Pre-Survey Average Rating**	**Post-Survey Average Rating**
How would you rate your understanding of **values** (that is the principles, attitudes, and qualities related to concepts of justice, equity, and responsibility)?	4	4.78
How would you rate your understanding of the **connection between values and sustainability**?	4.25	4.78
How would you rate your understanding of **futures thinking** (that is, the ability to anticipate how problems might evolve or occur over time)?	4.25	4.67
How would you rate your understanding of the **connection between futures thinking and sustainability**?	4.38	4.67
How would you rate your understanding of **systems thinking** (that is, the way that problems cut across different systems and domains of knowledge)?	3.88	4.67

How would you rate your understanding of the **connection between systems thinking and sustainability**?	4	4.56
How would you rate your understanding of **strategic thinking** (that is, how intentional plans and deliberate coordination can be leveraged to achieve transformational goals)?	4.25	4.67
How would you rate your understanding of the **connection between strategic thinking and sustainability**?	4.13	4.56
How would you rate your understanding of **collaboration** (that is, how communication, leadership, empathy, and negotiation can achieve goals)?	4.25	4.78
How would you rate your understanding of the **connection between collaboration and sustainability**?	4.63	4.78

Table 1. Comparison of student's self-rated understanding of sustainability competencies before and after the enrichment week.

These results demonstrate that even a short week of experiential learning can achieve significant gains in student understanding. Additionally, 100% of survey respondents said they would recommend the experience to another student.

4 CONCLUSION

The development process of the Sustainability Enrichment Week has been effective in terms of encouraging knowledge exchange between two universities and their industry and community partners, recruiting diverse students, and developing unique integrated and experiential learning opportunities that promote student and staff mobility. These learning experiences have shown to increase student understanding across five sustainability competencies.

The Sustainability Enrichment Week was developed by capitalising on what was already happening in the two institutions and leveraging existing resources and relationships. It took a themed learning approach that was not dependent on specific technical knowledge and that spoke to integrated, interdisciplinary approaches which will be increasingly important in both engineering education and achieving breakthroughs in sustainability. It got a lot of people within and beyond the universities excited about this work, and introduced students to a variety of perspectives and potential career paths. The experience in developing the Sustainability Enrichment Week can serve as a template for other institutions seeking to achieve similar aims.

ABSTRACT

Pedagogical developments in the virtual learning environment (VLE) are constrained by technical expertise which impacts the design and delivery of online learning, including the implementation of varied feedback strategies. In recognising this dilemma, the paper addresses the question, *"What are the technical and pedagogical challenges of implementing feedback strategies in a VLE?"* This short paper presents an initial critical, reflexive account on the challenges to embed and manage feedback strategies, including automatic feedback, peer feedback, and tutor-led feedback, on the VLE of a blended module provided to over 1,200 engineering and business students at a UK university. As a result, the authors recognise the importance of upskilling engineering educators to technically innovate

their VLEs to enhance student learning and connections through feedback. Further investigations to evaluate the impact of the varied feedback strategies on student learning will occur at a later stage in order to advance this work in progress.

1 INTRODUCTION

The Covid-19 pandemic has renewed interest in the development of feedback practices in a virtual learning environment (VLE) [1]. Yet engineering educators face barriers to implement a variety of feedback strategies, including automatic feedback, peer feedback, and tutor-led feedback, in online learning spaces. Therefore, this short paper addresses the question, *"What are the technical and pedagogical challenges of implementing feedback strategies in a VLE?"*

Feedback is important for student learning, because it can "raise students' consciousness of the strengths of their work, boost students' confidence and self-concept regarding personal strengths and abilities, provide guidance on areas for further development of skills and enhancement of work, [and] enhance students' own judgement, understanding of assessment criteria and ability to self-audit their own work" [2]. In addition, embedding a variety of feedback strategies is significant for curating a dynamic environment that facilitates flexible learning, individualisation, and connection. However, pedagogical justifications for feedback are compromised by a feasibility to manage resourcing of feedback provision and a technical ability to implement different feedback strategies. This is the case for the design of a VLE for a blended module on transferrable skills and research methods provided to over 1,200 postgraduate engineering and business students at a UK university.

The scope of the paper is on the feedback strategies implemented on formative learning activities embedded in the module's VLE. These activities are accessible to over 1,200 postgraduate students across 20 unique sessions delivered on a weekly basis. The activities were created and managed by the four authors who form the module teaching team. This high student-to-teacher ratio is a constraint that intensified the challenges of pedagogical and technical design and delivery of feedback.

This short paper is a reflexive account by the authors on facing and resolving challenges to embed varied feedback strategies in a VLE for a large student cohort. By presenting initial findings that interrogate the tension between pedagogy and technology, this work in progress provides initial suggestions for engineering educators who seek to innovate their VLE and enhance student learning.

2 METHODOLOGY FOR PROVIDING FEEDBACK IN A VLE

Five feedback strategies were employed on the VLE of the module. These include: (1) *'No virtual feedback'* for activities in which feedback was delivered outside of the VLE (e.g. a poll to engage students to see how their responses compare with other students). Another strategy was automatic feedback, or when feedback was provided immediately following the completion of an activity, and was divided into two categories. (2) *'Automatic feedback – quiz'* is contrasted with (3) *'Automatic feedback – response available',* as the former is individualised feedback based on incorrect responses while the latter is a 'good example' provided to students after activity submission to enable critical comparison. (4) *'Peer feedback'* includes forum activities in which students respond to other students' posts. This enables student learning communities to form online. Finally, (5) *'Tutor-led feedback'* is the provision of personal feedback on an activity by a member of the teaching team. This is important for creating connections between students and staff. Since the focus of this short paper is on feedback strategies in a VLE, *'No virtual feedback'* will not be discussed here. Nonetheless it is significant since in a blended module, feedback is also provided in a synchronous, face-to-face environment.

Each feedback strategy had its own unique benefits to support the different learning needs of students and enable connections between student and student, or student and teacher. Further, different feedback strategies may be more sustainable considering tutor workload at a time during module delivery. For instance, during an intensive work period in which the teaching team was reduced from four to two individuals, it was only feasible to provide automatic feedback since there was no flexibility to provide or technically support alternative forms of feedback.

To account for the number of feedback strategies employed on the module VLE, a frequency analysis is presented in Table 1, below. There were 85 formative learning activities on the VLE split across 20 asynchronous sessions. All 1,200 students could access these activities, though not all students completed them since only some of these students completed the module for credit. The number of activities varied across sessions; this caused concern about student workload. Hence, in response to mid-module feedback, the number of formative activities decreased for sessions 15-19 to enable deeper learning and higher engagement. Consequently, the number of opportunities for feedback on formative learning activities was also reduced as a result of this change in response to mid-module feedback.

Table 1. Feedback strategies employed in the module VLE

Feedback Strategies						
	No virtual feedback	*Automatic feedback -*	*Automatic feedback –*	*Peer feedback*	*Tutor-led feedback*	

		quiz	*response available*			
No. of activities	16	47	15	6	1	N = 85 (100%)

It is noticeable that *'Automatic feedback – quiz'* appears more often than other forms of feedback. This reflects the over-reliance of the teaching team on one form of feedback due to the technical ease of using an online quiz to provide feedback on student learning. In contrast, *'Tutor-led feedback'* did not occur frequently due to concerns that marking individual submissions and providing personalised feedback to scale would compromise the workload of the team while removing flexibility of student learning by imposing a deadline for submission.

3 CHALLENGES TO IMPLEMENTING FEEDBACK STRATEGIES IN A VLE

3.1 Balancing pedagogy, workload and technical ability

In analysing the reflexive accounts of the teaching team, a key dilemma to implementing various feedback strategies was balancing pedagogical design with academic workload and technical ability. For instance, a challenge of tutor-led feedback was managing the high student-to-teacher ratio on an online platform. While there are technical solutions for reducing feedback administration time, such as embedding a standard rubric to the VLE or viewing student submissions online rather than downloading, providing individual feedback en masse severely compromised the workload of the team. While a justification can be made for generating feedback by artificial intelligence [3], the extreme workload to provide individual, tutor-led feedback in the absence of technical confidence supported the design of *blended* learning in which synchronous, face-to-face seminars, drop-in sessions, and office hours offered the opportunity for tutor-led feedback.

The lack of technical ability by the team meant there was limited use of software and applications to create multiple modes in which feedback was communicated to enable students to select feedback relevant to their skill level and/or learning style. For instance, the team frequently utilised automatic feedback that was relayed in standardised text. This meant it was not possible to alter the vocabulary or meaning of the feedback to ensure it was understood by all students [4]. Therefore, upskilling educators on how to create and embed automatic feedback in creative ways, such as audio and/or video recordings, and pitched at different levels of knowledge, can enable students to select how they best learn [5].

3.2 Problematising student learning and connection

To support student learning, it is important that students engage and learn from feedback. However, in an online environment where students can move freely through activities, it is possible that students are not engaging deeply. For instance, in analysing the data on the time duration taken to complete a quiz, the tutors identified students who purposely failed a quiz to quickly receive the correct answers, so these can be inputted as fast as possible in order to complete the activity. Technical design can resolve this by reducing the number of attempts available to pass a quiz. Yet, while it appears students are moving quickly through activities as part of surface learning, there is no data available on how students engaged with the feedback. For instance, it was not clear if students moved quickly through the activity to spend more time with the feedback in order to learn from ‘correct’ or ‘good’ answers or how students applied this feedback to their future learning and practice. Hence, this work in progress plans to undertake further evaluations to explore student literacy of feedback in a VLE, as well as the unique influence of each feedback strategy on student learning [6].

Peer feedback is a means to develop virtual learning communities and a sense of belonging through frequent interactions that build student connections. This is important since students with a higher sense of belonging are more motivated to engage and learn, and therefore achieve [7]. Yet these positive outcomes were undermined by a lack of technical ability of the teaching team to create multiple small groups of students. As a result, each forum was shared by all students; this weakened the formation of meaningful and stable student connections due to the large class size. Therefore, technical upskilling also concerns an ability to manipulate organisational settings of the VLE, such as establishing unique user groups that exist across peer activities, to improve student connections.

Furthermore, while guidance was provided to students on how to give peer feedback on posts, this did not mean the guidance was followed, since forums are assessed on participation and not learning. To overcome this technical challenge, a pedagogical solution is to provide a marking checklist or rubric to enable depth and consistency to peer marking that can be embedded in the VLE for common use. This can enhance learning since expectations to the application, analysis, and evaluation of knowledge in the activity are clarified for students.

4 CONCLUSION

This short paper provides a reflexive, critical account of technical and pedagogical challenges to implement varied feedback strategies in the VLE for a module with a high student-to-teacher ratio. A key theme is the need to upskill educators on the technical capabilities of VLEs and use of accompanying software and applications, so the design of feedback is based on pedagogical innovation rather than technical comfort. For instance, resolving the team's over-reliance on text-based automatic feedback by ensuring time is made available for prototyping and testing feedback strategies so they can be embedded within the learning design. Enhancing the technical skills of engineering educators to innovate their VLE would benefit students' deeper learning. Also, in the case of this transferrable skills and research methods module, it would improve the quality of the learning experience, so students do not spend most of their time applying their knowledge in independent activities that receive monologic feedback.

Furthermore, greater consideration must be made to sustainable feedback that does not compromise the workload of the teaching team and students. Hence, when testing feedback strategies in a VLE, it is important to consider the time needed to create and disseminate feedback, particularly in regard to the quantity and quality of feedback provided to students throughout the module. Also, the decision to use one feedback strategy over another will be made following further evaluation of student preferences for, and impact of, different feedback strategies on student learning in the VLE. Therefore, this work in progress will extend these initial suggestions through further evaluation of the online feedback strategies on student learning and connections in order to advance engineering education.

ABSTRACT

The study investigates and reports on the process of engagement in learning through the innovative pedagogical framework – Challenge-based Learning (CBL) – their changing perspectives of learning and their interaction with each other while conducting authentic challenges. This gives way to understanding how learners construct and create meaning out of learning activities, course content and beyond the course objectives. Our mixed method research explores potential impact dimensions of the implementation of challenge based learning on teachers and students. To reveal the potential impact we conducted a focused group interviews with the learners who took part in CBL-integrated lessons and surveyed 68 number of learners who participated in CBL trainings. Our preliminary findings showed that learners undertook news roles by driving their own learning, developing collaborative skills, exploring knowledge to be acquired, and establishing relevance of course content in real contexts which made it meaningful for them to understand. In our presentation, we would like to discuss the implications of CBL implementation on the way higher education can be redesigned by assigning learners a more active role in learning and the engagement that occured during their learning experiences.

1 INTRODUCTION

1.1 Why Challenge-based learning?

With long-standing experience and successful implementation of problem-based learning (PBL) we propose in this paper that the PBL concept should be taken one step further to strengthen modern European higher education institutions, instigating the pedagogics of challenge-based learning (CBL) together with external stakeholders to foster learner engagement and at the same time building communities by utilizing authentic challenges into the learning process. The difference between PBL and CBL is its strong emphasis on the opportunities to investigating real immediate world problems, the focus on the process and skills that they can then apply beyond the challenge and their education. While PBL´s aim is to identify diagnostic problem and the process or working out the solution, CBL addresses "societal challenges" and sustainable societal goals with engineering and business development (Malmqvist et al., 2015).

1.2 Definitions of CBL

Challenge-based learning (CBL) is is `a multidisciplinary approach that encourages learners to work actively with peers, teachers and stakeholders in society to identify complex challenges, formulate relevant questions and take action for sustainable development´ (Rådberg et al. 2020, p. 21). It follows a specific structure, which consists of three main steps: engage, investigate and act (Nichols et al., 2016). Implementation of CBL is recommended in engineering education to allow for combining technology, principles of modern industry, and at the same time skills of communication that are personalized, collaborative and relevant to the needs of society (Conde et al., 2017; Membrillo-Hernández et al., 2021).

1.3 Purpose of the study

This is an inquiry to look into the participation of UiS students partaking the challenge-based learning initiative where the main purpose is to investigate their collaborative work and engagement during the challenge-based learning experience. Beside their weekly regular lessons, all team members which consisted of learners, CBL experts, and external stockholders met and worked on the CBL project once a week over the semester period of three months. They also had several appointments with the stakeholders to collect information for developing their solutions. The challenges developed by the learners were, for example, sustainable digitalisation, food waste, sustainable construction industry, efficient army resources, and efficient warehouses. Each of the three main steps consists of smaller activities, 1) Engage: Big Idea; Essential Questions; The Challenge, 2) Investigate: Guiding Questions Guiding Activities and Resources; Analysis, and 3) Act: Solution; Implementation; Evaluation and Publishing. We can see that these challenges require multidisclinary efforts from innovative insights from all fields of study.

2 METHODOLOGY

2.1 Research objectives

The study employs a questionnaire survey and interviews as the methods of data collection. The aim is to reach the two following research objectives:

- To investigate the learning opportunities and engagement perceived by the CBL learners and teacher assistants during and after the trainings

- To provide pedagogical implications for CBL educators and recommendations for future trainings schemes

2.2 Participants

The first sampling was 68 Bachelor-level students who applied the ECIU challenge-based learning initiative in their project in a 9-ECTS course titled *Information and Technology Management* arranged by the University of Stavanger. They were contacted either through the CBL expert, or their advisor to complete our questionnaire survey. The second sampling consisted of five learners in the team, two students who expressed their interest in partaking in the interview and three teacher assistants.

2.3 Research instruments

A survey The survey took 15 minutes to complete. It had 4 questions that asked for name, department and whether they were an international or a local learner. The survey questions were divided into 2 parts, with the total of 21 questions. It had 5 scales, ranging from `strongly agree´ (5) to `strongly disagree´ (1).
An Interview The interview consists of around 10 questions. It took approximately 45 minutes per interview, and they were recorded. The interview included open-ended questions about their learning experience during the challenge. Because in CBL all participants are considered learners and life-long learners, the teacher assistants were included to be interviewed about the process of learning as well.

3 RESULTS

3.1 Survey results

The results in the first section will be presented in the following seven constructs distributed in the 20 questionnaire items. The learners´ perceptions of their CBL learning experiences. The result trends were found to be positive.

Table 1. Average perceptions of learners during the CBL engagement

Clusters	Average
Roles and engagement (defined, changed)	3,27
Feedback	3,4
Knowledge in CBL	3,4
Abilities gained during learning process	3,8
Interpersonal skills and team working	3,96
Knowledge in content of challenge	3,6
Real-world learning	3,3

Most leaners reported that their roles during the process of CBL were clearly defined but they were allowed to change the roles during their interaction with other team members. The learners found the feedback they received from their peers, the expert and the stakeholders to be equally helpful. They reported to learn about how to undertake challenge-based learning quite well and that they gained knowledge and skills and abilities from working on the challenge. Their interaction during CBL was reported to increase their interpersonal skills quite a great deal. Their knowledge in the content of the challenge was found to be high but they reported that real-world learning was just above average.

3.2 Interview results

In the following section, we will present the codes, categories and themes of the data base on our interpretation of the extracts. Ultimately, we have found three main themes from the overall analysis as follows.

Theme 1 Cognitive engagement

- Prolonging problem-solving process
  ´It's still really good to focus at the beginning or not rushing to the to the solution and really looking at the problem from all perspectives and bringing everybody in your team with their backgrounds and their skills too. (TA1)
- Personalising learning experiences
  It was also related to public policy and community asset development and my work background is in public policy because I worked in London for over 8 years in public policy rules for UK Health department.´ (TA3)
- Relating skills to CBL process
  So we have to make a connection between our knowledge or two hour course and our materials with the CBL process and also with the real world companies that we are working with their challenges or problems they're facing. (TA2)
- Constructing own understanding
  But in this CBL process, the main thing is no. Now it's not at the starting point. You don't have to think about solution that please first think about your problem. Think about the situation you are in. (TA2)
- Associating with life-long learning
  ´You have to zoom in your problem. And yeah, then you got the idea where you can implement a solution. OK, yeah, so that's what we also learned with the students and it was a really great experience and we are still learning. ´(TA3)
- Risktaking
  ´I wanted to meet and explore a lot of things, so I accepted the challenge. I applied for it and it was really really good because I was only there and actually I didn't know exactly what I'm I was there for, which was really interesting.´ (ST2)

We can see that the teacher assistants, as learners, stress that the process of CBL allows for cognitive engagement in different ways. One mentions that it occurred by prolonging the process of finding solution as long as possible, which is the principle of CBL to not jump to the conclusion quickly. In CBL, all members work as a a community of practice, to utilize their content knowledge and negotiate through different approaches to find possible solutions. This foster their capabilities of constructing their own understanding beyond classroom.

Theme 2 Social engagement

- Collaboration
  ´Collaborating there can actually create a real business proposition and online companies and leave it with all these connections and and new knowledge to go and make a difference in the in the real world as well.´ (TA1)
- Teamwork
  ´And all the members and how we just fix, you know the teamwork and CBL really help us to guide us´ (ST1)
- Learning environment
  ´Go with fellow for us, so that's why we were so motivated and the environment of the people actually help us because we were always discussing and adding, having more perspectives and was like the flexibility.´ (ST2)

The students and the teacher assistant reported that their contact with group members and external stakeholders brought them with experiences which facilitated their exchange of knowledge about business and real-world issues related to their studies. They reported that their CBL experiences led them to relate to the mechanism of group work and thus utilize this mechanism in this group work.

Theme 3 Connectivist engagement

- Relating theory with real life
  ´Actually read the materials and the professor actually give us some structure that that that's how the theory says you can do that.´ (TA2)
- Putting knowledge into immediate practice
  ´Organizations are national and local level on data on policy and how they can improve things like for example, waiting times in exit emergency. ´(TA1)
- Multidisciplinary collaboration
  ´really good because it's like a real challenge and we can integrate our knowledge and then get more new perspectives from the others.´(ST1)
- Sense of self-development
  ´We can integrate our knowledge and then get more new perspectives from the others. And that's what I really want. And I I'm here to try to actually expand my mindset as well.´ (ST1)

The learners reported the benefits of CBL as to contribute their ability to connect knowledge, skills and practice. They refer to their content subjects and how CBL can help them relate and integrate what they learned in new perspectives with the content interaction and current issues at hand. Potential advantages stem from their CBL experience when it is in combination with other theoretical perspectives (Leijon et al., 2021; Tang & Chow, 2020).

4 SUMMARY AND ACKNOWLEDGMENTS

These results indicate the importance and value that CBL can help place on the learner´s experiences while becoming prospective future workers. Higher education institutions should provide facilities with availabilities of learning environment, materials, technologies and social resources and trainings or teachers to become confident coaches and students to be self-directed learners (Pepin & Kock, 2021). During interaction in class and beyond, the facilitation of learning and opportunities to explore issues are needed. As educators in higher education, we ensure that facilitation of positive engagement, such as these ones are established. Activities that can contribute to learners' sense of trust, collaboration, shared educational achievements should be provided. We have also learned that students should be encouraged to engage in CBL integrated learning in multidimensional manner. With CBL, we can maximise meaningful interaction amongst themselves and with the experts. Interaction with stakeholders can provide real-world context-specific perspectives. This is found to be highly vital especially development of soft skills for students in the fields of hard sciences. Lastly, learning activities such as CBL can provide space for students to reflect critically on the challenge and their own learning.

ABSTRACT

Project and challenge-based learning typically require students to navigate personal and professional relationships within a team, in order to collaboratively solve authentic problems. These collaborations are often interdisciplinary in nature – an arrangement that adds increased complexity to the team's functioning. This is due to distinctions in approaches, epistemologies, ethos or jargon. The ability to provide (and receive) appropriate and constructive feedback to peers, within the team, is a key skill that can enhance team functioning and ultimately, output. Furthermore, it is a competence that aids in lubricating social and work impediments that may be causing bottlenecks to creativity, or the manifestation of ideas. The aim of this study, set within three different interdisciplinary bachelor modules, is to determine to what extent the use of the 'Buddycheck' application for peer review, is appreciated by students and teachers. The application, hosted within the learning management system of the university, allows students to rank their peers' performance according to teacher-set criteria, as well as through flexible open-format feedback; in order to facilitate opportunities for enhanced communication and expectation alignment. We wish to ascertain to what degree team functioning is enhanced through the scaffolded communication opportunities, by highlighting and creating openings to discuss undesirable behaviours, through the feedback application. Preliminary results appear to favour this mode of feedback facilitation, albeit with certain caveats,

detailed later. Since teamwork is universal in tertiary education, these insights may be helpful for educators attempting to further improve the evaluation of the process of their projects or challenges.

1 INTRODUCTION

Teachers implementing project and challenge-based education, use collaborative teamwork as a conduit to facilitate, and practically apply, some of their intended learning outcomes. Cooperative or collaborative learning in tertiary settings is well established, as the knowledge, skill and cognitive benefits surpass alternatives such as individualistic or competitive learning [1],[2]. However, students working in teams can experience encumbrances such as unfair distribution of work or group process deficiencies [3]. Specifically, poor communication and free riding are noted as common deficiencies. Peer feedback on process and behaviour - not to be confused with peer feedback on tangible contributions, such as quality of written submissions - can encourage students to become self-analysing reflective learners [4]. Therefore, a facilitation mechanism where giving and receiving constructive peer feedback on team process and behaviour, could plausibly assist in mediating the above issues. This could be by opening avenues to personal development and, hopefully, improvement of individual conduct. It must be noted however, that the perceived credibility of peer feedback is mixed; some researchers indicate it may act as a deterrent to negative behaviour; but timing and frequency are crucial[5] thus must be opportunely planned. Further, there has been doubt cast on whether students are completely honest when giving feedback [6], rather choosing to temper their complaints and protect the team dynamic and maintain the status quo [7]. From an instructor's perspective, gaining evaluative or developmental insights from the peer review reports can be a valuable resource to draw upon when allocating rewards or identifying key moments to intervene [8]. With the above factors in mind, a trial was implemented to discover: 1) to what extent the peer-review application 'Buddycheck' was seen as useful to enhance team functioning (i.e. facilitate communication discord, etc.) within student groups; and 2) to what extent information gleaned by tutors from the feedback application was considered useful for evaluative or developmental purposes.

2 METHODOLOGY

2.1 Case study setting

Three interdisciplinary modules (15 European Credits) working on either challenge-based (societally linked) or project-based (authentic) assignments, incorporated the peer-review application (PRA) into their processes. The PRA enables students to rank their peers (from one to five, with clear descriptors) on teacher-set criteria (e.g. work ethic, communication, etc.) and give open feedback (a tip and a top) for each of the team members, on their unique contribution. The peer feedback opportunities were offered mid-way, allowing students the opportunity to reflect and improve, as well as near the end of each module. On both occasions, students were prompted to complete the forms. Furthermore, students were offered feedback skills scaffolding, in the form of either information slides, videos or micro-workshops, in order to practise and improve their feedback abilities.

2.2 Case study instruments & data analysis

Instrumentation: digital surveys were sent to all students of the 3 modules (see *Table 1*). The pertinent part of the survey consisted of 4 agreement statements (Likert scales). Furthermore*,* open-question answers from the PRA were collated. Tutor perspectives were gained from interviews or open question surveys. *Analysis*: open answers from the PRA and tutor perspectives underwent thematic analysis (separately), where recurring themes were grouped and defined (see *Table 2*). Poignant quotes of each theme are provided for reference to illustrate the range of student and tutor-themed perspectives, see results section.

Table 1. Summary of Cases and Data Sources.

Case Study and Module Details	**Student Survey Response**	**(Feedback Skills) Scaffolding for Students**	**Peer-review Application (Open Question)**	**Survey (Likert)**	**Tutor Perspective**
Case 1: Mathematics & Computer Science *N=280* *Year:2020/21*	*N*=47 (17%)	Self-directed slides	*N*=155 (55%)	Yes	N/a (no tutors)
Case 2: Engineering, Design&Management *N=380* *Year:2021/22*	*N*=56 (15%)	Self-directed videos	n/a (No open question)	Yes	Survey
Case 3: Multiple Discipline Minor *N=42* *Year:2021/22*	*N*=12 (29%)	Micro-workshops	*N*=24 (57%)	Yes	Interview

3 RESULTS

Our findings are summarised below, in *Table 2*. It shows the range of perceptions about the PRA, for both students and tutors. The students from the different modules had a range of value perceptions for the PRA, but were mostly positively inclined. Tutors, too shared positive to mixed perceptions of the PRA.

Table 2. Summary Table Student & Tutor Perceptions of Peer-review Application

	Case1	**Case2**	**Case3**
Students' Themes			
Likert Survey			
Useful for team	*N*=33 (70%)	*N*=31 (54%)	*N*=11 (82%)

Positive Perception	-	*N*=7 (58%)	*N*=3 (50%)
Mixed Perception	-	*N*=4 (33%)	*N*=3 (50%)
Negative Perception	-	*N*=1 (8%)	0

Sample responses of the students and teachers illustrate the positive, neutral and negative perceptions, below. Generally, students had more positive than negative comments on the PRA.

Positive perception - Students

"I believe the BuddyCheck was useful in two ways. First of all, I was able to better formulate feedback for my teammates. The Buddycheck allowed me to think about the project on a

deeper level then I normally would be, working in a team. Providing my teammates with good feedback enables them to improve their work and keep the team going forward. Working on the project goes smoothly and the quality of the final product is much better when we as a team have a good understanding of each other's ideas. Secondly, I can better orientate myself with the feedback my team provides me with. That way I can work on improving my weak skills much better as they would be pointed out by my team members."

Neutral perception - Students

"I don't feel like it impacted team functioning much either way."

Negative Perception - Students

"I see no use in using Buddycheck, it doesn't hinder progress. However, it seems kind of redundant, either a team member is responding just fine, in which case it seems like an awful idea to indirectly tell them: "Hey, you're doing a bad job" I think that's really bad for group chemistry. If a group member isn't responding, that's a different story, but I would assume people would instantly message one of the project organizers about it, instead of saying it via here. In short, giving each other indirect feedback seems like a great way to create a toxic environment during the project. Encourage direct feedback and a good healthy group environment where problems are quickly sorted out instead of building up only to find out via this buddycheck system."

Positive remarks - Tutors

"Useful, helps for students to consider their own work / contribution in context of others, and helps me in assessing if my own impression of group members is correct."

Neutral remarks - Tutors

"Useful in theory, but it's not by definition a representation of the actual perception of student's peers within their group. Students might tend to be too optimistic or 'soft', to not lose fragile team dynamics."

Negative remarks - Tutors

"Not very good. Although it could be useful for the students, as tutor it was more of a hassle than actually helpful."

With regard to tutor perceptions, the majority found it a useful addition that helped them gain insights to their teams; some even used the information to guide or justify feedback. However, some tutors felt that the students held back from openly criticising their peers, even when clear offences were committed. This is despite student training and encouragement to provide constructive feedback.

4 CONCLUSIONS & DISCUSSION

We conclude that across the three studies, the PRA is considered a useful tool. Either as a starting point for a conversation about team behaviour, an option as a formal and relatively safe space to express oneself, or as a means to gain insight into how peers perceive one. With regard to the application alone, making a large impact on the team functioning, there is less conviction. Highlighting the need for further process support from educators. This can be in the form of targeted skills training; mediation meetings with tutors, and making the consequences of poor performance more explicit. To summarise, simply assigning the PRA to a course as a panacea to resolve team issues is unrealistic, rather this type of aid is more beneficial when used in conjunction with well-considered soft skills support and process scaffolding with a tutor. Further, there are indications that some students remain reluctant to be completely honest when sharing negative feedback; this is in line with other studies. Educators must therefore be cognisant of this when allocating points based on peer assessment. For tutors, the PRA is mostly considered useful to gain insight into the inner workings of the team, as a reference for intervention, as well as a resource for feedback.

through identical syllabus and assessment practice but are taught locally at each campus.

The authors had noted some frustration among the teachers involved in these courses, and were interested to investigate the reasons for this frustration, and ultimately to inform the development of these multi-campus courses.

This project emerged from a realisation that literature on multi-campus courses is often associated with distance learning, while in this case, the actual teaching is provided locally. Concepts associated with teacher collaboration, such as collaborative culture versus contrived collegiality, collective versus fragmented collaboration, and depth of collaboration seem like a viable way forward in understanding the dynamics between teachers in a context like this.

In this paper, we present early results from this ongoing project, which include interviews of teachers involved in these physics/chemistry courses. Preliminary results from these interviews suggest that the expressed frustrations stem from contrived collegiality. Although the teachers experience sufficient freedom in terms of choosing their own teaching methods, several teachers raise concerns about the lack of common aims for this course cluster, which reduces collaboration to coordination of mere practical tasks.

1 INTRODUCTION

At a European multi-campus university, parallel study programs such as engineering and nursing studies are offered at every campus. The appurtenant courses are coordinated, to ensure similar quality and systematic development. How these courses are coordinated and organised differs - some courses have joint lectures and identical course content for all students and appear as one course, while others only have the syllabus in common. As these multi-campus courses are fairly new to the university, and also scattered across different faculties, there are few regulations and structures to support course development.

The organisation of these multi-campus courses has been developed independently across the different study programs. This has made way for a flexibility in terms of tailoring courses in accordance with aims, scope and external conditions. However, this also means that teachers, who have been used to working in solitude, find themselves in a collaborative state, with potentially little structure to guide their collaboration.

In this paper, we present a case from such a multi-campus course, consisting of a cluster of basic courses in physics and chemistry for first-year Bachelor engineering students. These courses are coordinated from the university's vice-chancellor level, with requirements to develop identical syllabus, assessment practice, and to use the same learning management system. However, the courses are *taught* locally at each campus. To meet these requirements, the teachers involved in these courses have regular digital meetings all through the academic year, where frequently visited topics are course content, mandatory exercises and assessment practice.

As colleagues of some of these teachers, the authors had noted some frustration regarding the collaboration, and we wanted to investigate the reasons for this, to inform further development of this course cluster. Six of the teachers involved in the physics and chemistry course were interviewed individually, to investigate and gain deeper insight into how the collaboration is organised and perceived by the teachers. Ultimately, the case presented here is part of a larger project that will investigate how multi-campus courses in general are organised and perceived, as a basis for further informed development.

2 FRAMEWORK

The term multi-campus teaching is often associated with remote (digital) teaching [1], some exceptions aside [2], whereas the teaching in the case described here is provided locally by teachers at each campus. Therefore, perspectives and concepts associated with teacher collaboration may offer valuable insights and provide explanations to the challenges that collaborative teachers may face that are not primarily rooted in geographical distance.

Teacher collaboration is seen by some as a prerequisite for realising the aims of students acquiring collaborative competence [3]. Furthermore, teacher collaboration is associated with increased self-efficacy among teachers [4]. Literature offers several terms to describe contexts where members of faculty are engaged in some form of joint activity towards teaching. However, there do not seem to be communal agreement about the definitions of these concepts, and thus they are to some extent used interchangeably [5]. Instead of trying to capture the collaboration among the teachers in this case into a single, and possibly ill-suited concept, we would investigate the activity in terms of characteristics associated with the joint activity. For this purpose, we have found the comprehensive literature review on teacher collaboration by Vangrieken et al. [5] very useful.

Vangrieken et al. [5] draw attention to the necessity of a collaborative culture, in which collaboration is considered the norm. Teaching in higher education is often associated with solitary work, which implies that a sudden shift towards collaboration probably will be regarded as contrived collegiality, which may weaken the teachers' motivation to engage in collaboration. The depth of collaboration is another important issue [5]. Whether collaboration is a matter of mere coordination of practical tasks, or a matter of sharing and negotiating pedagogical motives [6] will influence the development of both the outcomes and the process of collaboration. However, deeper levels of collaboration mean tapping on people's personal beliefs about teaching which may induce disagreements and conflicts [5], [7]. Lastly, without a sound collaborative culture, a collective of teachers may be prone to balkanisation, in which fractions of the teachers collaborate, at the expense of the teacher collective[5].

3 METHODOLOGY

To gain insight and in-depth knowledge to how a multi-campus course is organised and how the coordination and collaboration is manifested, the teachers involved were interviewed individually. The interviews were semi-structured, and the interview guide initially addressed practical aspects, such as number of students, profile of the study program, preferred teaching and learning activities. This introduction was followed by questions concerning the teachers' views and reflections on students' learning in relation to teaching and assessment practice. In the last part of the interview the teachers were asked to describe how the multi-campus course was coordinated and organised, how the teachers collaborated and how they interpreted their own role compared to the other teachers in the group.

The project and interview guide were validated by the Norwegian Centre for Research Data, which approves data collection and management. The teachers all volunteered to participate in this project, and were informed about the purpose of the project, and subsequently asked to sign an informed consent. Each interview lasted between 45 to 60 minutes and were recorded and then transcribed verbatim by the authors. In this paper we present preliminary findings based on an initial familiarisation with the data material and thorough discussions between the authors.

4 RESULTS AND DISCUSSION

All teachers reported that the collaboration they engaged in collectively through the physics and chemistry course cluster were basically concentrated on coordination of practical tasks, which corresponds to a relatively low level of collaboration, according to Havnes [6]. Initially, the reasons for this could perhaps be found in a perception of contrived collegiality [5]: The teachers have been instructed to come up with common syllabus and assessment scheme, the collaboration is not a result of a "bottom up" initiative.

However, there are other findings which suggest that the reasons for this rudimentary level of collaboration could rather be found in a fragmented collaborative culture [5]: While several of the teachers reported an appreciation for being able to choose their own teaching methods, they also raised concerns about the lack of common aims for the course and signaled a wish for better and deeper communication and collaboration. The teachers all independently agreed that they were teaching prospective engineers and not physicists. This meant little emphasis on derivations of formulas and the fundamental aspects of physics expressed in rigid mathematical terms. The point at which the teachers diverge concerns what they *do* emphasise: Some reported taking a pragmatic approach, concentrating on solving contextualised problems, while others emphasised a teacher-driven, multimodal approach, where practical and simulation-based experiences with phenomena and physical theories became central.

From this we can make a provisional explanation of the relatively rudimentary level of collaboration: The divergence in emphasis may render deeper levels of collaboration irrelevant from the teachers' perspective. The fact that the teachers in question untill recently were used to manage their own courses individually, suggests that the basis for developing a collaborative culture is currently fragile, and may act as an obstacle for pursuing common aims and emphasis, overcoming this apparent irrelevance. Perhaps the mere coordination of practical tasks can be seen as an implicit, collective measure to avoid possibly destructive conflicts between the collaborative teachers. In a well-established collaborative culture, disagreements would be perceived as necessary and constructive for development, rather than an element which might weaken collaboration. This interpretation may also provide some clues to balkanisation, as some of the teachers reported collaborating closer with a fraction of the teacher collective. The differences in emphasis across the teacher collective combined with an expressed lack of common aims, and an implicit wish to avoid conflict may explain why teachers who find themselves sharing similar views on aims and means collaborate on a deeper level, at the expense of the teacher collective.

It should be noted that deep levels of collaboration are also dependent on external conditions. In this case, different study programs, the number of students per course, online students mixed with campus students in the same course, available teacher resources locally at each campus, and classroom affordances varied across the physics and chemistry course cluster. These local differences will influence the degree of alignment regarding teaching and learning among the collaborative teachers.

5 SUMMARY AND FURTHER RESEARCH

The teachers sketch a complex picture of their inclination toward collaboration: they report a wish for more and deeper levels of collaboration, but at the same time they wish to preserve a certain level of flexibility. This balance between ownership and autonomy on one hand, and collaboration and negotiation on the other is something that needs to be addressed in the forthcoming analysis of these interviews. We still have interviews with teachers from other courses and campuses we want to add to this project, at a later stage.

We see the need for establishing a forum where teachers can exchange ideas and experiences from multi-campus courses, to improve course development. We also recon that this will benefit the students if the course structure and elements are more similar and recognisable. Establishing a collaborative culture seems necessary for obtaining robust and sufficiently deep levels of collaboration. But getting there is by no means a trivial matter [5].

6 ACKNOWLEDGEMENTS

We would like to thank all teachers who volunteered to participate in this project.

ABSTRACT

This paper builds upon the authors' previous research on Technical and Further Education (TAFE) teachers' conceptions of (first paper), and approaches to (second paper), ICT-enhanced teaching in professional education (third paper). This paper aims to examine relationships among the above three aspects, that is: between TAFE teachers' conceptions of, and approaches to, ICT-enhanced teaching

[1] Corresponding Author

doi:10.5821/conference-9788412322262.1260

and their associated view about ICT use in the workplace. Phenomenography, a qualitative research approach that emphasizes the importance of people's experience of a phenomenon, was selected as a research methodology for this study. A cohort of 23 teachers from three TAFE institutions in NSW, Australia, participated in semi-structured, in-depth interviews. This study found that teachers' conceptions of, and approaches to, ICT-enhanced teaching, and conceptions of ICT in the workplace are linked. More specifically, TAFE teachers who hold a particular conception of ICT-enhanced teaching tended to adopt related approaches to ICT-enhanced teaching that are further linked with conceptions of ICT in the workplace. TAFE teachers who expressed 'student-centred/activity-oriented and/or industry-oriented' conceptions of ICT-enhanced teaching were more likely to adopt a 'student-focused' approach to ICT-enhanced teaching. The teachers within this group were more likely to hold an understanding of the role of ICT in the workplace as an effective or essential tool in professional activities. This paper offers new insights that contribute to bridging the gap between ICT in teaching and ICT in workplace practice. These findings could help develop new initiatives to address the existing gap between teaching in TAFE institutes and current practices in the workplace.

1. INTRODUCTION

Discrepancies between what is taught in engineering education and what is practiced in the industry is a fact that has been reported in the literature [1]. In order to address this claim, the short paper builds upon the authors' previous research on Technical and Further Education (TAFE) teachers' conceptions of, and approaches to, ICT-enhanced teaching in professional education. It investigated three aspects related to ICT use in technical (engineering) education. The first article (published) identified two broad conceptions of ICT-enhanced teaching in technical education: (i) teacher-centred conception, which comprises three categories of description: ICT is used to meet external expectations, ICT enables to gain access to information and resources, and ICT is a delivery tool, and (ii) student-centred conception, which includes two categories of description: ICT is a media for active learning, and ICT is a means of preparing students for their future profession [2]. The second article (published) found two broad orientations with five approaches to ICT-enhanced teaching: (i) teacher-focused orientation with three teaching approaches: comprising information-oriented, feedback-oriented, practice-oriented, and (ii) student-focused orientation with two teaching approaches: activity-oriented and industry-oriented teaching [3]. The third article (published), further investigated how TAFE teachers conceptualized the role of ICT use in the workplace and found three conceptions: using ICT for various regular work-related tasks; helping accomplish a job more effectively; and using ICT as an essential tool in professional activities [1]. In order to build a relationship among these three articles (above three aspects), this short paper aims to examine relationships between technical teachers' conceptions of, and approach to, ICT-enhanced teaching and their associated view about ICT use in the workplace. The rest of the short paper is organized into three sections: 'Methodology' explains phenomenographic research approach and brief procedure of the study; 'Results' provides associations among prior studies; 'Discussion and Conclusions' synthesizes the results and discusses its contributions.

2. METHODOLOGY

Phenomenography, a qualitative emerging research approach for engineering education that emphasizes the importance of people's experience of a phenomenon, was selected as a research methodology for this study [4]. In phenomenographic research, it is often depicted as how people understand, perceive, discern, conceive or experience the aspect of the world around them which is articulated by the one word “conception” [5]. Sample selection, data collection and analysis of data, therefore, was followed by the principle of the phenomenographic approach. A cohort of 23 teachers (P01 to P23) from three TAFE institutions in NSW, Australia, participated in semi-structured, in-depth interviews. Interviews data were transcribed verbatim and analysed by following seven steps, such as *familiarisation*, *compilation*, *condensation*, *preliminary grouping*, *preliminary comparison of category*, *naming of the categories*, *and outcome space* [2]. From this analysis,three outcomes were revealed (i) teachers’ conceptions of ICT-enhanced teaching, (ii) teachers’ approaches to ICT-enhanced teaching and (iii) teachers’ conceptions of ICT in the workplace. In the second stage, we identified 23 participants’ dominant attributes(qualities) towards these three findings. Each of the participant’s dominant attributes was placed in the relationships and was built into two relationships: *Associations between conceptions of ICT-enhanced teaching and conceptions of ICT in the workplace*; and *Associations between approaches to ICT-enhanced teaching and conceptions of ICT in the workplace.*

3. RESULTS

This study found that teachers’ conceptions of, and approaches to, ICT-enhanced teaching, and conceptions of ICT in the workplace are linked. Table 1 shows associations between conceptions of ICT-enhanced teaching and conceptions of ICT in the workplace for which students are prepared. The associations indicate that the two conceptions are related.

The table 1 presents two areas of association for 21 teachers out of 23 teachers. The first area, circle one (1), conceives of ICT-enhanced teaching as a ‘teacher-centred/content-oriented’ and this is linked with Categories A and B in the workplace. In this area, technical teachers who hold ICT-enhanced teaching as a ‘teacher-centred/content-oriented’, tended to understand the role of ICT in the workplace from supplementary to effective. The second area, circle two (2), perceives ICT-enhanced teaching as ‘student-centred/activity-oriented’ and ‘student-centred/industry-oriented’ conceptions and these conceptions are connected with Categories B and C in the workplace. In this area (2), technical teachers who viewed ICT-enhanced teaching as ‘student-centred/activity-oriented and / or industry-oriented’, tended to understand the role of ICT in the workplace from effective to obligatory in nature. However, two teachers in this study did not express conceptions that followed the stated associations. Therefore, they were not placed within the two marked areas (See Table 1: P01 and P08).

Table 1 *Associations between conceptions of ICT-enhanced teaching and conceptions of ICT in the workplace*

Conceptions of ICT-enhanced teaching		Conceptions of ICT in workplace		
		A	B	C
Teacher-centred/ content- oriented	A	P22	1	
	B			
	C	P16, P23	P07, P10, P15, P17, P21	P01
Student-centred/ activity-oriented	D		P11, P18	P02, P03, P04, P14, P19
Student-centred/ industry-oriented	E	P08	P06, P09, P20	2 P05, P12, P13
Conceptions of ICT-enhanced teaching, ICT is used: (A) to meet external expectations. (B) to gain access to information and resources. (C) as a delivery tool. (D) as a medium for active learning; and (E) for preparing students for their future profession.		Conceptions of ICT in workplace, ICT- (A) could be used for various work-related tasks (supplementary). (B) helps to accomplish a job more effectively (effective); and (C) is an essential tool in professional activities (obligatory).		

The associations indicate that both approaches to ICT-enhanced teaching and conceptions of ICT in the workplace are related (Table 2). The table presents two groups of associated areas for 21 teachers out of 23 teachers. The first group, highlighted as circle one (P1), conceives of approaches to ICT-enhanced teaching as a 'teacher-focused approaches and this is linked with Categories A and B in the workplace. In this area, technical teachers who hold ICT-enhanced teaching as a 'teacher-focused' teaching approach tended to understand the role of ICT in the workplace from supplementary to effective. The second area, marked as circle two (P2), is included under a 'student-focused approaches' and these approaches are connected with Categories B and C in the workplace. In P2, technical teachers who viewed ICT-enhanced teaching as a 'student-focused' teaching approach, tended to understand the role of ICT in the workplace from effective to obligatory in nature.

Table 2 *Associations between approaches to ICT-enhanced teaching and conceptions of ICT in workplace*

Approaches to ICT-enhanced teaching		Conceptions of ICT in workplace		
		A	B	C
Teacher-focused	A	P22		
	B	P1	P07	P01
	C	P16, P23	P11, P15, P17, P21	
Student-focused	D		**P06, P18**	**P02, P03, P04, P14, P19**
	E	P08	**P09, P10, P20** **P2**	**P05, P12, P13**

Approaches to ICT-enhanced teaching: (A) a teacher-focused, information-oriented strategy with the intention of effectively delivering subject content. (B) a teacher-focused, feedback-oriented strategy with the intention of achieving intended course outcomes. (C) a teacher-focused, practice-oriented strategy with the intention of linking theoretical and practical knowledge. (D) a student-focused, facilitation-oriented strategy with the intention of providing active learning for developing students' understanding; and (E) a student-focused, industry-oriented strategy with the intention of developing students' knowledge and skills to meet the industry's needs.	Conceptions of ICT in workplace, ICT- (A) could be used for various work-related tasks (supplementary). (B) helps to accomplish a job more effectively (effective); and (C) is an essential tool in professional activities (obligatory).

However, two teachers did not express approaches to teaching that followed the above-stated associations; therefore, they were not placed within the two marked areas (See Table 2: P01 and P08).

4. Discussion and Conclusions

Technical teachers who hold a particular conception of ICT-enhanced teaching tended to adopt related approaches to ICT-enhanced teaching that are further linked with conceptions of ICT in the workplace. The relationships of this paper have an impact on teachers' pedagogical practices in technical education (Tables 1 & Table 2). For instance, teachers who conceived of ICT as obligatory and effective instruments in the industry are more likely to introduce knowledge and skills related to ICT in their teaching. This means that, the students will be acquainted with using different forms of ICT in the classroom instruction (teaching and learning) that will facilitate them linking with their future workplace (industry). This paper provides further insights that contribute to bridging the existing gap between teaching in technical (engineering) educational institutes and current practices in the industry where there is a particular focus on using ICT. These findings could help improving engineering teacher professional development programs, minimising the existing gap between teaching practices in engineering institutions and real practices in the workplace. The extended elaboration of these associations and the reasons for showing this nature would be discussed in the upcoming journal article.

ACKNOWLEDGMENTS

This short paper was produced from the data of the first author's doctoral (PhD) thesis.

ABSTRACT

This paper is of methodological nature. We present the empirical research methodology of a study that focuses on student learning experiences, in particular of mathematics students in an innovative learning environment, such as Challenge-based Education (CBE) at a Dutch university of technology. In this study, we present the case study of CBE in an innovative mathematics course on modelling, the mathematics "Modelling Week". We draw attention to the methodology used to study this modelling course, where we investigated students' learning experiences in a monodisciplinary CBE-oriented master course. We explain the design of the study and the associated data collection strategies regarding students' use of resources (Schematic Representation of Resource system- SRRS) and their learning processes. In the poster presentation, we will show selected results that come from the different

instruments to help us understand student learning experiences in innovative/CBE related mathematics courses.

1 INTRODUCTION

An increasing number of universities of technology are attempting to adopt challenge-based education (CBE- we use the term to include approaches to teaching and learning). In CBE students work on authentic and real-world focused engineering tasks, generally in multidisciplinary teams, with technology-enhanced learning and multi-stakeholder collaboration [1]. In this educational approach, students learn how to create connections between real-world problems and engineering concepts, principles, and methods. This paper addresses the issue of CBE learning experiences, which Malmqvist et al., identify as [1]:

> "A challenge-based learning experience is a learning experience where the learning takes place through the identification, analysis and design of a solution to a sociotechnical problem. The learning experience is typically multidisciplinary, takes place in an international context and aims to find a collaboratively developed solution, which is environmentally, socially and economically sustainable."

We hold that essential characteristics of CBE can also be applied in monodisciplinary courses, for example in mathematics, where the application of advanced knowledge in a multidisciplinary setting is not straightforward for students. In such a context, we seek to grasp and understand the students' learning experiences in an innovative first year master course in mathematics: the Modelling Week.

In this paper, our aim is to present the methodology used to produce and manage the data in this course so as to account for the way students perceive their learning experiences while orchestrating different resources.

2 THEORETICAL FRAMEWORK

2.1 Challenge-Based Education (CBE)

Challenge-based education is a student-centered educational approach that arises from the concern to prepare engineering students for the new challenges of this century and aims to contribute to the solution of societal problems through collaboration between industry and universities. This type of effective collaboration and hands-on experience is characterized by encouraging students to work with peers/tutors, teachers/instructors, and experts to develop in-depth knowledge and skills on various topics.

2.2 Lens of Resources

In our research we link the development of students' knowledge and skills, during the solution of a problem in the context of CBE, to the use of different types of resources. Thus, we draw on the instrumental approach [2] to observe both how different resources influence students' practice and understanding, and how they modify and adapt them according to their own needs. We follow the categories of resources outlined by Pepin and Kock [3].

3 THE STUDY

This ongoing study uses a case study approach, to investigate and develop a deeper understanding of students' learning experiences in several courses in the curriculum of an Applied Mathematics program (Bachelor and Master) in a university of technology in the Netherlands. One of these courses is the Modelling Week.

3.1 Modelling week

The Modelling Week is part of a mandatory course (Professional Portfolio) in the Applied Mathematics master program on professional skills development. During one week, first year master's students work in groups on realistic problems posed by company/research institute representatives (the ”problem owners”). The main outcome of this process is students' interpreting and proposing a solution and recommendations for companies via formulating a mathematical model of the given problem and applying mathematical methods in their solutions. Our study has taken place during the Modelling Week of November 2021. Before the modelling week started, two different activities took place. First, a “Kick-off” lecture was given by the course organizers in order to give relevant information regarding the modelling week process and the creation of the student teams related to their interest areas. Eight teams (6-8 students) were created, four of which agreed to volunteerly participate in our research. Next, a team building workshop (“Lego workshop”) was organized with the intention of helping students to get to know their teammates and to learn about team dynamics. Following these events, the Modelling Week started for a period of one week (all day, Monday to Friday). On the first day , problem owners presented the problems for the first time and students were allowed to discuss the details with the problem owners, ask questions for clarification and also request for resources. During the week, students worked as teams to find a feasible and effective solution to the problem. They were guided and supported by university supervisors and problem owners, who also provided feedback on their work. The Modelling Week was concluded on Friday afternoon with the presentations of each team sharing their results. For the majority of students, Modelling Week was the first time they worked on a realistic mathematics problem, posed by an external stakeholder.

3.2 Data Collection strategy

In table 1 (below) we present the data collection strategies used to investigate students' learning experiences in the modelling week.

Table 1. Data collection instruments of the modelling week

Participants	Data Collection Strategy
Students	Exit Cards, Interviews, Observations, Schematic Representation of Resource System-SRRS [4], Survey
Supervisors (Applied Mathematics)	Interviews and Observations
Problem owners	Interviews and Observations

In our poster presentation, our main focus is on demonstrating how the instruments would allow us to analyze student learning experiences [5].

4 PRELIMINARY RESULTS

In terms of results, we present below the different instruments and in which ways they helped us to investigate student learning experiences:

1) With the help of the exit cards, at the end of three data points during the modelling week (Monday- Wednesday- Friday), we were able to get ‘snapshots’ of students’ views regarding their learnings, their feelings towards the achievement of their goal up to that time, their best liked activity, and problems they encountered. This helped us to trace a trajectory of their learning development throughout the week.
2) We made daily observations of students’ team work session and interactions with their supervisors and problem owners. We made field notes and took photos (e.g. of student whiteboard notes, calculations, screenshots of software used, schemes). This gave us information about their conversations, the concepts they used, the guidance they received and about their ways of progressing in solving their problem. The observations also showed how ideas from the resources used by the students reappeared in their work-in-progress.
3) The interviews with both the supervisor (university teachers from the Applied Mathematics department) and problem owner helped us to get a better understanding of how their expectations and experiences developed in terms their roles (e.g., from instructor to coach). The interviews also helped us to triangulate the observations of students’ learning experiences in class.
4) The student interviews provided us insights into what and how the students perceived and learned in this challenge-based learning environment. The interviews helped us to interpret students’ SRRS, so that we obtained an overview of the resources students used (material, digital, social/human), the support they received, different phases and tasks they experienced in the process of solving their challenge/problem, and the important decision making moments in their learning paths.

Together these different kinds of data provided us with a rich picture of students’ learning experiences. For example, they helped us understand the role of the resources provided to and found by the students in the teams’ work towards developing prototype solutions to the challenges. Moreover, the data gave insights into the characteristics of the problems (posed by the problem owners), as well as their affordances and constraints; the mathematical problems students encountered and how they sought help and support for solving them; the critical incidents and breakthroughs during a ‘pressurised’ week; the roles students assigned to different participants of the group; the different roles of the problem owner and mathematics tutor, and the alignment and nature of their feedbacks. We will share further explanations and examples during the poster presentation.

5 ACKNOWLEDGMENTS

This study was funded by the Innovation Fund of 4TU.CEE at Eindhoven University of Technology. The authors would like to thank to the students, supervisors, and the problem owners for allowing us to conduct the observations and interviews.

ABSTRACT

Due to the COVID-19 pandemic, online teaching methods have gained more interest. Most formats of teaching can be easily transferred into an online format from a technical point of view. However, this is more difficult for practical courses in a laboratory. Together with partners from three European universities, we tackled the issue of providing a practical online course for higher education levels in the framework of the EuroTeQ university. In this work, we present our concept of the course and discuss the course goals and further improvements. We tested the remote lab setting in order to offer the course on a yearly basis in future.

The remote lab was focused on energy engineering and was open to students from different engineering disciplines and countries. The course was comprised of three blocks, each consisting of one lecture on the broader context of the topic and one experimental laboratory session. The experimental session was streamed via a video broadcasting service. Students were required to either deliver a written report or to write a newspaper article for each of the three blocks.

The learning outcome of the course was that students on the one hand learn about the technologies discussed in the course and on the other hand learn about intercultural communication skills. The goal was to show the diversity of technologies and to show the significance of each technology for a specific country. The online experimental sessions proved to deliver a clear explanation of the topic for the students when provided with sufficient course material adapted to online formats. Contrary, keeping a high level of interaction with students during remote experiments was found most challenging.

1 INTRODUCTION

With the COVID-19 pandemic, a new urge for developing remote labs was born [1]. Due to the pandemic, many countries restricted the access for students for on-site learning in university premises. Classical teaching formats like lectures can easily be transformed into an online format from a technical point of view. For laboratory and practical exercises this is more difficult. Transforming existing experimental setups or developing new experimental setups is challenging in terms of time and cost. Nevertheless, to limit the consequences of the pandemic on students' practical education, many approaches to teaching practical experience were undertaken [2]. Remote labs were already developed and used before the pandemic (for example [3] and [4]). A review on remote labs indicates how former reasons for these types of labs were for example space constraints or cost savings, as well as advancements in information technologies, which facilitate their implementation.

Additionally, the concept of "European universities" was developed in 2017 [5]. EuroTeQ emerged from this, as a platform for European engineering education between six partners (Technical University of Munich, Technical University of Denmark, Eindhoven University of Technology, École Polytechnique, Czech Technical University in Prague, Tallinn University of Technology). Offering online formats in teaching is an alternative way to provide courses to the students. In order to also provide students with hands-on teaching and practical experience, remote labs are a necessary solution for situations when on-site practical learning is not possible, and when the cooperation between institutions allows students the possibility of doing remote practical work in facilities and equipment their institution does not possess.

The remote lab concept presented here satisfied the need for practical education during the pandemic and contributes to the EuroTeQ course catalogue. The “Remote Energy Lab” offers an international cross campus education involving three partners from European universities. Our course is classified as remote lab since it comprises a real experimental setup and distant access of the user [6].

2 THE COURSE CONCEPT

The course “Remote Energy Lab” was offered in the framework of the EuroTeQ University in the winter semester 2021/2022. The course was designed for master's students in engineering. A graphical representation of the course is shown in Fig.1. A prerequisite is a bachelor's degree in engineering. The number of participating students was not sufficient for a robust survey. Therefore, the valuable student’s feedback was not incorporated.

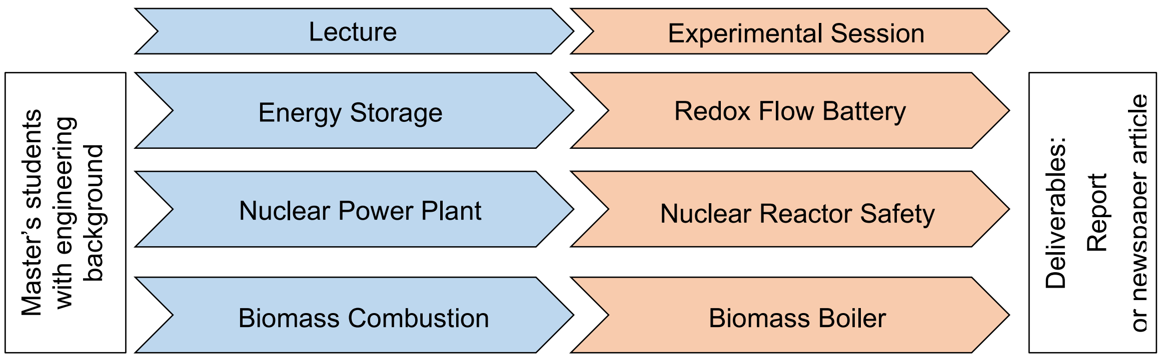

Fig. 1. Schematic representation of the course layout

2.1 Learning Objective

The learning objectives of the course focus mainly on communication skills in an international context. Additionally, students should learn new technologies related to energy engineering solutions. Students are supposed to:

- Learn how to work effectively in an international team.
- Learn to communicate and work with people from different disciplines and cultures.
- Learn how to communicate online.
- Present technologies in an easy and understandable manner.

2.2 Course Content

The course was split into 3 topics. Each block consists of one lecture and one experimental session. The following blocks were offered:

1. Redox flow battery for energy storage

2. Low emissions household heating with a biomass boiler
3. Nuclear reactor safety

The lecture (90 minutes) was given before the experiment and introduced the students to the broader perspective of the topic. Additionally, the lecture introduced important concepts and background information needed for the experimental session. This is important since students with a broad variety of study backgrounds can participate in the course. The experimental session took between 60 and 180 minutes. Students participated during the experimental session via an online conference platform like Zoom for example. For topics 1 and 3, the experiments were performed live during the session. For topic 3, students used a software at their computer that allowed them to directly read data from the reactor. This enhanced the hands-on feeling. For topic 2, the experiment was recorded and played during the experimental session, due to the inherent long duration of the experiments (over 5 hours).

2.3 Deliverables

Students were asked to write either a short report or a newspaper article. The type of deliverable was determined before the course by the instructors. Reports and newspaper articles were graded, and a mean grade was assigned to the students based on the grades from all three topic blocks.

The report was limited to 5 pages and should include only necessary information and results of the experiments. The idea behind the newspaper article was to make the students write about the investigated technology for a general audience. The focus of the article was not further specified to not limit the creativity of the students. With this deliverable the fourth learning objective to present the technology in an easy manner could be assessed.

3 IMPROVEMENTS AND CHALLENGES

The most relevant challenges and possible improvements are listed here based on our experience from the winter semester 2021/2022. Some challenges were already overcome before the course started. Others were noticed during the course. A total number of 7 students split in 2 groups participated in the course. We received 4 reports and two newspaper articles. The following challenges and improvements were identified:

1. <u>Group work:</u> In the remote lab, the student's work was done individually, as student split their tasks. In a typical lab setting, student’s collaboration within their group would be more intense. A solution would be the creation of breakout rooms within the video broadcasting platform to foster collaboration between students. The collaboration for the preparation of the deliverables is organized by the students and cannot be influenced by the instructor.
2. <u>Complexity of the topics:</u> Considering that the students could have different engineering backgrounds, the complexity and depth of the topics could hinder a proper understanding of the remote practical sessions. Each topic selected was

specific to an energy technology solution, whose working principle was connected to a different engineering field (energy storage, solid fuel conversion, nuclear energy). Therefore, it was necessary to have a practical session joint with a theoretical session to introduce the scientific background, operating principles, and basic concepts related to each topic. We were able to contextualize and introduce the technology with the help of the lecture before the experimental session.

3. Time of experiments: The experiment “biomass combustion” requires over four hours for completion due to the need for a complete analysis, collection of data, and the need to explain the experimental setup and procedure prior to the experiment. A solution to this was recording the experiment and dividing it into multiple video records of each experimental step from the start up to the data collection. Compared to an on-site experiment, the time of interaction with students was shortened during the online version. Therefore, we see the advantage of showing longer experiments in a shorter time period.
4. Visibility: It was observed the impediment of a small field of view for some experiments due to the large size of equipment (for example biomass boiler and peripheral equipment) that is used in the experimental process. This prevented a proper recording or display of the equipment, affecting the student's understanding. To avoid misestimation of the real measurements a schematic, flow chart, as well as diagrams and description of the equipment were provided to counteract this weakness. Compared to an on-site session, this material would also be provided, but less detailed.
5. Interaction between students and instructor: During the experiments, it was hard to interact with the students. Questions were only asked via the chat. A lively discussion did not take place. Activating the students to participate with online quizzes did work. Nevertheless, in comparison to an on-site lab, the interaction needs to be improved to foster the learning outcome. Triggering the interaction during an on-site experiment is easier than for the online session.

On the other hand, remote practical sessions can overcome some of the challenges that are commonly faced in on-site laboratories. For example, one challenge in on-site laboratories is that students are often grouped together in large groups to perform experiments, this can compromise the student chances of success at a meeting. This challenge is addressed in remote labs, by providing the students the possibility of rewatching the recorded practical session as many times as necessary, until conceptual clarity is obtained.

4 SUMMARY

The course was a first attempt to offer hands on experience to students via an international remote lab. The concept of three partners offering one experiment each guaranteed a variety of different topics. The observed challenges contributed to determining what aspects can be further improved in a future remote energy lab course. The course with the improvements mentioned above will be offered again in winter semester 2022/2023. Our experience gained throughout the course can also be transferred to remote labs in other fields except engineering.

ABSTRACT

This paper presents recommendations for a Multicampus course, developed through a Student as Partners project. In this project students, a teacher and an educational developer collaborated following the principles of the Students as Partners framework. Through interpretation of previous course evaluations and discussions, we created a shared understanding of how the course had worked and what to improve. Our main recommendations are to have lectures and learning activities that are diverse and adapted to the students' different needs. These recommendations are not groundbreaking in themselves, however, the grounding in a common understanding through the use of the Student as Partners framework is novel and gives new perspectives to course development and educational development in general.

1 INTRODUCTION

1.1 Students as Partners

Evaluations represent a source for information and quality assurance in course development. In these evaluations it is not only the ratings that are essential but the discussions they may lead to and possible improvements of teaching and learning activities [1]. To ensure sustainable development both student and teacher involvement are important in this process. A way to include students in course development is through a Students as Partners approach. This framework challenges the traditional roles and responsibilities of students and teachers. Cook-Sather et al. define *"student-faculty partnership as a collaborative, reciprocal process through which all participants have the opportunity to contribute equally, although not necessarily in the same ways, to curricular or pedagogical conceptualization, decision making, implementation, investigation, or analysis"* (p. 6-7) in [2]. According to Matthews, a good Students as Partners practice should aspire to the five propositions: *"1. Foster inclusive partnerships, 2. Nurture power-sharing relationships through dialogue and reflection, 3. Accept partnership as a process with uncertain outcomes, 4. Engage in ethical partnerships, 5. Enact partnership for transformation"* (p. 2) in [3].

We used the Student as Partners framework in a pilot project where a resource group was formed which consisted of six students, a teacher, and an educational developer. The students were selected through a recruitment process. To foster an inclusive partnership the students received a salary. The aim of the project was to develop recommendations for a first-year introductory course in physics and chemistry.

1.2 Course description

Ten teachers are involved in this first-year introductory course in physics and chemistry. It is a multicampus course that runs for 11 different Bachelor of Engineering programs at The Norwegian University of Science and Technology. Students and teachers are situated at three different campuses. The teachers have cooperated regarding exams, exercises and course content. All teaching resources, such as notes, calculus exercises, and lecture recordings are shared and available to all students and fellow teachers in the learning management system as described in [4].

2 METHODOLOGY

2.1 Data

Previously collected data from three anonymous questionnaires were used as a source for information. The first two surveys were conducted in the spring of 2020, before and after the online transformation, and the last one in 2021 when almost all activities were online. The questionnaires consisted of questions where the students were asked to rate how satisfied they were with lectures and mandatory exercises on a Likert scale. To get detailed and rich information about their experiences the students were asked to elaborate their ratings through open questions [5]. In the questionnaires, the students were encouraged to describe what had worked well, and what had not, and also come up with suggestions on what to improve. In addition, the students answered questions about: their previous knowledge of physics and chemistry, how often they used the different online resources available in the course, and what they would recommend the teachers to preserve from the online format.

2.2 Work method

The questionnaires were used as background information which we in the resource group examined. We divided the data material among us and split into pairs to extract the essence, which then was presented to the whole of the group. These presentations laid the foundation for deeper discussions which formed the basis for a common understanding in the group. After each group meeting, all participant wrote individual reflections which were shared online. All elements: the essence of the original data, our discussions and individual reflections, formed the basis for the course recommendations that we developed. These were presented to all the teachers involved in the course.

3 RESULTS

3.1 Short summary of findings

The results from the questionnaires showed a decline in students' satisfaction regarding the lectures in 2020, due to the transition to an online format. However, in 2021 the students rated the lectures higher, compared to the pre-pandemic situation, even though they were still in an online format. There are, however, some variations between the campuses.

Several students mentioned that the difference in students' prior knowledge both in physics and chemistry, is a challenge. Some students have had courses that go beyond the admission requirements. There seems to be a tendency that these students do not participate in the lectures or engage in the course as long as they are familiar with the topics. At the same time, other students find it challenging to master the course and ask for a more thorough introduction to the syllabus.

Further, the students found it engaging and motivating when the teacher used quizzes to activate them. This was especially important in the online format, where the students reported that they easily got distracted. In addition they reported that using breakout rooms lowered the threshold for asking questions, but they still missed not having the opportunity to talk with the teacher individually.

There are differences in student satisfaction between the campuses regarding the mandatory exercises. The students that had mandatory attendance and did the exercises as part of a group work with practical exercises, were the most satisfied. While the students that had individual multiple choice tests were least satisfied. After the onset of the pandemic, it was not possible to have physical attendance and practical exercises, and the overall satisfaction decreased.

Recurring in all the surveys is a frustration with the online textbook, which is open source. This dissatisfaction is mainly because it is digital and the fact that it is an English textbook. Most of the students report they rather use the lecture notes produced by the teachers. The students that report reading the book use it as an encyclopedia.

3.2 Recommendations

Our recommendations for improving the course are divided into three categories: Lectures, Learning activities and Online resources.

Lectures adapted to the students' different needs

To facilitate the different needs and enhance the students' understanding we recommend replacing some of the lectures with short thematic videos, where the aim is to give a brief and pedagogical presentation of the topics. These thematic videos will be used asynchronously, and the students should be encouraged to watch them at their own pace, and as many times as they want. In this way, the videos can serve dual purposes, both as introduction and repetition. The remaining lectures should be synchronous, preferably physical lectures, and use active learning methods to increase students' learning and understanding. Since the students already are familiar with the topic, the teacher can to a greater extent design for student activity as well as give further explanations and show practical demonstrations.

Response systems can be implemented to activate and increase students' motivation and engagement, for example by using quizzes to check the learning outcome, or by asking questions about their learning experience. We also recommend that the teacher involves the students to a greater extent in the design of the lectures, to better align the teaching and learning activities to the students' different needs.

Learning activities and support adapted to the students' different needs

For online supervision, we recommend having digital tools available, for example, tablets for drawing and doing calculations by hand. These notes can be shared and made available to the students online.

When it is possible to meet in person, we see it as valuable to have the teacher present in addition to student assistants during exercises. Long response time or inadequate response can affect the students' work effort and motivation, and influence whether they participate or not. In addition, the teacher achieves valuable information about the students' learning.

Another recommendation that applies to both optional and mandatory exercises is to have variation and flexibility. Students should to a certain degree have the opportunity to choose whether they want to collaborate with other students or work individually. In addition, these should include both practical and calculus exercises.

The exercises should preferably have a connection to the specific study program and contribute to contextual learning. This can be challenging since the resources are shared among the different study programs, but nevertheless something to strive toward. One way to embed the basic physics and chemistry course into the specific study programs is by introducing a larger project that allows different content.

Online resources

To make the textbook more accessible for the students we recommend that terms and words are introduced using both languages, to improve the students' vocabulary and understanding. Another recommendation is to have a shared discussion forum where all 1000 students have access, and where both students and teachers make comments and answer questions. The discussion forum should have a well-defined structure where it is easy to navigate and find related questions. To lower the threshold for participation we recommend that it should be possible for the students to be anonymous.

4 AFTERTHOUGHT

The suggested recommendations were presented to the teachers involved in the course. In an open dialogue, we discussed the recommendations and our interpretation of the course. Afterwards, the teachers used this information for course development. One of the suggestions that has been implemented is the use of short videos as part of a flipped classroom design. A set of videos are now distributed to all students and followed up by student active sessions facilitated by the teachers. This is a course design that has been discussed earlier among the teachers but needed encouragement from the students to be applied.

The recommendations we suggested are not novel in themselves, however, the Students as Partners approach where students and teachers are collaborating on equal terms might have contributed to higher credibility.

Using the Students as Partners framework contributes to a more holistic view on course development. The students have first-hand experience not only with the specific course but with the entire study program, while the teachers on the other hand, tend to focus on their own courses.

Course development is an ongoing process and this paper presents a pilot project. For a continuous and sustainable course development, it will be valuable to use the Student as Partners framework not only in a pilot project but on a regular basis.

EMPOWERING MASTER STUDENTS TO SOLVE REAL-WORLD ENGINEERING PROBLEMS

V. Kraft [1]
JMP Statistical Discovery

Conference Key Areas: *engineering skills; student engagement*
Keywords: *problem solving, data skills, employability*

ABSTRACT

In engineering, the importance of multi-disciplinarity and the need to “think outside the box” are obvious. However, subjects in engineering education are often treated in an isolated fashion. The kind of problems solved in these subjects are often just simplified artificial exercises. To ensure employability of new engineers, students need to practice how to “convert a mess into a problem”, and then use the scientific method in context to solve it.

Good data skills (including data collection, exploration, and modeling) are essential to solve problems. These data skills are the “backbone” of the scientific method. The use of real data (coming, for example, from real applications in industry) can be motivating in teaching and stimulating to connect engineering topics.

This paper explores possible reasons why many subjects in engineering are still taught in a way disconnected from real life. It also suggests solutions, and shares teaching tools and resources to improve student employability.

1 INTRODUCTION

1.1 The importance of multi-disciplinarity and real-life problems

If we ask engineering teachers if they think multi-disciplinarity is important in their field, probably all of them will answer affirmatively. However, when we look at subjects in engineering degrees, they often look isolated. How many subjects are taught together by teachers from different departments? Real-world problems bring multi-disciplinarity in a natural way. One given situation in a process may require chemical knowledge, but also statistical analyses to make the process stable, and economics to make it viable, plus an environmental study, and so on.

Students in engineering degrees are usually young. Most of them have never worked in industry or business. However, it is obvious that we wish our students learn the skills needed to solve real-life problems. How can they learn these skills at university if they are only exposed to prepared “artificial” exercises? While these exercises have the benefit for the teacher making reviews easier, it is not what happens in real situations where problems are more complex and somewhat blurred [1].

A hands-on approach with cases that use real situations and data also require many soft skills as needed today, like being able to learn autonomously, working in teams or communicating efficiently.

If we agree on the importance of multi-disciplinarity and the need to prepare students to real-world problem solving, why do we have difficulties in achieving this?

1.2 Some difficulties when using real world problems

Facing students with real world problems implies shifting the focus from the teacher to the students. There are still many teachers that feel comfortable conveying knowledge in a unidirectional way: the teacher speaks (and sometimes fills blackboards), and the students listen and take notes. Probably something similar happened before Gutenberg invented the printing press: it was the only way to make copies of written knowledge. This passive approach is no longer possible when using real-world problems, that necessarily encourage discussion. The teacher becomes more a supervisor, a colleague who walks together with the students through a discovery process. Therefore, a required first step is changing the paradigm in how we teach engineering subjects [2].

The second requirement is having case studies to be used in the classroom. This teaching material could mainly come from three sources:

1. The teacher (or team of teachers) invents an industrial or business situation that looks realistic, adds the context information, and simulates the data. This is extremely difficult to do well. The teacher needs more imagination than J.K. Rowling writing Harry Potter and requires a deep subject understanding of the process at hand. Even if this can be done at the end, it is very time consuming.
2. The teacher has done some consultancy work or research with a company, perhaps working together with operators and technicians in industry for many months. She/He has learnt a lot about the process, and the data are accessible

that can also be used in the classroom. Teachers can then write a case study but will probably need the help from the industry people also involved in this collaboration. Finally, the result can be good, but it also requires a lot of time.

3. The teacher uses cases from a collection of well-curated real-world situations. As before, these cases often come from commercial projects, but they are already designed for classroom use. The fact that these case studies are used by many educators also implies that they can be improved in every iteration of use. Also, the range of topics is huge: something that cannot be achieved otherwise.

The next chapter introduces a good example for the third option.

2 THE JMP CASE STUDY LIBRARY

More than 50 problems are shared for teaching use in the JMP Case Study Library [3] (Fig. 1), listed by field, subject, statistical concepts, and complexity. Each case can be downloaded for free including dataset(s) and a PDF documentation. Many cases have been directly developed by practitioners in industry. Some companies are named in their cases, while others are anonymized.

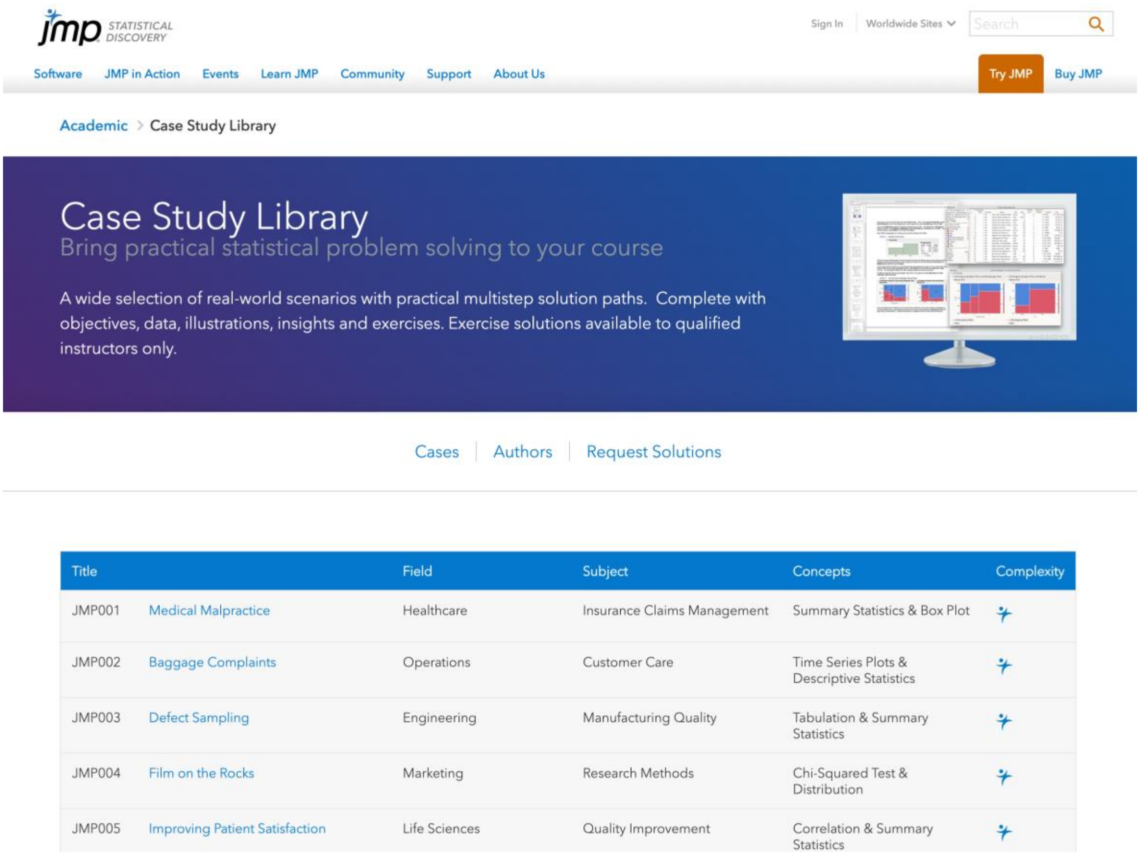

Fig. 1. Examples from the JMP Case Study Library published at jmp.com/cases

All case studies follow a consistent format and scenario which starts with a description of the problem, followed by questions or tasks at hand and a description of the data. This is followed by a multistep illustration of the solution followed by a summary of the statistical and managerial insights. These are followed by exercises that expand or pose “what if” scenarios, which solutions can also be shared upon request.

While educators can use case studies for in-class demonstrations, the most effective use are assignments to students as homework or group projects. The cases can stimulate discussions about which steps to take or comparisons of alternative solutions. Students can also be asked to present the learning outcome to “other decision makers”, or to explain why and how certain methods have been applied.

2.1 Compliance with GAISE recommendations

As outlined in [4], the JMP case studies support extremely well the recommendations for teaching statistics to college students, especially these four: 1. Teach statistical thinking 2. Focus on conceptual understanding 3. Integrate real data with context and purpose and 4. Foster active learning.

More information about the JMP Case Study Library and hands-on experience using some select cases for engineering will be offered during a SEFI workshop [5].

3 SUMMARY AND CONCLUSIONS

Multi-disciplinarity and empowering students to solve real-world problems are needs in engineering education nowadays. The use of case studies can facilitate achieving these objectives. When you talk with former engineering students who have entered the workforce, they invariably explain the value that real case studies had in their learning. Moreover, they can remember and refer to many case studies. The authors have confirmed this by talking to engineering students some years after they finished their degrees (the live presentation of this paper does include some of these video testimonials).

As creating realistic case studies from scratch is difficult and time consuming, good case study libraries can be very useful. As an example, select engineering cases from the JMP Case Study Library have been introduced. All cases from that collection are freely available, proven by hundreds of educators worldwide and will be continuously enhanced to cover more problems, applications, and engineering skills in the future.

IS THE ENGINEERING STUDENTS' SELF-ASSESSMENT ACCURATE? ANALYSING MIDTERM TESTS IN TERMS OF SELF-ASSESSMENT ACCURACY

Nárcisz Kulcsár [1]

Conference Key Areas: *Mathematics at the heart of Engineering, Assessment*
Keywords: *self-assessment accuracy, Dunning-Kruger effect, feedback, constructivist learning theory, drop-out*

ABSTRACT

There is a high drop-out rate in engineering higher education, the reasons can be grouped into four categories: economic explanations, individual pedagogical-psychological, learning-related reasons, socio-cultural influences. This paper discusses the problem of the accuracy of self-assessment among the individual pedagogical and psychological reasons.

During the maths midterm tests, students self-assessed on each task, which was compared with the points given by the teacher. More than 80% of students overestimated their actual performance in all midterms, and this overestimation was moderate. Based on the relationship between accuracy scores and test results, students who achieved better results in the midterms gave more accurate self-assessments than those who performed poorly, which confirms the Dunning-Kruger effect in engineering education. Feedback based on their performance may affect the accuracy of self-assessment. Feedback from the midterm caused a significant improvement in self-assessment for students who met mid-term requirements, while there was no such improvement for those who did not. Thus, underperforming students did not benefit enough from the feedback from the first midterm, and the accuracy of their self-assessment did not improve.

The fact that there is a significant difference in the accuracy of self-assessment between students who fulfilled mid-term requirements and those who did not. The self-assessments of the former was closer to the teacher's evaluation than those of the latter. This may be problematic because weaker students are less aware of their deficiencies due to their inaccurate self-assessment, and thus they may stop their preparation short of what is necessary, and may not ask for help when needed.

1 INTRODUCTION

The high drop-out rate in engineering education can be reduced in several ways, one of them is a step-by-step growth supported by an instructor. Next to a personalised tutoring, self-assessment activities can be a simple way of supporting learners to organise their personal learning and to learn to self-manage their learning [1].

Self-assesment is a descriptive and evaluative act carried out by someone concerning his personal abilities, processes and products [2] which is an integral part of learning according to constructivist learning theory. It assumes that the individual learner actively builds new knowledge and skills on his current constructs (schemas), for which external environment only provide the opportunity. In order for learners to progress and move towards their personal development goals, they need feedback (formative) and assessment (normative) on their performance [3] (Fig.1).

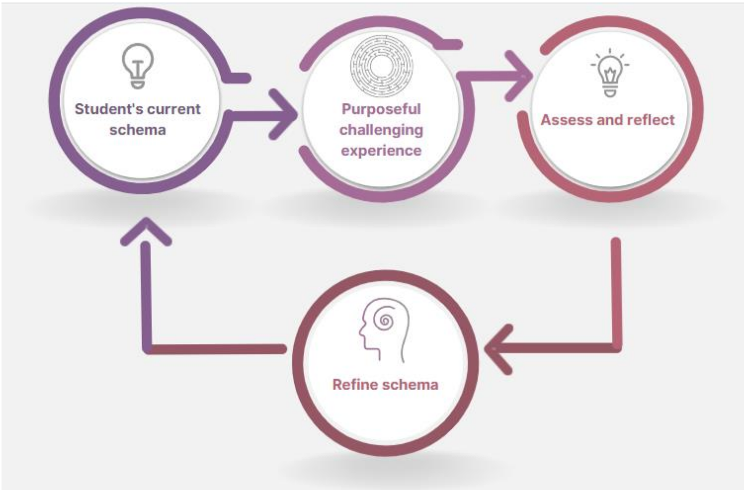

Fig. 1. Constructivist learning model (based on [3])

Harlem and Belski's [4] research refined the constructivist learning model by showing that novice and expert engineers reflect at different stages of the learning process. Their study found that novice engineers reflect only when they make mistakes while expert engineers tend to reflect continuously when they solve problems. In addition, expert engineers reflect on both problem solving processes (planning and implementation) and personal assumptions (understanding the problem), novice engineers reflect only on processes.

Differences in self-assessment are not only observed on the basis of proficiency in a particular field, but also on the basis of competences. Self-evaluation errors of poor and top performers differ too. Based on Dunning–Kruger effect, poor performers in many social and intellectual domains appear largely unaware of their lack of competence. Their deficiencies make it doubly difficult - on the one hand, they make mistakes because of their incomplete and incorrect knowledge, and on the other hand, these same deficiencies prevent them from recognizing when they are making mistakes [5].

2 OBJECTIVE

The purpose of this short paper is to reveal accuracy of self-assesment of engineering students, some relationships between self-assesment and performance, and the impact of feedback on self-assesment. Therefore, the present study aimed to answer the following questions:

1. To what extent are engineering students overestimating and underestimating their performance in the course Mathematics 1?
2. Is there a significant interrelationship among accuracy scores and performance?
3. Is there a significant difference in the accuracy of self-assessment between students who fulfilled mid-term requirements and those who did not?
4. Does the accuracy of assessment change during the semester?

3 METHODOLOGY

3.1 Measure of self-assesment

Several indices of self-assessment can be distinguished, e.g. the accuracy (reliability) and the direction of the bias (validity). Based on the literature [6] the accuracy and direction of students' self-assessment was measured using two indicators: the realism/bias score and the accuracy score.

Realism/bias score = (Average self-assesment score over all items in the test) – (Average performance score[2] over all items in the test)

Accuracy score = the absolute value of the difference between the self-assesment score and performance score for each test item, summed over all items on a test, and divided by the total number of items

During the semester, students wrote two midterm tests and an exam. To take the exam, students must achive a score of 50% in the two tests together. Those who did not meet this requirement could take a make-up test. Each test consisted of 6 tasks for 2 points per task. Before the test, students were given the opportunity to take a mock test and learn the scoring rules for each task. Students graded each task scoring 0, 1 or 2 points. Teacher assessment could also be 0, 1 or 2 points. Based on this, the bias value could take a value between -2 and 2, where a positive value indicates that the student overestimated his performance, while a negative value indicates underestimation. Values close to 0 indicate a lack of bias. The accuracy score could take a value between 0 and 2, where 0 indicates complete accuracy and 2 indicates complete inaccuracy.

3.2 Participants

258 engineering students took the course Mathematics1, 235 students wrote the first midterm test, 214 the second and 114 the make-up midterm test.

[2] Performans score is given by the teacher.

4 RESULTS

The realism and accuracy scores were calculated from the results of self-assessment following the midterm test and from the teacher's assessment which provided the two indices to evaluate the accuracy of self-assessment. More than 80% of students overestimated their actual performance in all midterms (Table 1), and this overestimation was moderate (Fig.1).

Table 1. Distribution of realism scores

	Realism score midterm test1			Realism score midterm test2			Realism score make-up test		
	<0	0	>0	<0	0	>0	<0	0	>0
Number of students	16	18	197	29	12	166	6	8	88

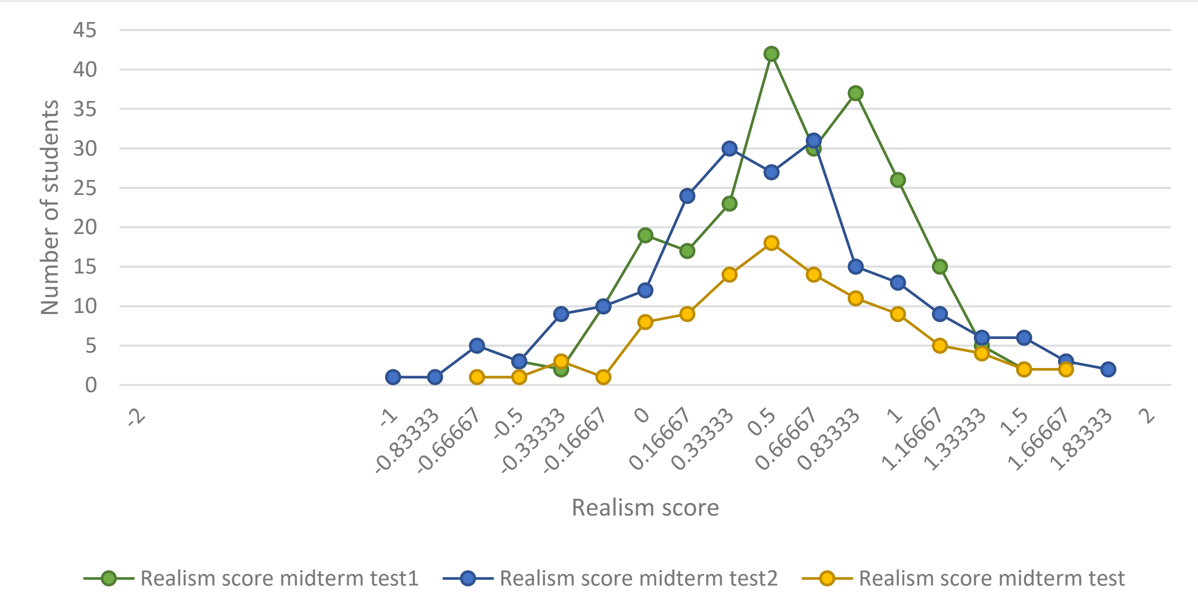

Fig. 1. Realism scores in the tests

In the following, we compare the accuracy scores with the tests' results. The results of the correlation calculation are shown in Table 2, which shows a negative correlation between the accuracy scores and the test scores. Thus, students with better results in tests have an accuracy score close to 0, i.e. they give a more accurate self-assessment of their own performance than students with weaker results. This result confirms the Dunning-Kruger effect in engineering education.

Table 2. Correlation between accuracy scores and test scores

	Accuracy score midterm test1	Accuracy score midterm test2
Midterm test1 score	-0,378**	
Midterm test2 score		-0,372**
Total score of tests	-0,312**	-0,305**

**p<0,01

The fact that there is a significant difference in the accuracy of self-assessment between students who fulfilled mid-term requirements and those who did not, adds nuance to this picture. The self-assessments of the former was closer to the teacher's evaluation than those of the latter. A similar difference is evident between those who pass the exam and those who fail. This may be problematic because weaker students are less aware of their deficiencies due to their inaccurate self-assessment, and thus they may stop their preparation short of what is necessary, and may not ask for help when needed.

Feedback based on performance (i.e. test result and mistakes made in the first midterm), and the opportunity to see the corrected test may affect the accuracy of self-assessment. Feedback from the midterm caused a significant improvement in self-assessment accuracy for students who met mid-term requirements, there was no such improvement for those who did not [Table 3]. Thus, underperforming students did not benefit enough from the feedback from the first midterm, and the accuracy of their self-assessment did not improve.

Table 3. Accuracy scores among students who met mid-term requirements and who did not

	Accuracy score midterm test1		Accuracy score midterm test2	
	Average	SD	Average	SD
Students met mid-term requirements	0,65	0,30	0,57	0,31
Students did not met mid-term requirements	0,76	0,33	0,79	0,45

5 CONCLUSIONS

Self-assessment and feedback can help the individual to make decisions on his developmental path, such as how much time and energy to invest in development, whether to seek external help, whether to continue on the path he has started. The results of the research confirmed that less talented engineering students are less aware of their deficiences and thus have a less realistic self-image to plan their development path which can easily lead to drop-out. One of the benefits of self-assesment can come from active participation in the learning process. There are two ways to enhance participation in this way, firstly by increasing the number of self-assesment opportunities and secondly by training in self-assesment.

ABSTRACT

Formative feedback is a valuable tool that enables educators to provide an immediate and ongoing feedback to improve the student learning [1]. Formative feedback can be done in a variety of ways and can be administered at various times during a learning process [1].

Many studies about feedback and assessment in entrepreneurship educations focus on measuring, assessing and evaluating the contribution of the entrepreneurship education to society etc. and only a few studies have focus on how the didactic question of assessment and feedback are done in entrepreneurship educations [2].

In this concept paper, we report and reflect on our experiences and learnings from implementing formative feedback as a mandatory part of an entrepreneurial introduction course. The paper builds on experiences from one course, which ran in January 2021, in June 2021 and in January 2022.

The feedback design used in this course can be categorized into three situations: (1) from student to student and (2) from student to educator, and (3) from educator to student. The purpose and outcome from using the feedback design is described and evaluated concerning further development. The discussion also includes which initiatives, we consider there are needed to support the further development and the implementation of formative feedback in entrepreneurial courses.

1 INTRODUCTION

The didactic question of how assesssment and feedback are used in entrepreneurial education are rarely described in literature. Instead the main focus is about how to measure, assess and evaluate the post-course contribution of the entrepreneurship education to society or the contributions of entrepreneurship education to students entrepreneurial attitues or intentions [2].

In general, two types of feedback exist - summative and formative feedback. The summative feedback is the assesment for certification and the formative feedback is the assessment for immediate learning. In this concept paper the focus will be on the formative feedback. Formative feedback can be carried out in many ways and is a well-known valuable tool to improve the student learning [1]. Formative feedback can be given from one student to another student, from the student to the educator, from the educator to the student and from one educator to another educator.

The feedback from one student to another student is also called peerfeedback [3]. Peerfeedback is known to increase the amount of feedback the students receive and furtheremore it is known to strengthens the students skills in giving and receiving feedback. However, as other forms for feedback, the peerfeedback needs to be instructed and supported, for example by having rubrics. One way to do the peerfeedback is to use the program Peergrade.io. The program Peergrade.io supports the assignment submission and the feedback process itself. The system provides overview of the students'activity as well as their feedback process [4].

The student's feedback to the educator is valuable data for the improvement of the course. In addition, the feedback can be used to ensure and optimize the quality of teaching and to enable the alignment between the intended goals and the actual learning [5]. Very often this feedback comes from the course evaluation performed at the end of the course. However it can also be done on a daily basis which enables for an immediately improvement of the course.

To give and receive feedback can be complicated and therefore the students need to learn how to do this to be able to do it in practice. There is therefore a need for a framework which clarify the roles and the rules regarding how to give and receive feedback. It is often the educator, who constructs this framework and sets up the criteria for the feedback, but it can also be done together with the students.

In this concept paper, we report and reflect on our experiences and learnings from the implementing of the formative feedback as a mandatory part of an experiential-based through learning entrepreneurship course. In this study, we do not have focus on the final evaluation (the summative feedback).

2 METHODOLOGY

The data are based on reflections from a three week course, which ran in January 2021 (52 students), June 2021 (22 students) and January 2022 (55 students) and were held at the Technical University of Denmark (DTU). The students came mainly from the bachelor of engineering education in Global Business Engineering with some few students from other bachelor of engineering programs at the University.

During the course the following feedback activities were carried out:

- Student to student feedback (peerfeedback) using the online program Peergrade.io
- Student to educator feedback done on a daily basis and at the end of the course
- Educator to student (individual/groups) several times during the course and final on the poster session

For the group work, the students were mixed in groups of 5-6 students by the educator. The group formation was performed based on a preference test, which the students did before the course. Students with different preferences where put together in the groups. During the course, the students worked with their own idea as an experiential process of learning through entrepreneurship. At the end of the course each group presented their solution at a poster session and documented the solution in a business report, which they submitted on the final day of the course. During the course, there were presentations and several hand-ins both as an individual and as a group.

Student to student feedback (Peerfeedback)

After the first week of the course the students handed in an individual report. The individual report concerned the entrepreneurial methods which the students had used and refleced upon. The maximum length of the report was set to five pages. The submission was done in the program Peergrade.io [4].

The peer feedback session consisted of four parts:

1) An introduction to the peerfeedback session and an introduction on how to give and receive feedback. Furthere more a short introduction to what constructive feedback is and how to use the feedback afterwards was given.
2) The peerfeedback session took place using the program Peergrade.io. The rubrics consisted of two criteria:
    a. Mention something your classmate did well.
    b. Mention something your classmate could improve.
3) After the peer feedback session each student met with the educator and reflected on the peerfeedback session.

4) In the final report, each students reflected on the peerfeedback session and the results (learning).

Each student had two hours to read and provide feedback to three fellow students. Afterwards each student received feedback from three other students and they had to respond to the feedback and do self reflection concerning the feedback given. Afterwards the educator read the feedbacks and had a follow up meeting with each student.

Later almost at the end of the course, there was a poster session. At this session, the groups gave feedback to each others presentations in regards to the content and the presentation itself.

Student to educator

Two types of student to educator feedback were used. At the end of the course, a survey-based questionnairy was sent to each student.This survey was carried out by the university and will not be discussed in this paper.

On a daily basis the students gave feedback to the educator. Two students volunteered to be the feedback persons for the day. The two students had to make notes during the day about the teaching material (papers, videos etc.) as well as the teaching activies like the activation of the students, the informations load etc. At the end of the day, the students and the educator sad together and the students gave feedback to the educator. On the next teaching day two other students were feedback persons for that day.

Educator to student (groups)

Several times during the course, formative feedback from educator to student (groups) were provided. This feedback was concerning the process.

The educator also provided feedback to the students after the individual report, so the students receive feedback from three fellow students and the educator with regards to their learning report (individual report).

Near the end of the course all student groups did a poster presentation. For this event the external censor was present. The student group received feedback from other groups, the censor and the educator. The feedback was given as formative feedback and the groups had the next two days to incorporate the feedback in the final report before submission.

3 RESULTS

A framework for giving and receiving feedback has been presented and the learnings and findings from using this framework will be presented here.

Student to student feedback (peerfeedback)

In this course, the student to student feedback is concerned with the entrepreneurial process and the students learning from using different entrepreneurial methods and tools. For the peerfeedback, the online progam peergrade.io was used. The output of using the program peergrade.oi has been described in previous paper for a similarly course [6]. The feedback from students were that they appreciated the way of giving and receiving feedback (see some statements below). However it is important to be clear about the expectations to the type of feedback. For example it should be made clear if the feedback is concerning the format of the report or the content. Therefore the framework for the student to student feedback can still be improved and in the future more introduction and clear expectation to the give and received feedback will be included to ensure a high output.

Statements from the students from the peerfeedback session:

- *" Overall, I liked the concept and I think feedback from other students is a good idea".*

- *"Peergrade was really a good tool to improves one's own report by both seeing how others have handled the task and but also by getting constructive feedback from others".*

- *"I personally got a lot out of giving feedback to others as I was required to familiarize myself with the report in order to provide a good contructive feedback to the person".*

At the poster session, each group had to provide feedback to another group concerning the content and outline of the poster presentation. The feedback was used to up date the final report. The student were very active in relation to give feedback in this session.

Student to educator

The focus for student to educator feedback is regarding the teaching activities and the teaching material. In this course, the feedback from the student to the educator is given in two ways – on a daily basis and at the end of the course. The feedback on the daily basis was informal semi-structured dialogues between the student and the educator concerning the teaching material and the teaching activities. The feedback giving on a daily basis was used to make directly changes when needed or to include extra material for the next lessons. The students were good at being volunteers and new students were giving feedback every day.

At the end of the course, the course was evaluated by a survey-based questionnairy. These evaluations were performed by the University and will not be discussed here.

Educator to student

The focus for the educator to student feedback is based on the entrepreneurial process. In this course, the feedback from educator to students are conducted several times during the course. The feedback from the educator to the students (group) with regards to entrepreneurial process is essential for the students to be able to create, to adjust and to help them to move forward with their projects.

Experiences from running these courses show that the students are actively involved in the feedback process and they positively appreciate the different ways of receiving and giving feedback. However a framework with clarify the rules and the roles for the feedback process is important to have.

4 SUMMARY AND ACKNOWLEDGMENTS

In this paper we have presented a feedback design used in an introduction course concerning entrepreneurship. The main focus in entrepreneurial education is often on the outcome of the entrepreneurial process and only rarely with focus on the didactical aspect. In this paper, we describe how feedback can be used to provide feedback between students, and between students and educators with a focus on both the entrepreneurial process and the students learning. The feedback from the educator to the students is essential for the students in entrepreneurship courses as the students projects and learning outcomes are created and modified based on the feedback they receive throughout the entrepreneurial process [2].

Our experiences show that the students appreciated feedback and they appreciate having an open dialogue about it. To have a feedback system is essential for the students learning process. But there is also a strong need to communicate to the students how the feedback is conducted and it's purpose in the particularly course.

The forms of feedback presented in this paper are all dialogue based with the aim of creating, adjusting and supporting the development of the entrepreneurial learning process and improve the teaching. However the framework for feedback can also be applied to other fields.

In this study, we have not had the possibility to conduct the educator to educator feedback. Feedback from one educator to another educator could be about having focus on how the course is progressing and to what extent the teaching is supporting the students in their entrepreneurial process.

Based on our learnings we will continue working with the framework for feedback and make more guidelines regarding how to give and to receive feedback.

ABSTRACT

In this paper we present the development of a matrix used to assist study boards and stakeholders in embedding digital competences into their engineering curricula. The matrix was developed by reviewing existing frameworks of digital literacy and competency at the citizen, upper secondary and higher educational levels and modifying them to suit the context of problem- and project-based learning (PBL) in engineering education. The matrix draws together three categories of digital competences (general academic competences, problem-based learning competences, and discipline specific competences) and an interdependent taxonomy of digital competences (user competences, development competences and reflexive competences), resulting in a matrix of nine distinct types of digital competences. The resulting matrix makes accessible the concepts of digital competences enabling different stakeholders in the curriculum design process (study boards, industry advisory bodies, students etc.) to make meaningful contributions to the curriculum development process.

1 INTRODUCTION

In the aftermath of Covid-19 lockdowns, online semesters etc., a focus on digital competences and general digitalization of higher education have received renewed attention worldwide. In Denmark, most major comprehensive universities have recently (re-)defined strategies for further digitalization of core practices, both at the organizational infrastructure level and across the main activities of research, teaching and learning. In most cases, this includes a revision of curricula for implementing learning goals for digital competences. Within engineering education so far, there has been an inherent tendency to attend more to technical digital skills, such as modelling and other user and developer skills in relation to technology. However, over time digital competences have developed from being regarded as purely instrumental to technical skills since digital technology has permeated more and more aspects of life. To further develop students' digital competences and digital practices, including practices related to the development of PBL skills, such as problem oriented, interpersonal, organizational, and metacognitive competences [1], a curriculum revision is necessary, guided by and grounded in theory and frameworks of digitalization, PBL and curriculum development.

At Aalborg University, curriculum development involves inclusion of different stakeholders, such as the university study boards, which are comprised of internal academics and students, as well as meetings with stakeholder panels including industry partners, representatives from relevant organizations, other related educational institutions, alumni, regional and municipal councils. Each of these members brings a valuable perspective to the curriculum design process; however not all have an in-depth theoretical understanding of the frameworks involved. To facilitate the contribution of all members, we reviewed the existing frameworks and expanded them to fit the purpose of implementing digital competences in higher education engineering education curricula. The resulting matrix makes complex concepts of digital and PBL competences more accessible to all stakeholders in the curriculum design process, as well as provide a framework and shared language for discussing engineering students' digital competences and digital practices across different higher education institutions as well.

2 FRAMEWORKS AND CONCEPTS OF INSPIRATION

It can be difficult to distinguish the abundance of existing frameworks and concepts, especially for non-experts. Furthermore, the concepts are to some extent tied to specific domains, identities, or professions, such as citizens, education, and industry, each of which need different digital competences.

Concepts include e.g., digital competences, digital literacy/literacies, critical digital literacies, digital skills, digital key competences and more [2]. A review of the two most commonly used concepts, *digital literacy* and *digital competence*, has shown that digital literacy has been linked to technical "know-how" via cognitive skills but also social practices and proactive engagement, whereas digital competency is often linked to competences related to values and ethics, but often also expands to include other areas towards professional contexts, such as higher education teachers' ability to use ICT in learning activities [2].

The different roles and characteristics that digitalization can take have already led to ideological debates concerning the purpose and direction of the digital futures for universities [3]. This is also illustrated by the lack of theoretical frameworks guiding the processes of implementing digital and transversal competences in higher education. Frameworks have been developed for primary and secondary school levels and citizens in Denmark and EU by researchers, and national and supranational councils [4,5]. However, in higher education, including the different disciplines and modes of education, mainly local, more generic frameworks are available, some of the more prominent being the JISC project [6], Near Future Teaching [7] and STAK [8].

These frameworks formed the basis for the matrix presented in this study [9]. From STAK, we adopt the following definition of digital competences: *"Academic digital competences are expressed when students combine digital technology, research methodology, and domain specific knowledge at the same time and with the same purpose; and when the three aspects support and complement each other* [authors' own translation]*."* [8]. DigComp 2.2 [5] was used to discuss the understanding of taxonomy. Whereas the DigComp 2.2 framework is based on a taxonomic understanding of progression from user competences (remembering, understanding) to developing and reflection (applying, evaluating, creating), our framework regards 'use', 'developing' and 'reflection' as distinct categories each incorporating their own taxonomic levels. The results of this work were coupled with the work with digital competences for citizens and in primary and upper secondary school in Denmark by Danish IT [4], which highlights three different categories of digital competences: user, creator, and reflexive competences that are partly overlapping and mutually dependent. Thus, they are not hierarchically ordered, but rather interdependent, and competences within all three categories are needed. The three categories cover:

- *User competences:* needed for the use of technology, that is to know and understand digital tools, access and evaluate information, and lastly manage information efficiently.
- *Creator competences:* enabling a person to create using digital technology, that is to e.g., produce, assemble, process, and exchange information for a specific task and repurpose digital elements. In an engineering context, this would include competences related to collaboration, design and development of IT-systems, analysis, modelling and structuring of data and data processes, i.e., to use algorithms and models to describe phenomena and processes.
- *Reflexive competences:* enabling individuals to act with awareness of possibilities and risks when using and creating digital technology. This also relates to handling ethical and legal issues, being able to create and present oneself in digital spaces as intended and understanding how digital technology affect society.

3 THE FINAL MATRIX

These three categories of digital competence furthermore need to be coupled with and contextualized within domains of student learning. At Aalborg University, the curriculum is strongly PBL based, which means that a third category is added to the distinction between ‘general’ academic competences and domain or discipline-specific competences; namely PBL competences:

- General academic digital competences such as searching, collecting, sharing and processing information, creating and using databases, producing and disseminating knowledge in different formats, i.e., competences typical across academic learning environments.
- PBL competences such as problem-orientation, interpersonal skills, management and leadership skills, and meta-cognitive competences, i.e., competences needed specifically in problem-based project work.
- Domain-specific digital competences such as modelling, simulation, grouping of data and others that are that are typical for a specific discipline or profession.

The distinction between the three types of digital competences is essential for capturing the complexity of digital competences and help guide the focus on the purpose of each of these competences, and the contexts in which they will be used. The final result is a 3 x 3 matrix that synthesizes the frameworks of the different domains of digital competence, making them accessible for non-experts in digitalization and PBL to contribute their perspectives to the curriculum design process. A copy of the matrix is represented below in table 1 with generic examples.

Table 1. Copy of the matrix with generic examples

	General academic	**PBL-specific**	**Discipline/domain specific**
User	*e.g. literature searches and use of academic databases*	*e.g. using digital tools to improve the team’s time/ resource management*	*e.g. use tools to solve discipline-specific problem*
Creator	*e.g. writing reports and making presentations*	*e.g. creating a collaborative hybrid working environment*	*e.g. designing new digital solutions to discipline-specific problem*
Reflexive	*e.g. reflecting on how to maintain motivation in online/hybrid teaching*	*e.g. reflecting on how online communication affects group dynamics and conflict management*	*e.g. reflecting on how digital solutions might bring new, unintended problems*

The adapted framework now orients itself towards higher education and especially universities using PBL or similar student-centered educational models. The multi-dimensionality of the framework allows for reflection on the complexity of digital competency in higher education and offers staff, students and study boards a point of departure for analyzing existing learning outcomes and for creating a shared language and practice around future digitalization within their discipline. The matrix also facilitates the elicitation of feedback and input from external stakeholders.

4 CONCLUSION AND FUTURE WORK

This paper has presented the development of a matrix that builds on and increases accessibility to complex concepts and frameworks that can be challenging and time consuming to understand. The matrix thereby helps to include internal and external stakeholders in the process of developing curricula by enabling them to contribute with their viewpoints on complex concepts in relation to digital and transversal competences, i.e., PBL competences. The matrix can be of use, or inspiration, for others who are facing the same process of implementing digital competences in higher education curricula in the near future. While this paper has presented the development and theoretical background of the matrix itself, future work will include reporting on the practical application of the matrix in curriculum development processes and identified potentials and challenges as well as the mapping and analysis of the types of competences that resulted from working with the matrix.

ABSTRACT

An Engineering student´s Final Degree Project based on the design and manufacturing of a 3D printed telescope is presented. The project involves both optical, mechanical, and electronic design, the construction of the instrument, and the numerical and experimental analysis of the prototype. Furthermore, the project explores the possibilities offered by the current 3D printed technologies for the manufacturing of telescopes that may be used both for teaching and disseminating Astronomy and the basis on how to build such instruments.

In this communication the current development of a student Final's Degree Project, consisting of the design and construction of a 3D printed Newtonian telescope, is presented. Both the project and the learning experience are shown as an example of the possibilities of this kind of study at the final stages of the academic formation of engineers, and the possibilities for outreach, education and dissemination of both science and engineering are explored.

1 INTRODUCTION

1.1 3D printing technologies

Since early 2000's, 3D printing technologies, which were originally introduced in early 80's [1], have done nothing less than keep expanding through the globe and becoming key in technological developments in fields such as medicine, fabrication methods or even in the aerospace industry with the design and fabrication of new rockets with many of its components 3D printed.

As an example, a recent work [2] has shown the possibilities of the practical implementation of 3D print optomechanical hardware with high-performance rates and with a cost much lower than if conventional commercial hardware was bought. This reference is an illustrative example (among many others) on how 3D printing technologies can be a game-changer in research and development in many areas of the optical industry.

1.2 Amateur Astronomy

Amateur Astronomy is a field in which different technical skills and needs converge. The amateur astronomical community is formed by thousands of motivated people that want to know more about the Cosmos and to transmit that knowledge to the public. Furthermore, a huge fraction of that community is also interested in do-it-yourself projects, such are specific arrangements and adaptations for the cameras used in astrophotography, among others.

The basic tool for amateur astronomers is the telescope. Telescopes are optical instruments that, in the context of amateur Astronomy, can be divided into three types: refractors, reflectors and catadioptrics [3].

Refractors ara based on the use of refracting elements (lenses). Despite there are several configurations and designs available, the main basic design for this type of telescope is the so-called Keplerian telescope, which is compound by two positive (i.e, converging) lenses (the objective and the eyepiece), and it is the principal design used nowadays (despite optical corrections such as the use of achromatic doublets or inverters for the case of terrestrial telescopes). Another common design is the Galilean telescope, which uses a negative (divergent) lens as eyepiece.

On the other hand, reflecting telescopes are based on reflection law instead of refraction. The objective is in that case, a mirror (the so-called primary mirror). Parallel beams of light enter the tube by the top opening and travel through the whole telescope until they reach the bottom, where a parabolic (or spherical) mirror reflects the light to a secondary mirror mounted on the spider at the top of the telescope. This secondary mirror reflects light to the eyepiece. One of the most popular designs of reflecting telescopes used by amateurs is the Newtonian telescope.

Finally, catadioptric telescopes are a combination of the characteristics of both refractors and reflectors, combining the benefits of the two approaches in order to obtain better images.

2 METHODOLOGY

2.1 Design and development of the telescope protoype

Considering the different commercial configurations used by the amateur community, and the commercially available low-cost optical components, a Newtonian configuration was chosen for that project.

The optical specification of the design is a F5 Newtonian telescope. The aperture of the instrument os 6 inches (152 mm) and the focal length of 760 mm.

For the mechanical design, a CAD software (SolidWorks) was used. Several iterations were done for the design and development of the components and a numerical analysis (by enas of finite-element analysis, FEM) has been carried on.

Figure 1 shows a view of the final CAD design.

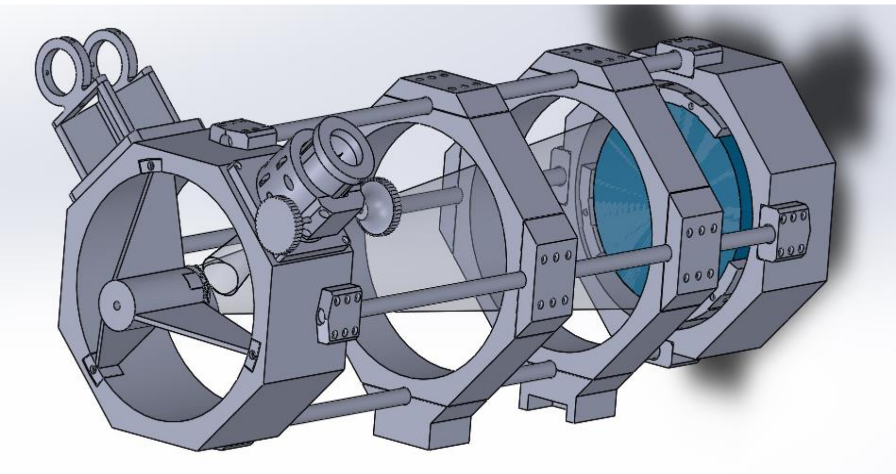

Fig. 1. Telescope design CAD. The shadowed surface represent the light-cone inside the optical path.

Despite the optical components (mirrors and eyepiece) and some aluminium and other metals parts (such as the bars), the instrument is fully manufactured with 3D printed components using PLA.

A wavefront analysis is going to be implemented in the next months for evaluation of the laboratory optical performance of the telescope, and the mechanical performance and stability of the instrument would be tested. Preliminar field observations had been done, as shown in the third section of this work.

2.2 Activities

The final objective of this project would be to present a free kit, which will cover the following topics:

- Building your telescope: a 3D printing workshop. A full workshop based on the basic development of the Final Degree Project presented in this configuration. The 3D files and an assembly annual will be available for students and motivated individuals to build their own 3D printed telescope.
- Fundamentals of telescope optics. A basic course of optical principles (refraction and reflection), telescopes and Astronomy, with experiments and experiences using 3D printed components.
- Hands-on activity: astronomical observation. The telescope would be used either as a demonstrator in fairs or schools, or to perform educational public observations.

At the time this short paper is written, the different tool-kits and manuals are being developed, and the implementation of this different activities has been scheduled for next months.

3 RESULTS

A final prototype has been built ensuring each piece was correctly printed and all the components fits precisely without any critical load. The final assembly is shown in Figure 2.

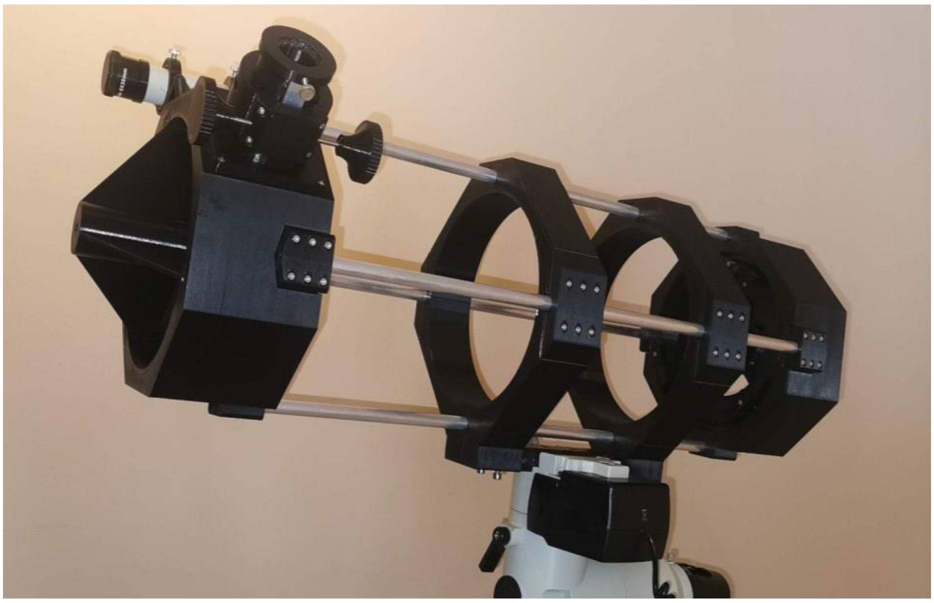

Fig. 2. Final assembly of the 3D printed telescope.

In order to test the capabilities of the designed instrument, an equivalent commercial system was borrowed to the COSMOS Mataró amateur astronomical association. The first test comparison is shown in Figure 3. Authors are currently waiting for an optimal observation night, to obtain full results of the telescope's real resolution and capabilities.

Fig. 3. Image of a telecommunication tower obtained with the Meade LXD75 telescope (a)) from COSMOS Mataró, and with the 3D printed F5 Newtonian (b)). Both images were obtained using the same equatorial mount.

4 SUMMARY AND ACKNOWLEDGMENTS

This work presents an engineering Final Degree Project based on the deign and manufacturing of a 3D printed telescope for educational purposes. A set of tool-kits and experiences using and working with such instrument are defined and will be implemented in the months after the SEFI conference.

Authors acknowledge their University and the COSMOS Mataró association for the possibility of develop such project. The corresponding author also wants to thank his family and friends, especially his parents, brother and uncle, who had inspired and encourage him to become a greater engineer.

ABSTRACT

Challenge-based learning (CBL) seeks to help students acquire skills necessary for collaborative real-world problem solving. It generally favours self-learning, in which students should seek out their own role in a problem-solving environment and choose their own set of skills to develop which are relevant to the challenge. However students from traditional degree programmes may enter with an expectation that their disciplinary expertise will count and be valued in the context of a project, but face a situation that the problem chosen by a group or the dynamics of a group render their expertise less relevant. In survey-based studies of two CBL modules, we explore the relationship between the roles students play and their levels of motivation. We find no evidence that the lack of a disciplinary role strongly affects student motivation. Rather the data suggests that if a CBL environment is properly framed around self-development and multiple potential learning goals students can relax any commitments or expectations related to their expertise, and take on different roles. This is good news for the CBL aims and goals. That said students do have a tendency to revert to disciplinary roles over the course of projects and are against their disciplinary roles being excluded when they are clearly relevant. Instructors can potentially avoid problems by having students evaluate their role choices against desired project outcomes.

1 INTRODUCTION

Challenge-based learning (CBL) is increasingly advocated as an important option for scientific and engineering curricula, as a means of preparing engineers and other scientific groups for solving real-world problems and engaging better with societal interests and values [1,2]. CBL aims to train interdisciplinary skills, important for real-world problem solving [2,3]. CBL is often (although not exclusively) offered as part of disciplinary programmes [3]. Such courses operate across university programmes and draw students from different disciplinary backgrounds. As such students bring their own expertise and potentially their own expectations regarding the roles they should play in a project team. For example a psychology student may enter a technological design-based challenge with a view that he or she will have a role evaluating how users might engage with a technology, only to find out that the most pressing issues are technical and there is little time or place to consider the psychological dimensions. This might be manifest in the way the challenge is constructed or the decisions groups reach about how best to complete the task. As a result though it is plausible to hypothesize that such events affect negatively student motivation. While the effectiveness of self-learning has been studied [4] the interdisciplinary aspects of CBL have lacked attention [5]. In this paper we pursue the research question: is the motivation of students from bachelor programmes entering CBL courses affected by their ability to apply their disciplinary expertise?

2 METHODOLOGY

2.1 Study design

To explore whether disciplinary roles (and resulting expectations) might affect student motivation we performed surveys of students in two CBL courses. Students were surveyed once in the first two weeks, and again in the last two weeks. Intrinsic motivation was measured with the nine-item version of the intrinsic motivation inventory in both surveys to detect variations [6]. Both surveys also included a variety of statements related to their more explicit motivations, expectations, based on their roles, and responses to behavior of fellow group members (1 to 5 Likert scale; strongly disagree = 1, disagree, neither, agree, strongly agree = 5). See Table 1 below for examples.

2.2. Included Cases

The first course titled “Course 1”, is taught in the third year of bachelor students and is open to students from across a Dutch technical university for one quartile (10 weeks; 15 ECTS). Students collaborate in interdisciplinary groups on a real-world product design problem provided by a “challenge-provider”; either a government agency, foundation or corporation. Challenge-providers provide a problem description and relevant group skills, and provide help on request from students. Learning goals for the module concentrate on developing collaborative and communication skills, integrating stakeholders into a solution and sound design-based decision-making. Students may be from technological or social science backgrounds.

The second course “Course 2” is run for European consortium of universties (5 ECTS; two semesters). Students collaborate on real-world tasks constructed by challenge-providers. Students may come from any background. For learning goals students should develop skills in analyzing complex societal problems and working in teams. But they are also given a choice regarding others; such as whether to work on presentation or leadership skill, design skills, or stakeholder involvement. Project outcomes are not graded. Students are asked to provide reflections on their personal targets, and personal and team development

3 RESULTS

3.1 Figures

Table 1: Sample of questions from the first survey round. Results are Likert averages.

Questions Round 1	Course 1	Course 2
	n=17 (/40)	n=17 (/31)
I selected the programme to work… on a real world challenge	4.2	4.5
…apply my disciplinary expertise to a real world problem	3.5	3.9
…apply non-disciplinary skills	3.5	4.1
… on new skills	4.3	4.3
I chose my challenge..…as societally relevant	4	4.5
…as relevant to my disciplinary skills	3.2	3.5
…as relevant to professional skills	3.2	3.5
.. to develop new skills	4.2	4.2

Table 2: Sample of questions from the second survey round. Results are Likert averages. Some questions, marked ‘X’, were only developed after surveys of “Course 1” students.

Questions Round 2	Course 1	Course 2
	n=7 (/40)	n=12 (/31)
Most of my challenge contribution has come from…my discipline	X	3.2
… professional skills	X	3.8
….new knowledge and skills	X	3.5
My contributions fit the kind of role I expected to play	X	4.0
The challenge did not offer all members the same chance to use their expertise.	2.9	2.3
We would have a more optimal solution if I had used my disc. expertise more.	3.3	2.7

3.2 Discussion

In neither course was there evidence that a failure to contribute disciplinary expertise played a substantial role in student motivation. This holds despite many students having a non-disciplinary role geared towards the use of professional skills or development of new academic skills (roughly half of Autumn Challenge students).

Overall student intrinsic motivation increased for each programme rather than fell, likely as a response to students becoming more familiar with their challenges, their roles and their group members.

In terms of the explicit motivations guiding their choice of these CBL programmes or their challenges students put more weight on developing new scientific/engineering skills outside their area of expertise or working on a societal problem over use/development of disciplinary skills or professional skills (see Table 1 below; first question round). As both courses explicitly allow students to consider and take different roles beyond their background expertise, not being able to use one's expertise is likely not considered an issue. The vast majority of students in the Autumn Challenge felt they performed a role in line with their expectations going into the programme. Students from neither programme felt that they were excluded from playing a disciplinary role if they wanted to. Fellow group members were generally open to including any approach. Further students did not feel it necessary to have a disciplinary role if this was not relevant to an optimal or indeed just a good enough outcome. This is good news for CBL which stresses flexible and personal outcomes.

However there are a few notes of caution before drawing the conclusion that students will always be happy to look passed disciplinary roles and be flexible. In the first place many students (around 25%) do still express a primary preference for having a disciplinary role, and for a fraction of students, being excluded, particularly those from the social sciences, is demotivating. Secondly in Course 2 projects were not formally assessed or graded, relaxing incentives for producing an optimal result. A majority of students in both groups did not feel that taking a disciplinary role would have improved the overall project outcome. However most students still felt that they would not be happy if their disciplinary expertise was excluded when it would produce a more innovative outcome. Most students agreed that if their discipline was equally important to a problem solution it should have an equal role. Further while students generally think that their group members respect their disciplinary expertise, and to a lesser extent are willing to learn from it there is a measurable change in how students perceive the willingness of their teammates to work outside their disciplines over the course of a programme. For the statement "*My fellow group members are willing to experiment with methods and ideas outside their background disciplines.*", which was asked both rounds average agreement dropped 25% in both groups. This suggests that students do revert somewhat to disciplinary approaches or familiar skills, even if initial attitudes are towards acquiring new skills, possibly because it takes time to recognize a disciplinary role or because it turns out easier.

Students were free to choose these programmes. Both were offered additional to their normal disciplinary education, rather than part of it. Applying CBL as say part of normal disciplinary education, in which projects are graded, thus might face motivational issues related to disciplinary roles on the basis of these student preferences. However with the right expectations, self-selection of students and opportunities for transversal skill development, educators should avoid potential motivational problems. Regardless there are different possible responses educators can take to manage such problems were they to arise. Students might be given an innovation management strategy (such as knowledge cross-fertilization or Scrum) which help students plan upfront their roles, and systematically integrate their expertise [7]. Students can be otherwise guided to explicitly consider their desired project aspirations when making role decisions; e.g. “Is my role choice likely to generate the most optimal or practical outcome? Do I want that?”. Further it can be useful for groups to consider the potential contributions of all disciplines before settling on an approach.

ABSTRACT

Technological innovation and scientific progress are important components for improving human condition and economic success. Therefore, a workforce that includes a critical amount of experts in science, technology, engineering, and mathematics (STEM) domains is needed. Evidence supports that males and females often present differences in their performance and preferences towards some STEM courses and occupations, especially engineering. Specifically, the number of women that decide to pursue careers in the engineering field is relatively low. One possible factor contributing to this gender gap that has gained a lot of interest recently is gender stereotyping and distinct gender roles among societies. Segregation between women and men's societal roles result in psychological gender differences, emerging from early childhood, and can later affect career choices. Additionally, different gender related standards imposed by the society drive women towards activities, majors and careers perceived as more "feminine". Another way gender stereotypes contribute to these differences is by affecting the development of cognitive skills that are hugely involved in engineer learning and thinking. Spatial abilities are part of such skills that play an important role in academic and occupational achievements in STEM domains, is strongly correlated with engineering education and can, on average, be less developed among women relative to men. In this paper we are going to review the literature on the influence of gender stereotypes on women's spatial ability development, and how this may later prevent them from pursuing a career in engineering.

1 INTRODUCTION

The topic of women's underrepresentation in certain science and engineering fields continue to attract the interest of many scholars [1][2]. Even though, women outpace men in higher education, earning 57% of all baccalaureate degrees, some disciplines remain sharply gender segregated. This phenomenon is very evident in engineering, an area where women complete approximatelly 19% of undergraduate degrees [1]. There are few explanations for the high rates of attrition among women, for example: 1) the chilly or unwelcoming environments that women come across and drive them to exit these majors [1][3]; 2) gender stereotypical approaches towards career among societies, for example people often paint certain professions and activities as masculine and other feminine [1][4]; 3) spatial abilities [3][4]. In general, segregation between genders and strong gender stereotypes among societies do influence a person's view of themselves and their perspectives, and ultimately their behaviour and participation in certain activities that contribute to their development[1][4]. These influences are observable from a very young age, even from 5 or 6 year old. Moreover, girls who are strongly influenced by their social role might not participate in activities (e.g., playing with blocks, using tools) that embrace the development of cognitive skills that play an important role in engineering learning and thinking [4]. While the levels of general intelligence do not differ between men and women, gender differences are sometimes present in more specific cognitive abilities. In particular, spatial abilities are one of the cognitive abilities that present the largest gender gap; on an average level men tend to outperform women in spatial abilities tasks [3][4]. In the following review we are first going to cover the important role of spatial abilities in STEM education, followed by the gender stereotypes, and then how the gender stereotypes may affect women's participation in engineering.

2 THEORETICAL BACKGOUND

2.1 Spatial Abilities & STEM

Early expertise in spatial abilities in children builds the foundation for the development of quantitative reasoning, a collective term encompassing science and mathematics. According to literature, early differences in spatial abilities show important implications for students' achievements in science, technology, engineering, and mathematics (STEM) fields [3]. But what exactly do we mean with the term spatial abilities; Linn and Petersen [5] defined spatial ability as the "skill in representing, transforming, generating and recalling symbolic, non-linguistic information". In other words, it includes the ability to realise and perceive spatial connections, to visualise spatial related stimuli like objects, and be able to transform or manipulate them – for example using mental rotation to imagine how an object would appear from a different point of view or perspective [3]. Therefore, it is understandable how these skills are important in STEM curricula, since tasks in these fields include identifying, explaining, and classifying the shape, position, and orientation of objects; manipulating spatial representations in the form of diagrams, graphs, or scientific models; picturing the processes of objects' movement in 3D coordinates; and tangling non-spatial phenomena by using spatial-thinking strategies [3].

Moreover, evidence from longitudinal studies strongly support this link between spatial abilities and STEM [6][7][8]. This evidence demonstrate that: (a) spatial abilities are a "salient psychological characteristic" to advance educational achievements in STEM among young people, who subsequently succeed in similar fields later in life; (b) spatial abilities are involved in shaping the academic and occupational outcomes for intellectually talented individuals and the general population; (c) recent talent searches lose many intellectually talented individuals by limiting their selection criteria to verbal and mathematical abilities measures [6][7]; and (d) students with higher spatial abilities show more interest towards STEM related subjects [8]. In addition to these longitudinal studies, research has highlighted the correlation between spatial abilities and mathematics [9], physics [10], computer science [11], geometry [12], chemistry [13], and engineering [14][15]. Therefore, it is understandable why this topic has drawn the attention of numerous researchers, and why the gender differences in this area pose a concern.

Prior research that focused on gender differences in spatial abilities have made the following observations: (a) not all categories of spatial abilities present gender differences, (b) most gender differences are in mental rotation tasks, (c) once gender differences are found they are detectable across the lifespan [5]. Due to evidence supporting that spatial abilities can be trained and improved via interventions, practice and training [16] and there seems to be a developmental progression of these differences through childhood with an increase later in adulthood, most researchers argue the gender gap is a result of social influences and sociocultural processes more so than biological changes [4]. Research has shown that gender differences in spatial abilities are due to gender differences in spatial experience, for example playing with spatial toys and participating in spatial school subjects [16]. These ideas created the foundations for socio-cultural theories, where the relevance of the stereotyping factor is clear [4]. Especially in late childhood, gender stereotypes offer a reasonable explanation for the gender differences in spatial abilities; and considering the implications of spatial abilities in STEM domains it can also explain females' underrepresentation in some of these fields [3].

2.2 Gender Stereotypes

One commonly held stereotypical belief is that spatial ability is an inherently male aptitude, that males are naturally gifted in this ability. In the long term, these beliefs regarding the masculinity of spatial abilities potentially result in gender differences in spatial achievements by affecting the consistency of how often girls and boys participate in spatial activities at home and school and by influencing their self-concept of ability [4][16]. Example of spatial activities that contribute in the development of spatial abilities include playing team sports and engaging with workshop activities, such as practicing with tools and repairs. Different gender socialisation may encourage boys to participate more in these activities than girls [16]. Moreover, in the short term, gender stereotypes, by activating negative or positive beliefs about a boy's or a girl's abilities, could result in performance differences between males and females during a spatial test situation [4].

The influence of gender stereotypes has similar effects in some STEM courses. For example, a general idea that boys are better than girls in mathematics might effect girl's performance in math tests and make them internalise this perceived general group characteristic ("girls are bad at maths") as a personal characteristic ("I must be bad at maths"); which off course is not true. Children from the age of 6 are aware of the existence of stereotypes and make important steps towards the development of self-concepts and abilities; and stereotypical beliefs are already present by the age of 10 [4]. It appears that boys and girls from young age adopt behaviours and characteristics in order to fit their gender roles as imposed by society, according to psycho-social theories [4]. The power of stereotypes can be very salient, they can occur unconsciously, get internalised and effect ones' image and behaviour without the person realising it.

2.3 The Role of Stereotypes in Engineering

Gender stereotypes towards the field of engineering potentially affect women's participation in this field. Stereotypical claims portrait engineering as a masculine domain and project the male dominance in this field [2]. Even though, women are more involved in the field than they used to be and they have made great contributions, based on stereotypes engineering is still commonly considered to be more suitable for men [2]; making women to often feel the need to prove themselves in the field. There is one issue which is often overlooked in this topic, it is the fact that women are not equally underrepresented in all engineering majors; but most of the studies do not specify in which fields women are more underrepresented [1]. For example, in 2013, women completed 40.6% of biomedical engineering degrees, and 36% of chemical engineering degrees, but they comprised only 13% of degrees in electrical and mechanical engineering [1]. The bigger percentage of women in the biomedical and chemical majors, suggests an interesting contrast within the area.

The reason for that could be explained by a theory suggesting gender dualistic approaches among practicing engineers. This dualistic thinking fit engineering practices, jobs, and even personal identities into mutually exclusive categories, for example: 1) technical versus social, 2) hard versus soft, 3) even abstract versus applied [1]. Although, not inherently gendered, the more technical, hard and abstract factors are tailored to the cultural understandings of masculinity, hence more suitable for men, while the social, soft and applied ones are perceived more feminine, hence more suitable for women [17].

In their study Blosser [1] observed that engineer faculty members give feminine or masculine characteristics to different disciplines and then imply that women’s seemingly natural taste and proclivities guide them to choose accordingly. For example, faculty members pointed out that biological and industrial engineering carry communication and socially relevant characteristics and this assumingly would attract more women and justify their presence in a major. On the other hand, the future workplace from the male dominated majors were considered by the faculty members as technical and dirty, characteristics that were deemed unappealing for female students [1]. Giving certain activities and majors feminine or masculine identities influence how women’s, and generally people’s, abilities and preferences are perceived from both their own and other people’s perspectives [2].

3 SUMMARY

In conclusion, cultural stereotypes about gender differences are still influencing people’s view, assisting to the maintenance of segregation between men and women across professional fields [1][2]. Of course, women are able to and do embrace parts of engineering that are considered more masculine. However, normative standards of appropriate masculine and feminine behaviour stand as guides and people are expecting to be judged by them; therefore, this leads to behaviour alterations in order to keep social sanctions to the minimum and adopt ways that are consistent with cultural understandings of the gender roles [1]. These risky notions drive women to avoid masculine engineering fields, as well as the opposite, it can drive them towards feminine fields by projecting their biased assessments of their abilities and strengths, by both themselves and others [1][5]. There is a need to understand that these stereotypical behaviours and ways of thinking do not suddenly emerge when people choose their majors, but rather start very early on throughout the development of a person’ s identity, from childhood to adulthood. Educators need to take under consideration the impact of gender socialization in a person’s abilities and preferences, and how this can be changed and reshaped.

ABSTRACT

Empathy and care influence aspects of engineering practice including collaboration and teamwork, stakeholder engagement, and quality of work. Empathy has been identified as a key employability skill for professionals, and is the foundation for many skills and attributes anticipated as required by future engineers. Therefore, the understanding of empathy and care, and consideration of the development of empathetic and caring competencies are increasingly relevant for engineering education. Recent studies have explored the conceptualisation of and value placed on empathy and care in engineering practice, from the perspectives of practicing engineers in US and German contexts. We broaden this to include the Australian setting. Engineers' perceptions of empathy and care within Australian engineering practice were collected using an online version of the Empathy and Care Questionnaire (ECQ) instrument developed by Hess, Strobel, Pan and Wachter Morris (N = 183). Statistical analysis of survey questions relating to the perceived

doi:10.5821/conference-9788412322262.1386

importance and benefits of empathy and care to engineers, and relevance within a range of engineering practice situations was undertaken. Analysis of gender, years of experience, and organisational role indicated that female engineers perceived empathy and care to be more important, and more impactful on engineering practice than male engineers. Perceptions of empathy and care did not vary with duration of engineering work experience, however engineers in positions of organisational leadership placed greater importance on empathy and care in their roles than others. These differences contrast with results of the US and German studies. Further analysis is required to understand where, when and why these differences occur.

1 INTRODUCTION

1.1 Empathy and Care in Engineering Practice

Empathy and care can be considered a core skill within engineering [1], underpinning many skills and attributes required by current and prospective engineers. The understanding of empathy and care, their role within engineering practice, and the consideration of the development of empathetic and caring competencies are increasingly relevant for engineering education.

The conceptualisation and relevance of empathy and care in engineering practice, from the persective of practicing engineers, is an emerging research area. Research in the US and German contexts indicate that practicing engineers perceive empathy and care as most important within relational aspects of their engineering work [2, 3]. Empathy and care relate to improved understanding of others, broadened perspectives, enhanced relationships, effective two-sided communication, collaboration and teamwork, relevant to meeting clients' needs [2, 4]. Empathy and care are perceived to impact engineering outcomes. Empathic and caring orientations promote an other-centric focus, awareness of broader impacts of engineering decisions, and an altruistic orientation to design and solution generation, impacting engineering outcome quality [4]. Organisational, task-related and individual factors influence the perceived importance and impacts of empathy and care within engineering practice, indicateing their contextual nature.

1.2 The Current Study

This short paper builds on recent research on empathy and care within engineering practice in US and German contexts [2-4], by exploring perceptions of the importance and benefits of empathy and care within engineering practice in the Australian context. This study contributes to a more expansive understanding of empathy and care within engineering practice, offering an increasing contextual and granular view of these concepts by considering diverse geographic and demographic variables. The research questions that frame this paper are: i) do engineers in Australia perceive empathy and care as important to and impactful upon their engineering practice?, and ii) what are the differences in perceived importance and impact of empathy and care, by gender, years of working experience, organisation role, and national context?

2 METHODOLOGY

2.1 Empathy and Care Questionnaire (ECQ)

Engineers' perceptions of empathy and care within Australian engineering practice were collected using an online version of the Empathy and Care Questionnaire (ECQ) instrument [2]. The online questionnaire was created within the Qualitrics™ platform. The survey contained 37 scale items to investigate the existence, nature and importance of empathy and care within engineering practice. In addition, the questionnaire sought information relating to respondents' demographic and work-related characteristics, and provided opportunity for additional written comments.This short paper reports on statistical analysis of responses to closed questions relating to: i) 2 items rating perceived importance of empathy and of care to respondents as engineers on a 100-point scale; ii) 12 items rating perceived importance of showing empathy and care in a range of engineering practice situations on a 6-point scale, (e.g.: Based on your experiences in engineering, rate how important it is for engineers to show empathy and care in the following situation - Working in teams); and iii) 7 items rating perceived potential impacts of an empathic and caring approach in engineering practice on a 6-point scale (e.g.: If empathy and care are effectively incorporated into engineering, to what extent do you think the following impact will occur? – Engineered products will fulfil users' needs).

2.2 Participants

Data were collected progressively from November 2019 to March 2021. Respondent recruitment was both purposeful and opportunistic, leveraging the researchers' professional networks. An invitation to participate with a link to the online questionnaire was distributed, consistent with ethics approval, by researchers and email by senior engineers in organizations and networks, and in engineering faculty alumni newsetters of two universities. Participation was voluntary and anonymous.

Respondents were 248 degree-qualified engineers practicing as engineers or working in related roles in Australia. This was reduced to 183 respondents (n_{male} = 125, 68.3% ; n_{female} = 58, 31.7%), with removal of 59 reponses due to insufficient questionnaire completion and three responses due to lack of demographic data.

Respondents were well-distributed according to years of engineering work experience, with the largest proportion indicating that they had been working as engineers for under ten years (n = 57, 30.2%), across a range of engineering disciplines. The most common organisation role held by repondents was 'technical role' (n = 71, 38.8% of respondents). Respondents frequently indicated two or more current organisational roles. For analysis purposes, organisational roles were catergorised as: i) technical role only, ii) manager/leader of a technical team (including in combination with other roles), iii) technical role, and other business roles, iv) leadership of company, and v) other.

3 RESULTS

3.1 Analysis

Mean scores were generated across the items for each of: *importance to respondents* (M = 79.22, SD = 15.69), *importance for practice* (M = 5.00, SD = 0.66), and *potential impacts* (M = 4.59, SD = 0.93).

To address the research questions, responses were compared by gender, years of experience, and organisational role. A multivariate analysis of variance (MANOVA) was performed (one for each of the potential moderator variables identified – i.e., gender, years of experience, and role). In each MANOVA, the three dependent variables were *importance to respondents*, *importance for practice* and *potential impacts*. Data were screened for conformity to multivariate analysis of variance assumptions, which produced satisfactory results.

The MANOVA for gender indicated a significant difference across males and females on the composite linear dependent variable, λ = .95, $F(3,179)$ = 3.04, p = .03, partial $\eta 2$ = .05. Univariate ANOVAs indicated significant differences across males (M = 4.47, SD = 0.97) and females (M = 4.85, SD = 0.79) on the *potential impacts* variable, $F(1,181)$ = 6.89, p = .01, partial $\eta 2$ = .04, and also on the *importance to respondents* variable, (M_{male} = 77.27, SD_{male} = 16.41; M_{female} = 83.45, SD_{female} = 13.18), $F(1,181)$ = 6.33, p = .01, partial $\eta 2$ = .03, but not on *importance for practice*, $F(1,181)$ = 1.41, p = .24. Both significant results reflected higher ratings for females than for males.

The MANOVA for years of experience indicated no significant difference across groups on the composite linear dependent variable, λ = .91, $F(18,493) < 1$. Therefore, years of experience was not a significant moderator of ratings across the three dependent variables.

The MANOVA for role indicated a significant multivariate difference across groups, λ = .88, $F(12,466)$ =1.78, p = .05, partial $\eta 2$ = .04. Univariate ANOVAs for each dependent variable indicated that using a Bonferroni-adjusted alpha level of .017, there was a significant difference across roles only on the *importance to respondents* measure, $F(4,178)$ = 3.37, p = .01, partial $\eta 2$ = .07. Follow-up Tukey HSD tests on this variable indicated that there were no differences that were significant or that approached significance across any groups other than differences in comparison to the 'Leadership of company or business' role group. Based on the Bonferroni-adjusted alpha level, this group differed significantly from the 'Technical and business roles' group (M_{lead} = 91.39, SD_{lead} = 8.44, n_{lead} = 14; M_{techbus} = 72.25, $SD_{techbus}$ = 19.89, $n_{techbus}$ = 22; p = .003). Differences between those in the Leadership of company or business role group, versus those in the 'Technical role' and 'Manager / Leader of technical team' groups also approached, but did not reach significance (ps =.04 and .06, respectively). All differences that reached or attained significance for role indicated higher scores for the 'Leadership of company or business role' than for those in other groups.

3.2 Discussion

The high mean rating for the three variables of *importance to respondents*, *importance for practice*, and *potential impacts*, indicate that Australian engineers perceive empathy and care to be important to themselves in their professional roles, and important and potentially beneficial to their engineering practice.

Female engineers in the Australian context perceive empathy and care to be more important to their professional role, and more impactful to engineering practice and outcomes, than male engineers. This contrasts with an absence of observed gender differences in the US study [2]. Gender has previously been associated with empathic tendencies. In the Australian engineering context, higher empathic tendencies have been reported in female engineering students [5]. Our findings suggest that female engineers' perceived value of empathy and care is sustained on entry to engineering practice rather than diminished through assimilation with male-oriented engineering values as suggested by [2].

The perceived value of empathy and care did not significantly vary with years of engineering work experience for Australian engineers. This contrasts with the greater levels of perceived prevalence and importance of empathy and care among more experienced engineers reported in both US and German studies [2, 3]. Engineers in organisational leadership roles placed greater importance on empathy and care within their professional role, in comparison to engineers in other organisational roles. Empathy is a vital leadership competency, and this finding may reflect effects of leadership development or presence of selective promotion processes within engineering organisations. The same level of value or relevance of empathic and caring orientations to engineering roles, other than organisational leadership, are not reflected by the respondents.

4 SUMMARY AND ACKNOWLEDGEMENTS

4.1 Implications and Further Work

Our study supports previous work that has established the importance of empathy and care to engineers and engineering practice, and the impetus for inclusion of these concepts into engineering education. Findings relating to perceptions of empathy and care and organisational role provide opportunities for both pre-professional and continuing engineering education. To progress the development of empathic and caring competencies in engineering, relevance of empathy and care to all engineering roles needs to be established and communicated through strategies targeted at students and practicing engineers. Our initial analysis reveals areas for additional research, including a detailed exploration of observed gender and organisational role differences, engineering practice situations and impacts. Interactions between the demographic variables should also be considered.

4.2 Acknowledgements

We gratefully acknowledge the professional engineers for participating in this research and the universities and engineers who invited participants.

ABSTRACT

Modular approach in education provides the advantages of student self-pacing, autonomy, and receiving frequent feedback from the instructor. In 2021, the project; CMODE-Up (an Upscaling of the earlier undertaken project Challenge-based Modular On-demand Digital Education) provided evidence-based design principles and an accompanying teacher guide for modular courses in engineering education. A next step towards actually implementing the design framework, is piloting it. In this pilot, we will ask teachers from our university to work with the framework to redesign their course into one or more challenge-based modules. We started off with a short workshop to get teachers motivated to work with us. Teachers were recruited based on willingness and experience with modular courses. During the workshop, the teachers engaged in course design exercises using the design framework. Transcibed audiotapes of the workshop discussions constituted the data for this study. To further improve the framework, the results from the workshop data were combined with results of a descriptive literature review. Relevant articles and conference preceedings were located that can shed light on issues such as design of a course with elective modules. Results collectively will lead to an adapted version of the design framework.

1 INTRODUCTION

Online learning environments and modular structures in higher education enable learners to define and pursue a personal learning path [1]. The modular approach is rooted in educational pedagogies such as programmed-instruction, learner-centered pedagogies, and computer-assisted instruction [2, 3]. Prominent characteristics of a modular approach in education include frequent feedback, self-paced learning, and flexibility in time and location [4]. Such characteristics have an important role in addressing the changing nature of the workforce towards sensitivity to individual interests and learning needs and to autonomous learning experiences [5].

Although a modular approach to course design has been frequently adopted in higher engineering education literature, design principles tailored to modular courses did not exist. In order to address this need, a conceptually grounded template for modular course design was developed in a previous study [6]. The design principles were: (1) course content, (2) module category, (3) alignment of content, (4) module development, (5) implementation, (6) learner engagement, and (7) evaluation.

The need to support teachers with empirically-grounded frameworks to design modular courses has been highlighted by previous studies. Felix-Herran et al. [7], for example, designed and delivered a training program to support engineering instructors' in designing modular courses. This study addresses the need to improve the developed course design framework [6] through a workshop for teachers and a descriptive review.

2 METHODOLOGY

2.1 Design

The first part of this research was piloting our empirically supported framework for modular courses in higher engineering education. Beginning with design principles based on existing research and expertise facilitated the process of piloting and testing during a teacher workshop. The second part included a descriptive literature review to further broaden our understanding on issues such as alignment of modules with other course components, modules in a challenge-based learning (CBL) course, and ways to offer mandatory and elective modules. Descriptive literature reviews are helpful in understanding similarities and differences in studies, while putting the focus on the certain features of interest [8]. In this study, qualitative methods of data collection and analysis were adopted.

2.2 Participants and data collection

Approval from the university Ethics Committee was received prior to data collection. Two teachers at the authors' university participated in the workshop, a full professor at the department of Chemical Engineering and a lecturer at the department of Applied Physics. During the two-hour workshop, the teachers engaged in structured discussions and exercises on modular courses using the framework.

The workshop was organized face-to-face and consisted of: a) an introduction about modular approach in education and the goals of the workshop, b) exercises for the teachers to reflect on designed courses using our framework, and c) a reflective discussion. The discussions were audiotaped. The discussions triggered the teachers to use the framework and to reflect on its improvement. In the descriptive literature review, 20 research studies were included, based on reporting on CBL and on elective modules; articles (n = 9), conference preceedings (n = 9), and book chapters (n = 2).

2.3 Data analysis

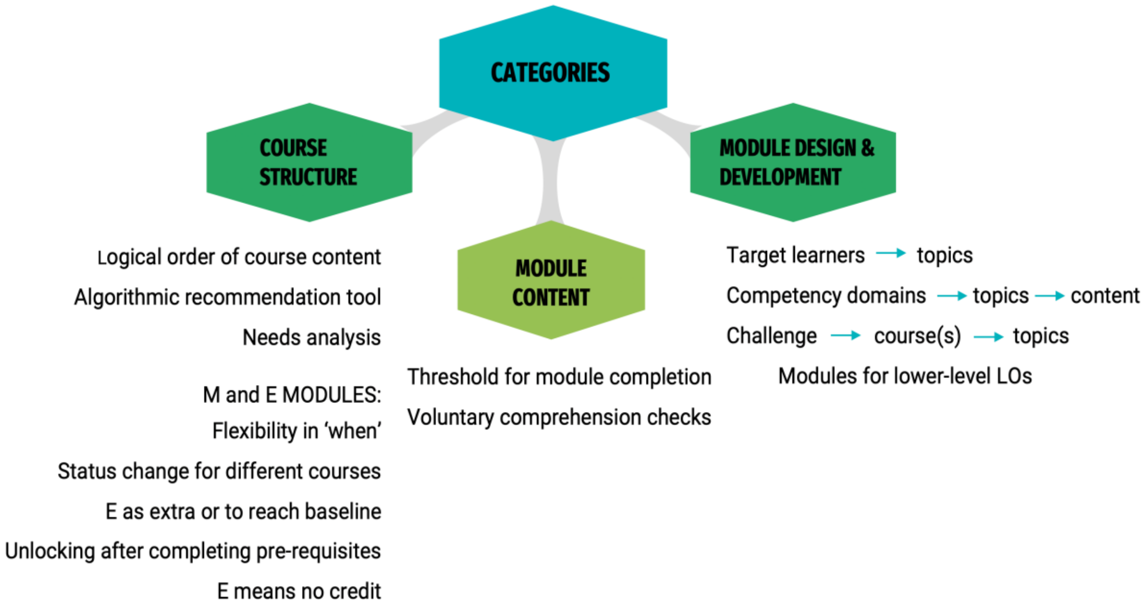
First, the audio recordings of the workshop discussions were transcribed verbatim. The qualitative analysis of the transcripts and the located research studies (n = 20) followed a content analysis method [9]. Following the separate analysis of the transcripts and the research studies, results were combined to reach a comprehensive overview.

3 RESULTS

Results are summarized in three categories: a) modular course structure, b) module content, and c) module design and development (see Figure 1). Figure 1 shows the codes that emerged under the categories. M and E stand for 'mandatory' and 'elective' respectively on the figure. The codes reported under each category represent new ideas to modify the design framework. For example, the codes given under the category, 'module design and development', reveal that the modular course design process can begin with considering learner profile first, the course topis, or the challenge. Similarly, the code; ‘status change for different courses’ under the category ‘modular course structure’ show that modules can be used as M or E in different courses. The researchers will now work on integrating the codes meaningfully into the course design framework [6].

4 SUMMARY AND FUTURE DIRECTIONS

Using the evidence-based design principles created during our former work, it was now time to focus on a practical implementation, as well as studying what place challenge-based education can hold here. The next step in this research is



incorporating the results presented here into the first version of the framework [6], to make it more practical for the teachers. Examples to that are, in a course with mandatory and elective modules, presenting elective modules as extra support for interested students or to help students reach an expected baseline level. The next step in the entire project is to collaborate with a teacher willing to modularize a course using the revised framework (with several elective modules) and work on the redesigned course.

ABSTRACT

For our students to work on the global challenges facing humankind, they should be raised to appreciate the importance of science and engineering in real-life contexts. Challenge-based learning (CBL) courses have merit in accomplishing this goal by facilitating students' innovative solutions to authentic, complex problems. The fundamental characteristics of CBL include real-world challenges, collaboration, and multidisciplinarity. The presented work describes a CBL course where applied physics and mechanical engineering students worked in multidisciplinary teams. An instrumental case study was conducted to identify factors that influence multidisciplinary teamwork in this CBL course. Data were collected using interviews, reflection reports, and observations of team meetings. Transcribed video recordings were searched for instances of demonstrating the codes revealed with analysis of interview transcripts and reflection reports. The research results showed the significant factors influencing multidisciplinary teamwork: a) disciplinary connections to the challenge, b) receiving tutor guidance, c) making presentations in teams, d) exchanging science and engineering perspectives, e) readings and videos on course Canvas, and f) student motivation. Implications are discussed, and suggestions for future research and practice are presented.

1 INTRODUCTION

Learning environments that address multiple disciplines have the potential to contribute to learning and to develop competencies such as critical thinking, problem solving, communication, and an awareness of societal problems [e.g., 1, 2].

Approaching an overarching theme or a problem with the knowledge and methods of multiple disciplines lies at the core of challenge-based learning (CBL) courses [3]. A recent systematic literature review revealed one of the core characteristics of CBL as multidisciplinarity [4]. In a CBL course, students work on real-world challenges such as food safety and sustainability as they gain or deepen knowledge and skills [3].

Having students work on challenges in multidisciplinary teams is a common practice in CBL courses [e.g., 1]. In multidisciplinary teams, students apply the knowledge and methods of their disciplines to communicate and to solve open-ended problems [5]. Multidisciplinary teamwork in CBL and similar project-based courses in higher education is evidenced to have positive impacts on students' skills development and learning of course content [e.g., 6].

This study addresses the need to identify factors influencing multidisciplinary teamwork in the context of the first pilot of a CBL course.

1 METHODOLOGY

1.1 Design

A case study approach was adopted to explore multidisciplinary teamwork in the course context [7].

1.2 Participants and data collection

The CBL course; "CBL Systems and Control" was designed to use the knowledge and methods of applied physics (AP) and mechanical engineering (ME) around the specified challenge: design and implement a real-time controller for a pick-and-place robot'. The hardware in used in the course was a robot arm set-up shown in Figure 1. The course included 30 second-year bachelor students. There were seven AP and 23 ME students who worked in teams. Each of the five teams consisted of six students. Data were collected from students (*n* = 12) and from the teacher team (*n* = 5).

Semi-structured interview questions were prepared considering the literature on factors that influence successful teamwork. In addition to the interview responses on the already existing conditions perceived as factors, participants also commented on how to address multidisciplinary teamwork in the course more effectively. Data also included students' individual reflection reports on their teamwork experiences. The reflection reports were collected at the end of the course.

Video recordings of team meetings were used to supplement the results of the interviews and the reflection reports.

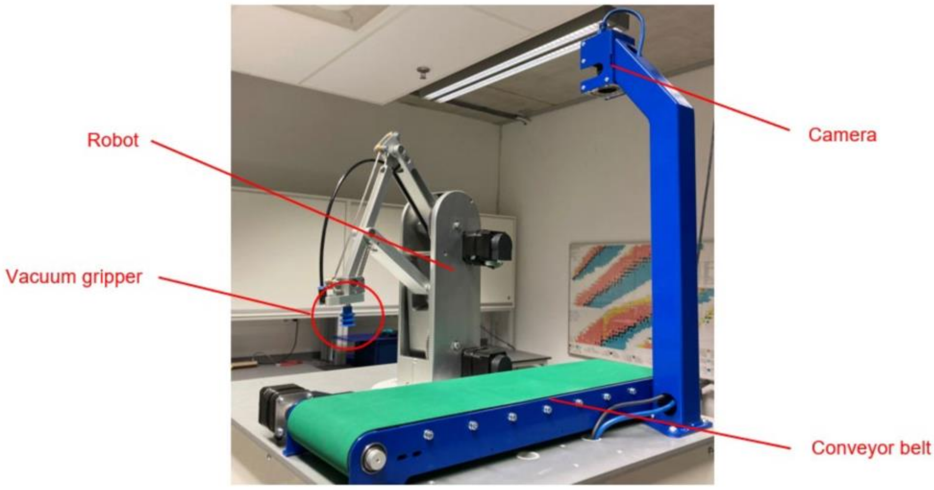

Fig. 1. Robot arm in the lab.

1.3 Data analysis

The qualitative analysis of the interview transcripts and the reflection reports revealed a codebook following a content analysis method [8]: 1) initial screening of data, 2) identifying themes and codes based on repetition and relatedness, and 3) finalizing the codebook with frequencies and percentages.

2 RESULTS

The results were sumarized in three categories: (a) individual factors (31%), (b) team factors (29%), and (c) contextual factors (40%).

For individual factors, findings revealed that *lack of pre-knowledge of control theory* (61%) acted as a barrier for multidisciplinary teamwork. ME students had to explain AP students about control theory in the first weeks of the course. Although the results indicated that *using online course materials* (17%); the lectures and videos on the course learning management system; Canvas was helpful in improving the necessary knowledge, the knowledge gap between AP and ME students were frequently addressed. An exemplary response was: *"AP students could catch up with the knowledge at the end of the project that let more ideas…Similar level of knowledge would have saved some time for teamwork."* The findings also revealed *prior experiences* (22%), team experience and experience in robotics as facilitators of multidisciplinary teamwork.

For the team factors, *communication* (41%) emerged as a facilitator of multidisciplinary teamwork. The video transcripts demonstrated team members' comfortably expressing their ideas and asking questions. *Exchange of disciplinary perspectives* (28%) between AP and ME students was suggested as another important facilitator of successful teamwork. One exemplary response was*: "…we were stuck in the methods part….and they (AP students) brought a different view to the project...".* Next, *making presentations* (16%) considering the presence of students from the other discipline facilitated teamwork.

The findings showed *the disciplinary connections of the design challenge* as the most significant contextual factor for successful multidisciplinary teamwork (54%). Results indicated that the design challenge, mainly drawing knowledge and methods from ME compared to AP was a barrier for teamwork. A teacher comment illustrated this point: *"I think the challenge being skewed to ME makes it tough in this case, to really guarantee that you can get the added benefits from both disciplines…"* Finally, *tutor guidance* (26%) is found to contribute by extending discussions where AP and ME students offered different insights.

3 SUMMARY

This work presents novelty by: a) presenting an example multidisciplinary CBL course and b) reporting suggestions on how to better promote multidisciplinary teamwork. An important conclusion is that although the disciplinary connections of the challenge task allowed for an exchange of disciplinary perspectives between AP and ME students, the challenge can benefit from a stronger connection to AP concepts. This suggestion is also related to the identified barrier; a gap on prior knowledge on control theory. The emergence of barriers to multidisciplinary teamwork, such as limited disciplinary connections and gaps in prior knowledge, can also be explained by the first piloting of a newly designed course. An improved understanding of the facilitators of and barriers to multidisciplinary teamwork can enhance the functioning of the teams and thus foster student learning in similar courses.

Keywords*: reflection, guidance, teacher skills, professionalisation*

ABSTRACT

The contemporary knowledge society of the 21st century requires students, among other things, to have the ability to think analytically and reflectively. Research into the disappearance of technical employees from the technical labor market also shows it is important to guide students in their professional identity development, in which reflection of students is crucial. Various studies show however that educational programs and teachers experience difficulty with the effective use of reflection in education. In the project ‘Strengthening reflection in technical higher education programs’, six technical higher professional education programs of two Dutch higher education institutes are working on the improvement of reflection in their programs. Teachers from these teams are also trained in guiding and assessing reflection activities of students. In this current research, the following research questions will be answered:

doi:10.5821/conference-9788412322262.1159

1. How do teachers guide students during reflection activities or conversations?
2. How do teachers assess students’ reflection activities?
3. Does the offered training contribute to an increase in skills of teachers with regard to guiding reflection activities of students?

A selection of teachers of the participating teams will be interviewed before and after the training. To assess teachers pedagogical and didactical knowledge and skills, video vignette interviews are used. Vignettes were designed to provide teachers with multiple authentic situations that are prototypical in their teaching context and which are depicted in video captions. Interview protocols were used to elicit teaching interventions and teachers’ rationales and thoughts behind these interventions in the depicted situations.

1 INTRODUCTION

1.1 Background

The labour market is transforming at such a fast speed, that education can hardly keep up with providing the actual knowledge that is needed for certain professions [1]. The present labour market is characterised by technological developments, complex challenges (or so called 'wicked problems'), flexibility and globalization [2]. Institutes for higher education are challenged to educate students in becoming professionals that do not only have sufficient knowledge and skills within a certain specific domain, but are also equipped with broader generic, often called 21st century skills [3]. Parallel to this movement, within these institutes there is an increased focus on personal learning trajectories of students with the aim to provide guidance from a wider perspective, for example by incorporating subjects such as "Bildung" or personal development [4]. Especially within the engineering, science, and technical sector, one of the main problems is the increased number of technical alumni that is not going to work in the sector they were actually educated for [5]. The reasons why students eventually do not choose for a job in this specific sector is not fully clear, but there seems to be an opportunity for providing improved guidance, to help students discover their potentials within the workplace and develop their professional identity. This means that students learn what their own qualities are, who they are, what kind of professional they would like to be, and how they would like to contribute to the labour market or society [2]. To achieve this with students and help them to become self-aware and self-directing professionals, education should stimulate the development of a reflective attitude [6].

1.2 Reflection (skills) and its use in education

The developments described above show, in a wide range, the importance of the use of reflection and the need for development of reflection skills in education. In addition, many authors argue that being able to reflect is a basic and essential skill for (future) professionals and, therefore, for current students [2]. To reflect or to stimulate a reflective attitude is, however, no sinecure. It is a skill that students really need to develop [9]. This means that educational programs should place reflection on the agenda of their curriculum, but also that they need to think about how they can guide the development of reflective skills throughout the study program from year one to year four.

At the same time, research shows that educational programs experience great difficulty in creating an effective learning environment for reflection [8]. Educational programs acknowledge the importance of reflection and use, for example, 'reflective practitioner' in the final goals of their program. However, the concrete design and execution of the concept of reflection differs between programs or is not always clear. Also, current reflection activities often take the form of writing assignments with questions like: 'describe what you learned from the assignment, what can you do better?'. Students often feel these kind of exercises are not relevant and motivating [6;8].

Engineering, science and technology programs experience even more difficulties because they often feel reflection is not easily adopted and implemented in their specific context [8]. Reflection is often designed in such a way that it requires good language skills, which is not always considered appropriate for students from engineering, science and technology programs. Many teachers in engineering, science and technology programs express the need to embed reflection in a concrete way in their programs and make use of reflection activities that suit their specific target group.

The project 'Strengthening reflection in technical higher education programs' addresses these issues; six technical programs from two Dutch institutes for higher education are working together with a project team for the duration of two school years on an improved vision and curriculum regarding the incorporation of reflection in their programs. In addition, efforts are made to improve reflection activities for students and professionalize teachers regarding the necessary guidance skills in order to help their students develop essential reflection skills.

1.3 Current study

The participating teachers of the above mentioned project are also trained in guiding reflection activities of their students. Alongside these training, research is being conducted that focuses on answering the following research questions:

1. How do teachers guide students during reflection activities or conversations?

2. How do teachers assess students' reflection activities?

3. Does the offered training contribute to an increase in guidance or assessment skills of teachers concerning reflection activities of students?Interviews with teachers will provide input for answering these research questions. Data collection is still ongoing at this moment. Therefore, the remainer of this short concept paper focuses on the design of this research.

2 METHODOLOGY

2.1 Participants

Participants come from two universities of applied sciences in the Netherlands. A random selection of four teachers of 3 participating teacher teams (Building & infrastructure, Information technology/ Electrical engineering and Fashion textile & technology) will be interviewed both before and after the training. The teachers voluntarily participated in the training and had different backgrounds in terms of experience with teaching, guidance of students, or the theme 'reflection'.

2.2 Data collection method

To assess these teachers' pedagogical and didactical knowledge and skills in terms of guiding students' reflections, video vignette interviews are used. Four video vignettes were designed to provide teachers with multiple authentic situations that are prototypical in their teaching context. Interview protocols were used to elicit teaching interventions and teachers' rationales and thoughts behind these interventions for the depicted situations. Video vignettes are considered a favourable method to capture the knowledge or beliefs that teachers employ, since they can cover multiple distinctive situations [7]. Moreover, direct and comparable assessments of teachers' knowledge and beliefs can be realised, since the interview protocol require each teacher to respond individually to each of the vignettes.

In developing the vignettes we focused on producing a set of hypothetical teaching situations that are prototypical and critical to teaching reflection skills in the context of science and engineering programs in a higher professional educational setting. In orderto cover multiple authentic situations in the particular teaching context at hand, the scripts for the vignettes were based on commonly occurring problems and prototypical topics with regard to students' reflections,. Each video vignette starts with a short description of the, containing information about a particular critical situation.During the interview, teachers were shown the video vignette one by one. After each vignette they were asked: 'How would you react to this situation?'; 'What would you do?' 'Why?'; 'What do you intend to promote in terms of student learning with your actions?'.

In order to gain insight into how teachers assess students' reflections, a selection of two excerpts from reflection reports was made. During the interview, teachers were asked: 'How would you characterize the quality of this reflection and why?; 'What feedback would you provide to this student and why?; Suppose this excerpt would be the starting point of a reflective dialogue with this student, what kind of in-depth reflection questions would you ask?'.

2.3 Procedure and intervention (training)

The first round of interviews is currently being conducted. After finalizing these interviews, the teacher teams will participate in three different workshops, focusing on guiding individual and group reflection and assessing reflection activities of students. After these training activities, the same teachers will be interviewed again, using the same interview protocol, video vignettes, and reflection report exerpts. Data will then be analysed to investigate whether teachers have extended their skillset in terms of guiding and assessing students' reflections.

3 ACKNOWLEDGMENTS

This project was funded by TechYourFuture. The authors wish to thank the involved teachers for their participation.

ABSTRACT

A pan-European network of universities connected with a common goal and involving both students and professors can be a strong catalyst for the professional, economic and social development of the university environment that positively affects not only the university itself but also the other agents or actors in its ecosystem. It is also widely recognized that training and education in entrepreneurship constitutes a solid strategic tool for regional development in which both public and private institutions around the world have made large investments over the past years.

The European Project EntRenew in which the Universitat Politecnica de Valencia - Spain (UPV) participates from 2019 is working in facilitating the exchange, flow and co-creation of new knowledge, enabling professors to teach transdisciplinary studies through innovative methods and stimulate synergies between universities and entrepreneurial support systems throughout Europe.

Ideas-UPV, the entrepreneurial service at UPV has a large experience of 30 years promoting entrepreneurship among students and professors. It also participates in different European projects establishing networks and future collaboration opportunities. The design of entrepreneurship education programs aimed at higher education students is also a core area of the service, not only addressing business plans but also the development of entrepreneurial skills.

This work analyses the current results of the EntRenew program and how this and other initiatives of Ideas-UPV have had an impact on the creation of student entrepreneurial ecosystems, fostering cooperation between the actors and establishing connections to the university environments.

1 INTRODUCTION

Training and education in entrepreneurship are elements of vital importance for local development. For this reason, institutions have focused their efforts and investments on this area and in most cases they define themselves as entrepreneurial institutions.

One of the ways to promote this regional development and foster entrepreneurship is by working on European projects, creating networks of universities that collaborate in achieving a common goal, and taking advantage of the talent of their students and teachers. This will have a positive impact on the development of the university itself, as well as on the other agents of its local ecosystem.

Ideas-UPV, the service that has been in charge of the entrepreneurship activities of the UPV for 30 years, participates in different European projects establishing networks and future opportunities for collaboration.

An example of these projects is EntRENEW in which 5 european universities (Pôle Universitaire Léonard de Vinci, France. Halmstad University, Sweden. University of Vaasa, Finland. Leiden University, Netherlands and Universitat Politècnica de València, Spain) have been working since 2019.

2 THE ENTRENEW PROJECT

2.1 Overview

The EntRENEW Project and the sharing of their good practices and the co-creation of new knowledge, aims at promoting a dynamic interdisciplinary perspective that articulates the corporate, scientific, and pedagogical skills and knowledge in renewable energy and entrepreneurship. The project contributes to increasing the capacity of European students in their way to becoming effective entrepreneurs and leaders, enabling them to address the challenges of Europe's future sustainable prosperity and the transition of energy sectors towards decarbonisation (as part of the European Green Deal) [1].

The project answers three major needs:

- The need to train new skills and competences in future MA graduates in business and environmental/energy studies, bridging the knowledge gap in the current HE curricula to answer the demand by new energy businesses.
- The need to increase the use of new and innovative pedagogies in HE to enhance students' motivation.
- The need to enhance the collaboration between European students and the entrepreneurial community

2.2 Methodology

In order to achieve the ultimate goal of creating a blended-learning course on entrepreneurship in renewable energies an exhaustive analysis of the needs of each university was carried out. This work included interviewing students to build a proposal of the most appropriate pedagogical methodology that meet their expectations, while also adapting it to the academic requirements of every partner university.

After this, all the contents of the blended course were developed collaboratively among all the partner universities, sharing knowledge, available academic content, etc. The developed contents consist of videos, presentations for face-to-face classes, gamification, tasks and exercises. At the same time, the contents that the trainers will need to teach the course optimally in each of the universities have been prepared as well as the teacher's guide.

For the online part of the course and for all the gamification that has been created for it, a platform is being developed on which all the necessary content will be uploaded and from which the students will be able to enrol and take the course.

The next steps will be to conduct a pilot test of the course with a series of selected students in each of the universities, to obtain feedback on the content, the materials and the methodology of the course. After the appropriate improvements and the final validation, the EntRENEW course will be officially launched, integrating it into the study plans of all the universities participating in the project, and carrying out the appropriate dissemination actions to attract students to enrol in this course.

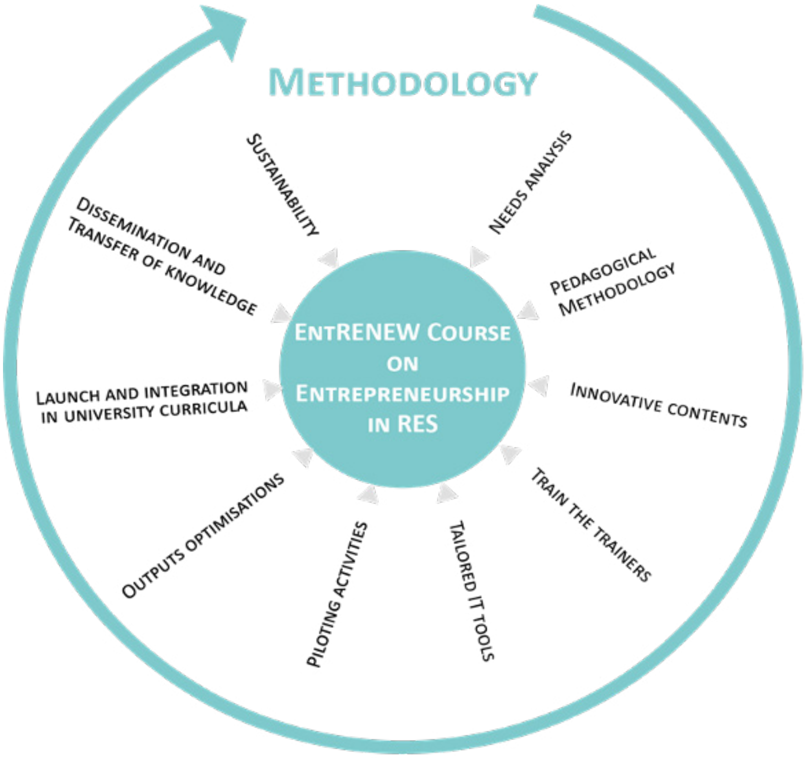

Figure 1. Phases of the implementation

-

3 RESULTS

As a result of the work carried out by the universities participating in the project, sharing good practices and the co-creation of new knowledge, a blended-learning course on renewable energies entrepreneurship has been generated as a short term result. This course is divided in different modules and topics:

MODULE 1: Renewable Energy Systems
1. Introduction: Sustainability and the 2030 Agenda 2. The Basics of Energy
MODULE 2: Entrepreneurial ecosystem
1. Background Open Innovation 2. Vibrancy Of An Entrepreneurial Ecosystem 3. The Life Cycle Of The Small Firm 4. Local Entrepreneurial Ecosystems
MODULE 3: Business model innovation and ecosystems in renewable energy

1. Business Modelling (based on [2]) 1.1 Traditional business models Vs Sustainable Business Models 1.2 Card game for Sustainable Business Model (SBM) 1.3 Customer Segments 1.4 Value Proposition (based on [3]) 1.5 Revenue Streams + Cost Structure (cash flow analysis) 1.6 Channels 1.7 Competitive Advantage 1.8 Key Activities + Partnerships 1.9 Business model as source of innovation 1.10 Barriers for developing business models **2. Climate Impact** 2.1 Life Cycle Assessment & Measure reduction in carbon emissions **3. Validation** 3.1 Validation Plan 3.2 Minimum Valuable Product 3.3 Prototyping 3.4 Talking to humans **4. Talking to investors & stakeholders** 4.1 One Page 4.2 Elevator Pitch **5. Marketing** 5.1 Designing a marketing strategy
MODULE 4: Business model innovation and ecosystems in renewable energy
Assignment: EntRENEW Project

Table 1. Modules of the course developed in the project.

The long-term impact of the EntRENEW project will be to create a new generation of decision makers who will explore concrete entrepreneurial solutions in support of EU countries facing the important challenge of maintaining their social and economic performance and being more eco-responsible, especially in the energy sector.

4 ACKNOWLEDGMENTS

The EntRenew project is financed by the European Union through Erasmus+ Program (2020-1-FR01-KA203-080630).

Keywords: *STEM Partnership, Role Model, Engineering, Collaborative and Creativity*

ABSTRACT

As educators committed to a transformative teaching and learning we need to actively engage with our new generation, promote critical thinking, and share knowledge and skills to promote sustainable developments in order to build that much needed Science Capital. At this moment the UK engineering industry is experiencing two main issues: i) a shortfall of 20,000 graduate engineers per year and ii) lack of female engineers. These two issues are a key challenge that must be addressed to guarantee a sustainable economy. To pursue these goals a STEM partnership between Glasgow Caledonian University (GCU), the Royal Navy and six Primary Schools was funded by the Royal Society Partnership Grants scheme. In this project GCU's students worked collaboratively with 250 primary pupils from age 8 to 11 on the design and manufacturing of a Luge start ramp. Different workshops related to design, manufacturing, mechanical properties, welding and beyond were delivered by the STEM partners, while the pupils provided ideas to enhance the ramp's design and teachers reinforced the topics prior and after each workshop. The

project enables the evaluation of aspects related to the impact of actively involving young pupils in an engineering real life problem, making them act as engineers, and their change in perception towards Engineering. Other aspects that will be analysed are the impact of positive role models not only on the pupils but on pupils' influencers (teachers and parents), as well as the inclusivity and diversity as part of the commitment to a transformative education.

1 INTRODUCTION

The UK engineering industry is facing a shortfall of 20,000 graduate engineers per year and lack of female engineers, issues that must be addressed to guarantee a sustainable economy [1-3]. However, to achieve a sustainable economy it is essential to invest in education in order to develop Human Capital in general [4] and more specific Scientific and Technical Human Capital (STHC) [5]; this is clear from the UN Sustainable Development Goals, outcome 4.7 which states that all learners should receive education to develop their knowledge and skills to promote sustainable developments [6]. On the other hand previous research has highlighted that the development of science capital should start at primary levels where sustainable approaches to primary science education are essential [7-8], together with the importance to develop meta-skills that include problem-solving, critical thinking, communication, creativity and leadership in order to thrive in the 21st century fast changing environment at economic and social levels [8], and all this is possible through a Transformative Education [9-10].

2 RATIONALE

One of the factors that aggravates skills shortage in engineering is the lack of role models [11] specially in deprived areas where the lack of facilities, lack of resources and lack of opportunities are amplified [12]. In order to stimulate and inspire new generation in the areas of Science Technology, Engineering and Maths (STEM) it is key to engage them with positive role models specially in underrepresented sectors where they are less likely to choose STEM subjects [13-16].

Glasgow Caledonian University have been ranked amongst the top 50 universities in the world for social impact and top 12 for gender equality and reducing inequalities [17]. As part of the commitment to the community and to increase the amount of girls in our engineering programmes our students are provided with the opportunity to be involved in different public engagement events, to not only introduce to the community the different aspects involved in engineering, but to act as role models to inspire the new generation. The opportunity to be involved in a collaborative project together with primary pupils will benefit univerisity students and primary pupils by allowing them to develop meta-skills through the participation and engagement in a real life engineering problem-solving activity with the help and support of all the STEM partners.

3 METHODOLOGY

A STEM partnership between Glasgow Caledonian University (GCU), the Royal Navy and six Primary Schools from varied demographic and SIMD (Scottish Index of Multiple Deprivation) was funded by the Royal Society Partnership Grants scheme. [18]. The Project entitled *The Olympic GB Luge team need a Luge starting ramp! Can pupils across Renfrewshire create the perfect design?*
The project entailed four GCU MEng mechanical engineering students being matched with 250 pupils from P4-P6 (ages 8-11) to Design and Manufacture the Luge Starting Ramp requested by the Royal Navy Luge Team .

The activity took place over a period of 10 months. Table 1 shows the activities led by each STEM partner involved.

Table 1. Activity delivered by the STEM partners involved and purpose

Partner	Activity	Purpose
GCU MEng Students	Workshops related to design, materials selection, material properties and welding.	Provide an understanding on factors that engineers need to consider during the design process with the aim that pupils could contribute on the enhancement of the ramp's design
Royal Navy Luge Team	Workshop related to Luge Sport and Winter Olympics	Awareness of Luge Sport and Winter Olympics. Development of competition skills
Royal Navy STEM Team	STEM workshops	Awarness of different types of engineering. Hands on activities in electrical circuits, coding, pneumatics, application of technology in submarines etc.
Teachers	Introduction and reinforcements	Optimal angle of the track to increase speed, effect of friction, testing materials, etc

The project was divided in 6 main stages as observed in Table 2

Table 2. Stages of the project

Stage	Description
1	Delivery of questionnaires to pupils, parents and teachers- before the project
2	Introduction of STEM partners to Primary Pupils- roles
3	Development of pupil's understanding in different topic-workshops- setting up challenges
4	Handover of the ramp- Visit to University-showcase the labs/workshops for the manufacturing of the ramp
5	Delivery of questionnaires to pupils, parents and teachers- after the project
6	Comparison and analysis of outcomes from questionnaires

4 RESULTS AND DISCUSSION

The STEM partnership provided the opportunity to bring positive role models to schools pupils, teachers and parents as part of a transformative education to build on meta-skills. The developed activities allowed pupils to work collaboratively, exchange knowledge, increase communication skills and apply critical thinking as part of the skills required for future career path ways, while observing further education at primary levels. A brief description of the impact on each participant is provided below.

4.1 Impact on Pupils

The project has allowed learners to develop their STEM skills whilst making links to further education and STEM careers. This is in agreement with previous research [14-15]

Pupil's quote: *"I have loved working with GCU students and the Royal Navy. Designing the luge for Team GB and getting the chance to try welding has been very cool."*

4.2. Impact on Teachers

The project has increased teacher confidence in teaching STEM as they have worked alongside STEM professionals from Glasgow Caledonian University and the Royal Navy. This collaborative and mutually beneficial approach has increased teachers' knowledge and engagement in the engineering element of STEM.

Teacher's quote: *"Every pupil has thoroughly enjoyed all aspects of the learning they have experienced. The unique opportunity to work with GCU and the Royal Navy has given pupils an insight of what it might be like to study STEM and to work in a STEM career in the future. It has certainly created a buzz around STEM in the classroom."*

4.3. Impact on Parents

Parents have commented on the fact that their children have the exciting opportunity to engage with universities whilst in primary school. This has allowed us to explore and tackle perceptions around university and highlight that a career in engineering in accessible whilst pupil engagement and interest increases in that field.

Parent's quote: *"My child hasn't stopped talking about all the class lessons/experiments and visits from GCU and the Royal Navy. I know when he has completed a task on the Luge project because he can't stop talking about it when he gets home!"*

4.4. Impact on MEng students

Students have mentioned how rewarding and satisfying the experience has been to be seen as role models to underrepresented sectors in general and to be able to engage with them by learning to use a simplistic language to communicate engineering concepts and provide the necessary information to interact with a young audience while keeping them engaged in the topic.

MEng student's quote: *"The STEM outreach program has impacted me on both a professional and personal level. Being able to impact the lives of young children is an incredible opportunity, and one in which I am proud to say I have been involved in. On a professional level, I have loved being involved in the outreach program. The positive experience and impact of the partnership and program has motivated me to pursue similar routes of STEM outreach and is something that I will endeavour to be involved in as I start my next chapter in engineering, post-graduation".*

5 CONCLUSIONS AND FURTHER WORK

- The value in outreach work between schools and university/industry cannot be underestimated as it widens learner perspective on engineering, and cultural capital whilst demonstrating the impact learners can make upon society through STEM skills
- Collaborative STEM projects allow everyone involved to develop/enhance meta-skills which will support learners to thrive in any environment (Social/educational/professional).
- This is an ongoing project and surveys to assess the quantitative impact before and after the project concludes will be conducted.

Keywords: *engineering ethics education, Sub-Saharan Africa, systemic change*

ABSTRACT

Unlike in the West, engineering practice in Sub-Saharan Africa remains mired in corruption, ethical malpractice, poor ethics governance and lack of effective leadership. This situation has, and continues to, negatively impact national infrastructure, health, education, and economies across Sub-Saharan African countries. Non-ethical engineering practices continue to occur despite the existence of national ethics legislation in Sub–Saharan African countries, and despite codes of ethics underpinning business operations in most public and private sector organisations that employ engineers. This is also despite the existence of codes of conduct and ethics prescribing professional engineering practice that have been developed, and are policed, by national engineering institutions and regulators. Increasingly, engineering education providers have incorporated engineering ethics education in their curricula. However, despite this, Sub-Saharan African engineering graduates transitioning into employment still face significant difficulties in dealing with the myriads of ethical dilemmas they meet in their professional practice. In this study we set out to establish the current state of engineering ethics education in Sub-Saharan Africa, and to assess the thoughts of engineering educators and researchers in the region on how engineering ethics education can be improved.

1 INTRODUCTION

Throughout Sub-Saharan Africa, governments and ordinary people are increasingly becoming aware that unethical conduct by engineering practitioners has financial, social, and health and safety implications [1]. For instance, in 2016 an online news site linked some construction disasters that had taken place in Nigeria, Kenya and Ghana to unethical practices by the professionals responsible for implementing the construction works [2]. Examples cited by the publication include the collapse of a church building in Nigeria in 2014 that led to 115 deaths, and the collapse of a six-storey building in Kenya that resulted in three deaths. The publication concluded by suggesting that unethical practices are behind most engineering failures in Africa [2]. A 2010 study on building collapses in Nigeria suggests that approximately 40% of all building collapses are due to professional incompetence and fraudulent practices [3].

All the Sub-Saharan Africa countries that we looked at had codes of professional ethics that govern the professional practice of their engineers. These codes of professional ethics are comparable to Western codes of ethics, for example the IEEE Code of Ethics [4]. All these countries have legal frameworks that govern the conduct of professionals and they have institutions whose role is to enforce the legal requirements demanded for their professional practice. However, corruption and ethical misconduct are well entrenched, and often involve powerful individuals and organisations, which makes it difficult to resolve these issues.

Given the relative intractability of professional and ethical malpractice, a number of educators and researchers are exploring the possibility of ethics education as a tool to address the problem of ethical malpractrices in the long term. This includes Asheshi University College Ghana, whih was launched in 2002 with a mission to ‘educate a new generation of ethical entrepreneurial leaders’ [1].

In this study, we set out to explore from published works on engineering ethics education how the subject is currently being taught in higher education institutions in Sub-Saharan Africa.We also sought to establish from the identified published works what engineering ethics educators and researchers in Sub-Saharan Africa think should be done to improve engineering ethics education. We used the following research questions to frame our study:

1. How is engineering ethics education currently being delivered in Sub-Saharan Africa?
2. What do engineering ethics educators and researchers think should be done to improve the teaching of engineering ethics education in Sub-Saharan Africa?

2 METHODOLOGY

Guided by our two research questions, we carried out a semi-systematic literature review [5] to establish the current state of engineering education ethics research in Sub-Saharan Africa. We did this by carrying out searches in Google Scholar and Engineering Village. We identified two key search terms from our two research questions. These are “engineering ethics education” and “Sub-Saharan Africa”. We took a sample of nine English-speaking Sub-Saharan African countries covering West Africa (Nigeria, Ghana, Sierra Leone), East and Central Africa (Uganda, Kenya, Tanzania), and Southern Africa (South Africa, Zambia, Zimbabwe). To cover these countries, we used the following search string on both databases:

“engineering ethics education” AND (Africa OR Ghana OR Nigeria OR Sierra Leone OR South Africa OR Tanzania OR Kenya OR Uganda OR Zambia OR Zimbabwe)

Running the search string gave us 142 potential publications. We then weeded out those publications whose titles were not consistent with our research questions, giving us 37 publications. Reading through the abstracts of these 37 publications led us to whittle down the number to 12.

3 RESULTS

Table 1 lists the publications that were identified in this study, together with the total number of researchers that we identitifed in each country.Only three countries are represented as our search could not identify any publications from the other six countries.

Table 1. Engineering Ethics Education Publications identified in this study

Country	Number of Publications	Number of distinct authors
Nigeria	3	7
South Africa	6	11
Ghana	3	7

3.1 Nigeria

Reference [6] is a review of ethics teaching in a software engineering course at the University of America in Nigeria. The review concludes that regardless of whether ethics is taught as a standalone course or embedded in other modules:

- Industry partners should be invited to present guest lectures on the specific ethics relating to their industry

- Industry partners should support higher education institutions in aligning their curricula to current and professional ethical concerns and how these concerns could be addressed and implemented in the workplace.

The authors of the review also suggest that rather than restricting ethics education to a single dedicated course, usually in the final year,ethics education should be embedded in course modules throughout the degree programme, and this should lead to a dedicated ethics course in the final year focussing on current ethical issues within the discipline.

Reference [7] presents a survey of ethical practices in the Nigerian construction industry that was admistered to final year civil/structural engineering students at the University of Benin. In line with the curriculum, these students had undergone three months of industrial attachment in the construction industry each year from the first to the third year and six months industrial attachment during the fourth year.Findings from this survey collaborate an earlier study of practising construction industry professionals [3] which found that unethical professional practice was the norm within the Nigerian construction industry. 50% of the surveyed students believed that it was OK for engineers to have vested interests in the projects they were advising on, thereby suggesting that they found nothing amiss with some of the unethical practices in the industry. To address this situation, the authors suggest

- all practising engineers should go on reorientation programmes on ethical practices
- the existing curriculum should be reviewed to place an emphasis on ethics
- Nigerian society needs to be reorientated to undergo mindset changes.

3.2 South Africa

Reference [8] is an analysis of ethics education within software engineering programmes offered by South African universities of technology. The study revealed that coverage of engineering ethics within computing qualifications is insufficient, incomplete and superficial, and provides only limited opportunities for students to develop software engineering ethical competence [8]. Another study by the authors finds that the majority of software engineering educators (54.5%) are not aware of the prevailing ethics codes in the software engineering industry, and as a consequence, coverage of the codes in teaching is minimal, and lecturers often fail to apply the codes practically during their teaching [9].

A survey of engineering ethics educators at two South African universities also revealed that whilst ethics education was viewed as important, ethics educators had different understandings of what should be covered in ethics courses [10]. Few of the engineering programmes explicitly highlighted ethics in learning outcomes or assessment procedures, and educators felt that they did not have the skills to teach the subject. The authors of the study subsequently suggested that engineering ethics educators needed more support to master their subject. In another study, the same authors also advocated the repositioning of ethics within the engineering curriculum as a transdisciplinary area that provides context and rationale for the selection and practice of technical skills and knowledge developed in the discipline [11]. The authors suggest that such an approach will help to bring ethics from the periphery of curriculum design consideration to a position where ethics is viewed as the basis by which engineers make the necessary technical, mechanical and process choices in pursuance of their professional and ethical responsibilities and obligations. The authors believe that this strategy is best implemented by integrating ethics in engineerign education at the accreditation level to ensure that ethics is properly embedded within the curriculum.

Reference [12] makes the observation that in South Africa engineering programmes tend to teach ethics in an isolated module on "Professional Practice" which is mostly covered in the the final-year. The paper argues that ethics education could be improved by nurturing and discussing ethical behaviour throughout the undergraduate degree. However, the authors also indicate that the promotion of individualism within modern day society mitigates against ethics education, and suggest that a communitarian approach which emphasises the 'good for all' may provide a better learning environment. Such a proposal chimes in with proponents of ethics education approaches based on African communitarian philosophies such as ubuntuism [13].

3.3 Ghana

Reference [14] describes the architecture of engineering programmes at Asheshi University College Ghana. This architecture places an emphasis on ethics, leadership and civic engagement in addition to the typical science, mathematics and engineering courses found on traditional engineering programmes. This includes dedicated ethics courses, as well as a Code of Ethics and an Examination Honour Code.

First year students are also required to attend a not-for-credit seminar entitled 'Giving Voice to Values' where they learn ethical skills through role play and real case studies based on the experiences of the university's alumni [1]. The university believes that this focus on ethics and leadership will help to develop graduates who are more inclined to behave ethically in their professional roles. The effectiveness of this approach is still to be evaluated, however a study on the ethical attitudes of accountants carried out within the context of Ghana indicated that curricula that place an emphasis on ethics education have a positive effect on graduates' ethical behaviour and attitudes [15].

4 CONCLUSION AND FUTURE WORK

This study set out to identify research on engineering education ethics from countries in Sub-Saharan Africa. Nine countries in which English is an official language were identified. These countries ranged from West Africa, through Central and Eastern Africa down to Southern Africa. Most of the work identified in this study comes from South Africa, Nigeria and Ghana. This highlights the challenges of accessing published works from Sub-Saharan Africa focussing specifically on engineering education ethics, as is the case with this study, and more generally on engineering education research.

In our thinking, there are three possible reasons for this, the first one being the likelihood that Sub-Saharan African reseachers in engineering education, in general, and in engerering ethics education in particular, tend to target regional and local journals and conferences that are not covered by Google Scholar and other mainstream research databases. Another possibility might be that Sub-Saharan African researchers may be prioritising technical engineering research at the expense of engineering education research. A third possibility may be that most African higher education institutions prioritise education at the expense of research, and high teaching workloads preclude many academics from research and publication. From our own experiences, we believe that all three factors contribute to the lack of visible publication on engineering education ethics from Sub-Saharan Africa.

Given the limited number of publications identified in this study, we intend to identify and collaborate with engineering academics who teach on ethics course modules in the nine countries that we identified. The advent of social media platforms like WhatsApp and video conferencing tools like Zoom has made networking across Sub-Saharan Africa easier, as evidenced by the recent establishment of the Engineering Education Research Network-Africa (EERN-Africa). We intend to use these platforms, alongside EERN-Africa, to identify and connect with Sub-Saharan Africa academics teaching and researching on engineering education ethics.

ABSTRACT
Approaches such as problem and project-based learning (PBL) are the cornerstone of modern engineering curricula. With a growing need to move these student-centred active learning curricula to online and blended learning environments due to issues including increasing cohort sizes and limited budgets, it is essential that instructional designers in engineering education understand the impacts that these differing mediums may have on student collaboration. This study is the beginning of a body of work with the aim to develop effective teaching and learning strategies for team project-based learning in online and blended learning environments. This case study was carried out in an Irish university in 2021 in a first-year engineering module during the COVID-19 pandemic. The study followed an explanatory mixed methods design in which a questionnaire and semi-structured interviews were utilised to collect data. The research data was gathered in two phases. Phase 1 included a questionnaire with both closed- and open-ended questions (N=94). Phase 2 was based on semi-structured interviews (N=7). This paper will focus on the qualitative datasets, including the open-ended questions and interviews. After completing a thematic analysis, we identified six themes and eighteen sub-themes that affect students' perceptions of team project-based learning (PBL) in an online environment. Each of these themes are discussed within this paper. The paper concludes with an outline of future research plans for the ongoing project.

doi:10.5821/conference-9788412322262.1183

1 INTRODUCTION

1.1 Overview

As a consequence of the COVID-19 pandemic and the growing need to deliver high-quality, student-centred engineering education to large and diverse student cohorts [1], interest in blended and online learning has increased significantly worldwide. Active and student-centred learning strategies such as problem and project-based learning (PBL) has been researched extensively in traditional on-campus environments; however, research on effective PBL implementation in online environments, especially in engineering is still emerging. With the rushed implementation of online and blended learning approaches during the COVID-19 pandemic, the need for a body of evidence-based pedagogical practices in PBL has been highlighted [2], [3]. In this paper, we argue that to begin developing evidence-based pedagogical guidance for engineering practitioners, researchers first need to explore students' perceptions of PBL in online environments. This process can identify both success and limitations perceived by the students in current strategies. These successes and limitations can then inform practitioner design decisions when implementing team PBL in online and blended learning environments.

1.2 Research Question

What factors affect 1st year students' perceptions of team PBL in an online environment?

2 METHODOLOGY

2.1 Overview:

This study was carried out at an Irish university over an academic semester in a first-year engineering module. The study follows an explanatory mixed methods design where quantitative and qualitative data were used to inform participant interviews. The quantitative data was gathered with the use of a student's attitude and satisfaction survey, Phase 1 (N=94). The qualitative data was gathered with the use of open-ended questions, Phase 1 continues, and a semi-structured interview, Phase 2 (N=7). In this paper, we report on the qualitative datasets and the results identified from the thematic analysis of this data.

2.2 Data Analysis

A six-phase inductive thematic analysis approach was undertaken to investigate both the open-ended questions and semi-structured interview datasets [4]. The main goal of the thematic analysis was to identify potential factors (Themes) affecting students' perceptions of team PBL in an online environment. All data from the open-ended questions and semi-structured interviews were uploaded to NVivo; however, the process was carried out with a mixture of both physical and digital documents to help identify all relevant codes, themes, and sub-themes.

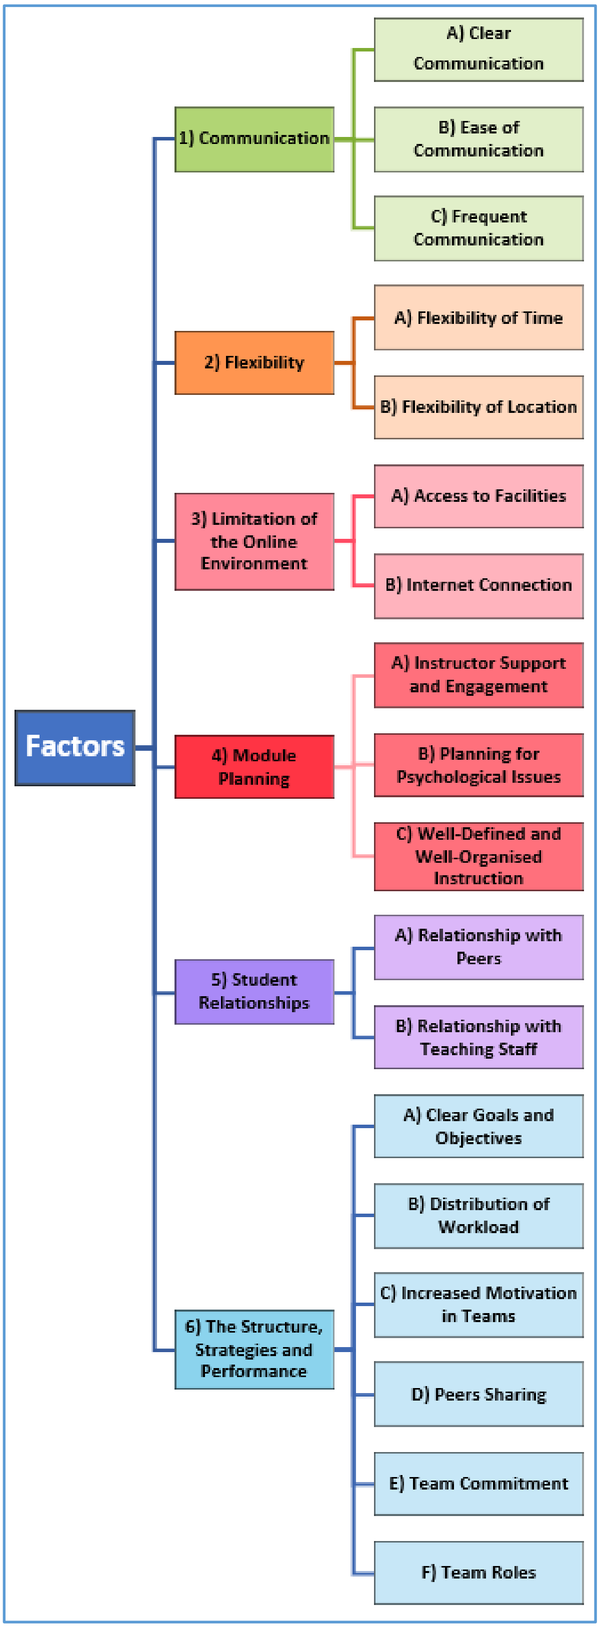

Fig. 1. Thematic Analysis Flow Diagram

3 RESULTS & DISCUSSION

3.1 Overview

Overall, the thematic analysis revealed that the participants demonstrated high satisfaction levels within their open-ended questions and interview responses within the module. However, we were able to identify several themes and sub-themes through the successes and limitations of the online format as perceived by students.

The following six themes and eighteen sub-themes, shown in Fig. 1, were identified to affect students' perceptions of team PBL in the online environment. The next section, 3.2, will discuss each theme and associated sub-themes in detail.

3.2 Themes and Sub-Themes

Theme 1: Communication (Student to Student and Student to Teacher): Communication was the second most common theme of discussion by students in both the open-ended questions and semi-structured interviews. It was clear from student responses that effective communication between student to student, student to teacher, teacher to student, teacher to teacher is essential for team PBL success within the online environment. Three sub-themes emerged from the data, including A) clear communication, B) ease of communication and C) frequency of communication. Although many comments were made referring to communication, students' main point of concern was the ease of communication. Students felt that their ability to communicate ideas with team members was limited in the online environment when compared to the traditional on-campus environment: (P.20) *"It is hard to fully explain and demonstrate ideas and concepts online, and I believe I would have a greater* *understanding by being explained there in person"*. Research suggests, many factors are shown to affect student performance in teams, while one of the most effective for improving it is the ease of communication between team members [5].

Theme 2: Flexibility of Online Environment: The increased flexibility of the online environment was seen as an improvement by many students. Two sub-themes under flexibility of the online environment emerged from the data, including A) flexibility of time and B) flexibility of location. One student stated how the increased flexibility was one of the benefits of working online: (P.19) *"I liked it in the sense I didn't have to actually set time aside to travel and meet the team". Increased flexibility is often highlighted to be a positive impact of online education*". Students, in general, perceive that online learning allows for more effective use of time than traditional on-campus courses [6], [7].

Theme 3: Limitation of the Online Environment: The students outlined two main limitations to teaching and learning in the online environment. These two limitations include A) access to on-campus facilities and B) poor internet connection. During the COVID-19 pandemic students were unable to access many of the on-campus facilities such as the university library, meeting rooms and workshops due to governmental restrictions. A few Students felt that limited access to the workshop impacted them negatively: (P. 27) *"we weren't able to go into the workshop […] mess around and create prototypes of the car […] we couldn't modify it in case something was wrong".* A lack of access to facilities in online engineering education is also shared in other publications [8]–[10]. Students also highlighted concerns around poor internet access: (P.23) "There are still drawbacks with online as not everyone can take a call or a live meeting due to internet issues". This concern is also shared by many other students working in online and blended learning environments [7], [11].

Theme 4: Module Planning: Three sub-themes were identified under the theme module planning. These sub-themes included A) instructor support and engagement, B) planning for psychological issues such as increased anxiety and decrease in motivation and lastly, C) well-defined and well-organised instruction. Most frequently, under this theme, students expressed the need for well-defined and well-organised instruction. When one student was asked to provide advice to the module leader planning a team-based project online he recommended: (P. 89) *"Always start on the right foot, start early and communicate roles effectively and clearly, and set deadlines and timelines for things to be finished at".* This also aligns with the finding of Ku et al.'s [12] publication on online collaborative learning. Ku et al.'s findings indicate that students expect instructors to provide a supportive collaborative learning environment and deliver well-defined and well-organised instruction for students.

Theme 5: Student Relationships: Two sub-themes emerged underneath the theme entitled student relationships. These sub-themes were A) relationship with peers and B) relationship with teaching staff. Students regarded making and maintaining good relationships with peers and staff member to be of high priority. Students had both positive and negative feelings towards building relationships in the online environment. Students felt that the team-based project gave them an opportunity to develop friendships that weren't usually possible in less collaborative modules: (P.1) *"it helped* *me to make friends and to communicate with my classmates in a way that hasn't been possible through online learning".* However, some students felt that the online environment in general made forming relationships with peers and teaching staff harder. This can be seen in the responses given by participant 21 and 27: (P.21) *"On campus also allows you to build a personal relationship and not just a professional one"* (P.27) *"I would have gotten to get know my group members better and been able to be more interactive with my teachers"*. Stenman [13] highlights that students perceive online courses as a negative experience when they feel a large transactional distance between instructors and their peers. She adds that online students view others as a number on a list rather than individuals, and this issue can influence whether a student will stay in or drop out of a course.

Theme 6: Team Structure, Strategies and Performance: Team structure, strategies and performance was the most common theme of discussion by students in both the open-ended questions and semi-structured interviews. Six sub-themes emerged from this theme included A) clear objectives and goals, B) distribution of workload, C) increased motivation in teams, D) peers sharing perspectives', experience, information and skills, E) team commitment and finally F) team roles. The most discussed sub-theme by student was peers sharing perspectives, experience, information and skills. The following comments highlight some of the sharing experienced by students: (P.48) *"everyone brings something else to the table and we had ideas that others came up with that I wouldn't have gotten myself"* (P. 1) *"I would have struggled with the maths and mechanics of the project had it not been for my teammates"*. This coincides with the findings presented by Volkov and Volkov [14] who found that students reported they attained deeper understanding through the sharing of students' skill sets while participating in teamwork.

4 CONCLUSION

4.1 Summary

Students' perceptions of courses influence the likelihood of success or failure when working online. It's reported that satisfied students are more likely to be successful in the online environment [15], [16]. This paper outlined multiple factors that instructional designers in engineering education need to consider that can affect students' perceptions of team PBL in online environments. Each of the factors (themes) outlined in the thematic analysis can be linked back to issues experienced by other practitioners in the field, and as such, solidifies the importance of planning for teaching and learning with theses factor in mind.

5 LIMITATIONS:

It should be noted that data for this paper was gathered during the COVID-19 pandemic and that students were experiencing many changes to everyday life in Ireland due to heavy governmental restrictions. This change in lifestyle may have affected students' responses during both the open-ended questions and interviews.

6 FUTURE RESEARCH

This conference paper is part of a larger body of research on team PBL within the online and blended learning environment. The project is conducted following an explanatory mixed methods approach were both qualitative and quantitative data is used to inform the results and discussion. The data for the project is gathered in two rounds, in the same module, one within the online environment (2021) and the second within the traditional on-campus environment (2022).

ABSTRACT

This pilot study explores engineering students' motivation for learning and studying through the lens of Self-Determination Theory (SDT). Five postgraduate students from a research-intensive Swedish university participated in semi-structured qualitative interviews about their study experiences from different Challenge-Driven Education (CDE) courses. It adds to the limited, existing literature on CDE and is the first to study it from a purely motivational perspective. As this is a pilot study, the primary intent of the data analysis concerns the first two phases of Braun and Clarke's (2006) thematic analysis approach - familiarisation and immersion in the data and generating initial codes. A combination of inductive and deductive approaches to analysing the data were used, and preliminary motivational factors emerged from the interviews are illustrated according to the SDT concepts. A variety of motivations for learning and studying, such as innovation, real-world problem solving, contribution to the society, and trial for following master thesis projects, emerged from the data and positioned on the self-determination continuum in which different types of regulations are guiding students' behaviours simultaneously. Furthermore, autonomy in the choice of a project, feedback and assignment deadlines, and relationships within group work, enhanced or/and undermined the three psychological needs defined by SDT; autonomy, competence and relatedness. Preliminary findings are discussed in relation to the SDT literature, and practical applications are suggested for supporting the motivational needs of engineering students. Finally plans for a continuation of the study are discussed in light of this initial phase.

1 INTRODUCTION

There is emerging interest in learning approaches where students are collaboratively engaged across disciplines in open-ended projects that concerns complex real-world issues and interaction with various external stakeholders. Such learning approaches can for example be referred to as challenge-driven education 'CDE', challenge-based learning 'CBL, or problem- and project-based learning 'PPBL (e.g. [1], [2]). There have been attempts made to define some of these concepts (e.g. [3]), still there are large differences in how each of these concepts are being interpreted and implemented (e.g. [4]). There are also many implementations of such learning approaches that are not explicitly associated with any of these terms and concepts. These differences and the lack of definitional clarity do however not pose any barriers to exploring features and key concerns that these learning approaches have in common. One such feature is the opportunity in these learning approaches to enhance students' motivation for studying and learning.

In this pilot study, self-determination theory (SDT) [5]&[6] is used as a lens for exploring factors that facilitate or undermine the motivation for studying and learning among students engaged in these kinds of learning approaches (for simplicity hereafter referred to as challenge-driven education, CDE). A qualitative methodology has been used to investigate the following research questions:

(a) What are the motivational factors that guide students engaged in CDE?

(b) How do they relate to the SDT self-determination continuum?

(c) How are the needs for autonomy, competence, and relatedness, as defined by SDT, experienced and fulfilled among engineering students engaged in CDE?

2 METHODOLOGY

2.1 Participants

Five students in three different CDE courses were engaged on voluntary basis as a response to an invitation to participate in this study; three students in a course named Innovations for *Emerging Cities*, one student in the course *Ergonomics in Challenge-Driven Product Development*, and one student in the course *Innovation and Product Development*. The small number of participants is of course a limitation not allowing for data saturation. It should however be noticed that this is a pilot study with the purpose of enabling the researcher to practise the interviewing techniques and investigate the appropriateness of the interview questions as preparation a larger following main study.

2.2 Study design and Data analysis

Semi-structured interviews were constructed, conducted and analyzed in conformity with two methodological approaches: (1) thematic analysis, providing an inductive process, coding the content of the data in order to reveal emerging themes [7]. Specifically, the first two phases of Braun and Clark's [8] thematic analysis approach followed: (a) reading and familiarisation of the data; (b) taking note of items of potential interest which seemed relevant to the research questions; (c) coding; (2) theory-driven analysis [9], analyzing the data in a deductive process, relating the content to SDT concepts, observing arguments with SDT, enhanced by remarkable aspects portrayed by the pilot study's participants. The design of the interview protocol is informed by these approaches, which included both general questions regarding learning and studying motivation and specific questions relating to SDT constructs.

2.3 Interviews

In this pilot study, the coordination of the recruitment process was held by the first author and a co-author, four interviews were carried out by the first author, and one interview was conducted by both the first author and a co-author to strengthen the trustworthiness. The interviews took place online through Zoom agreed upon with the student. Each online interview lasted approximately 45-60 minutes, and all participants were interviewed in English. All interviews were audio/video recorded and transcribed verbatim for analysis.

3 FINDINGS

Two major categories emerged from the data. The first category gives a preliminary insight to the first research question — what are the motivational factors that guide CBL students in their studies? It focuses on motives that the students argued for studying a CBL course. Subsequently, answering the second research question, four motivational factors were identified and positioned progressively along the self-determination continuum [5]-[6], from the most extrinsically regulated behavior, to more self-determined behavior. The second category corresponded with the psychological needs described by SDT and with the third research question, examining how the needs for autonomy, competence, and relatedness are experienced and fulfilled by engineering students in different CBL courses. The categories and representative quotes are illustrated in Fig. 1.

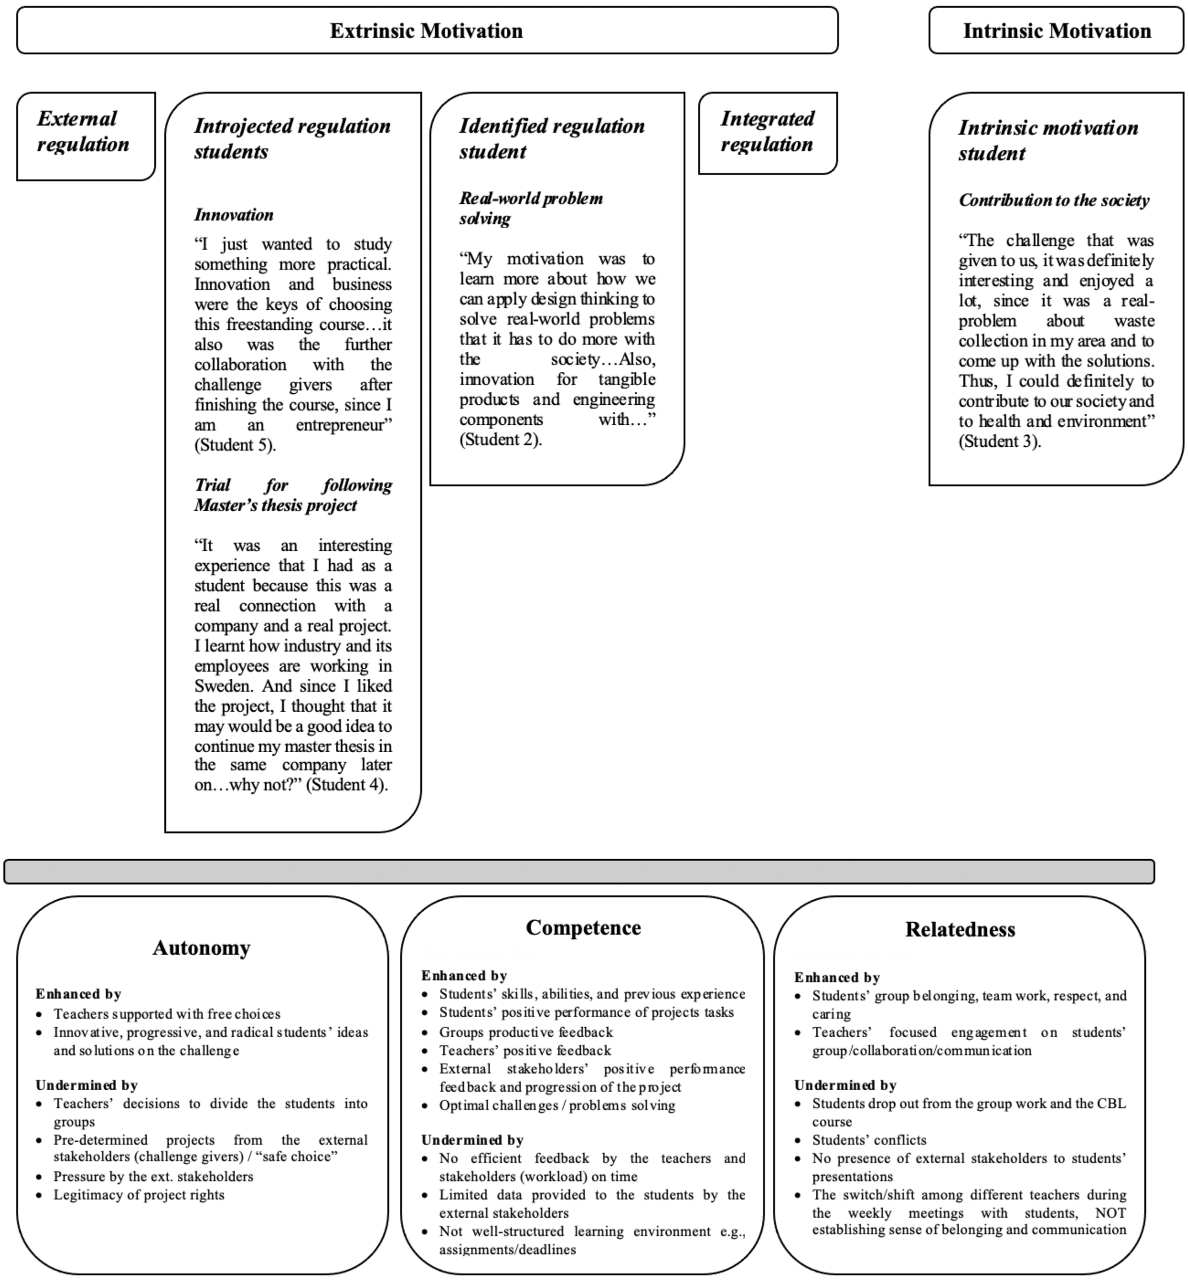

Fig. 1. Emerging categories and quotes, positioned along to the self-determination continuum [5]-[6], and in relation to the three psychological needs postulated by SDT

4 DISCUSSION

A variety of motivations for studying a CBL course emerged from the data. Innovation and further collaboration with the external stakeholders were motivations for studying CBL courses by an entrepreneur student. Additionally, a student who included a CBL course for his studies argued that it would be a good opportunity for doing a Master's thesis in the same company which collaborated with during the course. According to SDT, these externally regulated reasons for studying and learning fit the common definition of introjected regulation, depending on internal rewards of self-esteem for success [6].

Another student argued that the design thinking construct of the CBL course motivated to develop problem-solving skills for addressing societal challenges. The experiences shared demonstrate how design thinking, real world problem-solving skills and values of society are internalized to become intrinsically voice identifying with the value of the CBL course activities as an aim for itself, and thus can be positioned within the category of identified extrinsic regulation.

Last but not least, the contribution to society was a motive for a student who studied a CBL course. This student's behavior was facilitated by interest, enjoyment, and engaging of the challenge, and thus can be positioned within the category of intrinsic motivation.

Students related implicitly to all three psychological needs defined by SDT as particularly fundamental of the motivational process: autonomy, competence, and relatedness. Components of all three needs were mentioned as positive factors when enhanced, and negative factors when these needs were undermined.

With regard to autonomy, it is argued that when students experienced a sense of choice, they felt more autonomous, and facilitated their performance in the project tasks, resulting in an increased intrinsic motivation for studying and learning [6]. Whereas research has shown that, controlling teachers' and external stakeholders' behaviors (e.g., using pre-determined project challenges) are negatively related with students' autonomous motivation [10] and are related to an increased frustration of the basic needs across the educational process, and avoidance of challenges [11].

With regard to competence, students' perceptions are agreed with SDT that according to Niemiec & Ryan [12], students' competence supported by teachers' allowance to them to test and to expand their competences and skills; providing them with appropriate tools and performance feedback; offering optimal challenges that students understand, engage, value, and master; and necessary feedback which downplays evaluation promoting students' effectance, providing guides on how to master the learning tasks at hand. Howener, the findings agree with previous research that students and teachers' heavy workload on CBL courses negatively affect students' motivation [9]. Furthermore, according to SDT, when external policies of the external stakeholders [13] and teachers' experienced work overload [14] affect the educational process then negatively associated with both teachers' and students' autonomous motivation and perceived competence.

With regard to relatedness, the findings showed that relatedness was enhanced by students' sense of belonging and connection with teachers and external stakeholders, respect, and caring within their groups work, relating to the CBL courses' construct of team work to encourage them. Relatedness is also highly associated with students' perception of that the teachers genuinely respect and value them, with students besides to internalize and accept as their own the practices and values of those to whom they feel a sense of belonging. Whereas students who experienced a sense of disconnectedness or rejection by teachers or/and other external stakeholders would be argued in this pilot study, are more likely to move away from internalization and intrinsic motivation for learning and continue study [12].

5 CONCLUSIONS

The current pilot study provides a preliminary investigation of students' motivation for learning and studying in different CBL courses. Preliminary findings support the relevance of the SDT framework and lead to practical implications, suggesting not only 'what works' in CBL courses learning practices, but also why certain learning environment adjustments are important, and what motivational needs they serve. All motivational factors that students experienced and presented in this pilot study which undermined the three basic psychological needs should be taken into consideration and eliminated by teachers, CBL educational developers, and external stakeholders. Additionally, all factors that facilitated and enhanced the needs should continue to be flourished in CDE. The included real-world challenges of CDE should continue to bring students 'closer to the real world' [15] increasing motivation and engagement [16] by having an impact on students' lives [17]. However, it also needs to be agreed with the perspective of Ryan and Niemiec [18] that the direction of SDT is to broaden the idea that universities are just about developing skills and competences for some future employment. Instead, in this view they are about developing abilities and attitudes that include enjoyment, curiosity, interest, access to resources and data for transparency, confidence, and empowerment. When universities and teachers embrace such a vision, they can become liberators and help students develop critical thinking they need to use for the transformation of society to be more progressive, productive, and increase human wellness.

ABSTRACT

Universities have a very important role in entrepreneurial education. University students are not only trained in their specific areas, but they are also trained in entrepreneurial skills to lead teams and to develop leading innovations that will be applied into different markets.

Since 2012, the entrepreneurial ecosystem from Polytechnic University of Valencia (Spain), StartUPV, has implemented several education programs for its community, creating a whole learning roadmap with specific training for each stage of the startup. For instance: hypothesis validation, sales funnel, finance, etc. However, one of the main challenges was how to transfer the know-how generated by each startup to the entire ecosystem.

Beyond mentoring some projects altruistically, the need was detected to create a framework in which the entrepreneurs themselves could share their knowledge with the rest of their colleagues in the ecosystem. To this end, StartUPV Academies were created in 2015.

These sessions consist of small training pills, led by a member of one of the startups in the ecosystem, on a variety of topics: a new programming language, tips for creating marketing campaigns on social networks, how to negotiate with investors, etc.

More than 200 entrepreneurs have attended the StartUPV Academies, and an average of 8 sessions have been held per year. In this paper we analyze these programs, including the main conclusions of more than 5 years of implementation.

1 INTRODUCTION

One of the objectives of the UPV is to train its students in entrepreneurial skills at all levels. Specifically, for those projects that access the StartUPV incubator program, an itinerary has been created according to the degree of maturity of the company and the phase of the program in which it is located.

Throughout this itinerary, they receive training on business model generation[1], sales strategy, finances for entrepreneurs[2], business strategy[3], etc.

Moreover, to complement this training provided by the university, entrepreneurs have developed considerable expertise to share with the rest of their peers. This knowledge, enriched by their own entrepreneurial experience, is of enormous value for the growth of the ecosystem.

In this paper, we will present the main initiatives that have been launched in the StartUPV ecosystem to transfer this knowledge among the entrepreneurs who are part of it.

2 TRANSFERRING KNOWLEDGE IN AN ENTREPRENEURIAL ECOSYSTEM

Through the StartUPV program, an entrepreneurial value chain is created where the entrepreneurs themselves nurture each other, enriching the ecosystem as a consequence. In addition, StartUPV entrepreneurs are a reference for all students of the university, serving as an example through the experience gained in the adventure of undertaking business projects.

As part of this entrepreneurial ecosystem, entrepreneurial projects, startups, and companies benefit and take advantage of the institutional support, the services of the UPV, and the whole network of experts of IDEAS UPV.

However, the challenge lies in how to transfer knowledge among entrepreneurs of the ecosystem. For this reason, in 2015, the StartUPV Academies were introduced and, later, in 2016, the mentoring program. With these activities, entrepreneurs contribute other projects with their experience, increasing the value of the ecosystem itself.

2.1 StartUPV Academies – Universal transfer

As the ecosystem grew, the need was detected to find a formula where the entrepreneurs themselves could share their knowledge with the rest of the startups. To this end, StartUPV Academies were created, consisting of short training sessions on a very specific topic of interest to the ecosystem in general.

2.2 Mentoring program – Personalized transfer

The fact that more than 30 startups are housed in the same space means that knowledge is transferred in a natural way. The entrepreneurs themselves generate synergies between them and help each other altruistically.

The problem with this unstructured mentoring is that it does not reach all the teams equally, and the involvement of the parties is not equal. For this reason, StartUPV launched the mentoring program in 2016, in which we match senior entrepreneurs who act as mentors with junior entrepreneurs.

3 RESULTS

3.1 StartUPV Academies

Since 2015, a total of 37 StartUPV Academies have been held on the following topics:

Table 1. StartUPV Academies topics

Branding	Guerrilla LinkedIn; Leadership; How to create a community of FANS of your brand on Twitter.
Marketing & Communication	Growth Hacking; Inbound Marketing; Introduction to SEO; 2-sided user acquisition; Social Media Marketing; Marketing Automation and CRM; Sales Funnel Canvas; Media Relations and Press Releases; SEO for startups: tips to improve your online presence; HubSpot: How to boost your startup using the most powerful digital marketing tool on the market.
Investment & Funding	Crowdfunding; Capital increases: Finances for entrepreneurs; TechTransfer; Tips for applying for the Fundación Repsol Entrepreneurs Fund; Investment Tips.

Product	Machine design and product approval; Product development; Introduction to Meteor.
Legal & Talent	Data Protection Compliance; Legal mechanisms to attract and retain talent. Legal and tax implications; How to attract talent at the UPV; Choose a successful team; Phantom Shares; Attracting qualified personnel; How to interview in selection processes; Legal doubts against COVID-19; How to make customers pay; Structure of a contract. Essential clauses.
Misc.	Stress management; Bitcoins for dummies; Business model for accelerated development of patentable technologies.

3.2 Mentoring program

Since 2016, a total of 104 pairs of senior entrepreneurs with junior entrepreneurs have been created. From 2018 to 2021, a total of 542.5 mentoring hours have been held in 309 meetings.

4 SUMMARY

Knowledge transfer in an entrepreneurial ecosystem takes place naturally by the very nature of the space and the people who form it. In recent years, the StartUPV ecosystem has detected the need to structure this knowledge transfer in specific activities in order to reach more beneficiaries and maintain a medium-long term commitment.

Keywords: *Sense of community, Social engagement, Blended learning, Teachers' and students' perceptions and practices, Higher education*

ABSTRACT

Blended learning is not a new concept, but has attracted increased interest among higher education institutions in preparing for future education. During the COVID-19 pandemic, many teachers have gained extensive experience with online and digital education. Yet, maintaining social engagement amongst and with students, while motivating them to actively participate in their learning, remains a momentous challenge for teachers working in a blended learning environment [1]. Poor social interactions cause a negative impact on the quality of blended learning [2], culminating in students feeling lonely, isolated, and losing motivation [3].

As such, a sense of community will be crucial, but may be difficult to achieve due to limited physical classroom time. This study addresses students' and teachers'

doi:10.5821/conference-9788412322262.1149

viewpoints, and seeks to answer the question: *What are the perceptions and practices of students and teachers regarding promoting a sense of community in a blended learning environment?*

A qualitative methodology is utilized, including non-participant observation, document analysis, and interviews for data collection and analysis. Firstly, the findings of this study enhance our understanding of teachers' perceptions, practices, and challenges for cultivating SoC. Secondly, this study provides information for professional development of teachers that carry out blended education. Finally, we hope this study can support higher education institutions in preparing and reshaping for the future.

1 INTRODUCTION

1.1 Blended learning challenges

Blended learning (BL) has gained considerable attention in higher education for more than two decades [2]. Research suggests that BL has the potential to increase learning flexibility, accommodate individual needs, and improve student results [4, 5]. Combining the advantages of online education, while still including face-to-face contact, BL has attracted increased interest among universities in preparing for education post-COVID-19. However, teaching during the pandemic revealed that maintaining social connections with students and motivating them to learn was difficult [1]. This confirms previous research indicating that poor social interactions can lead to students' feelings of loneliness, isolation, and motivation loss [1, 3]. In this situation, a sense of community (SoC) is essential, representing ‘a feeling that members have of belonging, a feeling that members matter to one another and to the group, and a shared faith that members' needs will be met through their commitment to be together’ [6, 7].

SoC has a beneficial effect on learning. However, it can pose certain challenges in a blended environment. Hence, this study aims to investigate students' and teachers' perceptions and practices in promoting SoC, to gain insights on how to support students and teachers for a quality BL in higher education. More specifically, this study seeks to answer the following question:

What are the perceptions and practices of students and teachers regarding promoting SoC in a blended learning environment?

1.2 Theoretical background

Blended learning

Alongside ongoing debates regarding the best definition of BL, two definitions from Graham [8] and Garrison and Kanuka [9] are most frequently cited in various literature. Graham [8] considers BL as a mix of traditional face to face (F2F) and online learning. Similarly, Garrison and Kanuka [9] acknowledge that the essential components of BL are F2F and online instruction or learning, and they further emphasize the importance of a '*thoughtful integration*.'

Sense of community in Blended learning

Despite BL's potential to improve the pedagogical richness and learning outcomes, some researchers have contended that it can be a double-edged sword if the social aspect in BL is overlooked. Learning is most effective when a strong sense of community exists [7]. Evidence suggests that SoC is associated with increased perceived learning, academic success, as well as students' well-being [7, 10].

SoC conducive to learning is important for the educational process, but it may be difficult to achieve, notably when physical classroom time decreases in BL. It is recommended for teachers to explicitly integrate SoC into both synchronous and asynchronous environments. To assist teachers in this area, Rovai [11] identified two critical variables to esthablish a strong SoC in BL: *connectedness* and *learning*. The connectedness refers to 'connectedness, cohesion, spirit, trust, and interdependence', while the learning focuses on the extent to which students impart educational goals and benefits through interaction with peers and teachers. Studies have further revealed that in order to build a strong SoC, three presences in BL are beneficial, namely: social and cognitive presence by students, and teaching presence [12-15].

- The ability of the students to project themselves socially and emotionally, as 'real' persons to develop inter-personal relationships in a trustworthy environment, is known as **Social Presence** [16]. Social presence contributes to the dimension of 'being connected' of SoC.
- Simply having good social relationships would not be sufficient for academic success. Interactive activities need to be structured and directed towards intellectual engagement. For this, **Cognitive Presence** becomes imperative. Cognitive presence is conceptualized as the extent to which the students are able to construct and confirm meaning through sustained reflections and discourse [17]. Cognitive presence focuses on the learning aspect of SoC.
- Teaching presence is the instruction, facilitation, and direction of students' social and cognitive presence for the purpose of realizing personally meaningful and educationally worthwhile learning outcomes [18]. Teaching presence is usually under the leadership of teachers and it is intertwined with social and cognitive presence to create a deep and meaningful learning experience for students [18, 19].

2 METHODOLOGY

2.1 Research framework

An effective SoC that encourages connectedness and learning is fostered by well-designed and organized interactive activities spearheaded by teachers. These activities are characterized as social, cognitive, and teaching presence. In this sense, the three presences serve as this study's interpretive lens, analyzing students' and teachers' perceptions of SoC-promoting activities (see the Figure 1).

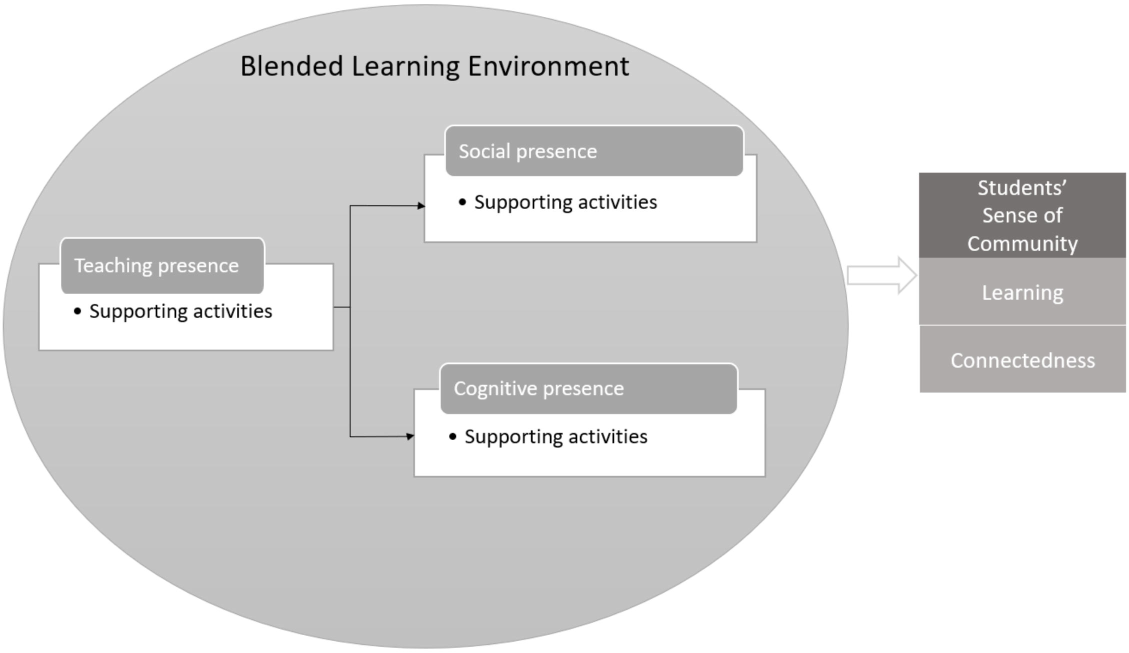

Fig. 1. Conceptual framework

2.2 Data collection and analysis

The university's ethics committee approved this study prior to data collection. Each participant was provided with a consent form and an information sheet regarding this study's aims, potential risks, and the option to withdraw from this study at any time. A blended course at one university was included in this study. This course was chosen as a sample for this study because it was developed over several years and complies with the requirements for a blended course as 'a thoughtful integration' of the F2F and online components [8, 9]. Additionally, the teacher of this course would like to investigate ways to improve students' SoC and interactivity, which would allow for a more in-depth examination of the course. The data collection spanned two phases: observation and document analysis were performed first, which provided input, directions, and knowledge to inform the interview questions in phase two, enabling a exploration of the participants' perceptions and practices on SoC.

- First, nine observation including both online and F2F sessions were scheduled at the beginning, middle, and end of the course, to explore SoC at various stages of the course.
- Secondly, this study obtained permission from teachers to access their courses via the learning management system (LMS). It scanned the course contents, assignments, and assessments and discovered specific course elements influencing students' SoC.
- Finally, one-on-one interviews with teachers and a group interview including five students have been conducted. The interview with the teacher provided

their perspective on their roles, teaching practices and their challenges in promoting SoC in BL. Interviews with students also revealed activities that would have contributed to SoC but were not supported by teachers.

The interview transcripts and the observation and document review notes served as the content analysis sources. The study generated two sets of codes to identify significant themes that would explain the perspectives of students and teachers on SoC. It utlized the pre-defined codes using the three presence categories and indicators [20]; while it established emergent codes by scanning obtained data to generate discoveries.

3 RESULTS

Although the study is still ongoing and the results are not yet fully available, preliminary findings indicate that specific pedagogical methods, practices, and tools that promote SoC in the BL environment can already be identified:

- A high-quality BL course requires teachers to consider students' social, emotional, and intellectual needs. A safe and open culture can be established by allowing students to express themselves without fear of repercussions.
- While it is easier to establish social bonds at the start of a course in a face-to-face session through icebreaker activities, teachers and students must work together to maintain them throughout the entire course.
- Personalize a BL course by including relevant personal stories, experiences, and examples. A video introduction with audio and video feedback are viable methods for boosting social presence. This strategy may encourage students to communicate their thoughts, feelings, and difficulties.
- Convert a static BL course into an active one with multiple opportunities for student engagement. Asynchronous activities (e.g., self-study and individual assignments) provide students with greater flexibility and control over their learning; on the other hand, synchronous activities encourage immediate personal engagement and more responsive exchanges (e.g., brainstorming, discussion, and live polling).
- Create an environment conducive to collaboration and encourage students to assist one another. It necessitates a shift in teachers' roles ‘from sage on the stage to guide on the side’ [21] by allowing students to assist one another first and then stepping in when necessary.

Additionally, this study shows that many universities are now required to offer hybrid education to allow corona-infected students to participate in online education. However, catering to online and on-campus students simultaneously is not easy; activities that should take place on campus (e.g., group projects) are forced to be moved online, raising concerns about the university’s educational quality. It is important to stress that hybrid education is not synonymous with blended education. Universities should transition from emergency remote teaching to quality education by making well-considered decisions about which activities should take place online while others are better supported by F2F instruction.

4 CONCLUSION

Quality blended learning requires that students have a strong sense of community in order to keep them engaged and motivated throughout the learning process. Teachers play a crucial role in this process by imparting knowledge and fostering a safe and productive learning environment for students.

Furthermore, we hope that the study's future findings will identify the barriers teachers face and the support they require to develop a high-quality BL. We anticipate that this study will shed light on future professional development opportunities in blended education at HEIs.

ABSTRACT

Managing Engineering Projects is a 3rd Year module of the 4-year MEng in Electrical and Electronic Engineering with Management degree. Its purpose is to provide students with innovation and project management skills in the context of engineering practice.

The format was modified during the 2020-21 academic year to include more elements of student-centred learning to increase engagement given the online delivery format due to Covid. The module comprised 10 x 2-hour weekly sessions. Students were sent the material for each of the sessions ahead of time, with the first hour being devoted to discussing relevant aspects or issues raised by the students. The second hour focused on a related case study or activity, where students were allocated to break out rooms on Teams for group work, then coming together for some general discussion and conclusions. Alternatively, guest industrial speakers would share their professional experiences to illustrate the theory covered in the first hour. There was also an opportunity for questions and general project management discussion.

The module was delivered in person this academic year, retaining the same flipped classroom format, case studies and industrial speakers.

This paper compares the feedback and insights gathered through questionnaires from the online and in-person cohorts. Initial evidence shows that both groups found the flipped classroom, practical group work, and guest talks more engaging than traditional lectures. However, the in-person cohort showed higher rates of attendance and students were more engaged in group activities.

1 INTRODUCTION

1.1 Background to the module

The “Managing Engineering Projects” module was designed and taught for the first time in the spring term (January to March) of 2019. It is offered to 3rd Year students on the Management Stream of our MEng Electrical and Electronic course.

The module comprised 10x2-hour sessions with 1 hour of traditional lecturing, or passive learning, and 1 hour where an industrial speaker would illustrate the material covered in the lecture, or the cohort would work in groups on a case study or management challenges.

The format was modified during the spring term 2021 to include more elements of student-centred learning [1] to increase engagement, given the online delivery format due to Covid. Using a flipped classroom, students were sent the material for each of the topics ahead of time, with the first hour being devoted to discussing relevant aspects or issues raised by the students. The second hour remained unchanged.

The module was delivered in person this spring term, retaining the same flipped classroom format, case studies and industrial speakers [2].

This paper compares the feedback and insights gathered via questionnaires as well as levels of engagement from the online (Group 1) and in-person (Group 2) cohorts.

2 METHODOLOGY

2.1 Student sample details

Two groups were sampled for this paper; Group 1 who experienced the module through online delivery in 2021 and Group 2 who attended face to face in 2022.

Table 1. Details of student sample

Group	Cohort	Delivery method	Cohort size	Attendance and engagement
1	2021	Online	49	69.39%
2	2022	In person	17	88.23%

2.2 Questionnaires

Both cohorts of students were asked to complete a 16-question questionnaire (see Appendix) anonymously. Only Questions 3 and 4 were considered for this paper.

Table 2. Questions 3 and 4

Q3. Class format - which format do you find most suitable for the way in which you learn?
Q4. Class format- please explain the rationale for your selection in Q3

2.2.1 Question 3

The purpose of Q3 was to establish which learning format was best suited to the respondent’s learning style. The responses included the options available in pre-Covid times (face to face, online pre-recorded and live discussions, a combination) and the most widely approach applied during Covid and the various lockdowns: online live. Respondents also had the opportunity to add their own method under the "Other" reply.

2.2.2 Question 4

Q4 was free text to allow respondents to elaborate on their answers for Q3. These replies gave great insights into their attitude and motivation towards learning in the context of the pandemic.

2.2.3 Level of engagement

The level of engagement was obtained by calculating the number of students who attended more than 50% of the classes as a proportion of the total number of students.

This threshold was selected as it is the minimum number of sessions students can attend and still have the knowledge necessary to successfully complete the coursework.

3 RESULTS AND DISCUSSION

3.1 Results

3.1.1 *Question 3*

Group 1 showed a clear preference for traditional lectures (46.1%) while Group 2 was equally divided amongst flipped classroom, traditional lectures, and a combination of both. The percentage for flipped classroom, however, remained almost constant, moving from 30.8% to 33.3%.

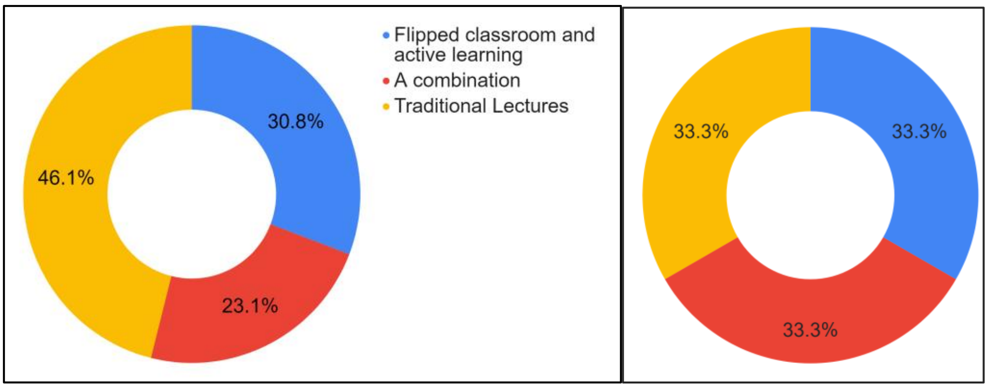

Fig 1: Q3 results for Groups 1 and 2

3.1.2 *Question 4*

Group 1 provided feedback with opinions on both passive and active learning camps:

"If the course consists of only traditional lectures, it can be boring, and I switch off. However, sometimes, it is useful to have the material explained by the lecturer"

"I like to view the content first and then have time to do further research after."

"I would maintain an element of pre-lecture preparation through case study readings"

Group 2 were more in favour of active learning, as the results show:

"This [flipped classroom] would help us gain information and exchange ideas more effectively for learning."

“It`s more interactive which is also suits the nature of the content being delivered”

“The pre-recorded videos are useful for learning new information as everyone learns at a different pace. However online discussions don't have good participation and should be face to face”

Fig 2: Group 2 students applying material from flipped classroom to a case study

3.1.3 Level of engagement

The results are quite disparate, with Group 1 scoring 69.39% and Group 2 88.23%. The reasons for this difference have been included the Discussion section.

3.2 Discussion

Group 1 were in the last term of their 2nd year during the first lockdown in March 2020, and had to adapt to online learning, exams, presentations, and assessments very quickly. Unfortunately, most of the following academic year was delivered online as well, resulting in students spending many hours in front of their screens listening to traditional lectures [3]. The level of uncertainty at the time meant that many academics made only slight changes to the material and the delivery since there was the expectation of a return to normal by October 2021.

After 2 terms of online learning, students attended online classes live but switched off their cameras, to do something unrelated while the class was on in the background. Other students took a “binge watching” approach to their learning by missing live sessions and then watching several sessions, one after the other.

This “screen fatigue” and the requirement to prepare material ahead of the class explain the level of engagement for this cohort being 69.39% vs 83.23% for Group 2.

Group 2 on the other hand, were in Year 1 when lockdown started and completed Year 2, the most demanding in the course, online. They had missed the social aspect of learning and were keen to return to campus and face to face teaching. Hence the important level of engagement.

There was consensus in the value of and appreciation for the industrial speakers, as they gave insights into potential career paths.

In conclusion, two separate cohorts enrolled on the same module had quite different experiences: online and face to face. Group 1 was less interested in a flipped-classroom approach since it involved preparatory work and online discussions, which students find intimidating. Group 2, in contrast, was more interested in active learning as the discussions were face to face and more productive.

Keywords: *STEM higher education, peer feedback, meta-analysis*

ABSTRACT

Recently, there has been a significant increase in the use of peer feedback in higher education. However, the evidence of the effect of peer feedback on students' academic achievement does not seem conclusive and, to our knowledge, there has not yet been a meta-analysis of the effect of peer feedback on general academic achievement in the STEM fields of higher education. Therefore, we conducted a meta-analysis to determine whether peer feedback is beneficial to STEM higher education students' academic achievement. The final data set for the meta-analysis consisted of 286 effect sizes from 90 independent samples in 75 studies, with a total of over 14,000 participants. All effect sizes were calculated as Cohen's *d* values. A random-effects model used to synthesise the effect sizes indicated a significant positive summary effect size (d = .421, SE = .037, 95% CI = .350, .493, p = .000). The variance of the true effect sizes (T^2) was .069. The Q_w value of 644.167 was significant (p = .000) and the I^2 value of 88.512 was high. Therefore, in order to identify the source of the between-study heterogeneity, moderator analyses were conducted to evaluate the influence of various methodological quality characteristics and peer feedback intervention characteristics on the effect of a peer feedback intervention. The results of this study will provide researchers, policy makers and practitioners with the information they need to decide whether or not to use peer feedback and to be able to design peer feedback interventions for maximal effectiveness.

1 INTRODUCTION

There has been a significant increase in the use of peer feedback in higher education. Peer feedback involves students providing their peers with feedback on their draft work and/or receiving feedback on their own draft work, followed by revising their work based on their peers' work and/or based on the feedback they received [1]. Research on the effect of peer feedback on academic achievement in the STEM fields of higher education found a positive effect (e.g. [2], [3]), a negative effect (e.g. [4], [5]), no effect (e.g. [6], [7]) or a limited effect (e.g. [8]). To come to a consensus on the effect of peer feedback on academic achievement in the STEM fields of higher education, this research used meta-analytic methods to synthesise the available literature to answer the following research questions:

1. What is the effect of a peer feedback intervention on the academic achievement of students in the STEM fields of higher education?
2. How do the peer feedback intervention characteristics moderate the effect of a peer feedback intervention on the academic achievement of students in the STEM fields of higher education?

2 METHODOLOGY

The data collection was based on [9] and was conducted in four steps.

2.1 Determination of Inclusion Criteria

To be included in the meta-analysis, studies should have have:

1. Been published as an English-language article in a peer-reviewed journal
2. Been conducted in the context of a course in STEM higher education
3. Involved the implementation of a formative peer feedback intervention
4. Been designed with a control condition and an intervention condition
5. Included at least 15 participants in each condition
6. Reported quantitative measures of students' academic achievement as the outcome measure

2.2 Search for Literature

To find articles for inclusion in the meta-analysis, three approaches were used: 1) searching through existing meta-analyses on peer feedback, 2) searching through electronic databases, and 3) backward and forward searching using the references and citations of the articles shortlisted from the first two approaches.

First, the articles included in the meta-analysis of the effect of peer feedback on academic writing by [10] were considered. Second, for the search through databases, four databases were selected (ERIC, PsycINFO, Web of Science and Scopus). A search string was created using the keywords 'peer feedback', 'STEM' and 'higher education', along with synonyms for these keywords. Third, once articles were shortlisted from the meta-analysis by [10] and the database search results, all English-language journal articles were identified from: 1) the reference lists of these articles, and 2) the citations of these articles found on Web of Science, Scopus, ResearchGate and Google Scholar.

2.3 Identification of Studies

This search for literature resulted in a total of 6,935 unique results. The titles and abstracts of these articles were put through a preliminary screening to determine whether the articles satisfied the second and third inclusion criteria, with articles not satisfying either or both of these criteria being excluded. The full manuscripts of the remaining 1,419 articles were sought, and the full manuscripts of the 1,330 articles that could be obtained were then put through a thorough screening using the second, third, fourth, fifth and sixth inclusion criteria. During this screening, 92 articles were selected for data extraction.

2.4 Data Extraction from Studies

An extensive data extraction form was created to obtain the data from the selected articles. Data from all articles was extracted and coded by two researchers. The two researchers' codes were compared to ensure reliability of coding procedures and decisions. Any discrepancies in the codes were discussed by the two researchers until a consensus was reached. Also, any doubts were clarified through discussion with a third researcher and/or a statistics expert. Some of the articles contained data for multiple effect sizes, resulting in a total of 367 effect sizes from the 92 articles.

3 DATA ANALYSIS

The data analysis was based on [11], using Comprehensive Meta-Analysis.

3.1 Summary Effect Size

In the case of studies with a pre-test post-test design, the pre-test results were compared with the post-test results. In the case of studies with a controlled trial design, the post-test results for the control group were compared with the post-test results for the intervention condition. In the few cases where a pre-test was conducted just before the peer feedback activity, the difference between the pre-test and post-test results for the control group was compared with the difference between the pre-test and post-test results for the intervention group. The individual effect sizes were computed as Cohen's *d* values.

Ultimately, of the 367 effect sizes, 30 could not be calculated and were excluded from the meta-analysis. Moreover, some of the effect sizes were not included in our final analyses, e.g., to include only mutually exclusive effect sizes within articles, to exclude articles that reported the same study and same effect size(s) as another article, and to exclude articles with extreme effect sizes. In order to avoid inflating the sample size, an overall effect size was computed for each study, and each study contributed only this one overall effect size to the meta-analysis. The final data set for the meta-analysis consisted of 286 effect sizes from 90 independent samples in 75 studies, with a total of over 14,000 participants.

A random-effects model was used to compute the summary effect size. Using the model, the summary effect size (*d*) as well as the standard error (*SE*), 95% confidence interval (*CI*) and significance (*p*) of the summary effect size were computed. For the summary effect size, significance was set at $p < .05$.

3.2 Between-Study Heterogeneity of the True Effect Sizes

To check for the between-study heterogeneity of the true effect sizes, the variance of the true effect sizes between studies (T^2) was computed. In addition, a measure of whether the observed variance was significantly different from that expected from within-study variance alone (Q_w) and a measure of the proportion of the observed variance that was from the variance of the true effect sizes (I^2) were computed. For the Q_w value, significance was set at $p < .05$. For the I^2 value, 25%, 50% and 75% were considered low, moderate and high heterogeneity, respectively [12]. If the Q_w value was significant and the I^2 value was high, moderator analyses would be justified [12].

3.3 Moderating Effects of Methodological Quality Characteristics

Methodological quality characteristics could have a moderating effect on the effectiveness of a peer feedback intervention. If the moderating effect is significant, caution should be exercised when combining studies with different attributes of the characteristic. Therefore, a series of moderator analyses were conducted to check for the moderating effect of pre-selected methodological quality characteristics.

3.4 Moderating Effects of Peer Feedback Intervention Characteristics

Peer feedback intervention characteristics could also have a moderating effect on the effectiveness of a peer feedback intervention. If the moderating effect is significant, it could help to explain the between-study heterogeneity of the true effect sizes. Therefore, a series of moderator analyses were conducted to check for the moderating effect of pre-selected peer feedback intervention characteristics.

A mixed-effects model was used to conduct each moderator analysis independently of the other moderator analyses. Using the model, a measure of whether the observed variance across the attributes of the characteristic was significantly different from that expected from within-study variance alone (Q_b) was computed. For the Q_b value, significance was set at $p < .01$.

4 RESULTS

4.1 Summary Effect Size

The meta-analysis revealed a significant positive summary effect size of peer feedback on academic achievement ($n = 286$, $k = 75$, $d = .421$, $SE = .037$, $CI = .350$, $.493$, $p = .000$), representing a medium effect size [13].

4.2 Between-Study Heterogeneity of the True Effect Sizes

The variance of the true effect sizes (T^2) was .069. The Q_w value of 644.167 was significant ($p = .000$), indicating that the true effect sizes in the primary studies were not the same, while the I^2 value of 88.512 was high, indicating that the proportion of true variance to observed variance was high. Since the Q_w value was significant and the I^2 value was high, moderator analyses were conducted to attempt to identify the source of the between-study heterogeneity.

4.3 Moderating Effects of Methodological Quality Characteristics

Moderator analyses were conducted to check for the moderating effect of the research design used in the study, the type of allocation used to create groups, the equivalence between the groups created and the blinding of the assessor(s) to the condition of the participants. For each of the analyses, the Q_b value was not significant. Since there was no evidence that the methodological quality characteristics had a moderating effect, it was deemed appropriate to combine studies with different attributes of the characteristics in a single meta-analysis.

4.4 Moderating Effects of Peer Feedback Intervention Characteristics

Moderator analyses were also conducted to check for the moderating effect of a range of peer feedback intervention characteristics, with respect to the nature of the task subjected to peer feedback, the nature of the peer feedback itself, the logistics of the peer feedback activity, the support for the peer feedback activity and the grading associated with the peer feedback activity. For each of the analyses, the Q_b value was not significant.

5 CONCLUSION

The meta-analysis showed that peer feedback is beneficial for improving academic achievement in the STEM fields of higher education. Therefore, it is recommended that peer feedback be incorporated in courses, where possible and appropriate.

It was hoped that the results of this study would provide the data needed to be able to design peer feedback interventions for maximal effectiveness. The way a peer feedback intervention is implemented can vary widely, and it can be presumed that the way in which it is implemented can influence the extent to which a peer feedback intervention is effective. While the moderator analyses in this study did not show a significant moderating effect of any of the peer feedback intervention characteristics tested, it does not rule out the possibility that (at least some of) these characteristics can make a difference. As explained by [14], moderator analyses are often insignificant and insignificant findings do not always mean that the characteristic does not have an influence on the effect. Therefore, it is recommended that, when designing a peer feedback activity, consideration is given to which design characteristics are likely to increase students' participation in the activity, elicit feedback of high quantity and quality and improve students' use of and learning from the feedback they provide and receive. It is also recommended that further research be conducted to increase the knowledge on how a peer feedback intervention can be designed for maximal effectiveness.

ABSTRACT

Summative peer assessment is an assessment method where the one's work is typically graded by several other anonymous peers using predefined criteria. The value of summative peer assessments in higher education stems from the fact that they can provide scalability in assessment for large enrollment classes for a variety of different assessment types. The main disadvantages of using summative peer assessments are questionable validity and reliability. In this paper, the first results of using summative peer assessments in a large enrollment professional skills course at the University of Zagreb, Faculty of Electrical Engineering and Computing are reported and discussed. The main research question of this work is how well, given specific conditions of the conducted summative peer assessments, do assignment credits assigned by peers correlate with assignment credits assigned by course lecturers. Data were obtained from four summative peer assessments through the course. A random sample of 50 submitted works per peer assessment was evaluated by course lecturers and corresponding assignment credits were compared to assignment credits awarded by students. Data analysis results suggest a moderate to high correlation between several measures of assignment credits awarded by peers and lecturers.

1 INTRODUCTION

Peer assessment is "*an arrangement in which individuals consider the amount, level, value, worth, quality or success of the products or outcomes of learning of peers of similar status*" [1]. Peer assessments can be either summative or formative in their nature [2]. The main goal of formative peer assessments is to to provide the author of the submitted work with feedback to help them plan their learning [2], while the main goal of summative peer assessments, also known as *peer grading* [3] or *peer marking* [4], is to assign grades or assignment credits to the author of the assignment.

Research results suggest formative peer assessments, in which students typically get feedback on their assignments through textual comments has a positive influence on learning outcomes related to the assignment as well as on other factors including learning strategies, academic mindset [5], [6], and motivation for learning [7]. When using peer assessments in a summative context, the psychometric properties of validity and reliability of peer assessments are a major concern since they depend on students' ability to produce valid and reliable evaluations of peers' work. While students tend to perceive peer assessments as beneficial, some students express a dislike of awarding a grade to their peers [8]. A meta-analysis of peer assessment research revealed the average Pearson's correlation coefficient between peer and teacher ratings of 0.63 [9]. Research has also indicated that quality of peer assessments' psychometric properties can be improved by training and experience of peer assessors. Student attitudes towards peer assessment are also positively influenced by training and experience [10], although some authors suggest peer grading can undermine effects of peer feedback [11].

This short paper contributes to the body of related research by reporting the first results of a research exploring the correlation between teachers' and students' ratings on a summative peer assessment conducted among the first-year undergraduate engineering students in a professional skills course called *Communication skills*. The assignment credits assigned by students (peers) were compared with those assigned by course lecturers to investigate how valid peers' credits are if they are used in summative context under conditions described in the paper.

2 METHODOLOGY

2.1 Context

This research was conducted in context of a first-year course *Communication skills* at the University of Zagreb, Faculty of Electrical Engineering and Computing. Around 700 students are enrolled in the course every year. Trough the semester, students have a total of six summative peer assessments in which the following assignments are assessed: (1) writing a formal email message according to an individualized scenario, (2) writing a cover letter and a narrative resume for a job application, (3) capturing a photograph, (4) capturing a video, (5) creating a slideshow presentation with narration, (6) creating a two-minute video presentation with audio narration and subtitles. The assignment credits a student finally receives are based on peers' ratings of the submitted assignment (~65%). A student can achieve the remaining assignment credits (~35%) by submitting ratings of five peers' assignments. Following the advice in published research [12], students are, aside from a small amount of assignment credits (external motivation), provided with a clear and understandable evaluational framework and they have a guarantee of anonymity in the peer assessment process. To submit their ratings students use an online form (Moodle *Quiz* type activity) with a set of evaluation questions which are available to them in advance. Questions typically have four offered answers to each question, for example:

> *Is there a paragraph (part of text) that states who the e-mail sender is and what is their role? Is that part of the text clear?*
>
> *a. No, that part of the text does not exist.*
>
> *b. Yes, that part of the text exists, but it is completely unclear.*
>
> *c. Yes, that part of the text exists and is written somewhat clearly.*
>
> *d. Yes, that part of the text exists and is written quite clearly.*

The evaluation form for each assignment contains questions that can roughly be divided into two categories: subjective questions like the above example, where the difference or exact criteria for answers b) and c) might vary between students, and objective questions like *Does the submitted work have subtitles?*, where the answers or answer criteria are close to indisputable. Answers to some of the objective questions (for example the presence of subtitles in a video file) are assessed automatically using software support. In order to discourage students from submitting invalid or unreliable assessments, students are warned that each of such attempts will results in losing all assignment credit for that complete assignment. This rule is enforced only on objective question are automatically removed from further processing.

2.2 Data

Data presented in this paper was collected during the academic year of 2020/2021 in four out of six summative peer assessments (all except (3) capturing a photograph, (4) capturing a video). In each of the peer assessments, ratings submitted by students are screened for inconsistencies in objective questions and assessments by their authors are removed form further processing. Additionally, about 5% to 10% of submitted works with highest standard deviation of assignment credits assigned through peer assessment are screened by lecturers. The assignment credits for each submitted work are afterwards awarded either by course lecturers or by averaging the assignment credits of the remaining peer assessments.

In order to investigate the relationship between assignment credits assigned by peers and those assigned by course lecturers, 50 randomly selected works for four peer assessments have been evaluated and assigned credits by both peers and course lecturers.

3 RESULTS

Results of the analysis of correlation between the lecturers' assignment credits and assignment credits awarded by by peers measured as (1) average value of peers' assignment credits, (2) average value of peers' assignment credits without minimal and maximal credits value, and (3) median value of peers' assignment credits, are presented in Table 1. The correlation coefficients (Pearson's *r*) are based on assessment of 50 submitted works for each peer assessment and are all significant above the p = 0.001 level. The average values (M) of lecturer's and peers' assignment credits are also given in the table for each of the peer assessments.

Table 1. Correlation between lecturers' assignment credits and other measures

Peer assessment	Lecturer's assignment credits	Peers' assignment credits	Peers' assignment credits without max and min	Median peers' assignment credits
(1) E-mail message	M = 81.92%	M = 85.63% r = 0.564	M = 86.52% r = 0.576	M = 86.60% r = 0.574
(2) Resume and cover letter	M = 91.52%	M = 88.47% r = 0.813	M = 89.87% r = 0.811	M = 89.90% r = 0.812
(3) Slideshow	M = 89.12%	M = 90.98% r = 0.686	M = 91.37% r = 0.708	M = 91.44% r = 0.705
(5) Video presentation	M = 88.45%	M = 89.01% r = 0.812	M = 90.24% r = 0.775	M = 87.99% r = 0.824

M – mean, *r* – Pearson's *r*

The overall results of peer assessments regarding the achieved assignment credits are relatively high, between 85.3% and 91.44% of the total assignment value. This can likely be attributed to the availability of evaluation criteria in advance helping students know what exactly is expected from them.

The three measures of calculating total assignment credits from peers' assignment credits have shown a strong correlation with assignment credits awarded by course lecturers. Overall, it seems that the average value of peers' assignment credits without maximal and minimal values best correlates with lecturers' assignment credits. The correlation values range from 0.564 to 0.824 indicating a strong correlation. The obtained results are encouraging regarding the potential of summative peer assessments in the described context. It is interesting that the correlation coefficients are the highest for the video presentation assignment, in which there are several objective questions, but also for the resume and cover letter assignment, where most evaluation questions are rather subjective in their nature.

4 CONCLUSIONS AND FUTURE WORK

In this paper the first results of a comparison between lecturers' and peers' assessments of students' work in a professional skills for engineers course are described. The obtained results suggest a moderate to strong correlation between peers' and lecturers' grades under given conditions and provide some support for claims about validity and reliability of this kind of assessments. Questions that remain and should be addressed in a follow-up in-depth investigation include how the relative ratio of subjective to objective questions affects the correlation of assignment credits, how high is the inter-rater reliability of course lecturers' assignment credits, and whether different assignment credit calculation models can be used, for example, to identify students whose evaluations are most similar to lecturers' and achieve a higher correlation by assigning a greater weight to their evaluations.

Conference Key Areas: *Ethics in Engineering Education; Curriculum Development, Engineering Skills, Lifelong Learning*

Keywords: *Ethics; Macroethics; Civil Engineering; Architectural Engineering*

ABSTRACT

This short research paper presents the early stage of an ongoing project in engineering ethics education. Given the impact of civil and architectural engineering and the profession's obligation to uphold public welfare and trust, students must understand macroethics, engineering's responsibilities to the human, natural, and built environment. The Bachelor's curriculum plays a key role in developing ethical responsibility, as a site of professional socialization and the only institutionalized training most engineers receive. Students are also exposed to ethics, values, and the societal impacts of engineering via informal learning before and during their university experience. The present project is designed to explore how civil and architectural engineering students make meaning of their societal responsibilities by examining their conceptualisation of the impact of engineering and the factors that influenced it. This study employs a constructivist grounded theory (CGT) approach and draws on interviews with Bachelor's civil and architectural engineering students in Belgium and the United Kingdom. Data collection and analysis are ongoing simultaneously with the aim of generating a novel theoretical model of macroethical development. This short paper introduces the theoretical and methodological approach of the study, anticipated outcomes, and next steps.

1 INTRODUCTION

1.1 Engineering Ethics Education

In charting the future of engineering education, Sheppard and colleagues point out that “engineering inevitably means intervening in the world,” and therefore “all engineering projects carry with them responsibility for the effects of those interventions” [1] (p. 9). They call for powerful learning opportunities, so engineers understand “that social and ethical connections are as important, if not more so, as electrical and mechanical ones” (p. 9). However, the integration of ethics in engineering education has lagged behind recognition of its necessity by both industry professionals (e.g., [2]) and accreditation bodies (e.g., [3]). An understanding of the process through which students develop their professional and societal responsibility can inform engineering education and improve the ethical impact of engineering practice.

1.2 Contribution and Significance

Extant theories of moral development (e.g., [4]) have limited application to engineering and to populations of diverse university students. In particular, existing theory tends to emphasize individuals’ decisions and actions without accounting for the environment in which those decisions are made or the sociocultural mediators of their agency, and this approach reflects microethics. Engineering practice, however, is increasingly recognising the importance of macroethics, the broader responsibilities of the engineering profession within organizational and societal contexts with respect to issues such as climate change, artificial intelligence, and social inequality [5]. Finelli et al. developed a conceptual framework of ethical development during university based on an input-environment-output model for studying students’ outcomes [6]. The framework posits that inputs (student characteristics) and the environment (inside and outside the classroom) inform students’ ethical development. Although the framework provides a helpful starting point for understanding the broad components that shape ethics education, it is conceptualised as quality (level of students’ involvement) and quantity (variety of experience and amount of time students invest) and has a microethical emphasis, as evidenced by how ethical development was measured in the student survey. Additionally, prior work aggregates engineering fields, but engineering is not monolithic with each discipline having a distinct culture, degree-specific outcomes, and relevant ethical issues [7]. As a result, it is instructive to disaggregate engineering to provide a more nuanced understanding of macroethical development. This study focuses on civil and architectural engineering due to its unique work at the nexus of the human and built environment.

2 METHODOLOGY

2.1 Study Design

This research employs a constructivist grounded theory approach (CGT) [8] to address the research question: How do civil and architectural engineering students develop their macroethical responsibility through their university experience? CGT is a qualitative systematic process for collecting and analysing data to generate new theory. The overarching perspective in this study is constructivism, which postulates that people construct knowledge based on their experiences. Instead of seeking an absolute truth, constructivism acknowledges that social and cultural factors mediate individuals’ ability to make meaning of their experience and knowledge.

2.2 Data Collection

The study takes a cross-sectional approach to include participants at every level of their Bachelor’s studies in civil and architectural engineering. The data collection and analysis occur in parallel until saturation is reached; around 30 individuals is common in CGT [9]. Participants are recruited via email invitations through the civil and architectural engineering programmes at one institution in the United Kingdom and one in Belgium. Intensive, semi-structured interviews [8] suitable to the need for flexibility to elicit the participants’ authentic perspectives and co-construct meaning through their experience, lasting approximately an hour, will follow.

2.3 Data Analysis

The analysis follows the coding procedure of CGT [8]. The overarching process is the constant comparative method and is defined by initial and focused coding. Initial coding stays close to the data to develop emergent understandings of actions and processes within the transcripts. It takes an incident-by-incident approach in which the unit of analysis focuses on critical incidents that can be compared within the interview. Focused coding involves synthesizing and sharpening the initial codes based on what is most relevant and significant in the data. The resulting more conceptual codes will reflect tentative attempts toward theory building. Given the interplay between data collection and analysis, theoretical sampling will occur in parallel, using emerging theory to select participants to fill crucial holes in the data and refine ideas.

Sensitizing concepts serve as guideposts in grounded theory to draw attention to potentially important aspects of the phenomenon under investigation. **Agency**, conceptualized here as the “socioculturally mediated capacity to act” [10] (p. 112). Engineering ethics education is often framed as developing individual moral agency [11]. However, a narrow focus on individual agency neglects environmental factors that enable and hamper agency, and as a result, practicing engineers often perceive their agency is limited in the face of ethical dilemmas [12]. Ethics training of future engineers should reflect agency in the macroethical perspective. **Engagement** has an important role in learning and student achievement. Drawing on Lawson and Lawson’s sociocultural framework [13], this research synthesizes engagement as a meta-construct with affective, cognitive, and behavioural components. This conceptualisation of engagement aligns with the affective, cognitive, and behavioural considerations in ethics while also integrating experiences inside and outside the classroom to reflect the multiple avenues through which students engage and develop an understanding of ethics. **Emotion** is inextricably connected to ethical decision making and risk evaluation in engineering [14]. However, engineering ethics education gives limited attention to emotion [15].

3 EXPECTED OUTCOME

3.1 Next Steps

Interviews were conducted with eight architectural engineering students at one university in Belgium in May 2022. Data analysis is ongoing and preliminary findings indicate minimal, if any, framing of ethics in the curriculum but each student pointed to a course or a professor who integrated notions of responsibility and impact. Since engineering is ubiquitous in the world around us, student expressed a background awareness of these concepts, but it was not until they were formally discussed in the classroom that students began to contextualize and internalize them. One participant described a single mention of responsibility by a professor as a “domino effect” after which he began to see responsibility throughout his understanding of architectural engineering. Students also expressed feeling anxiety and pressure related to their future responsibilities given the impact of engineering on human lives and the built environment. Data collection will continue with students in the United Kingdom in September and October 2022.

3.2 Theoretical Model Development

This research will develop a theoretical model of civil and architectural engineering students’ macroethical development with the aim of addressing how agency and engagement can be fostered in the classroom and how informal outside of the classroom can be leveraged.

4 SUMMARY AND ACKNOWLEDGMENTS

This study is designed to explore civil and architectural engineering students’ conceptualisations of societal responsibility and the impact of engineering. The aim is to contribute a novel theoretical model of macroethical development with implications for engineering educators, administrators, and policymakers seeking to prepare students for the sociotechnical realities of engineering practice and the ethical expectations of the profession.

This project has received funding from the European Union’s Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement nº 945380

ABSTRACT

Atenea is the Moodle virtual platform of the Universitat Politècnica de Catalunya (UPC) with about 31000 users and 5000 active subjects from 16 school centers. Atenea indicators give information on the teaching activity of the users and centers. This is specially relevant when teaching is online, as was the case in the Covid-19 period. The UPC already has a Atenea's Bussines Intelligent platform (BI), which has recently been launched. In this 1st phase the Institute of Science of Education (ICE) has actively participated in the design of the application. Currently it shows basic indicators over a period of time where one can filter or compare by centers or type of users. The paper presents this design and make a proposal for the extension of the BI, for the future, with respect to: 1) the inclusion of some key indicators for measuring the subjects' activity, 2) a proposal for cross-referencing data with academic performance.

1 INTRODUCTION

1.1 Teaching at the UPC

The teaching and learning development at the Universitat Politècnica de Catalunya (UPC) take place phase to phase at the schools, in classrooms or laboratories. Like most universities, the UPC also has a virtual learning environment to facilitate access to content, resources, documentation and to deliver digital tasks. The UPC has a unique Moodle virtual platform, named Atenea, which manages about 5000 courses and has 31000 registered users in the various school centres and Faculties (total 16), about 3000 are teachers. The regulation of training, learning opportunities, educational technology adoption, updating, and recycling of the knowledge of lecturers is managed by the Institut de Ciències de l'Educació de la UPC (ICE-UPC) [1].

1.2 Backgroun of Moodle indicators at the UPC

ICE is also responsible for training lecturers and managers in the use of learning management systems that are based on Moodle. In July 2019, ICE-UPC began the extraction and initial analysis of Atenea indicators. These practices and tests during over a period of two years gave us an insight into how to gain the maximum benefit from these indicators. Atenea's corporate business intelligence indicators (BI) for the UPC are currently being designed with advice from ICE, and right now a first limited version is already accessible for all the community [2,3].

During the period Covid-19 (from March to June 2020), lecturers were trained by ICE with online teaching and the use of Moodle tools, so the Ateneas platform use was extensive [4,5]. That background with the use of virtual techniques will surely enrich the traditional teaching, where a continuated evaluation across virtual platform will arise. For this reason it is important to study the virtual indicators that provide important information regarding the type of teaching activity—such as online continuated evaluation, the level of teaching activity for a given subject (even including assignments that were completed per user in a subject).

2 METHODOLOGY

2.1 Global key indicators

Atenea's BI, right now is designed that gives a global UPC useful information during a fixed period of time[2,3]. The indicators viewed are classified in:

1) Sessions/Users: Logged in sessions, logged in users, active users.
2) Activities/resources: Created (by teachers), Read (by students).
3) Qualifications: Input of grades and visits to rating grid

Graphs of the evolution of time are displayed where the unit of time can be chosen (hour / day / week / month). In addition, it can be filtered and compared over time by groups (Teachers (PDI) / administratives or estudents), units (school centers or departments), degrees (Degrees or Masters) and in some cases, by type of activities or resources. Finally, the relative weight of the indicator by groups, units and degrees throughout the period can be compared in bar charts. See examples in Fig. 1.

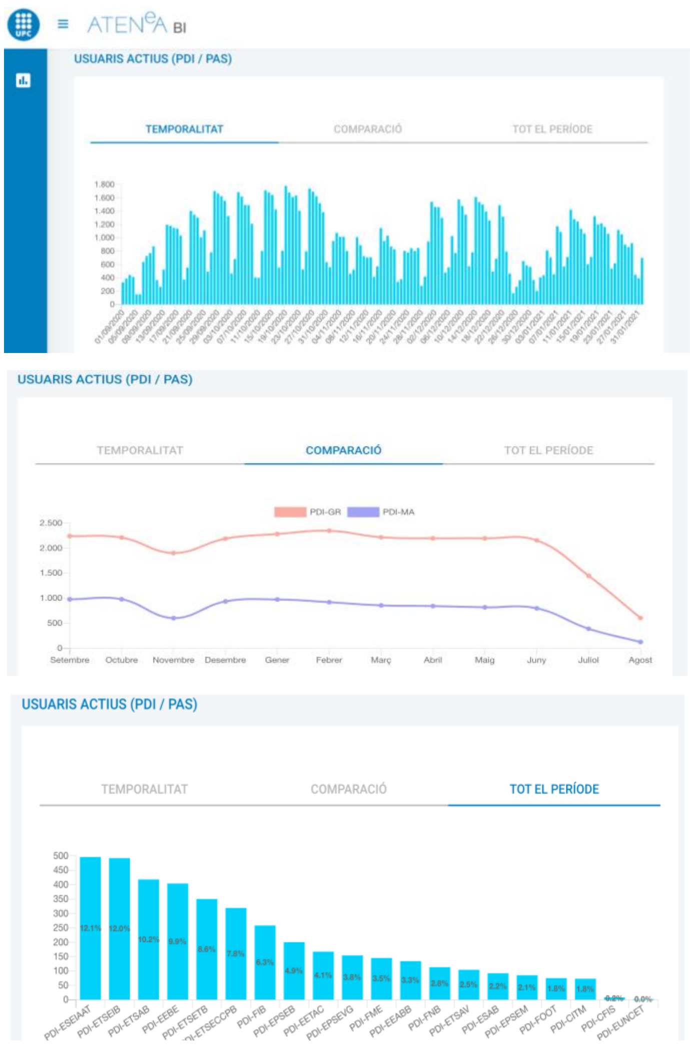

Figure 1. The Atenea's BI platform. Different displays during the academic year 2020-21.

2.2 Key indicators for measuring the online teaching activity

One useful teaching key indicator is the *Level of activity* of a subject during a term [2]. The subjects are classified according to the level of activity: low, medium, hight. We defined the level of activity depending on the number of actions by user in mean value. The reference values were taken from a 'normal' period of teaching (before covid-19 pandemics, for instance). The division was done, so that 66% of the subjects are medium activity and the rest are equally divided between high and low activity levels (see Fig. 2 like the application to a real example).

This is a good indicator to measure activity within a subject but to properly characterize the use of Moodle resources should be added:

- an indicator of *Intensity of use* for each resource / activity duly standardized similar to how it is done with the level of activity, and

- an indicator of the *Variety of use* of resources / activities used that simply counts the different number of resources/activities used.

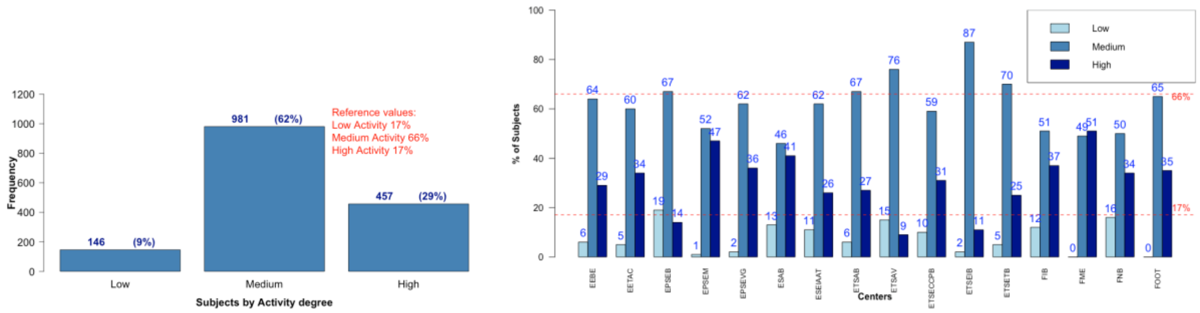

Figure 2. Left: Number (and %) of UPC's subjects during Q2-2020 term classified according to the level of activity and the reference values before Covid-19. Right: Comparison of the level of activity between UPC School Centres.

3 RESULTS

3.1 Proposal of extension of Atenea BI

Thinking in terms of measuring and compare the subjects activity in a period of time seems natural to perform a heat map of the activity of all the subjects. A proposal of this is to use the 3 indicators in section 2.2 : *Activity level, Intensity of use* and the *Variety of use*.

A display proposal of a **heat map Atenea's activity of a center** is shown in Fig. 3, where the subjects activity of a unit is measured during a semester: each row is a different subject and in each column are ploted the three indicators. In this case the subjects are ordered with respect to the *Activity level* of subjects (see left row). The central colum of *Intensity of use* is ploted like a matrix where rows are the subjects and columns correspond to each type of Moodle resources/activities (files, tasks, quizzes,…), in addition the color of cell, gradated from white to blue, depends on the intensity of use, for instance measured from 0 to 5. The Variety of use is plotted directly like the frequency of different resources used.

An extension of this idea can be applied to see the **heat map of activity of the UPC centres,** changing subjects by school centres.

The heat map would be useful to cross-referencing data with academic performance, for instance with the percentage of non presented students. Is the engagement of students bigger when the indicators of activity of a subject are big?

Figure 3. Proposal of heat map of activity of a unit during a semester. Every row is a unit's subject

DIGITAL DOCUMENTATION AND PLANNING OF STUDENT PROJECTS IN ENGINEERING AND PRODUCT DESIGN USING E-PORTFOLIOS

Christian Riess[1], **Michael S. J. Walter, Maria Tyroller**

Conference Key Areas: *Curriculum Development, Digitalisation and Hybrid models*
Keywords: *project-based learning, e-portfolio, engineering design, digital laboratory*

ABSTRACT

The use of e-portfolios is very rare among academic teaching on engineering design and product design especially in Germany. Written exams and reports are not always suitable to evaluate competencies and skills of students gained through such projects. A wide range of competencies is required and a variety of results (sketches, 3D-CAD-models, real prototypes, user feedback, etc.) are generated, that cannot be adequately represented in a written exam or report. We see the use of e-portfolios as a solution to this problem. Our goal is to enable the documentation and planning of the entire product design process using e-portfolios for student projects in a course on product design - and thus also include the production and assembly of the individual parts until the real final product.

This short-paper will detail the necessary preparations and changes in content and organization to a course on product design and how the students are introduced to the use of e-portfolios. We develop a three-step process, that supports i) the preparation of e-portfolios (in advance to the course), ii) the design of individual e-portfolios (during the course) and iii) the evaluation at the end of the course.

The main findings of this work are seen in a provided recommendation on structure and design of an e-portfolio based course on product design (integrating required and useful software-tools and manufacturing machine interfaces) as well as the identified specific requirements of students and lecturers that need to be fulfilled to successfully implement e-portfolios.

doi:10.5821/conference-9788412322262.1269

1 INTRODUCTION

The existence of e-portfolios and their use in the academic world are known and tested for many years [1]. In Germany however, e-portfolios are hardly used in academic teaching especially in MINT subjects [2]. Therefore we started to explore how to implement these personal, user centered online spaces to store data and project progress from student projects at our university. We use the open source e-porfolio software Mahara in a course on project-based product design within the bachelor's program on Sustainable Engineering to test and evaluate the use of e-portfolios as a digital option to document and grade student projects.

Until springtime 2022 students had to prove their acquired skills by a seminar paper at the end of the semester. From now on we plan to implement e-portfolios as a tool for documentation, reflection, and presentation of the acquired skills. The creation of an individual e-portfolio by each student as proof of the acquired skills will replace the seminar paper as the examination method.

This short paper is structured as follows. Section 2 details the necessary preparations and changes in content and organization to the existing course on product design. Section 2.2 will explain, how the students are introduced to the use of e-portfolios. Section 3 describes the evaluation of the changes implemented in the course and provides the results as well as conclusions and an outlook for the future of the project.

2 PREPARATIONS AND CHANGES TO IMPLEMENT E-PORTFOLIOS

To successfully implement e-portfolios as a new examination method and a new form of documenting and planning student projects in an existing course on project-based product design, changes to the course have to be made. These are detailed in the following sections.

2.1 Content and organizational changes to the course

The course on project-based product design for bachelor students used to test the use of e-portfolios during this research project is a mandatory course of the bachelor program on Sustainable Engineering at our university of applied sciences in Germany [3]. This is the only course focusing on product design in the curriculum of the bachelor program. In addition, there is no separate course in the students' curriculum that focuses on the fundamentals of project management. Therefore, we merged those two topics and designed a course that both satisfies the demands on product design education and provides an adequate first experience of project management for the students [4]. The students face a challenge to plan, design and build a first prototype of a wooden product for children (age: 3+) or a useful wooden product for teenagers (up to 16 years) [5]. They are free to decide on the target group for their product.

The course includes two 90-minute slots in the weekly curriculum over 14 weeks during each summer semester. The course is structured in two main parts, each spanning the entire semester and ends with a written seminar paper.

The first part is the theoretical part. It is assigned to the first 90-minute slot each week and includes seven lectures and five workshops that provide the content on relevant aspects of project management and product design, which are seen to be essential for the students and the success of their design projects.

The second and practical part is assigned to the second 90-minute slot each week. During these time slots, the laboratory for creative prototyping is open to all students to discuss their projects and designs with colleagues, the lecturer as well as the lab engineer. Furthermore, the students can get to know the available manufacturing machines and tools in the lab, take part in safety training and (usually rather later in the project) manufacture and assemble their prototypes.

These parts had to be shortened to make room for the workshops described in section 2.2. Therefore the lectures where shortened a little and the workshops on relevant aspects of project management were reduced to four. This makes room for a 60 minute time slot for the introduction of e-portfolios each week. Enough time to support the students with their task on planning and documenting their project as well as to answer their questions and collect feedback.

In preparation for the course and the added use of e-portfolios an e-portfolio system within the universitys network infrastructure was set up. We use the open source software Mahara combined with the learning platform moodle to provide the necessary infrastructure to digitalize the course and make everything accessible for students and staff members of the university. Within the moodle platform we set up a digital version of the mandatory safety instructions for the laboratory including a test to provide proof and documentation for further traceability. All operating instructions and safety instructions for the machinery within the laboratory like CNC carving machines, milling machines and different power tools are combined to an e-portfolio within the Mahara system. The necessary URLs for the different browser based design and manufacturing software tools to be used for the realization of the projects are also provided via a moodle course.

The legal aspects of a new examination method in the form of e-portfolios are also checked and discussed with the responsible people at the university.At the moment exists no final decision on this subject but a change of the general examination regulations to allow the use of e-portfolios seems inevitable. Our test within the research project is not affected by this.

2.2 Introducing students to e-portfolios

To introduce e-portfolios to the students we use weekly workshops and example portfolios as a source for inspiration. These weekly workshops are always led by the same person of the research team and supported by the others regarding student questions and technical issues with the system. The workshops are designed with a constant development of complexity and entitlement in mind. They provide the students with the necessary competencies to create their own e-portfolios out of their project task. Example portfolios show the students a selection of possible layout strategies and stored data (e.g. sketches, 3D-CAD-models, time schedules, etc.). The example portfolios also outline the requirements of the lecturer regarding the contents of the e-portfolios. These have to be fulfilled by each student to get the e-portfolio graded.

3 RESULTS AND CONCLUSIONS

The regular evaluation of the project progress, the feedback from the students and the lecturer as well as the evaluation of the e-portfolios created by the students provide the information, if e-portfolios are a sufficient way to digitalize the documentation and planning of student projects. At the current time only the first student group of the course and the corresponding e-portfolio work can be evaluated. After some problems with the user authorization and the setup of the Mahara system the received feedback is consistently positive.

We found, that the use of e-portfolios has different advantages compared to written seminar papers. They allow parallel working on the design project and the exam and thus allow the students to safe time and effort at the end of the semester as well as optimize their available time to work on the project itself and the documentation. E-portfolios additionally allow a creative and free design of the documentation and support the reflection and cooperation skills of the students via the peer to peer and tutor feedback within the portfolio software. The global availability of the e-portfolio via the internet and the opportunity to share it easily with a selected audience are significant benefits. Students can proof their acquired skills to future employers based on data and facts instead of plain conversations. E-portfolios also provide a better understanding of relatively complicated projects or unstructured ideas.

The final e-portfolios of the projects done by the first student group lead to the conclusion, that e-portfolios are a suitable way to document and plan engineering related projects within university courses. The variety of opportunities and the added creativity have a positive impact on the quality of the students work. However, it must be mentioned that there is still room for improvement with regard to the possibilities for project panning and project management within the e-portfolio software (e.g. milestone planning).

Further the lecturer will reflect his own seminary based on the course proceeding, the e-portfolios of the students and their evaluation of the course. This comprehensive critical analysis is very important to further develop portfolio work and to increase common knowledge in the field of e-learning by sharing the experiences with others.

4 ACKNOWLEDGMENTS

We thank the Stiftung Innovation in der Hochschullehre for funding our research project "3-Klang" and the CLAAS Foundation for funding a CNC carving machine in our laboratory.

ABSTRACT

The pandemic has forced higher education to radically change the teaching format from face-to-face mode into virtual or hybrid format. Also, intensive courses, workshops and seminars have been conducted totally or partly online. These formats include lots of students` team work in order to succeed. Starting to work virtually with strangers might be difficult for students. Our paper presents how we developed and conducted two interdisciplinary team learning projects during the academic year 2021-2022 and the results we got. Our projects were implemented in the BSc degree programs of engineering, business administration and nursing at two Finnish UAS and at two foreign partner universities. After the courses we collected qualitative data from students´ learning diaries and other reflections and performed content analysis which revealed that there are supportive and hindering factors for virtual team work and they should be considered while designing the learning experiences.

1 INTRODUCTION

At this time with the pandemic, the learning curve for virtual cooperation has been dramatic, for both companies and public organizations, including universities and other educational institutes. The digital transformation combined with a pandemic has both forced and allowed us to work and learn on distance. We have witnessed a dramatic growth of meetings in virtual platforms within the two past years (2020-2022) and those platforms have become everyday tools in studying as well. Our students are now used to work both alone and together virtually, but what type of factors are affecting their collaboration in the virtual context?

Previous research gives consistent hints that getting along with each other is essential in groups, in terms of both performance and well-being. The term used for this is cohesion, which is also related to concepts such as involvement, coordination, communication and trust [1]. To successfully continue working together virtually, these factors must be considered.

Also, we need to underline the importance of common understanding and shared interpretation. Unshared understanding is often regarded as hindering collaboration and communication, but on the other hand, versatile knowledge based on various disciplines is needed especially in contexts where the aim is to innovate and create new ideas and solutions. An argument can be made that in order to have both shared and opposing views in a team, coordination must be wisely used, in order to understand the different phases of cooperation: when innovating you need to accept various views without confrontation, and when making decisions you need common acceptance among team members. This is an interesting paradox as both convergence and divergence are needed in order to produce good team performance.

Psychological safety is an old concept [2] but during the last decades it has been further developed, researched and applied to different team work situations and learning by e.g. Edmondson [3]. Psychological safety (PS) is a “condition in which person feels included, safe to learn, safe to contribute and safe to challenge the status quo without fear of being embarrassed, marginalized or punished in some way [4]. Psychological safety has been found, e.g., to facilitate team learning [5].

In this paper, we aim to shed light on the topic of how to support cohesion and psychological safety in virtual student teams in order to achieve good team learning performance. We describe preliminary findings from our teaching experiments which were two interdisciplinary intensive courses, which we have planned and executed at two universities of applied sciences in Finland together with two partner universities abroad.

2 METHODOLOGY AND DATA COLLECTION

The first course implementation (hybrid version) was organized in autumn 2021 simultaneously both in Finland and in one location close to the western border of China. There was a time difference between the locations which had to be considered in the course implementation. This course consisted of students´ pre-work online and one face-to-face intensive week at two campus locations and at two touristic destinations. During the intensive week, the multicultural group of students from different BSc engineering disciplines (mechanical, material and environmental engineering) learned different waste management and energy related issues and how to use a multi-criterion decision-making tool (MCD). This tool was then used by the student teams in the touristic sites for solving the team project task which was suggesting a suitable waste to energy solution for the touristic location. The task solution was based on interview data and other data collected by the students on the sites. This data was then processed with the MCD. In the end of the week each multinational team presented their suggestion for the site given to the team. During the week one part of the activities, lectures and teamwork were performed online and another part onsite face-to-face.

The latter course implementation (online version) took place only in Finland during the spring 2022 at one Finnish university of applied sciences. In this implementation, there were students from three different disciplines, namely engineering, nursing and international business BSc students. These students worked in international, interdisciplinary teams of 4-6 students for an intensive week. They were given a problem from a client organization and the teams worked with the problem, innovating solutions to be presented at the end of the week. The students were working only online all the time.

Our preliminary analysis is based on content analysis of written student reflections given after each course implementation. The interpretation of these reflections has aimed to understand what type of meanings the participants have attached with their experiences of virtual teamwork and learning. The reflections have been qualitatively analysed by reading them and analysing how and to what extent their perceptions differ. By comparing similarities and differences, different categories of description have been formed and reflections with similar meanings grouped in the same category.

2.1 Supportive factors

When analysing the different categories, we were able to distinguish two main categories: those elements which *supported the cooperation* and other elements *hindering the collaboration*. Then, we looked at the differences between the different disciplines in terms of how they perceived supportive factors of teamwork in virtual context (see Table 1).

We can notice from the comments that all students mention *respect, listening, sharing ideas, encouragement and having different visions* as supportive factors for virtual team work. All of them are factors describing psychological safety according to the previous research. Students also mention having fun and joy to be important supportive factors in virtual team work and learning. This is perhaps something teachers easily forget when they are planning the learning experiences?

Table 1. Supportive factors experienced in virtual context according to the study field

Engineering	**Nursing**	**International business**
-sharing the same goal -respect -encouragement -having fun -inspiring each other -group thinking -agreeable personality types *"Different point of view combined creates good results"*	-focusing on the task -open mindedness -respect -understanding -needing something from each other -listening skills -sharing ideas -making things together -being professional *"We all needed something from each other, they all knew from their field, we made them all together"*	-equal effort -energy and passion -having different visions -coordination efforts such as time management and solving misunderstandings -communication -fun -being professional -encouragement *"My observation is that the team must move forward together somehow"*

2.2 Hindering factors

In Table 2 we can see which factors students perceived to be hindering their virtual teamwork. Our results show that *communication* was the most frequently mentioned factor that was hindering the effective virtual teamwork and learning. The communication problems were caused by many reasons. Students mentioned the following ones: unreliable virtual technology, poor English language skills and communication problems caused by the time zone differences. They also perceived difficulties to communicate in such a manner that the students from other disciplines would understand their message. In addition, they mentioned comprehension problems caused by the language and terminology used and the way of presenting ideas etc. Although students had some training for team development and diversity issues, it seems that not all teams were able to apply this knowledge in practice in their teams.

Table 2. Hindering factors experienced in virtual context according to the study field

Engineering	Nursing	International business
- communication - Internet connection - difficulty in understanding each other - language barrier - difficulties to agree - coping with different personalities - time management - thinking outside the box *"We had difficulties to communicate: express our ideas and being understood by the foreign team members"*	- time difference - understanding different personalities - communication - responsibilities taken were not equally shared -misunderstandings -hard to work with different disciplines as ideas are so different *"Due to different fields some people were very familiar with certain stages but because others are not familiar it would take more time."*	- understanding each other - the lack of communications or difficulties in communicating properly - having a lot of different perspectives, opinions and priorities -problems with some members not being involved in discussions -different levels of expertise *" It can be frustrating if some study field students are not used to doing tasks like this."*

3 CONCLUSIONS

Students mentioned that the teachers should have forced them to communicate more with each other. When planning especially the hybrid course the teachers decided beforehand that the students were free to use any virtual communication tools. After reading about the communication problems in the reflections and comments in the students` learning diaries and feedback formulas we have to conclude that perhaps it was a mistake to leave the communication issues for the students to organise by themselves only.

There might have been some psychological safety issues meaning that not all students felt safe enough to ask "dumb" questions from their virtual team members while being afraid of losing their face. As cameras were not used much in the students´ virtual team meetings the gestures and body language could not be seen, and this might have caused some of the communication problems too.

Based on both theoretical and empirical analysis, in order to create psychological safety the teacher should design the educational situation so that following four elements are present: *openness* (tell who you are, let people get to know you), *direct talk* (dare to raise the problems and also difficult issues into discussion), *credibility* (be consistent, no nonsense, take responsibility of your sayings) and the most important one *approval* (listen, everybody has a value, dare to reveal /tell about your own failures etc.). These elements form collective trust needed.

ABSTRACT

Atmospheric turbulence is one of the limiting phenomena in interesting applications and fields such of optical telecommunications and Observational Astronomy. Both Telecommunication and Aerospace Engineering students may encounter those

[1] *F. Salazar*

doi:10.5821/conference-9788412322262.1308

applications in their professional careers, thus, there is the necessity to introduce this phenomenon and its impact on those fields at the academic formation stage.

In order to teach students of the principles and effects of the atmospheric turbulence in optical propagation, and to illustrate how to solve these problems, two different applications written in MATLAB© were developed.

In this communication both applications and the theoretical background are presented, and the designed activity for Telecommunication Engineers is shown. Results obtained by students and their experience performing the activity are also presented.

1 INTRODUCTION

The atmospheric variations due to fluctuation of the different meteorological parameters (pressure and temperature) affects the refractive index of air, thus modifying the propagation of optical signals throught the atmosphere.
Those variations on the trajectory of the signal have a great impact in Optical Telecommunications and Observational Astronomy, among other fields. Being aware of the growing interest of the optical telecommunications market, and the necessitity of improvement of Adaptive Optics technologies, aiming the necessity of enlarge the recruitment of new engineers, and the fact that, typically, atmospheric turbulence is poorly analyzed in the academic formation of such future engineers, a MATLAB®-based application has been developed, in parallel with a computational workshop that has been designed in order to introduce this topic to Telecommunication Engineering students.

This communication summarizes the basis of this application and the future implementation of the said workshop.

2 METHODOLOGY

2.1 Physical basis

To simulate the effect of the atmospheric variability and turbulence on the propagation of a light beam, wto basic theories are considered. First, the simulation of the atmospheric turbulence is done by means of the so-called Kolmogorov's theory of atmospheric turbulence.
On the other hand, the diffraction theory of light provides the theoretical mathematical basis for describing the propagation of an optical signal (usually a two-dimensional signal which propagates in the third dimension). As is deeply described in the existing literature, diffraction is, by definition, the deflection of waves around the corners of an obstacle or through the aperture in the region of a geometrical shadow of the obstacle. Thanks to Huygens principle, the diffracting object or slit effectively becomes a secondary source of the propagating wave. This framework is useful for describing two-dimensional light sources and the propagation of its corresponding radiation between different planes.
The combination of both theories allows to the simulation of the propagation of a light beam throught atmospheric turbulent layers, hence, allowing the simulation and evaluation of the harmful effects that the beam suffers. Figure 1 shows a schematization of the process that is implemented in the next subsection based on this two mathematical and physical frameworks. Both mathematical descriptions are

widely exposed on the existing literature. The interested reader is referred to [1], [2], [3] and [4].

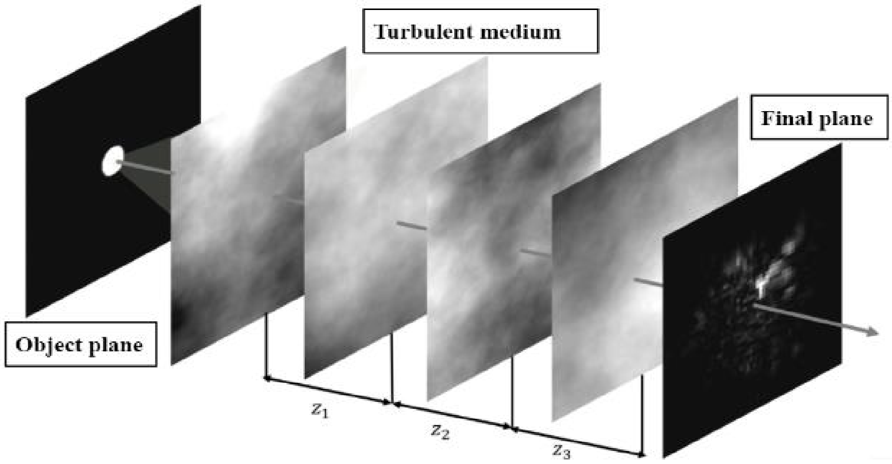

Fig. 1. Propagation of an optical signal through a turbulent medium. First, an emitting object in 2D is defined (in this example, a circular emitting source). Later, the different phases screens corresponding to several turbulent planes are generated at the corresponding distances $\mathbf{z_i}$ from the original plane (the object plane). Finally, the resulting amplitude in the final plane is obtained. This working scheme is valid for both the analysis of the effects of the turbulence on the optical quality of an astronomical observation and for the case of a communication between an optical emitter and its corresponding receiver.

2.2 The application

Applying the above-exposed theories, an application written in MATLAB® was developed.

The software presents two different options for simulations:

- Astronomical observation. This option allows the user to simulate an astronomical observation from a ground-based telescope under different meteorological conditions. Furthermore, this option permits to analyze the wavefront distortion due to turbulence and to implement a correction using Adaptive Optics. See Figure 2.
- Satellite communications. This option permits the simulation of the optical link between a ground station and a satellite, and to analyze the effects of the bad meteorological conditions to such communication. See Figure 3.

3 RESULTS

The application developed for this work is capable of provide interesting computational results for engineering in the fields of Adaptive Optics and Free Space Optical Communications.

As an example, the following figures show the main capabilities/possibilities of analysis of the developed code.

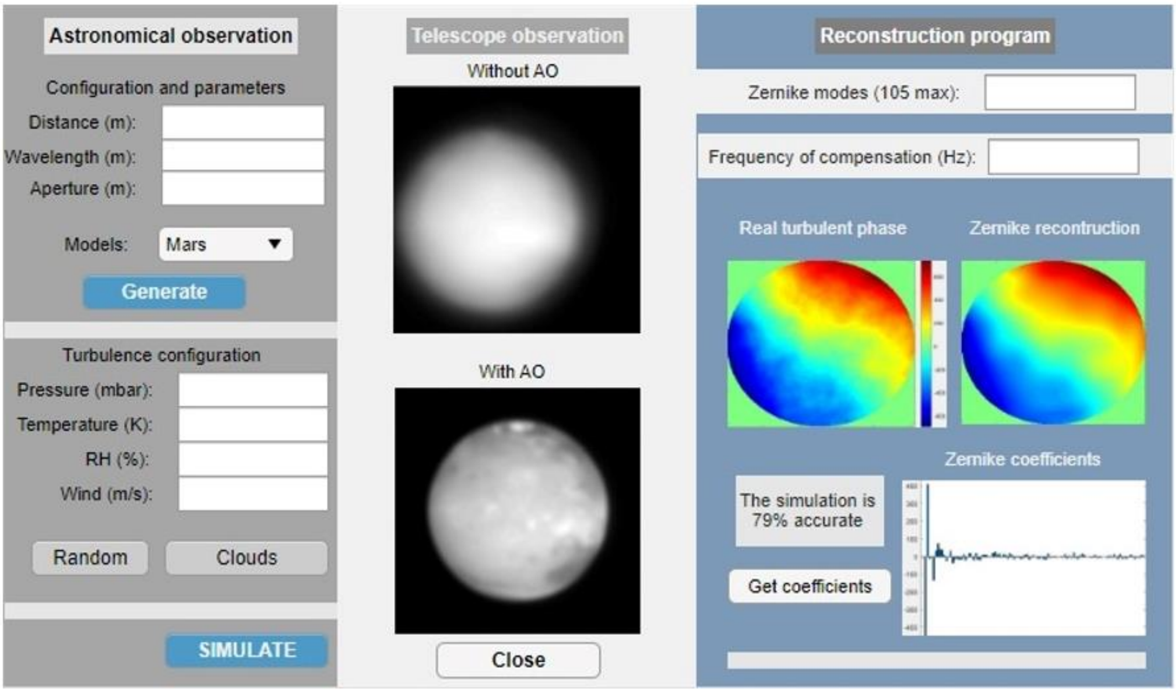

Fig. 2. Main window of the Adaptive Optics application. The software allows to simulate a situation without the implementation of Adaptive Optics and also a solution implementing Adaptive Optics. The program also represents the distorted wavefront.

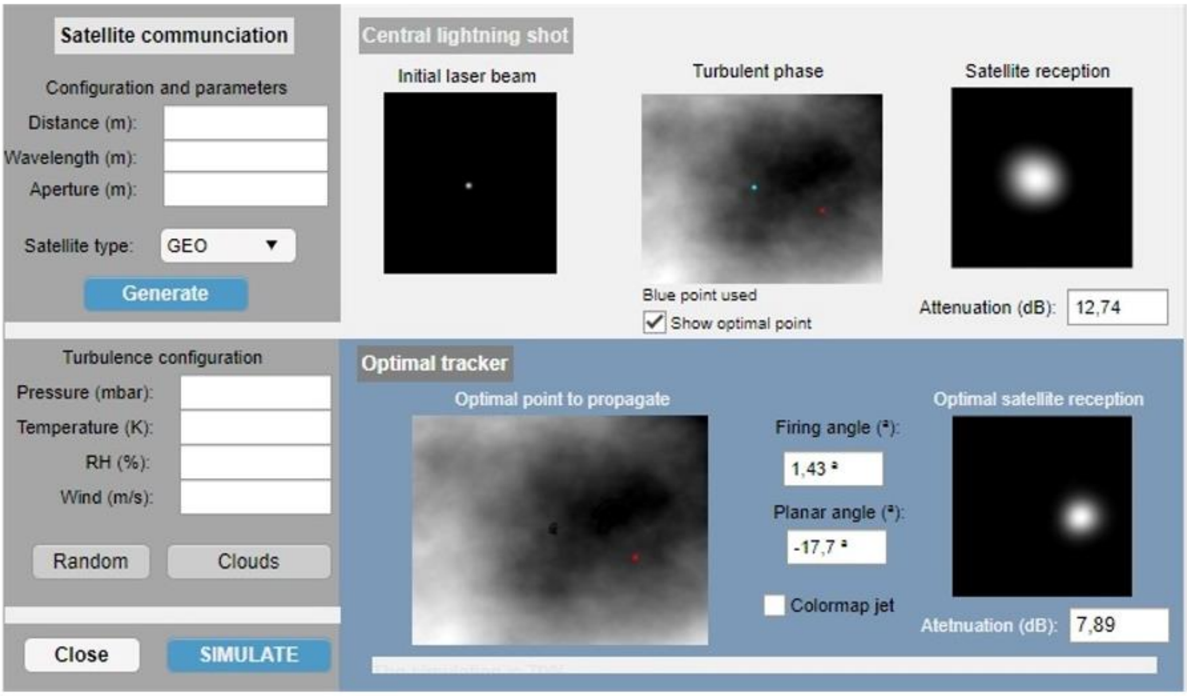

Fig. 3. Main window of the Optical Communication application. The software allows to evaluate the loss on the signal introduced by the atmospheric tubulence. Furthermore, the application prmitts the estimation of the optimal path for the propagation of the optical signal.

4 SUMMARY AND ACKNOWLEDGMENTS

Using the software presented in this paper, which has been developed during a student final degree project, two different workshops has been designed. First, a workshop to set up the basis of Adaptive Optics and design of such kind of systems for Ground-based telescopes has been designed. Second, a workshop introducing the Optical Communications basis and atmospheric turbulence influence in the optical channel has been written. Both workshops are going to be performed in next months, with the participation of Telecommunication and Aeroespace Engineering students. A future work will present the early results obtained with the software and the students' feedback.

EDUCATING ENTREPRENEURIAL ENGINEERS - TO BE CONTEXT-AWARE OR GENERIC?

Juha Saukkonen

Jyväskylä, Finland

Conference Key Areas: *Curriculum development, Entrepreneurship education*
Keywords: *context-awareness, engineering, entrepreneurship, education*

ABSTRACT

Entrepreneurship education (EE) is high on the agenda of governments and universities globally. With the new forms of entrepreneurship, there has been a surge of specific training programs and materials, e.g. ones dedicated to social entrepreneurship as well as for science & technology-based entrepreneurship.

Parallel to this division of EE into subsegments, tools and methods such as the Business Model Canvas (BMC), Lean Start-Up and Customer Development methods, or Disciplined Entrepreneurship by MIT have spread to be used by EE practitioners globally.

With the increasing globalization, virtualization, and mobility of learners, EE courses have learners differing in 1) their cultural context that reflects in their values and beliefs, 2) their educational and professional background, and 3) in the area - market and industry - where they aim to start their business. E.g., the process of entrepreneurship is likely to differ in dynamics when going into medical technology vs. mobile gaming, yet some aspects may be mutual to both businesses.

Thus, EE education is facing a dilemma: How unified and non-context specific should the approach of the educator be to deliver EE in scale and keep the EE program manageable vs. how much to focus on the individuals or teams and their specific context.

The paper draws its conclusions based on the quantitative survey done among 60 entrepreneurship educators globally in February-March 2022. The global respondent pool consisted of educators diverse in the context they come from, institutions and faculties they work at, and the type of entrepreneurs they have trained. The data analysis is based on descriptive statistics based on the assessments done by the respondents on 4- or 5-step Likert scales on perceived current EE practices and the perceived importance of different factors in successfully context-aware EE. The core taxonomy used to elaborate on context is the PESTEL-analysis of the environment, consisting of Political, Economical, Social, Technological, Ecological and Legal factors.

The results indicate that the economical-technological consideration is weighted in today´s EE generally speaking, whereas the truly context-aware EE would balance that leaning to economical and technological matters with more factors, especially the one of social context. Another takeaway to participants is a set of proposed EE designs that deal with the contradicting forces.

doi:10.5821/conference-9788412322262.1104

1 INTRODUCTION

1.1 The meaning(s) of context

Context is a construct both wide and widely used in research and development across disciplines. In business and industrial research, context can mean a specific set of environmental variables in which an organization operates (external context) but also the characteristics or a category of the organization under study (internal context). In addition, contexts can be studied either as the possession of specific characteristics of an individual or of a community. Individuals are likely to interpret their surroundings differently because of their differing habits, routines, and intelligence. Parallel to that individual interpretation, however, we identify ourselves not only as individuals but as parts of social systems we link to [1]. In practice, since these two scopes are inbuilt and interdependent. What we perceive as our context (our habits, experiences, values, etc.) has been and continuously is affected by other individuals and institutions around us – the schools we go to, courses we take as well as companies and markets we operate in. Institutions such as Higher Education Institutions (HEIs) engaged in business, engineering, and entrepreneurship education act as a context relevant for this study. Likewise, industries and companies offer specific contexts to which individuals and entrepreneurial teams adapt.

Since engineering is fundamentally built on science-backed findings in natural sciences, technology-related views and skills have the potential to be less context-dependent than more culturally bounded functions in business activity, such as HRM or marketing. In other words, “technology travels well”. In the same vein, it can be argued that in technology-based entrepreneurship the market opportunity and competition are global, whereas in cultural and service-based industries the scope is more likely to be local or regional. Despite a potential lowering of contextual boundaries, the context has still been claimed in research to play an important role in issues such as innovation, inter-organizational learning, and entrepreneurial actions.

For the scope of this study, we synthesize the prior research on context stating that 1) context is both situational as well as a prevailing condition that in its part explains, directs, and delimits action, 2) context is both an individual as a social/institutional construct, and 3) context is present – consciously or subconsciously – in multiple areas of entrepreneurship and engineering (education) research and practice.

1.2 Context and context-awareness as factors affecting educational practice

Following the ideas of the previous section, understanding the concept of context is a solid starting point for analysis of how context(s) affect education. Adaptive

context-aware learning environments (ACALEs) are expected to detect learners' context and adapt learning contents to match the context identified to make education more relevant to learners [2]. Context-aware systems understand the situational needs and offer at the right time the relevant information.
Learning context consists not only of individual learners with differing contexts but also of the social fabric they jointly create and to which also the educators pertain. The concept of learning spaces consisting of physical, social, cognitive, and virtual environments captures in a wider meaning the context for education.
Also, the context that an educator brings into a learning space moderates the learning process. Some studies like conclude that the "teacher effect" outweighs the effect of the methods used in learning efficiency and student achievement [3]. It has become imperative that educators in the modern world with characterized by increased mobility of people, immigration, refugee crisis, etc. acquire competencies in the diversity of contexts present. Does this apply also to subsegments of education in engineering and education – and their combination?

1.3 Context and context-awareness in entrepreneurship

A big part of the entrepreneurship education within HEIs' entrepreneurial courses and incubation/acceleration programs focuses on students in business and science /technology majors. Companies born in these environments are so-called *born globals.* These companies conduct international business at or near the founding of the firm. Events in recent decades – primarily globalization and the emergence of key technologies – have facilitated the rise of born globals.
As a result of the opportunities and role models offered by successful young but global entrepreneurs, EE has embraced methodologies suited to the goals of growth and internationalization. Methods such as Customer Development, Lean Start-up, Business Model Canvas, Design Thinking, and MIT's Disciplined Entrepreneurship have spread to entrepreneurial programs across continents, universities, and faculties. This trend depicts EE as a rather context-independent phenomenon. However, entrepreneurship as an activity has been described as a context-laden and context-bounded phenomenon worth studying with the context in focus [4]. There are studies on the impact of regional, technological and institutional context on EE. This paper adds to the body of knowledge on context-aware entrepreneurship education, with a focus on the technology element of context.

2 METHODOLOGY

The research method of this paper is a quantitative one based on a survey directed to scholars who had published within the last 4 years in the regional and local conferences on entrepreneurship education (EE) and/or were known by the researcher team to act as entrepreneurship educators. Some of the respondents had written their studies based on EE within Schools of Engineering, but the organizational background of respondents or research focus outside the "entrepreneurship education" definition was not a selection criterion. The survey link was sent to some 250 respondents, in addition to which the receivers were requested to spread the link to their EE network. The assumption on the response rate is some 20 %. Data were collected in February-March of 2022, as a cross-sectional explorative study aimed at identifying the interesting areas for further studies with larger data sets and a qualitative approach focusing on the root causes for the findings reported in this paper.Demographically the respondent pool was heterogeneous, 43.3% of the respondents were females and ages were distributed to 5%/20-30 years, 21.7%/31-40 years, 40%/41-50 years, 20% /51-60 years/ and 13.3%/over 60 years). Present educational contexts were: in North America 20%, Mid- and South America 1.7%, Europe 60%, Africa 1.7%, and Oceania16.7%, thus Mid- South America and Africa are underrepresented. On average respondents had acted 12 years as an entrepreneurship educator. The learning spaces of respondents were described by 28.3% as monocultural, 46.7% as somewhat multicultural, 7% as quite multicultural, and by3% as very multicultural. Due to a relatively small dataset gathered at the time of writing this paper, the results are presented with descriptive statistics, further papers are targeted to contain more data and analyses on statistical significance.

3 RESULTS

3.1 On current practices of context-aware entrepreneurship education

First, the respondents' views of the general context-awareness practiced in entrepreneurship education were screened, after which it could be mirrored in the respondents' self-perceived view on their context-awareness in EE.

	Is very rarely context-aware	Is sometimes context-aware	Is often context-aware	Is very often context-aware	Is always context-aware
Entrepreneuship education…	6,8%	37,3%	30,5%	20,3%	5,1%

Table 1. Q: "How well do you perceive contextual issues are taken into account in Entrepreneur education generally speaking?"

	I am not context-aware	I am sometimes context-aware	I am often context-aware	I am always context-aware
In my Entrepreneurship education…	1,8%	17,5%	71,9%	8,8%

Table 2. Q: "How would you describe your context-awareness in Entrepreneurship Education?"

As a comparison of Tables 1 and 2, it can be stated that the study attracted EE practitioners with higher context-awareness than their average EE peers. This may *lead to overinterpretation of findings, but also the findings may act as a model for more context-aware (if that is needed, see section 3.2.) EE of the future.*

3.2 Is context in entrepreneurship education technology-sensitive?

A common way to describe a context/operational environment made of elements is the PESTEL-analysis, made of political, economic, social, technological, ecological, and legal factors. Our findings (Tables 3-5) propose that a) different PESTEL areas of context enjoy varying perceived importance in successful EE, b) the current practices highlight the importance of context as a technical-economic system, and c) the context-aware teachers (our sample) perceive themselves to be context-aware in a more balanced way across PESTEL-factors, but still d) they put even more weight into economic-technological context than they perceive to be common in EE.

	Very unimportant	Quite unimportant	Not important nor unimportant	Quite Important	Very important
Political context	5,2%	12,1%	17,2%	39,6%	25,9%
Economical context	1,7%	1,7%	3,5%	31 %	62,1%
Sociological context	3,4%	1,7%	8,6%	46,6%	39,7%
Technological context	1,7%	1,8%	8,8%	33,3%	54,4%
Environmental/ ecological context	3,4%	5,2%	19 %	25,9%	46,5%
Legal context	1,7%	5,2%	13,8%	44,8%	34,5%

Table 3. Q: "How would you rate the importance of contextual issues for a successful entrepreneurship education?"

	Never taken into account	Sometimes taken into account	Often taken into account	Always taken into account
Political context	10,1%	42,4%	39 %	8,5%
Economical context	0 %	17 %	52,5%	30,5%
Sociological context	1,7%	37,3%	55,9%	5,1%
Technological context	0 %	23,7%	42,4%	33,9%
Environmental/ ecological context	1,7%	42,4%	44,1%	11,8%
Legal context	5,3%	38,6%	45,6%	10,5%

Table 4. Q: "Which contextual elements do you perceive are taken into account in Entrepreneurship education generally speaking?"

	Never taken into account	Sometimes taken into account	Often taken into account	Always taken into account
Political context	10,2%	35,6%	37,3%	16,9%
Economical context	0 %	6,8%	45,8%	47,4%
Sociological context	1,7%	18,6%	47,5%	32,2%
Technological context	1,7%	19 %	36,2%	43,1%
Environmental/ecological context	6,8%	22 %	45,8%	25,4%
Legal context	5,1%	35,6%	28,8%	30,5%

Table 5. Q: "Which contextual elements do YOU take into account in YOUR Entrepreneurship education?"

One interesting finding is the weak focus on legal matters as compared to technological/economical factors. If the legislation was able to reflect the prevailing trends in business and technology, the legal considerations would match in importance a) technology areas such as artificial intelligence, cybersecurity, and robotics would follow, and b) business trends and models such as marketing automation, platform businesses, etc. As this is not the case in our data, we conclude that the technological/economical context keeps developing and changing at a higher clock speed than other areas of PESTEL affecting EE.

4 SUMMARY AND ACKNOWLEDGMENTS

We conclude our findings by stating that context still matters, despite the "global village" of mixing cultures and the fast-spreading of novel technologies across the world. The technological context still is a powerful contextual moderator. We suggest the research community pay attention to technological context and adapt the prevalent models to the degrees of technology sophisticatedness and intensity.

We aim at adding with our future work to add to the knowledge pool on the subject through qualitative research. We also encourage research on the technological context and studying that phenomenon via the constituents that make it: What are the differentiators between different technological contexts relevant to be taken into account in engineering-based entrepreneurship: Infrastructure, skill levels, availability of technology suppliers, technology levels of potential customers?

Due to the limited size of the sample, the generalizability of the results is limited, especially in African and Mid-/South-American contexts. Despite that shortcoming, our aim at exploratory research that would help to understand the phenomenon under study better and indicate areas for further study was reached.
Acknowledgments for this study's achievements belong to Dr. Alexandros Koukaris from the University of Peloponnese in Greece for joint data collection and analysis.

ABSTRACT

As digitization and Industry 4.0 progress, the need for smart products and innovative business models increases. This contribution presents the underlying novel concept of the collaborative course “Smart Products, Engineering and Services”. The objective is to enable students of mechanical engineering to develop and work with smart products, and to derive possible business models for their use. A combination of traditional lectures, flipped classroom exercises and a development project characterizes the unique character of the course. The presented topics range from the basics of sensing machine elements, intelligent mechatronic systems and the use of artificial intelligence in the latter. Further, it comprises product development methods such as agile development, V&V methods and the usage of rapid

manufacturing technologies. The flipped classroom exercises serve as preparation for the project work and allow students to gain practical experience with additive manufacturing processes as well as cyber-physical systems. As part of the project work, students develop a smart product which must complete the control task of balancing a body on vertically excited surface by minimizing the bodies movement. For this purpose, the kinematics, the controller, and the usage of a force-measuring ball bearing as a sensing machine element are predetermined. Missing components must be designed and manufactured in a Makerspace using 3D printing or laser cutting and the developed controller must be implemented. The smart product is finally tested on a specially developed test rig.

1 INTRODUCTION

Nowadays, an engineer will not be performing the same task throughout his work life. In our fast-paced world, quickly learning and transmitting newly acquired knowledge to team members has become much more important (Castaneda & Cuellar, 2020). It is paramount to know and understand technologies such as AI, Big Data, rapid prototyping etc. in order to grasp the potential and the development implications for new products. Equally important is the ability to manage a team through an environment with limited resources in time, material, and availability of production capacities. Especially with regard to time, rapid prototyping can be leveraged to achieve quick transitions from concept to prototype, thereby accelerating development speed. The new Master's course Smart Products, Engineering and Services (SPES) is held for the first time in 2022. The concept is a response to the growing need for highly versatile engineers that not only dominate their own domain, but in addition show expertise in neighbouring areas. The topics of the lectures range from the basics of smart mechatronic systems and smart machine elements over rapid manufacturing technologies and agile development methods to the application of smart systems for e.g. condition monitoring. Furthermore the lecture covers market analyses and business models in order to discuss and analyse the economic potential of smart products and services. Accompanying the lectures, Flipped-classroom exercises and a complex mechatronic development project subsequently to the lectures are performed in groups of five. The flipped-classroom exercises topics expand the concepts presented in the lectures and facilitate the application of theoretical knowledge throughout the development project. The project itself assists students in the transition from theory-driven university to the industry.

2 METHODOLOGY

The teaching concept integrates the idea of deepening theoretical knowledge gained within the lectures into two student-centered teaching approaches. After conveying the key knowledge in compact lectures during the first five weeks, SPES aims at breaking through the simplifications of a purely theoretical course and confronts students with problematics that arise when working on an engineering problem. Prior to the project work the students can participate in the flipped-classroom exercises as a team. The format incentivises students to prepare their works individually and present their findings shortly. This enhances communication and presentation skills. As a motivation, a successful participation improves the student's final grade by earning a small bonus. The flipped classroom is a method to teach problem solving skills for more complex tasks. Developed by Bergmann and Sams (2012) for schools and adapted for higher education it flips the traditional way of teaching and learning. Instead of learning the basics in face-to-face classes and reinforcing what they have learned by solving assignments at home, students prepare for a lesson by learning the basics individually. In the lesson itself, the students solve tasks together or discuss the learning content (Werner et al., 2018). Cho et al. (2021) list studies that found various advantages and disadvantages of using flipped classrooms in mechanical engineering teaching. It is shown that the flipped classroom leads to a higher learning success, as long as the number of participants is not too large, or is managed appropriately. With approximately 25 students, the number of students is similar to the size of a school class and is therefore suitable for the Flipped Classroom.The final project phase is accompanied by a limited number of optional helpdesks where students can seek counsel regarding engineering topics. This teaches them to self-identify their weak spots and carefully choose on what questions they need aid. The final grade is based on the written exam at the end of the project phase as well as the evaluation of a written project elaboration and an oral colloquium of the project results.The results of exercises and project work are included into the curriculum to iteratively improve the course for future terms. Doing so the work of participants has a direct influence on the orientation of SPES and aligns the discussed topics to the need of students and the industry.

3 RESULTS

The concept of SPES is based on a review on state-of-the-art teaching methods. Ten lectures convey the basics for the successful realization of a smart product. Lectures about business models, market analysis and acceptance, innovation management, and concepts for generating ideas give an overview to get in touch with methods and the jargon of economics. Additionally, eight lectures cover a wide range of interesting methodologies in growing R&D areas. Core ideas transmitted are implications and methods for developing products in a fast-paced world leveraging available technologies such as rapid prototyping, AI methods, and Big Data. Even most recent research results are introduced to the auditory in order to enable innovative smart products utilizing current research trends were possible, (Reichwein et al., 2020). Up-to-date norms are discussed in the context of the classical V-model for product development as well as agile development.

3.1 Flipped Classroom exercise

The flipped classroom concept encourages students to deepen their knowledge and to train teaching and presentation skills. First, the individual student teams are given a list of tasks, of which they individually choose two tasks, complete them and teach their insights to the other teams within the flipped classroom environment. Research associates as well as student tutors are providing expert knowledge and supervision during the preparation of the tasks as well as the flipped classroom lectures, to ensure a sufficient quality of the lectures. Necessary fundamentals are taught through traditional lectures as well as supplementary material available online (catalogs, tutorials, scientific articles, etc.). The exercises are intended to deepen the content of the lectures and to prepare students for the practical project phase. Different tasks for every group vary from exercises in the field of 3D printing or programming microcontrollers and on the other hand of a theoretical nature, in which the current state of research is analyzed and discussed. The students have 3 weeks to complete the assignment. For the practical tasks, the Makerspace is available as a place to elaborate the solution. The results are presented by each group to all students and discussed in short presentations. Particularly good or interesting results extend the content of the lectures in subsequent years and enable students to actively contribute to the continuous improvement of the lectures quality as well as the coverage of state-of-the-art topics. The presented topics of the first term varied from rapid manufacturing techniques up to trends in artificial intelligence.

3.2 Project phase

Following the flipped classroom units, the participants develop a smart product, representing a balancing system, which will be field tested in the course of a final presentation. The test environment is a damped two mass oscillator, which represents a quarter car and is shown in figure 1. The students will design parts of the kinematic and manufacture the system using FFF and SLA printers, as well as a laser cutter. For assembly and post processing an open Makerspace including all necessary tools is accessible to the participants. To conduct the control task, the teams have to develop a control strategy, calculate the control parameters and implement the control system using an autonomous calculation unit. The smart product consists of the developed kinematic, predefined sensors and actuators and the controller which is designed and implement by the students. Sensors are available in the form of displacement and acceleration sensors as well as a sensing rolling bearing as sensing machine element. The sensor data serves as input for the control system as well as for data analysis and the use of artificial intelligence to e.g. predict future behaviour of the test rig.

ABSTRACT

A monitoring system embedded into a virtual learning environment (VLE) can assess student progress to ensure no student is left behind. This is significant to support student engagement and learning in a blended transferrable skills and research methods module delivered to over 1,200 students from 15 different postgraduate engineering and business courses at a UK university. Therefore, this short paper addresses the question, *"How can a monitoring system for student progress be implemented in the VLE?"*, through a reflexive evaluation of a monitoring system that recognises individual student's weekly progress using a series of badges. A badge is awarded to a student when they have successfully completed or passed a set of required learning activities, and it enables students to self-monitor their progress. As a work in progress, this short paper presents a way to implement a monitoring system using badges in a large class VLE, along with an initial discussion about the challenges for implementing this system and the use of this system to prompt interventions. Further research will advance this short paper by examining the impact of badges to motivate student engagement and learning.

1 INTRODUCTION

Virtual learning environments (VLEs) have enabled engineering educators to gather vast data with which to track and evaluate student engagement, learning, and progress. This data can be used to monitor student engagement, learning, and progress as a foundation for interventions to re-engage students, improve student learning, and encourage student retention [1]. Yet how to design a monitoring system is a key concern. Furthermore, it is necessary to consider how data is gathered to monitor students and communicated to students so they can self-monitor their progress. Therefore, this short paper answers the question, *"How can a monitoring system for student progress be implemented in the VLE?"*

This research concerns the experience of the authors to design a monitoring system to evaluate the progress of over 1,200 postgraduate students from 15 unique engineering and business courses enrolled in a transferrable skills and research methods module at a UK university. Of these students, there are 270 from two courses completing the module for credit. While all students enrolled on the VLE of the module are accounted for in the monitoring system, the research scope is specific to students participating in the module for credit. This blended module is delivered with a strong online component due to the high student-to-teacher ratio since the teaching team consists of four academics, including the authors.

Badges embedded in the design of the module VLE can aid engineering educators to monitor student engagement, learning, and progress in a way that is practical and to scale. This work in progress provides insight into the experience of implementing this monitoring system to support engineering educators to innovate their own VLE to assess student progress in online learning. Further work to evaluate the impact of badges on student engagement and learning will occur at a later stage.

2 METHODOLOGY FOR MONITORING ONLINE LEARNING

Embedded in the VLE of the module is the 'monitoring system' comprising of 20 badges, achieved by students on a weekly basis by completing or passing a series of virtual activities (such as group forums, reflective questionnaires, and quizzes). Badges are a form of gamification that motivate students to engage in learning [2]. These tokens are a visual indication of progress that students can self-monitor on their VLE profile. Badges facilitate individuation with each student responsible for their own learning with the aim of achieving all badges [3]. These badges constructively align with the module content in preparation for students' module assessments. Students enrolled on the module for credit achieve badges as 'continual assessment' to promote continued engagement with asynchronous learning [4]. This means a student can earn up to 20% of their module mark by achieving 20 badges (1 badge = 1% of module mark).

The monitoring system is an accumulation of four monitoring points that check student progress during the module and are aligned with assessment dates or term breaks to fit within the student learning journey. One cycle of the monitoring system is illustrated in Figure 1, below. First, a student must complete or pass a set of activities available each week on the VLE. An activity is marked complete when all components have been answered, such as a questionnaire, or passed when a minimum mark has been achieved, as in a quiz. On successfully completing or passing these activities, students earn a badge for that session. Second, students must earn a set of badges to pass a monitoring point. Third, students who do not earn all badges for the monitoring point are sent an email. A student's course leader is also notified by email of students who have missed the monitoring point. Finally, students can continue accessing additional weekly sessions and their activities to achieve further badges regardless of whether a prior monitoring point is complete or not.

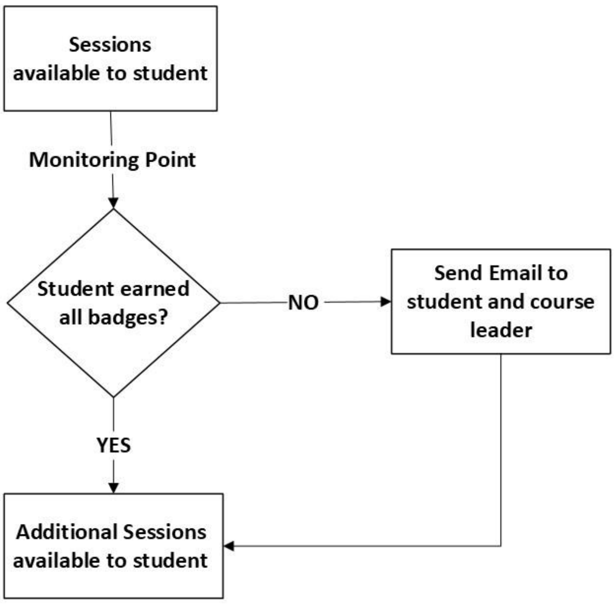

Figure 1. One cycle of the monitoring system (Student completes virtual activities in each session to earn a badge and for each monitoring point a student needs to earn 4-6 badges, depending on the monitoring point)

The monitoring system is overseen by the teaching team who are responsible for embedding the monitoring system in the design of the module, technical deployment of the badges on the VLE, analysing badge attainment, and communicating notifications of non-engagement to students and their course leader at each monitoring point. The authors' initial findings of the monitoring system are presented as a work in progress focusing on two themes: challenges to embed a monitoring system and interventions to support student engagement and learning. These findings are based on reflexive interrogations on the use of the monitoring system. Future work will evaluate the impact of badges on student engagement and learning.

3 INITIAL FINDINGS

3.1 Challenges to embed a monitoring system in the curriculum design of a large class VLE

An initial challenge to implement a monitoring system was the lack of technical ability to design activities. For instance, early session activities focused on a topic or skill rather than in combination due to a lack of technical skills to design complex activities. This resulted in a high number of online activities created for each badge. Some students who were overwhelmed by the number of activities needed to pass a monitoring point resolved this by rapidly clicking through activities. A VLE that includes a high number of activities, or similarly too many materials and links, can compromise deep learning as it undermines the learning experience [5]. Therefore, to avoid surface learning, the team later designed complex virtual activities that included multiple components that weave together many topics or skills to reduce the overall number of activities in remaining sessions. Hence, to implement a monitoring system on a VLE, it's important that module design is informed by technical expertise to create virtual activities that, once completed or passed, form the qualifications needed to achieve a badge.

The team also experienced an additional consequence of the high number of activities used to monitor student engagement and learning: data overload. The teaching team did not have the time and necessary resources available to analyse the extensive data that was captured through monitoring activity completion or marks, so it was difficult to enact strategic decisions to adapt content or delivery of online learning to respond to gaps or barriers in student engagement and/or learning. Therefore, it is important the design of a monitoring system considers the amount of data it will generate and the extent this data is useful for pedagogic decision-making. Hence, construction of a monitoring system must be based on quality rather than quantity of data.

Monitoring points enabled the teaching team to evaluate the extent of an individual's progress to complete or pass learning activities during the module. Yet an issue in using a monitoring point for several badges, rather than a weekly deadline for each badge, is that students achieved a series of badges at the last-minute as evidenced in data captured on when a badge was achieved. While a deadline for each badge was avoided to enable flexibility for students, as some students would be unable to achieve a badge during the week due to conflicts with intensive one-week-block module teaching, it may have compromised the quality of learning. This is significant since the transferrable skills and research methods taught in the module have long-term implications on students' dissertation and professional success. Therefore, further work is needed to evaluate how students perceive monitoring points and how changes to temporal structures of monitoring, such as a deadline to achieve a badge, would impact student progress.

3.2 Interventions in a monitoring system to support student engagement and learning

A benefit of a monitoring system that can assess student progress is that this information is quantifiable for dissemination to course leaders who can follow-up directly with their students who are not progressing in the module. For instance, at each monitoring point a list of students who did not complete the required badges were identified for each course. This list of students was emailed to the relevant course leader with students categorised as 'incomplete progress' or 'minimal to no progress.' The latter category concerned students who missed the majority or all badges for the monitoring point. This categorisation enabled the team to communicate to course leaders if there were students who may require further support, such as a wellbeing check-in, due to a consistent lack of engagement and learning over a series of weeks. This was a beneficial practice for improving the learning community in which an individual student is supported by a network of staff who are aware of, and knowledgeable about, the student and their circumstances [6]. Yet, further work is needed since it is not clear the extent course leaders did follow-up with these students or the extent course leaders found the communication about the monitoring point helpful.

Students who did not complete a monitoring point received a personal email about their module progress. The email had two key messages. First, the importance of achieving badges as these constructively aligned with the module's summative assessment (as well as counting towards continual assessment). This emphasised the significance of attaining badges as part of learning in addition to engagement. Second, since a lack of progress, learning, and engagement can be due to poor wellbeing, guidance on how to access wellbeing support was included. Many students immediately responded to this email intervention by contacting the teaching team to raise concerns and questions related to their learning experience. As part of an ongoing evaluation of the monitoring system, additional analysis on how the email intervention improved student engagement and learning is needed. For instance, how quickly students began to re-engage with the learning activities following the email intervention.

4 CONCLUSION

In evaluating the monitoring system embedded into the VLE of a module delivered to over 1,200 students, there are two key considerations for practice. First, engineering educators keen to embed a monitoring system using badges must consider the quantity and quality of activities, as well as the timing of badge achievement, to avoid surface learning. It's also important that engineering educators are provided technical skills training so they can design and implement their own monitoring system. Second, collecting information about student progress in the module can be communicated to students and course leaders to enhance student engagement and learning.

This short paper shares reflexive evaluations by a teaching team to oversee a monitoring system of student progress for a transferrable skills and research methods module. Suggestions for future work to advance this short paper include evaluating the impact of badges to motivate engagement and learning, as well as the impact of the email intervention to re-engage students to learn. Further research would also benefit from evaluating the impact of other forms of gamification beyond badges that can be used to monitor student progress.

doi:10.5821/conference-9788412322262.1324

ABSTRACT

This work describes experiences learned in teaching photovoltaic (PV) courses in Engineering Master Degrees at the UPC. These PV courses are included as elective courses in the Master of Energy Engineering included in the international master programs: Environomical Pathways for Sustainable Energy Systems (SELECT) and Renewable Energy (RENE) and in the Master Degree in Electronic Engineering at the Universitat Politècnica de Catalunya (UPC) in Barcelona, Spain.

These Master Degrees are aligned with the objectives of the European SET plan and the objectives of KIC InnoEnergy in the field of renewable energies and aim at delivering education for high competency and quality engineering skills in the field. The content of these programmes is focused to the renewable technologies concept of “learning by doing”, so combining deep theory knowledge (top-down approach) with internship in industry co-advisored by the university and the industry (bottom-up approach) in an international environment.

1 INTRODUCTION

1.1 Contents of the courses.

The courses are focused in PV as a renewable energy source to its use as an energy service including social and environmental dimensions in order to help students to make value judgments. The duration of both courses is one semester: 15 weeks- 5 ECTS, and the courses include stand-alone and grid connected applications of PV systems considering both technical and economic criteria to select the most appropriate electrical equipment for a given application and solutions for a smart control and fault detection in the generation systems in order to optimize the generation of energy and costs. Professional software tools are presented in order to help the students in the design, evaluation and analysis of the behaviour of the whole system. Contents are technical and self-contained.

1.2 Engineering skills.

The courses are focused on technical skills required for engineers in the field of PV applications. Moreover, from a transversal point of view, an special effort is done to enhance training the students in soft skills such as communication, economics, business administration and, very specially, to promote the orientation to innovation and the entrepreneurship spirit by means again, of the “learning by doing” concept.

2 METHODOLOGY

2.1 Teaching methods.

The teaching methodologies are as follows: Lectures and conferences, knowledge exposed by lecturers or guest speakers and participatory sessions including collective resolution of exercises, debates and group dynamics. Classroom presentations of activities, individually or in small groups, are also included.

Homework: Resolution of short exercises, writing reports on technical issues that include the approach, results and conclusions, individually or in groups.

Project-based learning: Throughout the semester, students organized in groups must carry out a real PV project design that is described in the next section.

Participatory sessions: Learning based on participation in the collective resolution of exercises, as well as discussions and group dynamics, with the teacher and other students in the classroom.

2.2 Project design.

An important part of the course is the sizing, design and planning of a PV project for a specific application. Students groups are required to study the irradiance and temperature profiles at the PV system location throughout the year and select the size of the PV array to meet the specified power demand in the selected application. Then, students must select : The PV modules, batteries, inverters if any, charge regulators and the rest of electronic equipament present in these systems taking into account the application requirements, loads present in the system, consumption profiles, cost of the whole system and its reliability.

The sizing and design of the PV system is carried out with the help of professional simulation tools that include characteristics and parameters of commercial elements of each of the parts of the PV system. For this purpose, students work with PV-SOL [1-2] and PVsyst [3-4].

The final results obtained in the projects are presented by the students for analysis and discussion with the teacher and other students in the classroom.

3 RESULTS AND DISCUSSION

At the end of the autumn semester of the 2021-2022 academic year, a survey was conducted of the students of the course corresponding to the master's degree in energy: SELECT and RENE. A total of 36 students out of 51 enrolled responded to the survey.

The results obtained are shown in table 1. The students value between 1 and 5 the degree of satisfaction of each section, with 5 being the maximum score. As it can be seen in the table, the students have highly valued the simulation tools used in the course in the development of group projects. Moreover, the development of these projects, the group work and the methodology presented in this communication and used throughout the course have also been very positively valued by the students.

Table 1. Sample of questions from the survey. The results show the degree of satisfaction of the students between 1 (min) and 5 (max) in each question.

Question	1	2	3	4	5	Average value (out of 5)
I found the contents of the subject interesting	0%	0%	21.05%	28.94%	50%	4.28
I am satisfied about the course and the skills acquired	0%	0%	15.78%	39.47%	44.73%	4.28
The teacher presents the contents clearly and the methodology used is appropriate	0%	0%	15.78%	31.57%	52.63%	4.36
Working in groups to solve the proposed projects has helped me learn	0%	0%	23.68%	15.78%	60.52%	4.36

The simulation tools used in the course are useful for the design of PV systems	0%	0%	13.15%	15.78%	71.05%	4.57

The students in this course have different profiles. Some enter with a degree in energy engineering, others instead come from degrees in mechanical, electrical or electronic engineering. This facilitates an interdisciplinary vision in the development of projects and facilitates the improvement of both technical skills and soft skills, valued with an average value of 4.28 out of 5 by the students. Throughout the course, the students have appreciated that the members of their group respect their disciplinary experience and are willing to learn from it. In addition, there is a change in the way students perceive the willingness of their groupmates to work incorporating skills not associated with their disciplines during the course.

ABSTRACT

First-generation students have been a focus in higher education research over the past ten years. However, limited attention has been paid to engineering students who are the first in their generation to enter university. The paper reports on data collected as part of a longitudinal study of first-generation engineering students at a South African university during the early stages of the pandemic. First-generation students, who already face multiple difficulties in their educational journey, were confronted with a juxtaposition during the lockdown. As engineering students, they are inducted into technical approaches to problem-solving via systematic and analytical exploration. Levi-Srauss contrasts this notion of the ingenieur, grounded in the Enlightenment belief in the superiority of rational scientific reasoning, with the bricoleur, who finds solutions by “doing things with whatever is at hand”. With the lockdown period being less amenable to structured problem-solving, students often had to resort to more improvised approaches to accommodate their studies and their shifted precarious everyday routines. The study not only adds to literature on first-generation engineering students, but also provides insight into the ways in which these students cope with obstacles over which they have little control. In the process

a picture of resilient agency emerges that challenges a narrow deficit view of students with limited resources.

1 INTRODUCTION

Much has been published over the past two years about students' experiences during the period of online and blended learning enforced by the COVID-19 pandemic. In this paper our focus is on how a specific group of first-generation students negotiated their engineering studies during this time.

1.1 First-generation students

The concept of first-generation students is useful to identify students who experience multiple intersecting disadvantages in their educational journey [1]. Challenges often include a lack of role models and pressure from communities of origin to succeed. Many students are unfamiliar with "what counts" in higher education. These students frequently face financial challenges, and for some, their prior educational trajectories did not prepare them adequately for higher education. Although attention to first-generation student experiences has increased in various higher education fields over the past 10 years, less attention has been paid to experiences from the global South, and specifically experiences of engineering students. It is also important to extend research foci beyond notions of deficiency and scarcity [2]. It is thus worthwhile to conduct research that sheds light on learning experiences in ways that avoid simply conflating accounts of first-generation students with those of poverty [3].

1.2 Precarity

In discussing these challenges, we adopt Butler's [4] distinction between 'precarity' and 'precariousnessas'. Precariousness describes the vulnerable human condition of innate interdependency we all share, whereas precarity refers to the politically induced condition in which certain populations suffer from failing social and economic networks of support and thereby become differently exposed to threats.

The events unfolding as a result of the global pandemic constitute an appropriate moment to reconsider what we think we know about vulnerability, precariousness and precarity. In a radically unequal society, such as South Africa, widely diverging social experiences are concerning realities, and first-generation students become disproportionately vulnerable as precarity accelerates..

1.3 *Ingenieur* vs *bricoleur*

In his influential publication, The Savage Mind [5], Levi-Srauss distinguishes two ways to relate to the world, that of the *ingenieur* and that of the *bricoleur*. These two figures approach problems differently: the *ingenieur* is rooted in the Enlightenment tradition of the historical French engineer – a belief in the superiority of the rational scientific reasoning process. *Bricolage* is a French loanword that refers to the creation of an artefact or solution to a problem, using a diverse range of objects or options that are readily available, "doing things with whatever is at hand" [5].

How do first-generation engineering students make sense of precarious changes in physical space? How do they navigate restricted identities back home where being a student intersects with being a child, a sibling, a caretaker? How do they manage challenging engineering studies online, often faced with almost intractable digital access problems? How do they make meaning out of digital sources to assemble technical knowledge and skills?

2 METHODOLOGY

2.1 The study

A group of 17 first-generation engineering students from four departments (chemical, civil and electrical engineering) at the university of Cape Town is participating in a longitudinal study to track their educational journey and path into initial employment. Students are interviewed annually in semi-structured interviews that are transcribed. This paper reports on the 2020 anonymised interviews that took place 3 months into the initial hard lockdown period at the start of the pandemic, an environment of accelerated precarity for these already vulnerable students.

2.2 Conceptual framework for analysis

Transcribed interviews were coded according to a set of categories developed from scholarly literature on the characteristics of *bricolage*: *bricolage* involves “making-do” [6] with whatever is at hand. It represents an “integration of conceptualisation and realisation” [7]. In *bricolage*, *repertoires* are independent elements that take on different meaning in association with other elements [7]. Coutu [8] argues that the *bricoleur’s* familiarity with their own environment helps to orient them to draw on that which is recognisable, using a way of practical reasoning or “science of the concrete” [5]. Finally, *bricoleurs* are marked by resourceful resilience [8].

3 RESULTS

3.1 Making do with what is at hand

The bricoleur takes stock of the context, the problem faced and then uses what is at hand to make do. Velani’s physical circumstances are less precarious than some of his peers, but he too faces resource challenges that impact greatly on his ability to work at his engineering studies: for him, internet access. He has to initiate requests that rely on the goodwill of distant family members. This leaves him feeling conflicted, and yet he acts: “If I have a test or an assignment… anything that is online, I have to go to another space... I have relatives around the area, even though it’s not close relatives, but I do go to them and ask them for some space so that I can just do my tests, because they do have network… But the disadvantage of that is that … I have to go there and use their space. I don’t know how they feel about that…. They still say they are okay with that but you can't really know… I think I'm disruptive to them and their living space.”

3.2 Practical reasoning: “science of the concrete”

At the start of the lockdown Mlungisi relocates from a campus residence to an informal settlement just outside Cape Town sharing a small shack with his two brothers. The single room dwelling is divided in two: his older brother has his own space with a small section where they can prepare food. The other two brothers share the second partition; this is where Mlungisi also has to study. He needs to improvise: “At the beginning, I thought there was no workspace since it’s … very small … there is a table which is very small, but at least I can study on top of it… I tried to move some things… against the walls of the shack. So yes, I tried to make some space for me to study, just to study…” Mlungisi’s improvised study consists of assembling elements from his environment according to simple rules (a small table in a limited shared space). Improvisation makes adaptation to challenges possible, often in a way that integrates thought and action – moments of conception and realisation become indistinguishable in disordered or unpredictable environments [7].

Mlungisi explains that they have electricity in their shack, and qualifies “and it is legal” (illegal electricity connections are common in the informal settlements where extension cables are run from the few legal provisions). They also have running water, possibly an irregular connection – Mlungisi’s brother “made a plan to have some water… he had pipes, so we do have water… I think it’s good water. I hope so.” However, for sanitation they have to rely on shared community facilities: “… around the area there are loos … some like municipal kind of things that are outside… so that’s where we can go… many people go there and it’s poor hygiene, but we have to because there is no other option”.

3.3 Repertoires: independent elements that take on different characteristics

Students have to repurpose resources they are familiar with and use these in new ways. An example is the way students adapt the use of WhatsApp groups during the early part of the hard lockdown. Classmates were displaced and sent home from campus that provided at least a modicum of equity in the WiFi access students shared in residences and on campus. WhatsApp, that once served exclusively as a means of social contact with friends, becomes a *repertoire* [7] to facilitate tutoring and contact with lecturers. Far from being a perfect replacement, the social media platform is reimagined to allow tutors to respond and clarify student queries. Matteo describes the way he has to go about getting feedback on a mathematics query: “…[with classroom] learning, you can kind of ask a direct question, you know, as the lecturer’s going through the notes, you can just point to a specific section on the page. Whereas if you [now] need to ask a lecturer [for clarification], you need to… take a screenshot, draw on it, indicate what, and then try and ask your question…”

3.4 Familiarity with own environment, drawing on what is recognisable

A rapidly changing environment can lead to feelings of being overwhelmed, resulting in paralysis or inaction, but Coutu [8] argues that the *bricoleur’s* familiarity with their own environment helps to orient them as they draw on that which is recognisable, using a way of practical reasoning or “science of the concrete” [5]. Students find various ways to try and impose structure on their days after being thrust into almost feature-less days. For Mlungisi, this means trying to stay warm during the cold rainy Cape Town winter nights and sticking to a similar timetable that he used before: “… during the evenings it’s very cold. During the mornings, it’s also really cold. So, I usually study during the day… I try to wake up at six o’clock … then try to study… I try… to make my learning as close as possible to the way I did at [university], to motivate myself".

For other students it makes more sense to use the night hours to work: Jerome works "… mostly during the night when it's really quiet because during the day it's really [noisy] in the house. The kids are running around and making noise". For others, like Luyanda, nights are used for study because data costs are slightly lower in off-peak hours: "I'm just using the data that [the university] gave us… it's not really enough… when the day data is finished, I tend to work in the night. But then, in the night there are not a lot of hours to work, because it's from midnight to 5AM and then it [the data] stops working".

3.5 Resilience, self-efficacy: "I am always an optimist"

In spite of challenging circumstances faced by these first-generation students, they respond in ways that demonstrate the remarkable resilience of the *bricoleur* [8]. Zinhle draws on past experience that saw her succeed through her school years: "…it's really a tight space and there's a lot of us [11 people in a small home], and during the day we are all awake and busy. I don't have a special place where I study… I just cope because this is where I lived when I was in high school, so some[how] I've found a way to make things work".

Mia draws on inner resources and a sense of self-sufficiency: "… many times, I would be like, I can't do this… Why did I decided to study this? And then it was always a case of, I can do this. If other people can do it, why can't I do it? And that always got me through it… And I am always an optimist. That's one thing. Even through this coronavirus… I am like, no, it's okay… at the end of the day… you have to realise whatever decision you make, you're going to have to deal with it.

Bakari even manages to keep thinking and planning a small business venture (temporarily on hold during the lockdown): "It's an agricultural-based project… we managed to get funding. We did a pilot phase of the project… last year. Now, we want to… start growing and selling microgreens in Kenya".

4 SUMMARY

Students enter engineering studies from a diversity of backgrounds. Our study contributes to the limited literature on first-generation engineering students with insights into ways in which these students cope with the stark realities of accelerated precarity brought about by a pandemic raging in a developing country context. Scholars emphasise that there is no such thing as pure *bricolage*, and that in real-life individuals function somewhere between the ends of the *bricoleur* and *ingenieur* [7] as context demands. Faced with situations over which they have limited control, and where their engineering training cannot provide neat, systematic solutions, these students nevertheless act as *bricoleurs*, exercise agency and draw on resilience to continue to study. Mlungisi explains: "I try by all means… to be very, very creative… One of the reasons why I don't give up is because I have a family. I have myself, I'm thinking ahead. What about my community in the future? If I give up, many things will fall down in my life... So, I don't give up; I try to endure".

ABSTRACT

Virtual reality has become a significant asset to diversify tools in the support of engineering education and training. The cognitive and behavioral advantages of virtual reality (VR) can help lecturers reduce entry barriers to concepts that students struggle with. Computational fluid dynamics (CFD) simulations are imperative tools intensively utilized in the design and analysis of chemical engineering problems. Although CFD simulation tools can be directly applied in engineering education, they bring several challenges in the implementation and operation for both students and lecturers. In this study, to tackle these challenges, we developed the "Virtual Garage" as a task-centered educational VR application with CFD simulations. The Virtual Garage is composed of a holistic immersive experience to educate students through a real-life engineering problem solved with CFD simulation data using a VR headset. The prototype is tested by graduate students (n=24). Participants assessed usability, user experience, task load and cybersickness via standard questionnaires together with self-reported questions and a semi-structured interview. Preliminary results reflect that the Virtual Garage is well-received by participants. We identify features that can further enhance the usability and user experience.

1 INTRODUCTION

Computational fluid dynamics (CFD) simulations are heavily applied in engineering design and analysis to solve engineering problems in a time cost effective fashion. Educational use of CFD simulations may be challenging due to expert-centric user experience in conventional simulation environments, which requires complex skills to perform CFD simulations and interpret obtained results to make justifiable decisions. Learning in conventional simulation environments often happens by learning-by-doing on 2D desktop settings. Such environments do not comprise any assistance except help options relevant to the usability of the tool. These conventional simulation environments have been criticized by educational scientists and were found less efficient than that of traditional instructional designs [1].

Utilization of virtual reality in support of immersive learning has been a hot topic in engineering education. Immersive virtual reality learning environments may reduce the entry barrier to complex learning subjects including CFD simulations. These environments can positively trigger cognitive skills with advanced interactions and easy-to-access technical content, as well as behavioral aspects of learning such as attracting and motivating students. This might open gates for user-friendly, high-quality complex learning environments assisted with CFD simulations. Many researchers have investigated the integration and implementation of CFD simulation data in virtual reality, especially for visualization purposes [2]. However, no study has been found in the literature implementing an immersive complex learning method with CFD simulations in a digital environment.

In this paper, we present the VR application “Virtual Garage”, as an immersive complex learning environment, composed of a holistic interactive experience to educate students through real-life engineering problems solved with CFD simulation data using a VR headset. Our fundamental objective is to develop an immersive learning environment and investigate its effect on cognitive and behavioral aspects. First, we should ensure a proper virtual reality experience to accomplish this. Therefore, as a preliminary investigation, we assessed usability, user experience, task load and cybersickness in the Virtual Garage based on available standard tests.

2 METHODOLOGY

2.1 Design of complex learning environment

A task-centered educational experience is adapted to design an immersive complex learning environment with the four-component instructional design (4C/ID) model. Among many interesting instructional design methodologies, the 4C/ID model has become a prominent tool to support complex learning environments in numerous disciplines [3]. The model presents four major components to enable complex learning; learning tasks, supportive information, just-in-time information and part-task practice. The learning environment in the Virtual Garage is fundamentally structured by applying the 4C/ID components together with various instructional design principles highlighted by the design tool. A sequential principle is set for the learning task to increase complexity in the learning environment gradually. Multimedia and signaling principles are mainly implemented in the supportive and just-in-time information, respectively. As a part-task practice, a pre-training module is developed to teach interactions in VR and let users explore the learning environment and routine aspects of usability in VR. The entire VR experience is divided into two subsequent sections, Module1 and Module2, as shown in Fig. 1. Module1 is composed of pre-training and theory sections. Module2 is the assignment with CFD simulations to solve problems introduced in the theory. Both sections take approximately 20 min to complete. Users are strongly advised to take a 5 min break between modules by taking the VR goggles off, thereby alleviating cybersickness.

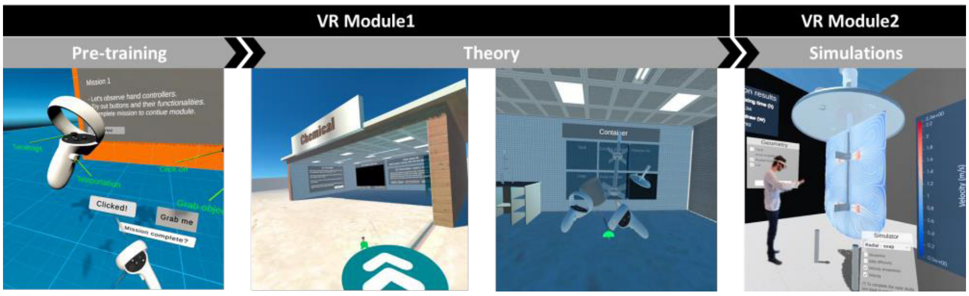

Fig. 1. Scenes in the Virtual Garage; Module1 and Module2

2.2 Software and hardware

To develop the Virtual Garage, we utilized the Unity game engine. CFD simulations were calculated in a workstation with COMSOL v5.6, and integrated into Unity using an extract-based data processing approach [4]. The VR experience was developed for Meta Quest 2 VR goggles.

2.3 Data collection

Usability, user experience, task load and cybersickness were assessed by participants. Questionnaires were repeated after each module. Participants additionally filled out other questionnaires to provide sociodemographic information, experience, and self-reported questions on content. Additionally, a semi-structured oral interview was carried out at the end of the session to point out positive and negative aspects of the Virtual Garage.

3 RESULTS

Experiments were conducted at the department of chemical engineering at KU Leuven with 24 participants from the graduate school. All participants completed the entire test without any issues. Prior to the study, ethical approval was obtained from the ethics committee at KU Leuven. National and regional safety measures with regard to COVID-19 were strictly applied during the experiments such as proper ventilation of the testing environment, disinfection of equipment and social distancing.

Preliminary results on the usability with the system usability scale (SUS) are shown in Fig. 2. Both Module1 and Module2 were well received by users resulting in mean scores of 74.37 and 73.85, respectively. A SUS score above 68 is considered good [5]. More interestingly, it appeared that participants scored differently between Module1 and Module2. Statistical analysis should be performed to clarify the reasoning behind participants' preferences to identify differences in these patterns, for example, experience with simulation content. For the time being, our data processing is still work-in-progress. Future work will focus on data processing to comprehend more participants' behavior. Fig. 3 shows overall scores measured with the NASA Task Load Index (NASA-TLX) test to assess the workload in the modules. Results showed that participants overall found Module2 more demanding than Module1. Only physical demand was lower in Module2, which can be explained by the simplistic design of the simulation environment in Module2. In Module1, users move inside the VR environment to consume supporting information that could be used while solving the problem in Module2 with simulation data.

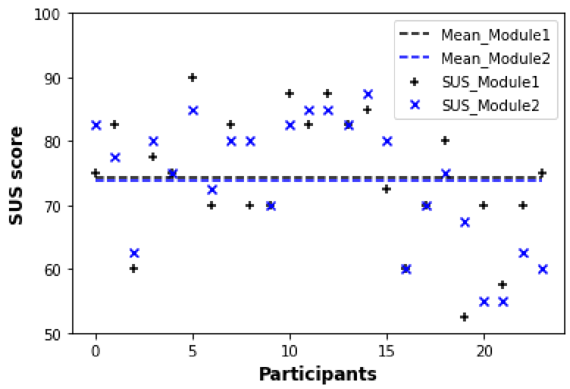

Fig. 2. SUS score

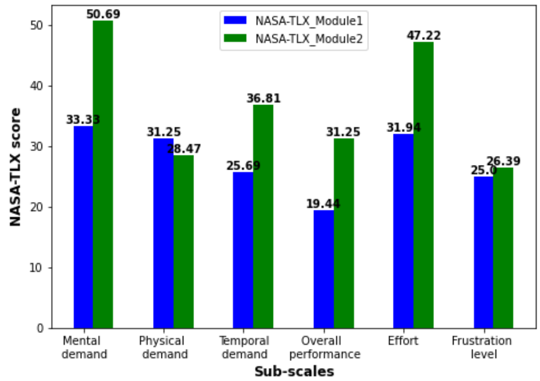

Fig. 3. NASA-TLX score

Meanwhile, Table 1 presents simulator sickness questionnaire (SSQ) scores for different subscales and total simulator sickness. Participants successfully completed the VR experience and didn't verbally report any sicknesses. Participants scored 23.53 for Module1 and 11.53 for Module2. Digital environments with an SSQ score below 40 are assumed to be safe in terms of cybersickness [6].

Table 1. SSQ scores in VR modules

SSQ	Total simulator sickness
Module1	23.53
Module2	11.53

4 SUMMARY AND ACKNOWLEDGMENTS

Our preliminary analysis has shown promising results regarding the development of an immersive complex learning environment with CFD simulations. Data processing is currently underway and more will be reported about the assessment from this set of experiments. Future work will focus on improvements in the prototype and assessments of knowledge gain, task performance and technology acceptance.

ABSTRACT

The Universitat Politècnica de Catalunya (UPC), the Czech Technical University in Prague (CTU) and the Universidade de Lisboa have recently undertaken the Engine4STEMers project, a joint initiative devoted to generating a new culture of young STEM graduates willing to assume early-career responsibilities, oriented to satisfy societal challenges. It also aims to provide guidance and motivation to help young graduates adopt early-career leadership and managerial skills. In this context, this short article describes the objectives and content of a short pilot seminar that is currently taking place at UPC and that is dedicated to the concept of service, a central educational tool of Engine4STEMers that aims to motivate students to proactively manage a successful transition from university to the labour market.

---

1 INTRODUCTION

1.1 The Engine4STEMers context and motivation

In order to cope with fast-changing social and economic environments, STEM graduates are increasingly in need for specific personal and professional development techniques aligned to their career evolution in the technology business [1][2]. Additionally, to embrace continuous innovation, companies get progressively flatter, less hierarchical, evolving from traditional pyramidal and segregated organizations to an organizational model of shared responsibility. This new and highly demanding context requires STEM graduates to undertake a rapid change in attitude and work

doi:10.5821/conference-9788412322262.1331

methodology to evolve from a user culture (student) to a service provider culture (employee or entrepreneur). That is, moving quickly from a task executor role (doing) to assuming greater responsibility in terms of management roles (directing) and finally to leadership roles (deciding).

While STEM graduates are usually aware of their scientific and technical knowledge, they often lack deep insight into their true potential as key drivers for innovation and to effectively impact industry and society. They are also often unaware of the skills and competences required to do so. As key players for innovation and entrepreneurship in the tech market, young STEM professionals should play a key role in developing a positive attitude in the industry and a new mindset towards sustainable development and a higher concern for the impact of technology on society. To address these goals, Engine4STEMers develops a “competences to become competent (C4C)” approach that includes a set of short teaching and learning modules arranged around three topics:

- Early career tools in the tech arena.
- Critical thinking for successful career development in STEM.
- Leadership: a STEM graduate as an effective human being.

We can find a lot of literature regarding the key transversal competences demanded by employers that, in general, give growing importance to social, emotional and higher cognitive skills [3]. In this sense, STEM education is progressively including programs devoted to developing these skills. What is scarcer, however, is space for students to reflect on their current set of skills to improve their self-awareness and self-esteem. Also, to find out what they need for their near future and, more importantly, to motivate them to acquire such skills in their transition to the labour market. This is a critical need covered by Engine4STEMers, which also aims to motivate STEM graduates to engage early in management and leadership responsibilities to provide fast added value to their employers and rapidly impact on industry transformation.

1.2 The concept of service as a self-awareness and motivation tool

Within the Engine4STEMers context, this short paper presents an innovative approach, based on the concept of service, aimed at facilitating a smooth transition to the tech job market mindset. The concept of service is envisaged to help students to improve their self-awareness and self-esteem by visualizing the key competences already developed in their academic stage, but also the early career skills that require further development and the need for career planning, with a short and long-term perspective.

The main thesis of this short paper starts by highlighting the role of universities as Higher Education service providers (Fig. 1). This service provider role has proved to be highly effective in the education of STEM students since just a few years are needed to provide them with relevant knowledge and competences related to scientific and technical work. It also develops a strong "user" mindset in students, which is useful to maximize the benefits that they obtain from the formal and informal learning activities undertaken during their university stage. However, students must be aware of this fact and take the path to become service providers in their transition to the labour market. In other words, a young graduate must smoothly switch from enjoying the benefits of university services to becoming fully responsible for their work in order to satisfy the needs of others. This change in service direction has strong implications that may require a change in attitude and work methodology to successfully accelerate career growth in the tech market.

2 METHODOLOGY

2.1 Improving self-awareness and self-esteem

Before trying to engage students to introduce and further develop soft skills and interpersonal competences, it is important to improve their self-awareness and self-esteem. In this sense, the seminar begins with a discussion of the general competences developed within formal STEM education that complement the general and specialized knowledge provided by STEM degrees (Fig. 2).

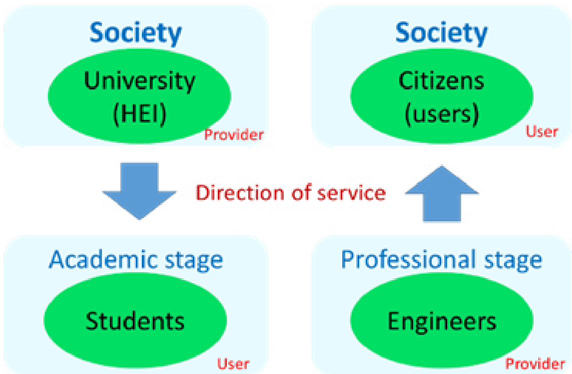

Fig. 1. From user to service provider

- Mental structure and logical thinking
- Methodical, rational and unbiased worker
- Analytical and synthesis skills
- Hard work capability
- Perseverance and resilience
- Creativity
- Skepticism
- Problem solving skills
- Orientation towards action and results

Fig. 2. Competences acquired at the university

Then, the concept of change in the direction of service (from user to service provider) is used for group discussion to help students visualize the need to undertake a change in the work methodology and attitude. These discussions are conducted through several key questions aimed to identify the main differences related to the tasks undertaken in the academy (as students) and the work in the labour market (Fig. 3). These discussions are used to help students envisage the need to further develop instrumental competences. An introduction to these skills is planned in other seminars within Engine4STEMers "Grow to your career academy": interviews, meetings, time-management, effective communication, basic interpersonal skills, positive attitude, career planning or self-management, among others.

In order to further introduce the instrumental competences and the need to further develop them, a set of case studies has been developed based on early-career "to do" and "not to do" situations [4]. These cases are constructed around situations that young graduates may have to face in their first jobs: work overload, poor supervision, unclear responsibility, poor communication, or interpersonal conflicts. Students discuss the likely causes that may have led to these undesirable situations and how a proactive attitude, soft skills, and interpersonal competences could have prevented the conflict.

2.2 Long-term career evolution

Finally, the seminar ends by introducing the need for long-term career planning. Discussions on formal and informal job performance evaluation lead to the concept of professional reputation, which is related to the evolution of professional competence (Fig. 4). The young graduates' career progresses as their comprehensive competence level evolves from a junior role to senior expertise. In this sense, the key competences are presented as Personal and Professional Development Techniques (PPDT), conceived as accelerators of experience, which aim to help a young graduate to reach senior roles faster and with higher levels of competence (Fig. 4).

- How is work performance evaluated?
- How is work organized and scheduled?
- How are work goals set?
- How is feedback grasped?
- How do individual and teamwork change?
- How does the role of expertise change?
- Work quality standards: What's important?
- How work responsibility changes?
- How does the decision-making process change?
- How do working rules and principles change?

Fig. 3. Discussing differences

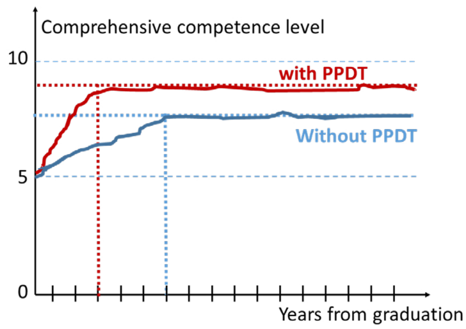

Fig. 4. STEM graduate competence evolution

3 CONCLUSION

Mastering the soft skills and competences required to develop a successful professional career in today's fast-changing tech labour market may require years. Some of them can only be properly developed along with the development of experience, working on real projects, and facing real situations. In this sense, STEM academic programs should motivate students to self-manage their professional careers and to develop the tools required to do so. This short article has presented an innovative approach for this purpose.

ABSTRACT

The Universitat Politècnica de Catalunya (UPC), the Instituto Superior Técnico (IST-Universidade de Lisboa) and the Czech Technical University (CTU) have recently launched the Engine4STEMers project, a joint initiative whose objective, among others, is to guide young graduates in their transition to the job market and motivate them to adopt management and leadership skills early in their careers. In this context, this short paper describes the objectives and contents of a Critical Thinking seminar, currently underway at UPC, which is aimed at motivating young STEM graduates to develop the principles of a skeptical attitude towards the information and stimuli that we perceive in order to face uncertainty, biased information and hidden agendas. Engine4STEMers needs analysis has revealed the importance of a good understanding of the concepts of perception and deception to develop effective interpersonal skills and, more importantly, to ease decision-making processes in a VUCA (volatile, uncertain, complex and ambiguous) environment.

---

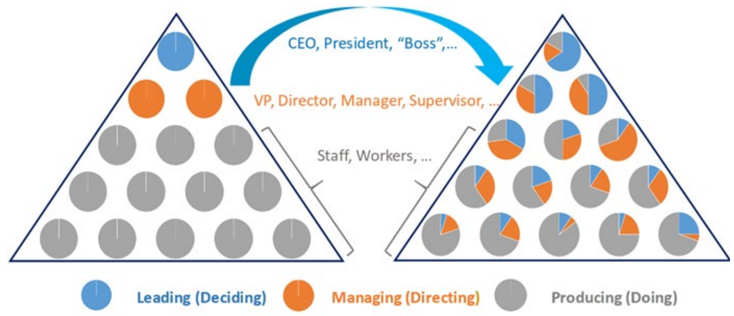
1 INTRODUCTION

1.1 The Engine4STEMers context and motivation

The emphasis of STEM student education has been almost exclusively on acquiring technical and scientific knowledge, leaving a gap in terms of their preparation for the labour market that needs to be filled. In order to cope with fast-changing social and economic environments, STEM graduates are increasingly needing specific personal

doi:10.5821/conference-9788412322262.1334

and professional development techniques aligned to their career evolution in the technology business [1][2]. To embrace continuous innovation, companies are progressively flattering, less hierarchical, evolving from traditional pyramidal and segregated organizations to an organizational model of shared responsibility (Fig. 1). This new and highly demanding context requires the STEM graduate to undertake a rapid change in attitude and work methodology to evolve from a user culture (student) to a service provider culture (employee or entrepreneur) (Fig. 2). That is, moving quickly from a task executor role (doing) to assuming greater responsibility in terms of management roles (directing) and finally to leadership roles (deciding) (Fig. 1).



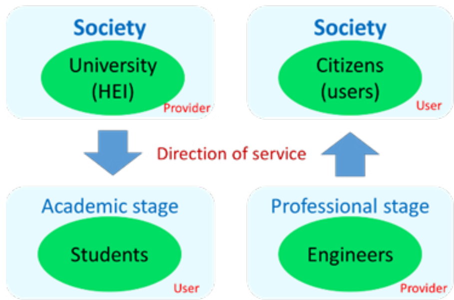


Fig. 1. Companies tend to be flatter and less hierarchical *Fig. 2. Direction of service*

Given the greater than ever impact of technology and engineering in our lives, STEM students are particularly important in leading XXI century societal transformation towards a sustainable and prosperous future, and must be ready to play that role. In this sense, Engine4STEMers aims to develop a set of short teaching and learning modules organized around three themes:

- Early career tools in the tech arena.
- Critical thinking for successful career development in STEM.
- Leadership: the STEM graduate as an effective fair human being

1.2 Critical thinking for successful career development in STEM.

The increasing acceleration of change, the need for continuous innovation, or the reduction in the useful life of products and services, requires a new brand of STEM professionals prepared to deal with VUCA (volatile, uncertain, complex and ambiguous) labour market demands. To attend to these demands, recent surveys give growing importance to social, emotional and higher cognitive skills, such as Critical Thinking, as key transversal competences demanded by employers [3]. In this context, Engine4STEMers aims to provide last year's students with a grasp on critical thinking basics: creativity and innovation, growth by generating added value, creative problem solving and (ethical) engineering design. Critical thinking has also emerged as a crucial skill in decision-making processes to manage the overwhelming amount of information we have to deal with. In addition, given that it is becoming increasingly clear that the information we perceive may be tainted with intentional or unintentional biases intended to influence our behavior, special attention should be paid to developing a skeptical attitude towards the information we perceive, as a fundamental step in the decision-making process. Likewise, STEM graduates must be aware that "what is technically impeccable does not necessarily have to be humanly correct". The motivation of final-year STEM students to start this path is one of the main objectives of the seminar presented in this short paper.

2 METHODOLOGY

2.1 Impact of perception bias on personal and professional development

The first block of this seminar is related to developing how information is generated, transmitted and perceived by people (Fig. 3). The main sources of perception bias are discussed with the students in terms of their impact on the development of personal and professional competences. Discussions focus on three key issues:

-Self-awareness: The seminar uses practical examples to discuss the fact that we do not react to the real world but to how we perceive it. Being aware of potential sources of information bias emphasizes the need to be skeptical, even of one's own beliefs and perceptions. This first section aims to motivate students toward a self-awareness attitude as the first step to self-manage their personal and professional growth.

-Interpersonal relations: The seminar presents how the fact that different people perceive the real world in different ways has a strong influence on how we interact and communicate. This stresses the need to develop open-mindedness and active listening: first, understand, be empathetic, then communicate in a fair, inclusive way.

-Proactivity. Discussions about perception bias and the limitations of self-awareness aim to emphasize the importance of inhibiting the automatic (emotional) reaction to the stimuli we receive. It helps develop the principles of the strong habit of making decisions based on reason rather than emotion. This is important in a number of situations, particularly when risk and uncertainty are involved, as illustrated by an introduction to the principles developed by Nobel Prize D. Kahneman [4].

This first block concludes with an introduction to the concept of selective perception to reinforce the need to be skeptical of the information we receive. It is illustrated with examples of fakes, frames, storytelling, and nudges to engage students in discussions and to raise their awareness of the need to be very proactive in understanding the big picture before any decision-making process.

2.2 Data literacy

The second seminar block is devoted to data literacy. While STEM graduates have a good ability to read, write, and communicate data in context, they are often not fully aware of the main sources of deception that they may have to address due to intentional or unintentional misuse of data (Fig. 3). The implications that data misuse deception can have on decision-making processes are particularly highlighted. To engage students in discussions, this concept is illustrated with examples extracted from the media and the literature [5]. The main sources of bias in (poor) data analysis are also introduced.

Finally, a section is devoted to probability. The general public's low knowledge of probability theory is a major source of non-rational decisions and is highly prone to be used in demagoguery and deception [4]. Students are challenged with probability-related examples to highlight that, in many cases, emotions can be more decisive than reason in decision-making. This section ends with some case studies related to conditional probability (e.g. the prosecutor's fallacy) and the important implications that a deficient understanding of the Bayes' theorem can have on trials or epidemiology studies, given as examples. As discussion exercises, challenged with misleading headlines, students are asked to ascertain the induced message and then to rephrase them in terms of conditional probability to provide a better insight (Fig. 4).

5. How to lie with statistics
6. Misleading graphics
7. Bias in (poor) data analysis
8. Deception by probability

Fig. 3. Critical thinking seminar content

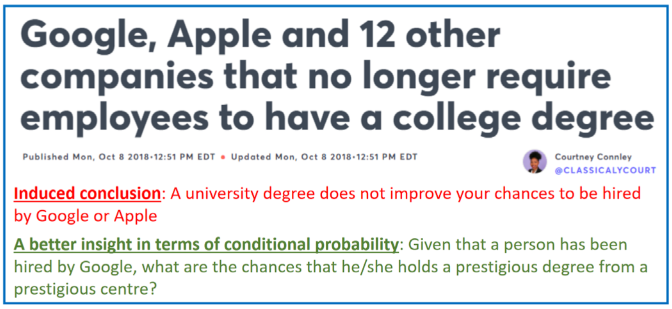

Fig. 4. Misleading headlines

3 CONCLUSION

This short paper presents a seminar on Critical Thinking that focuses on how we acquire and transfer knowledge and the main sources of information bias that a young STEM graduate may have to face. The main objective of the seminar is to introduce STEM students to the concept of perception and highlight the great influence that self-awareness and the knowledge of how others may perceive reality can have on the development of personal and professional skills. It has also been highlighted that, to thrive in the tech labour market, in a fair and responsible way, STEM graduates may have to deal with potential sources of deception in graphs and statistics, with (poor) data analysis, and with people's misunderstanding of probability.

ABSTRACT

This study describes the methodology followed to design, build and operate a pilot green wall treating greywater from a vocational training center. The study was carried out in the framework of a master thesis in Environmental Engineering carried out in collaboration with the vocational training center where the pilot system was built. The system consisted of several pots arranged in rows planted with different species of macrophytes. Results showed a successful removal efficiency of the main pollutants (total solids and organic matter), while further post-treatment would be needed to reduce turbidity and pathogens in order to fulfill water reuse standards. This work shows how teaching in certain engineering studies can focus on sustainability and perform a practical work involving younger students from a vocational training center.

1 INTRODUCTION

1.1. Background and motivation

Green walls are Nature Based Solutions (NBS) able to provide several benefits such as greening, CO_2 trapping, O_2 production, climate regulator, and household insulation. In addition, they are able to minimize wastewater treatment footprint and to provide an onsite solution and a local source of reclaimed water. This technology responds to Sustainable Development Goals 6, 11, 13, 14. However, green walls have only been

[1] *Corresponding Author (All in Arial, 10 pt, single space) Intials Last name e-mail address*

doi:10.5821/conference-9788412322262.1145

used for wastewater treatment in a few specific cases [1, 2] and treatment efficiency still needs to be further proven and optimized before the massive implementation of this technology.

The study consisted in designing and building a pilot plant for the treatment of greywater by phytoremediation in a vocational training center with about 1,000 students, located in Barcelona.

The study was carried out in the framework of a master thesis in Environmental Engineering at the Universitat Politècnica de Catalunya. This included dimensioning, design, set-up, operation and monitoring of the pilot plant. The students from the center were involved in the design, in charge of the construction and actively participated in the operation of the system.

The Center, as a Green School, promotes activities with two objectives: (1) to raise students' awareness of the importance of their carbon footprint, and (2) to use training activities that promote good practices within their profession, encouraging respect for the ecosystem and the fight against climate change.

At the curricular level, the project was developed in the 2nd year of the course on Gardening and Floristry. This is a synthesis and consolidation of the modules related to gardening and plant nursery, and the transversal modules studied throughout the degree.

1.2. Objectives

The main educational objectives of the study were: (i) to consolidate the learning outcomes achieved throughout the course; (ii) to experiment new ways of treating and reusing wastewater for irrigation; (iii) to implement a scientific research through the design, construction and evaluation of a pilot plant; and (iv) to participate in a real and relevant professional context for the Gardening and Floristry sector while promoting the transfer of knowledge between vocational training and the university.

Regarding the research objective, the main goal was to test the feasibility of greywater treatment in a vertical garden at pilot scale, in order to assess the treatment efficiency and the possibility of generating a local source of reclaimed water.

2 METHODOLOGY

The project was based on learning through active methodologies. The most important aspects of the teaching methodology were:

- The challenge of the project was fully contextualized in the reality of the school and in the professional reality of the degree.
- The students worked in self-managed groups with puzzle methodology and specific roles to design the prototype of the pilot plant.
- Each phase of the project presented activities that contained research elements that students, with the support of the teacher, must solve.
- Cooperative teamwork was evident in all phases of the project.

- Diversity was taken into account as students could work at different paces and present prototypes and projects with multiple possibilities, depending on their interests and skills.
- The staff of the university introduced the scientific method in the project and at the same time, positively encouraged students.
- The designs and projects created were shared with the group, looking for spaces and activities. This helped students to contrast ideas, include improvements, and generate new ideas.
- Both co-assessment and student self-assessment had been included, especially with regard to teamwork, oral communication, student autonomy and initiative.

The project required a dedication of 86 teaching hours, spread over 14 weeks, and was divided into the following five phases:

Phase 1. Presentation of the project (challenge) and student's theoretical training, during the first sessions of the module, students received theoretical training on the specific topics and contents of phytoremediation and vertical gardening.

Phase 2. Design of the pilot plant by groups (3-4 people) under the leadership and advice of the university staff. The puzzle learning technique was used in this phase; the roles of responsibility encompass the main areas of work of the project in order to present a prototype to the class. The university advised and evaluated the proposals. From this process, the prototype that best suited the needs of the project was selected. The prototype was designed emulating a 3-step subsurface vertical flow wetland (Figure 1). The system was organized in three rows and four columns. The influent wastewater (greywater from the sinks of the toilets of the center, dosed with primary sludge of a wastewater treatment plant) was fed by drop irrigation pipes on the top row and then percolated vertically through the rows of pots. This configuration enhances oxygenation, hence improving treatment performance. Different substrate materials were tested in the different columns (two columns with mineral and the two others with organic substrate), dividing the system in 2 modules working in parallel.

Phase 3. Construction of the pilot plant, the whole class group worked collaboratively to build the pilot plant (Figure 1).

Phase 4. Commissioning and monitoring of the pilot plant, the pilot plant was started up and then operated and monitored for one month. Samples of the influent and effluent water were took by the students twice a week and transported to the university where the master student performed the lab analysis in order to evaluate the performance of the vertical garden in terms of organic matter, suspended solids, turbidity, pathogens and nutrients removal.

Phase 5. Drafting of a vertical garden to treat the waters of the sink of the center. With the results obtained during the pilot study (loads, retention time, plant species, substrates, efficiency, etc.), the students designed a full-scale vertical garden capable of treating the greywater from the sinks of all the toilets of the center.

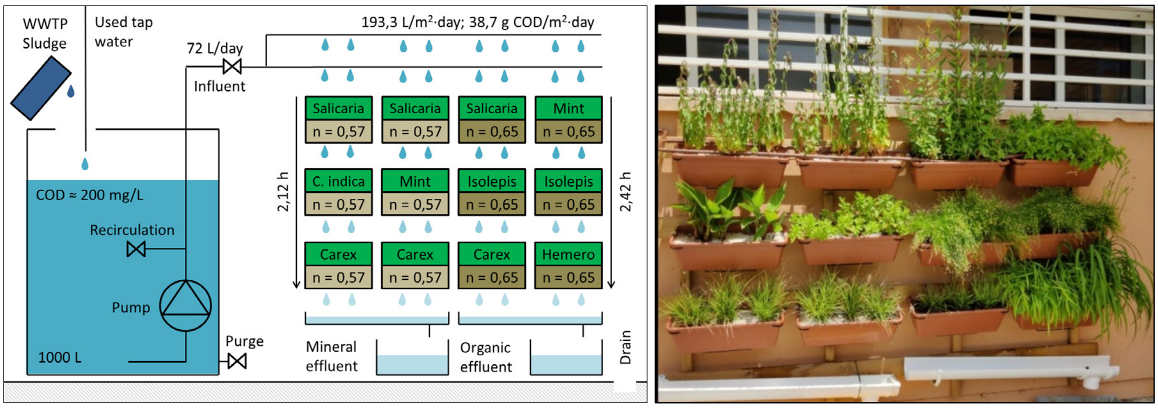

Figure 1. Scheme of the pilot plant (left) and picture of the vertical garden (right)

3 RESULTS AND CONCLUSIONS

The prototype was designed, built and operated and monitored according to the methodology described above. Overall, the expected performance was achieved in terms of wastewater treatment, achieving suitable removal of pollutants (>60% removal of total solids and organic matter), while further post-treatment would be needed to fulfill water reuse standards (turbidity and pathogens).

Moreover, this methodology and this study can be used to respond to different Sustainable Developing Goals. Indeed, nature-based solution applied in the field of wastewater treatment are directly linked with SDG6 (clean water and sanitation) and SDG14 (life below water). Green walls are also a suitable solution for cities, contributing to SDG11 (sustainable cities and communities). Finally, considering the positive effect of green walls in terms of CO_2 trapping, O_2 production and water sanitation, also SDG13 (climate action) is addressed.

Concerning students' experience and participation, a reduction of school absenteeism was observed compared to data from previous academic years. Phases 3 and 4 of the project (construction and monitoring, respectively) were the most motivating activities for students and had the best learning results. These also prepared their problem-solving capability to later develop a full-scale vertical garden project.

This work shows how teaching in certain studies as civil engineering, architecture, and environmental engineering can focus on sustainability and SDGs, performing a practical work involving younger students from a vocational training center.

ABSTRACT

We present preliminary results of a pilot study investigating the reasoning skills of students in logistics and mobility in the context of hydrodynamics. Particularly, we were interested in the students' thinking of parcel flow in logistics and steady-state pipe flow.
Our goal was to investigate if students of logistics would show more, less, the same, or different misconceptions commonly found in students confronted with hydrodynamics problems. We hypothesize that, due to their exposure to flow-like systems (transport chains, band conveyors, hub systems etc.), students develop a certain intuition about flow processes.
Interviews were held with several students that attended "Transportation and Handling Technology" at Hamburg University of Technology (TUHH) in the two winter semesters of 2020/2021 and 2021/2022.
We found that half of the students were unable to solve questions regarding the parcel flow on a band conveyor or the steady-state flow in a narrowed pipe, while the other half of the participants showed the correct understanding of flow processes to solve all the problems. We present evidence that misconceptions about hydrodynamics strongly affected participants' ability to solve logistics problems.
We also discuss the application of our findings for instruction in logistics.

1 INTRODUCTION

In their studies and later careers, students of logistics are confronted with a variety of flow processes, such as transportation on band conveyors, supply chains, hub systems and material transport in mines, factories and harbours. Based on this, we raise the question if these students obtain a certain intuition about the continuity concept. This encompasses the laws of flow processes, mainly the idea that material cannot be lost which leads to various conditions for possible flows.

doi:10.5821/conference-9788412322262.1232

Continuity and flow are usually discussed in physics in the context of hydrodynamics, but students of logistics have rarely contact with a formal education in this field. Therefore, we designed several related questions in logistics and hydrodynamic to shed light on the following research questions:

A) Do students of logistics have any intuition about flow processes and can they transfer these insights in order to solve problems of hydrodynamics?
B) What are their thought processes and possible misconceptions when confronted with these problems?

We know that hydrodynamics problems are often difficult to solve for students of various fields. Whereas this problem is known and relatively well documented for students of physics and engineering ([1],[2],[3]) few studies have been conducted on the intuition and reasoning skills in students of logistics.
Therefore, we are not only interested in the existence of an intuition about the continuity concept, but also in misconceptions the students might have if they lack this intuition. Such insight into students' ideas may help design better instruction for the field of logistics where flow processes play an important role.
There have been several studies concerned with knowledge and skill transfer between known concepts and novel situations [4]. This cognitive ability is troublesome and difficult [5]. Though there are many psychological and didactical models to understand transfer, these lie outside the scope of this paper. For now, we are focusing on observing transfer (or the lack thereof) and will postpone the discussion of appropriate cognitive models to a later point in time.

2 METHODOLOGY

We conducted interviews in January and February of 2022 with four bachelor students who had attended the lecture "Transport and Handling Technology" in the winter semester of either 2020/21 or 2021/22. All students had attended introductory mechanics and math courses but none had had any instruction in fluid mechanics. This makes for an interesting background because we can assume that their intuition about fluid dynamics either stems from logistics or day to day intuition and not formalized education in these fields.
Here we present and discuss two of the four items that had been given to the students. These two items yielded the most interesting responses and give a first look into the understanding of flow processes in the participants.

<u>Question I</u>

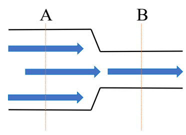
"Two band conveyors (A and B) are serially-connected and are packed with small parcels that are separated by a long distance compared to their own size. At the end of A the parcels fall an band conveyor B and both band conveyors operate with the same speed.
Due to a malfunction, the speed of band conveyor B must be reduced by half of its original speed. After a long time, does the delivery rate increase, decrease or stay the same?

Our expected answer is that the delivery rate stays the same. While the velocity of band conveyor B is halved, the parcel density is doubled. Therefore, the delivery rate stays the same, except for the time the less densely packed parcels need to reach the point where the delivery rate is measured. However, since we want to look at a steady state, students are asked to consider the delivery rate "after a long time".

In this question, the parcel flow behaves like a compressible steady state flow. We wanted to see, if students could make this (or another helpful) connection to solve the problem.

Question II

In the following drawing, we can observe a liquid flowing through a pipe. At one point the pipe narrows. Which statements can be made about the volume flow and the velocity of the liquid? Explain your reasoning.



This is one of the many variants of a common hydrodynamics problem.
As in question (I), the volume flow stays constant; for an incompressible fluid, however, this means, that the velocity must increase.

3. RESULTS

Two of the participants had little to no problems solving the tasks. The other two struggled and revealed some misconceptions about the topic.
We will focus on Participant 2 and 3, who did show misconceptions in their rationale.

3.1 Question I: Failure to see or ignoring the density change

In question (I) the misconception we anticipated is that students might think that it is imperative for the delivery rate to go down after the second band conveyor goes to half its original speed. This misconception is presented well in the following statement from participant 2:

> *"The delivery rate is of course reduced because the velocity is reduced by half. This means the delivery rate is also reduced by half."*

Interestingly, participant 2 did realize that the space between parcels must be smaller:

> *"The same amount [of parcels] reaches the end but later…or slower with a smaller space in between."*

While participant 2 realized conservation of parcels as well as the decreased space between parcels, they did not see a connection to the delivery rate.
Participant 3 had similar problems, even though imagining two identical set ups (1 and 2) next to each other but with one band conveyor system (1) running without malfunction (A1 and B1 have the same speed.).
While they may have realized that the parcels move slower on B2 but with a higher density compared to the unthrottled system they still arrived at the wrong conclusion:

> *"The delivery rate of band conveyor 1 would be of course greater."*

3.2 Question II: Inferring lower flow rate because of decreased diameter

In question (II) we saw similar reasoning. Both participants argued that the volume flow must be smaller due to smaller volume in region B. Participant 2 stated about the volume flow:

> *"Of course, the volume in A is much larger than in B.*
> *(…) Naturally this leads to a jam and the velocity is lower in B."*

Here, the use of the term "jam" even hints at some form of compressibility. According to participant 2, liquid must backlog at the narrowing.
While both first stated that the velocity must therefore decrease, Participant 3 later changed their mind and argued:

> *"Either the velocity stays the same and the flow decreases*
> *or the volume flow stays the same and the velocity increases."*

But they finally decided on the wrong conclusion:

> *"The volume flow is decreased because if the pipe is smaller, less liquid can fit inside."*

We found that the relation between velocity, density and delivery rate/volume flow is not clear for these students.

4. INTERPRETATION

Though small, the study showed interesting results.
Half of the students could solve all questions with ease, the other half showed common misconceptions about flow processes. This suggests that we can indeed expect a certain level of intuition about hydrodynamics from students of logistics.
On the other hand, the results also indicate that some students have similar struggles as other populations and their misconceptions are related to the idea of continuity.
At this point we can only speculate about the exact mechanism that leads to these misconceptions. Both questions are very similar in design. The difference lies in the variables that are fixed by the scenario and the variables that depend on these.
For question (I) it is the velocity that is changed through the malfunction. This leads to an increase in density so that the delivery rate ultimately stays the same. The compressibility adjusts for the reduction in velocity.
In question II the change in velocity is the result of a disturbance (narrowing), not the disturbance itself. But since the density cannot change, the velocity must increase. In either case the flow rate stays the same.
One could argue that the students have the same intuition about both problems: that a change in velocity must lead to a change in flow rate.
In both scenarios, compressibility and its implications are not well understood.
In question (II) students failed to see the incompressibility therefore concluding that the flow rate must decrease. In question (I) they recognize the compressibility but do not see its implication for the (unchanged) flowrate.
Interestingly, the conservation of mass seems to be clear. The liquid in question (II) cannot disappear, therefore there must be a jam at the narrowing, participant 2 argued. This is, in this mind set, a logical conclusion. The concept of continuity

seems to be understood to some extent but it cannot be brought to its practical and logical conclusion.
Question (I) might reveal a certain confusion about the steady state character of the problem. Future questions might adjust for that by rephrasing the problem in terms of comparison of two time independent situations.
Further study is needed to pinpoint the exact mechanism of these misconceptions.
The results encourage us to look further into the reasons why some students of logistics seem to be able to handle hydrodynamics problems well and how this transfer of intuition, and its failure, works.
During the upcoming semester, we plan to interview more students of logistics to get a broader picture of their reasoning skills.
Our findings suggest an early and focused treatment of flow processes in logistics education, with a special emphasis on the underlying principles of continuity and (in)compressibility.
Since the first submission of this paper, six more interviews were conducted. These showed similar results and opened up a deeper view of the subject. The combined results could not be submitted in this paper, but will be discussed in the presentation of our work at the SEFI Annual Conference in 2022.

Acknowledgment

This study is part of the GENERATING project [6], funded by the German Federal Ministry of Education and Research (BMBF).
We want to thank Ferdinand Kieckhäfer and Dimitri Eckert for their support during and feedback after the interviews. We also want to thank Dion Timmermann for his substantial support during the whole research process. We want to thank Ole Grasse for giving us the opportunity to addend logistics tutorials and to get in touch with the students.

ABSTRACT

Education focusing on developing interdisciplinary skills is gaining traction in Higher Education. Often this type of education takes shape through project-based learning. Prior research shows that the focus of such interdisciplinary learning should lie on attaining synthesis and that the end result of an interdisciplinary project should be more than the sum of its disciplinary parts and be truly synergetic. Two important prerequisites of successful interdisciplinary (project)work are reaching a common goal in which each discipline is of added value towards synthesis and attaining a common ground of methods, concepts and views.

In this research project, the focus was on mapping if students were able to reach a common ground and synthesis during working on an interdisciplinary project. The context is the Smart Solutions Semester of Saxion University of Applied Sciences, where third- and fourth-year students from three or more (engineering) disciplines work together in project teams on large (25 ECTS) projects, provided by research groups and the business community. A learning activity was developed for and conducted with four student teams after which semi-structured interviews were held with the students and corresponding tutor. Results confirm the importance of a common goal and common ground. Additionally, results show the importance of fostering interdisciplinary exchange and the crucial role of the tutor in guiding students toward synthesis.

1 INTRODUCTION

1.1 General introduction

Complex challenges in society ask for innovative, out of the box, solutions. These solutions often take shape by utilizing various perspectives and ideas, both within and between disciplines. Interdisciplinary group work is increasingly present at universities, focused on fostering skills for students to work on these complex challenges. At Saxion this takes shape in the Smart Solutions Semester (3S). In this semester students from various disciplines work together in project groups on large, complex challenges which are provided by the business community and research groups. One of the goals of the 3S is to challenge students to cross their disciplinary boundaries towards creating ‘smart solutions’.

1.2 Theoretical Framework

Various definitions and interpretations of multi- inter- and transdisciplinarity exist. During this research the following definition of interdisciplinarity has been used: *"The capacity to integrate knowledge and modes of thinking in two or more disciplines or established areas of expertise to produce a cognitive advancement, such as explaining a phenomenon, solving a problem, or creating a product, in ways that would have been impossible or unlikely through single disciplinary means"* [1. pp. 219]. In concrete terms this means that **synthesis** between disciplines is crucial on both the project level and the subtask level [2].

Four processes are key to interdisciplinary collaboration [2].The first being **setting common goals**. This first step concerns matching the correct disciplines to the complex challenge at hand and identifying the added value of each discipline. Subsequently a **common ground** has to take shape. This entails further exploring the added value of each discipline concerning knowledge, methodologies, terminologies etc. to obtain a common framework from which the challenge can be addressed. During the entire project it is important to foster an attitude of **critical awareness**, e.g. being able to constantly reflect on the possibilities and limitations of each discipline concerning the complex challenge. Finally, students should constantly aim for **synergy**, e.g. interdisciplinary collaboration on the complex challenge at hand should be more effective and rewarding for participating disciplines compared to going at it by themselves. To obtain a common goal and a common ground students should understand and appreciate the perspectives of students from other disciplines [3]. Fostering **interdisciplinary exchange** revolves around being able to relate their own disciplinary perspectives and matching motives and intentions to the motives and intentions of students that are grounded in/based on other disciplines.

Interdisciplinary exchange concerning the complex challenge thus is the core of the initial phase of an interdisciplinary project. Prior research [4] showed that students in the 3S struggle to exchange, utilize and integrate disciplinary knowledge. Therefore, the focus of this current research is to map if students were able to reach a common ground and attain synthesis during their 3S project.

2 METHODOLOGY

2.1 Context

This research project was executed during the 20/21 academic year. Two researchers (e.g. the first and third author) were involved in the data gathering. The research took place in the 3S, in which third- and fourth-year students of 22 bachelor programs collaborate in interdisciplinary project groups of 6-8 students (25 ECTS). Over a 1000 students and 100 tutors work and learn in this semester. During the semester students develop competencies in three domains: professional behaviour, application and development of research capabilities and application and development of knowledge and skills from their own and other disciplines. Each project group is supported by a tutor.

2.2 Research questions and design

The main focus of this research was identifying to what extent students are able to obtain a common ground through interdisciplinary exchange whilst working and learning in an interdisciplinary project group and to what extent they are able to reach synthesis. A learning activity (see 2.3) to foster interdisciplinary exchange was designed and conducted with four project-teams (see table 1 for their composition), five weeks after the start of the semester. This session took place online and was recorded. The four teams participated in a focus group which took place within two weeks after the learning activity. The focus group was partly semi-structured around the four processes crucial to interdisciplinary collaboration and partly based on questions concerning recorded chapters from the learning activity. The focus of the interview laid on both project-work leading up to the learning activity, as well as the learning activity itself. Furthermore an interview took place with the tutor of each group, leading to three interviews (one tutor was absent). This interview mimicked the semi-structured part of the focus group interview with students. Because of Corona-measures, all these interviews took place online via Teams.

Table 1. Composition of project-teams

Case	N	Disciplines
1	6	Nursing (4), Information and Communication Technology (1) and Creative Business (1).
2	8	Forensic Research (1), Civil Engineering (3), Archaeology (2) and Mechatronics (2)
3	7	Nursing (3), Industrial product design (1), Technical Informatics (1) and Creative Business (1)
4	6	Archaeology (2), Forensic Research (1), Technical Business Administration (1), Information and Communication Technology (1) and Creative Business (1).

2.3 Learning activity

The goal of the one-hour learning activity was fostering interdisciplinary exchange to reflect on if a common ground was attained. One researcher led the learning activity and the tutor was not present during the activity. The learning activity was based on the concept of triangular reflection [5] and revolved around three subsequent activities. Students were asked to complete a mindmap in which they both explained the added value of their own discipline for the challenge at hand and reflected on the added value of the other disciplines within the project group. The first phase was aimed at *exchanging* relevant disciplinary knowledge and skills from their own discipline. The second was aimed at *creating* the coherence between disciplines and the complex issue at hand. The final phase was aimed at *reflecting* on how to integrate interdisciplinary knowledge and skills throughout the further course of the project.The researchers challenged students to put under words their own perspective concerning the complex issue, but also explain how and why the other disciplines were of added value for solving the complex issue.

3 RESULTS

3.1 Common ground and synthesis

An analysis within and between cases was conducted focused on whether a common ground and synthesis was attained within the cases. A rubric for ranking interdisciplinary work [6] was used to determine the amount of interdisciplinarity in each group. Results showed that only one group was partly able to attain synthesis.

Several factors negatively affected the ability of students to reach synthesis. Firstly, the complex challenge was not truly an interdisciplinary challenge in three out of four cases and did not offer the possibility for interdisciplinary collaboration aimed at synthesis. Students noted they did not see the “match” between their own discipline and the challenge. In addition, students did not have the opportunity to decide the common goal for the project because in two out of four cases this goal was already set by the client. Furthermore, even if the challenge offered the opportunity for student goal-setting and synthesis, students often organized themselves multi-disciplinary by working with for instance only the nursing students on sub-tasks, since synergy was not necessary for solving the challenge. Finally, only one out of four project groups focused on interdisciplinary exchange prior to engaging in the learning activity and was able to reach some sort of common ground. Critical awareness thus was not fostered during working on the project. The 3S is the first time for most students to engage in interdisciplinary collaboration. Whereas students have no or limited interdisciplinary skills when enrolling in the semester, these need to be fostered in order for them to reach synthesis whilst working on complex challenges.

Support offered by the tutor on guiding students to attaining a common ground through interdisciplinary exchange differed between tutors. Mostly tutors mentioned the importance of getting to know each disciplinary background, but left it to students to take action on engaging in this dialogue. Results showed tutors focus mostly on supporting research activities of students and on personal introductions. Professional (disciplinary) introductions and disciplinary orientation concerning the complex challenge received little attention by both students and tutors. Possibly tutors lack the insight in the importance of fostering interdisciplinary exchange, which led to them being passive on this matter.

3.2 The learning activity

Students from all four cases responded positively to engaging in the learning activity. The level of perceived impact of the learning activity differed based on the phase of interdisciplinary collaboration. When students had not yet engaged in any interdisciplinary exchange and working towards attaining a common goal and common ground, the learning activity made them aware of the importance of interdisciplinary exchange. When students already had engaged in interdisciplinary exchange prior to the learning activity, participating in the learning activity invited them to elaborate on their insights concerning the common goal and common ground. It led to confirmation of their own insights related to the insights of other group members.

3.3 Recommendations

This exploratory case study further strengthens insights concerning interdisciplinary collaboration. Although the number of cases was limited, combined with the prior research mentioned earlier [3], it is plausible that a larger number of students within the 3S and within higher education in a broader sense are unable to reach synthesis during interdisciplinary collaboration. Four recommendations are at the core of improving and fostering interdisciplinary collaboration in higher education when working on complex interdisciplinary challenges. First, to be able to collaborate interdisciplinary, it is important for students to be able to work on complex and **ill-defined challenges** where they truly have enough room and **autonomy to set or adjust the common goal**. This allows them to consider whether and by which means their discipline can be of added value for reaching synthesis. Second, to encourage interdisciplinary exchange, **learning activities** can play a crucial role, for example focused on **reflecting on disciplinary knowledge and skills** related to the complex challenge. Third, when guiding students during interdisciplinary collaboration, **tutors** play an important role in guiding students when working on complex challenges. By showing tutors the means through which they can foster interdisciplinary collaboration and offer them opportunities for practice, the impact on student learning should increase. Finally, when developing interdisciplinary education, it should be taken into account that this requires **complex skills which should be developed throughout the curriculum**. It is important that students are offered opportunities to get acquainted with interdisciplinarity early on in their studies. This allows them to realize and determine when interdisciplinarity is of added value and which processes are important to take into account when working on complex challenges across disciplinary boundaries.

ABSTRACT

Educational transformations require educators with competences to deliver quality education. This raises the issue about capacity building in staff and in particular in the engineering disciplines where pedagogical practices are heavily reliant on didactic approaches such as traditional lectures and tutorials. The global Covid19 pandemic has forced educators to move away from traditional approaches and although the response was quick it is unclear if many of these changes will remain in future, given that they were not done by design but as a reaction to the unexpected situation. This study considers the training of engineering educators in different engineering disciplines and in a number of higher education institutions in Zimbabwe who were part of a HEPSSA-Royal Academy of Engineering UK project. At this conceptual stage the study explores how effective capacity building activities are in enabling educators to transform their practice to an active student-centred approach both in face-to-face and online modes. It further explores how the training experience might empower educator's sense of agency and change their identity within the boundaries of their institutions and country. The research design is grounded on the theories of agency and, self-efficacy and motivation. It uses an interpretative approach, Qualitative Content Analysis, for the analysis of data collected via interviews with the engineering educators participating in the project. This research design aims to find how engineering educators can be supported through their educational transformation journey and also to inform policy makers at institution and national level in order to enhance sustain development.

1 INTRODUCTION

1.1 Background

The socio-economic development of Zimbabwe requires capable engineers able to face current and future challenges in the country. This makes it essential for institutions delivering on engineering education to consider the best approaches to provide students with opportunities not only to develop their knowledge but also the skills for meeting societal needs. Didactic pedagogies where the students are passive recipients of knowledge [1, 2] are the most common current approaches in compulsory education in sub-Saharan countries [3]. These same practices persist through higher education, and, until recently, were prevalent in engineering education in Zimbabwe, hindering opportunities for students to develop professional skills. Pedagogical approaches that are student-centred and promote active learning support the development of professional skills [4, 5] so needed by graduates to be able to face new and uncertain career situations.

Although Kurasha and Chabaya [6] conclude that curriculum development in higher education should adapt to global trends Tabulawa [7] argues that past failure of educational reforms from didactic approaches to student-centred approaches has not been based on deficiencies in the implementation of innovation but rather in the oversight of the socio-cultural context when trying to embed new pedagogical practices. The epistemological stance of educators and their perception on the purpose of education as well as social structures plays a key role in determining the success of sustained pedagogical change in schools [7].

Clearly, educational transformations required not only changes in systems and structures but also educators with competences to deliver quality education. This raises the issue about capacity building in staff in relation to adequate pedagogies for professional skill development and how we can establish what support is needed and why educators might or not be inclined to change their practice.

In 2019 the Zimbabwean government launched their Education 5.0 initiative as a policy driven approach to support the transformation of the higher education sector in areas of education, science and technology [8].

The Higher Education Partnerships in Sub-Saharan Africa (HEP SSA) scheme, supported by The Royal Academy of Engineering through the GCRF-Anglo-Platinum Foundation, focuses on training engineering educators in the broad range of academic activities and to enable them to build their capacity in research and teaching and in turn transform the educational landscape of their country. It is within the context of a project sponsored through the HEPSSA programme in Zimbabwe that the current research is situated. Pedagogical transformation in practice requires more than simply participating in a set of training activities. The socio-cultural and professional context of educators needs to be carefully considered if changes are to be sustained. The questions that this study explores are how do capacity building and training activities impact on the development of the engineering educators' agency and identity and how these activities can produce sustained change.

1.2 Theoretical framework

A critical element of this study is the importance of context and the understanding of the individual's experience and their social constructions and, therefore, this study is framed within the Interpretativist paradigm [9,10]. In addition, the theory of human agency [11] serves as a framework to guide the research design and later as a lens to interpret the data. The research design is primarily guided by the ideas that individuals as agents can self-regulate their actions and influence themselves and the environment around them. Similarly, individuals do not operate in isolation but rather in socially situated contexts given raise to interpersonal transactions where each one can act as someone else's environment. A key element, within Bandura's theory of human agency, that is relevant to this study is the idea of self-efficacy which is a key aspect associated to personal development and change [11].

Based on different approaches to agency Eteläpelto et al. [12] have conceptualised the idea of professional agency at work, that is, an approach to agency that pays "attention to [the] subjects' construction of their identity position at work, and focusing on how they negotiate agency in education and working life in order to construct meaningful careers and life courses". Given that the current study considers the socio-cultural context as critical in understanding the potential success of pedagogical training, this approach will serve as a lens for the data analysis.

2 RESEARCH DESIGN

This study is specifically defined within the context of two workshops, with participants from a range of institutions and industries, were carried out at different points in time during the life of the HEPSSA project and, led by Midlands State University in Zimbabwe. The first workshop (early 2019) focused on participants' discussions about state-of-the art of curriculum in Zimbabwe whereas the second workshop (late 2020) was delivered online and focused on active-learning and student-centred pedagogies including online delivery.

The analytical approach considered to explore the data is Qualitative Content Analysis which in line with the questions to be explored [13]. Data will be collected via means of interviewing engineering educators working in different engineering disciplines within different higher education institutions in Zimbabwe. The interviews are carried out online and recorded for subsequente transcription. Only people who participated in the capacity building activities of the project were invited to take part in this study. Ethical approval has been obtained from the University of Strathclyde Departmental Ethics Committee.

3 SUMMARY AND ACKNOWLEDGEMENTS

Data collection has unfortunately been delayed due to slow participant recruitment and interview availability. Results and analysis are not available yet as interviews are being conducted. However, the research design and theoretical framework used for the study of 'professional identity' [12] provides benefits for the larger engineering community. The review of the literature reveals that any educator training needs to attend to the local needs and cultural expectations of those participating in the learning process (i.e. students and staff alike). Sustained change requires to alter the epistemic stance of educators in relation to their belief about knowledge, the goal of education and their roles as educators. This study will provide answers to these questions and will help to inform policy making.

ABSTRACT

Information and communications technology (ICT) engineers play a key part in our society's digitization process. To foster that role, the Castelldefels School of Telecommunications and Aerospace Engineering (EETAC) of UPC's Degree in Network Engineering currently includes a new competence termed digital awareness. This report demonstrates the initiative's first outcomes, including the teaching resources created, and feedback from students and teachers. In addition, the findings of a high school poll are presented, indicating a high level of interest in this new competence.

1 INTRODUCTION

1.1 Context

The digitization of our society is most likely the first technology transformation that can be termed universal and essential. In this era, controlling individuals' data, the digital gap, fake news, algorithm bias, and cybercrime are all key issues that society, governments, and corporations are dealing with at the moment. Engineers in ICT play a vital role in this challenge. To overcome this, we feel it is critical to introduce a new competence known as digital awareness into their education. Its goal is to analyse both the positive and negative elements of a certain technology or technical solution, and to provide guidelines not only for its design, which should adhere to digital awareness guidelines, but also for its righteous use.

Digital awareness relates various topics linked to the safe and responsible use of technology, which we categorise as follows [1]: digital wellness, cybersecurity, reliable information, digital identity, online education, digital parenting, digital inclusion, digital development, data protection, and digital citizenship. Some of them can also be found in the new release of the European Digital Competence Framework for citizens [2]. Currently, we are incorporating digital awareness competence into the Castelldefels School of Telecommunications and Aerospace Engineering (EETAC) at UPC's Degree in Network Engineering following the plan presented in [1]. Note that the number of girls enrolled in this degree is below 20% [3].

1.2 Motivation

This paper aims to show the initial results of this initiative. The educational materials designed and their level of success, are determined by conducting a poll research and comparing the results to instructor evaluations.

One additional reason for building this ability is to investigate the impact of technology on society, thereby providing a social viewpoint to engineering courses, which is often lacking. This new perspective has the potential to increase the number of girls pursuing technical education [4][5]. Then, we provide the preliminary results of a poll conducted in high schools to determine whether acquiring this new ability could increase the attraction of this degree, with a special focus on the interests of female students.

2 METHODOLOGY

2.1 Introduction of the competence in the degree

Five topics related to digital awareness have been introduced this academic year. Taking Bloom's taxonomy [6] as reference, the competence is presented in "Business Management" (1st course) and understood in "Internet Architecture and Protocols" (2nd course); the upper levels of the taxonomy are worked in "Mobility Networks and Services", "Applications Engineering", "Network Security" (3rd course) and, in the future, in the bachelor thesis (see the syllabus here [7]).

To work the competency, audiovisual content is used, typically one video for each subject. Teachers offer a description of the video material and supervise the script, which is generated by a specialised firm, as well as the production, which is handled by the campus's audiovisual services. A single video [8] was created and tested during the first semester test this approach. Teachers used it in the project-based course "Applications Engineering" to convey the notion of digital awareness in the context of their subject matter, so that students may incorporate it into the design, execution, and presentation of their project. The competence is addressed similarly to any other evaluable part of the project. In other words, its progress is reported on in follow-up meetings, and its execution is evaluated in the project presentation. In other disciplines, the videos created will be used to develop H5P-based interactive elements that will aid in the competence evaluation.

2.2 Poll-based study

A survey was carried out at the end of the first semester to assess the introduction of the competence in the "Applications Engineering" subject from the student's perspective. Its findings are compared to the data provided by the teachers. During the second semester, a more comprehensive investigation was conducted among students from three high schools: two in the province of Barcelona, and one in the province of Tarragona. We asked 26 questions in four blocks concerning the film itself, its content, as well as their interest in studying engineering and, in particular, ICT, and the viability and relevance of adding social impact concepts such as digital awareness in their studies.

3 RESULTS

3.1 Undergraduate students

All 17 enrolled students responded to the survey by offering examples of their digital awareness projects. However, some of the responses show a superficial or possibly incomplete attainment of the competence. The feedback supplied by teachers reinforced this perception. Better results are expected when students have worked on this competence in multiple disciplines. A whopping 94.1% believe they will use this skill in their careers. Concerning the film itself, teachers have used it as a classroom material, and 94.1% of students agree it is beneficial for presenting digital awareness content.

3.2 Secondary school students

We received 221 responses, with 46.6% male (blue), 48.9% female (red), and 4.5% undefined. The distribution of courses is as follows: 27.5% from the first compulsory secondary education course (12 years old), 5% from the second, 30.6% from the third, 21.2% from junior high-school, and 15.8% senior high-school. Regarding the response values, 5 signifies "strongly agree" and 1 means " strongly disagree."

Figure 1 illustrates that the concept of digital awareness is relevant to most people (98.2% ≥ 3). The average values, shown by dashed lines reveal only minor variances across genders. When asked if app developers should follow digital awareness guidelines, students responded in a similar way". Fig. 2 shows a poor interest in following engineering studies, particularly among females: 18.45% more girls are not interested (answers ≤ 2) in these degrees, while 15.03% more boys are (answers ≥ 4). Respondents' interest in a subset of engineering degrees, namely the ICT area, deteriorates slightly, as expected: 48.4% rate it as 1, and 19.6% rate it as 2, showing similar gender disparity.

When it comes to the appeal of including the social impact of engineering and digital awareness in engineering or ICT degrees, respectively (see Fig. 3), the global responses are quite balanced. Looking into the level of studies and gender, senior high-school students show the highest interest, with girls having higher average values than boys: 3.71 vs 2.83 for adding the social impact of engineering, and 3.73 vs 3.16 for digital awareness inclusion in ICT degrees. This is also noteworthy given the poor interest in engineering and ICT degrees, with average values of 2.33 and 1.85.

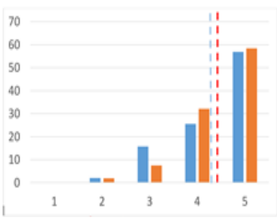

Fig. 1. Importance of digital awareness

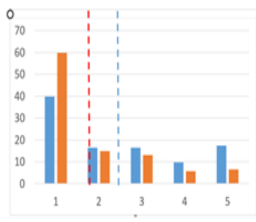

Fig. 2. Interest in follow a engineering degree

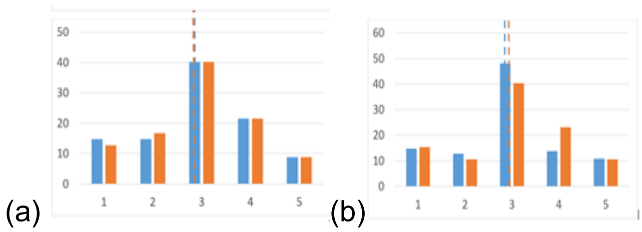

Fig. 3. Attractiveness of social impact of engineering (a) generic (b) digital awareness in ICT degrees

Both studies show the interest in the digital awareness concept. For undergraduate students, its incorporation as a competence will demonstrate if, as in the situations discussed in [5], more EETAC girl students pick the Degree in Network Engineering at the end of the common courses. Concerning secondary school, our aim is to conduct studies related to talks and experimental activities similar to [4] but focused on digital awareness, to better know its capacity to attract girsl to ICT degrees.

4 ACKNOWLEDGMENTS

This work is supported by the teaching innovation project “Introduction of the competence of digital awareness in the degree of Degree in Telematics Engineering”, ICE-UPC 2021. The authors would like to express their gratitude to the "Applications Engineering" teachers and students, as well as the teachers and support personnel who made the high school survey possible.

ABSTRACT

Maker education has been shown to effectively raise children's interest for STEM subjects. Creative maker activities, which mostly take place in informal learning environments such as museums and libraries, hold potential to teach children scientific concepts and train cognitive abilities that are critical to success in engineering in an engaging way. One of these often-overlooked skills fundamental to STEM is spatial ability, which is known to commonly function as a gateway skill to STEM disciplines. Spatial ability is malleable, and training can effect gains not only in psychometrically assessed spatial ability but also in mathematical skills, further demonstrating its importance to STEM learning. In practice maker education often lacks explicit pedagogical attention to the development of scientific skills and cognitive abilities such as spatial ability, instead overemphasising technological skills, and thus limiting its potential to increase learning related to science and engineering. Therefore, maker education practice would greatly benefit from a pedagogy that recognises spatial elements and scaffolds spatial ability development. In this paper the opposing pedagogies that lie at the roots of the maker education

and spatial ability education are examined, as a prerequisite step to redesigning maker education practice. The final aim is to transform maker education practice into a STEM learning practice through which spatial ability development is scaffolded and can be assessed. This would help realise maker education's potential for scientific learning and may help a wider audience to meaningfully partake in STEM-related activities from a young age.

1 INTRODUCTION

1.1 Maker education

'Making' is often described as using both high and low-tech prototyping tools to design and build physical and virtual objects [1]. Over the last decade, this type of activity has garnered significant interest from educational circles [2]. The type of activities that have come to be known as 'maker education' have their roots in the progressive and constructivist tradition of education and take place in both formal and informal education settings [2]. Maker education interventions in schools have been shown to successfully improved self-reported measures such as motivation for STEM [3]. Throughout Europe, South-East Asia and the United States, informal learning centres have also emerged in places such as museums and libraries [2]. Aimed mainly at children of primary-school age, and sometimes secondary-school age, activities in these makerspaces generally revolve around a playful process of iterative problem solving of an open-ended or challenge-based task with a strong emphasis on the children's creativity [4].

1.2 Potential for STEM and spatial ability learning

Educational maker activities have been ascribed significant potential to link science and technology learning in a creative way [2]. An important feature of these activities is the ability to break the commonly-held belief of a dichotomy between hands-on and intellectual work. Scientific concepts such as e.g., force, friction, momentum, motion, or electrical circuitry become tangible as they are explored as integral parts of the educational maker activities the children take part in [2]. Furthermore, children realise that they can engage with scientific matter, instilling a positive attitude toward science and engineering from an early age [4].

Fig. 1. Typical project integrating crafts and electrical circuitry from a library maker education workshop

Through the creative and constructional characteristics often found in maker education activities, there is significant potential for the development of spatial ability. Spatial ability is often overlooked in traditional education, but the critical role it plays to success in STEM disciplines, particularly engineering, has become increasingly clear [5]. For a variety of reasons, from lack of access to spatial toys to gender-related stereotypes, girls and children of low socioeconomic status tend to underperform on measures on spatial ability [6]. Through educational maker activities, children could be reached with activities that would help them develop this crucial cognitive ability.

2 DEVELOPING SPATIAL MAKER PEDAGOGY

2.1 Maker education practice – potential and limitations

The term 'making' originates from a movement of people gathering in shared spaces, referred to as makerspaces, where members of a community, club, or university can make use of shared traditional workshop tools as well as more technologically advanced prototyping tools such as 3D printers and laser cutters [7]. Maker education efforts taking place in out-of-school contexts such as museums and libraries form the bulk of implemented interventions and hold significant promise for reaching a wide variety of children [2]. Most maker education efforts are rooted in the belief that letting children explore the available prototyping tools will give children unique learning opportunities and allow them to express themselves creatively [8]. This mirrors the way in which professional designers use these tools to ideate and prototype to explore solutions, which is described by Kirschner as confounding epistemology for pedagogy [9]. Within this constructionist pedagogy, children are supposed to construct an understanding of e.g., scientific elements as a natural by-product of the self-defined projects in a makerspace [10]. In contrast to other forms of constructivist/constructionist forms of education such as project-based learning and design-based learning, maker education activities often lack explicit attention to pedagogy [2]. However, contrary to this constructionist approach to learning, in practice maker education activities are often extensively planned and pre-structured by facilitators due to the technical skills required to make use of typical ‘maker tools’ found in makerspaces and the time constraints of (after-) school activities [4]. The current value of these activities to participants’ STEM learning is questioned by educators, as scientific learning is most often not explicit and not actively assessed, and if present, is subordinate to the successful use of the technological tools to create an attractive product during the activity or workshop [1][2]. Furthermore, studies on teacher preparation and effectiveness of maker education activities, both in formal and informal education settings, are not well-represented within the maker education literature [8]. Despite these current limitations, maker education holds significant potential, particularly as a valuable form of additional education in parallel to formal curricula, with room for multiple epistemologies; room for exploration and creative freedom, while also integrating explicit learning about scientific concepts in hands-on way, to bring engaging STEM-learning to a wider audience.

2.2 Approach to training spatial ability

Recent interventions aimed at developing spatial ability have generally centred around direct instruction aimed at improving the performance on tests measuring the psychometrically determined factors of spatial ability. One of the most illustrative examples of this is an extensive course that has proven to be effective at developing spatial ability among first-year university engineering students, showing that through well-structured direct instruction and scaffolding of activities spatial ability can be developed [5]. Similar examples of successful spatial training exist for younger age groups in primary school [11] as well as middle school [12]. The educational approach taken in these interventions is seemingly opposed to that in most maker education efforts. However, there is a good indication that construction activities with an emphasis on spatial elements within them will particularly help children to develop spatial ability [13]. The hands-on creative design activities often associated with maker education thus hold potential to not only teach scientific concepts, but also to significantly aid the development of spatial ability of participants. This could be realised by creating applied and hands-on instructional elements within maker education activities that specifically elicit the same mental transformations also elicited by paper-and-pencil tests that measure spatial ability. To effectively develop spatial ability through maker education activities it is crucial to develop an effective pedagogy for spatial maker education.

3 DEVELOPING AN EFFECTIVE SPATIAL MAKER PEDAGOGY

3.1 Scaffolding of spatial concepts and transformations

By emphasising and scaffolding specific spatial transformations described in the psychometric literature, similar to the direct training of spatial skills [5], maker activities can be developed to aid in the development of spatial ability. This could be done through making spatial transformations required steps of the activity and slowly increasing the complexity of those steps as integral part of the challenges posed to the participants. Maker education can employ pedagogical approaches from crafts and design and technology education, utilising clear instructions and a strong emphasis on first sketching and copying, after which the reins are gradually loosened to allow for more creative freedom and increasing the cognitive load on factors of spatial ability. Therefore, activities need to be designed that take this type of spatial scaffolding as a core element of the activity. This will also allow facilitators to assess the spatial ability development of participants during the workshop.

3.2 Assessment of spatial ability

To develop spatial ability effectively through maker education activities, it would be beneficial to allow facilitators to assess the spatial ability of participating children during the activity. The assessment of spatial ability usually relies on the use of psychometric tests, as it relies on internal thought processes [14]. Especially within maker education, where constructionist pedagogy is leading and success is hinged on children's voluntary engagement with the activity, it is less suitable for facilitators to extensively test children with these paper-and-pencil based tests. First attempts have been made to develop assessment resources and strategies to identify children's use of spatial reasoning during play-based activities [14]. For example, through identifying the use of non-verbal cues such as gestures, movements, and creative output within the context of play-based spatial activities, educators' ability to assess spatial reasoning was improved, allowing for the children's learning to be supported [14]. Within a maker education activity this could for example be realised by assessing the performance on the scaffolded spatial transformations that are required throughout a pre-designed spatial maker education activity. For a facilitator to assess a participant's spatial performance on the targeted spatial transformations, a tool that allows a facilitator to assess the participants' spatial ability more informally during activities will be particularly effective. As this type of more informal assessment can happen during the activities, it will allow facilitators to intervene to scaffold the activity more actively with struggling participants with low spatial ability.

3.3 Professional development for spatial maker pedagogy

For this pedagogy to be implemented successfully, it is imperative to train facilitators to integrate these elements in their teaching practice. Therefore, future work will consist of an approach taken around professional development of educators, akin to training for spatial ability education [11][12], applied to a maker education context. Assessment of the effectiveness of the proposed pedagogy for maker education is centred developing a mixed-method design to qualitatively assess and co-design the pedagogy in practice, and quantitatively assess its effects on participants' performance on traditional psychometric measures of spatial ability.

4 SUMMARY AND ACKNOWLEDGMENTS

The creative construction element of maker education holds significant potential for increasing spatial ability by exposing children to spatial elements in a crucial stage of their development. This could be of particular benefit to those who are generally underexposed to activities and toys of a spatial nature in childhood, a group that is over-represented by girls and children of low socio-economic status. This short paper argues for the development of a spatial maker pedagogy that considers how to scaffold and assess the development of spatial ability. By adding a spatial pedagogy, maker education practice could be advanced from an engaging way to increase motivation and interest in STEM into a worthwhile STEM learning practice that fills a gap of creative craft-related teaching and spatial ability development.

ABSTRACT

We participated in collaborative development of more than six hundred comprehensive online teaching materials for higher professional schools in the Czech Republic. The paper focuses on explaining the procedures and methods that we used to make the development process as efficient as possible, which was necessary with respect to the quantity of the materials and the limited time. Managing the logistics was the key, as several hundred people took part in the project. We are also describing, from the edagogical point of view, the OER structure, its division into educational blocks, and types of educational objects.

1 INTRODUCTION

1.1 The Project in a Nutshell

Our department had the opportunity to collaborate on three major nationwide projects that focused on innovation in higher professional education. Within this project, we were in charge of the complete provision of the technical and logistical background for the development of so-called Open Educational Resources (hereinafter referred to as OER). The assignment was – in addition to ensuring high professional quality, which was based on the selection of authors and other creative staff – to guarantee smooth progress of this demanding operation (orchestrating the work of more than 600 people to develop more than 600 OERs) as well as high quality of the ouputs (in terms of graphics, form and structure). It is also very important that all ideas, guidelines and recommendations for the authors (as well as for other creative) staff had to be available before the start of their work; that is, at a very early stage of the project, when it was not yet possible to imagine all the situations that might arise. The completed OER set is available in the library [1].

1.2 Context and Motivation

The project activities builds on our long-term (since the 1990s) efforts in the field of modern teaching methods, modern education and innovative work in the field of pedagogy and didactics.

As for the high-volume development of teaching materials, their largest numbers can be observed in relation to various MOOC platforms, such as edX, Coursera, FutureLearn and many others. However, such teaching materials are comprehensive courses, while the discussed project aims to create supplementary teaching materials, usually for blended learning. What they have in common with the courses provided on the MOOC platform is their openness, i.e. unlimited free access, as the licenses from the Creative Commons family apply to the newly developed OERs.

Large-scale production of online materials is more common in the commercial environment, often without the possibility of general access to the outputs. In this sense, our open-source project is unique in a way.

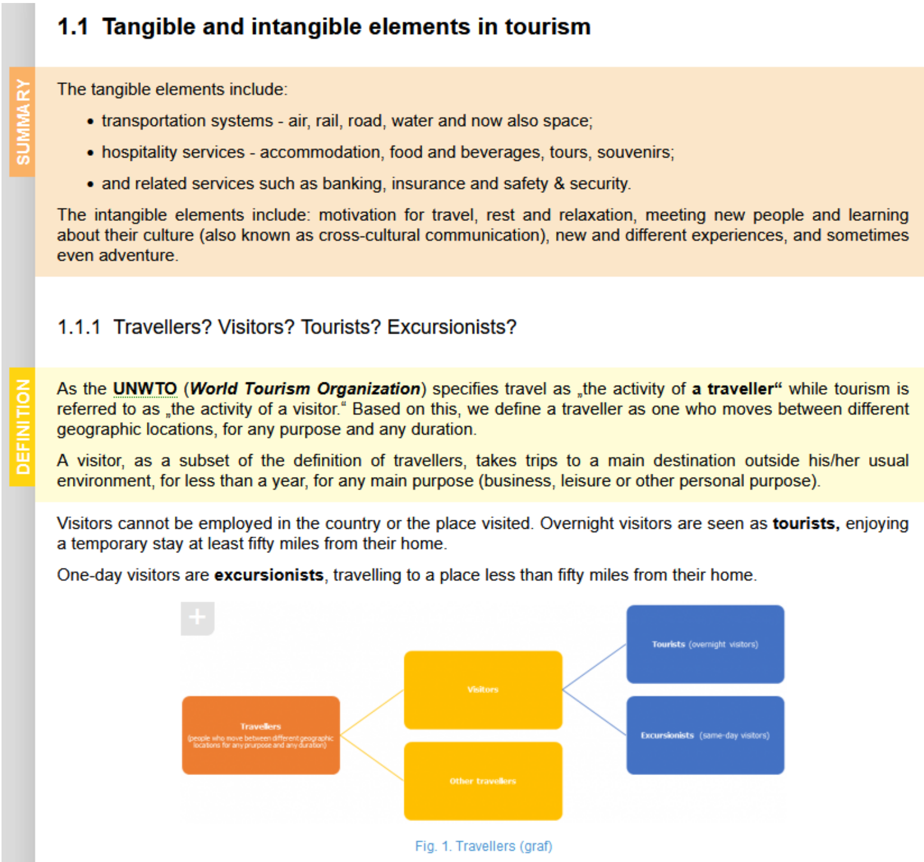
The motivation for the preparation of a large number of teaching materials was the idea of creating a universal environment (bookstore) that would accommodate a large amount of them, will therefore be frequently visited, which will put further pressure to expand the number available of teaching materials. At the same time, our major advantage was the massive financial injection for the creation of the basic set of learning packages.

2 PEDAGOGICAL POINT OF VIEW

Having the intention to create a huge library of teaching materials, we needed to prepare a solid pedagogical and didactic concept of the individual OERs and the library as a whole. This concept is based on defined sets of mandatory and optional elements, which are available to authors and other creative workers, and which can/must be (according to the given rules) integrated into larger units.

2.1 Structure

The highest-level hierarchical element is the storage organized in a clear way as an electronic bookstore. There we can find the individual topics (inaccurately: “books”) which, after clicking on their “envelope”, offer basic metadata about the topic, namely: title, list of authors, annotation, license, year of origin, price, language, methodology for use, and feedback (rating, errata reporting). It is then possible to open a page with further details about the OER, such as objectives, keywords, required level of study effort, references and recommended resources.



1.1 Tangible and intangible elements in tourism

SUMMARY

The tangible elements include:

- transportation systems - air, rail, road, water and now also space;
- hospitality services - accommodation, food and beverages, tours, souvenirs;
- and related services such as banking, insurance and safety & security.

The intangible elements include: motivation for travel, rest and relaxation, meeting new people and learning about their culture (also known as cross-cultural communication), new and different experiences, and sometimes even adventure.

1.1.1 Travellers? Visitors? Tourists? Excursionists?

DEFINITION

As the **UNWTO** (***World Tourism Organization***) specifies travel as „the activity of **a traveller**“ while tourism is referred to as „the activity of a visitor.“ Based on this, we define a traveller as one who moves between different geographic locations, for any purpose and any duration.

A visitor, as a subset of the definition of travellers, takes trips to a main destination outside his/her usual environment, for less than a year, for any main purpose (business, leisure or other personal purpose).

Visitors cannot be employed in the country or the place visited. Overnight visitors are seen as **tourists,** enjoying a temporary stay at least fifty miles from their home.

One-day visitors are **excursionists**, travelling to a place less than fifty miles from their home.

Fig. 1. Travellers (graf)

Fig. 1. Educational blocks

Subsequently, it is possible to explore the actual educational content. We have defined the following standard educational parts (functional blocks):

1) *Basic text* – not marked in any special way; used for common learning content.
2) *Definition* – serves to clearly separate definitions of basic terms.
3) *Note* – educational block suitable for providing additional explanations.
4) *Example* – in this block it is appropriate to enter the assignment of solved and unsolved examples or tasks (e.g. calculations) or questions.
5) *Solution of an example* – a special block where the solution of a task or example according to the previous point can be stated; the special nature of this block consists in the fact that it is hidden by default, and revealed only after clicking on it (which displays the correct solution of the task or example).
6) *Advantages* – simply to highlight advantages of what is described in the text.

7) The block of *disadvantages* is defined in a similar way.
8) *Summary* – suitable for placement at the end of a section (chapter), where it can summarize the most important findings.
9) *Interesting* – additional facts, trivia or even jokes can be contained there.

The educational blocks are highlighted in color in the final version of the teaching material, thus helping to make the content clearer, as can be seen from Fig 1.

2.2 Educational Objects

The educational objects belong – similarly as educational blocks – to the basic parts of the OER structure. They can be used, in principle, in any part of an OER, either within the *Basic text* educational block (most often) or within other types of blocks. We defined the following basic learning objects:

1) *Text, equations, formulas* – common content of a “book” publication. From a formal point of view, it is necessary to follow the set format, specifically the consistent use of styles. This will help to seamlessly convert the learning material into HTML (a format that is optimal for displaying on the Internet); it also makes the learning material significantly clearer and unifies the form of different learning materials by different authors, which means significant added value for students.
2) *Figures, tables, graphs* – again it is a common “book” format, which is suitably transformed into HTML. Even in this case, it is mandatory to use a unified format so that the results are formally and graphically identical in all OERs.
3) *Videos, animations, sounds* – effective inclusion of multimedia elements is only possible with electronic materials, so this is an added value of online courses. Multimedia elements are one of the essential attributes that distinguish “book” publications from e-learning teaching materials. For technical reasons (storage reliability, bitrate), the multimedia elements are stored on the YouTube platform. In the teaching materials, the authors can use either their own multimedia elements, or elements by other authors (typically videos) placed online. In such a case, however, OER would often not be able to have a free Creative Commons license; therefore, such elements have a warning notice and the element used (video, image, etc.) is not a part of the material – only a link is available.
4) *Tests* – it is appropriate to include a comprehensive part of the explanation at the end. Both *1 of n* and *m of n* types of tests are available. It is possible to assign an explanatory or additional comment (feedback) to each answer (whether it is correct or not). The evaluation of the correctness of the answers typically takes place at the moment chosen by the user (student).
5) *Interactive elements* – we consider them to be one of the most important parts of OER. These are various interactive tasks that can only be included in electronic learning materials. There are 13 template-based types of interactive elements (online tasks such as text with drag and drop / delete / delete words, matching, sorting, grouping, flashcards, crossword puzzles, interactive videos); examples in the Czech language are available in [2]. It is also possible to create tailored ones, which is, of course, demanding and expensive. See an example in Fig. 2.

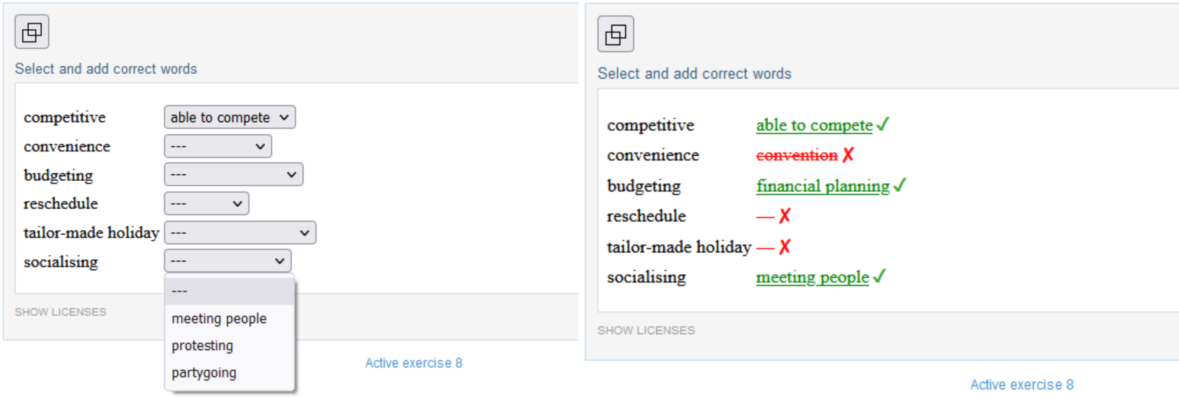


Fig. 2. Example of an interactive element in the text (the first image shows an assignment; the second one shows a solved and evaluated task)

The use of a variety of learning objects in an OER will ensure that the material is varied, interesting and readable – from a pedagogical point of view, there is nothing worse than boring textbooks that contain only long paragraphs of text; and from the point of view of modern teaching resources located in the virtual world, there is nothing worse than teaching materials without interactivity.

2.3 Variety of Topics

Thematically, the individual OERs touch a number of fields, divided by the following professional areas: Technical, Agricultural, Economic, Medical, Pedagogical, and Social.

3 LOGISTIC SCHEME

The OER library currently contains 662 teaching materials. More than 600 people from various parts of the Czech Republic took part in their development. The production process of each OER involved over 15 major steps (including corrections and reviews). It was necessary to guarantee the high quality of individual OERs and the purity of the content from the point of view of copyright (preservation of the Creative Commons licensing model [4]). The related procedures are outlined in [3]; Therefore, we present only the basic ideas here:

1) *Competent worker* – each creative worker underwent basic training (face-to-face or online), had a complete set of supporting online materials and the option of telephone/e-mail support.
2) *Robust workflow* – defined flowchart for creating OERs with 15 essential steps, relative timeline and many feedbacks for outputs quality control.
3) *Sophisticated task manager* – the managementof the development process was supported by a semi-automatic web tool, which monitored the production of the individual OERs step by step (entering and submitting partial tasks), pointed out problems (especially work delays), saved all outputs (including partial ones), monitored and archived time stamps of work and individual actions. To give an idea of the scope: during the three-and-a-half-year project, a total of 666 people registered in the task list and 7231 sub-tasks were assigned.

4 EXPERIENCE FROM PRACTICAL TESTING

The OER library is currently a widely used tool to support teaching at many schools. Although the individual OERs were originally intended for a specific segment of higher professional education, we know that the individual teaching materials are used for both secondary and higher (bachelor and Master) education. Every month, several thousand users visit the library.

4.1 Quantity data

The data obtained from the production server show a relatively strong use of the individual OERs. The server has been in operation since February 2020 when we stored the first OER on it; we had been gradually supplementing other ones until approximately October 2021 when the above-mentioned number of more than 600 OERs was reached. Thus, as of September 2022, the serverhas been in full operation for 12 months.

For technical reasons, out of those more than 600 OERs, 427 are included in the evaluation. A total of 143,913 users (from unique IP addresses) have viewed individual OERs during the monitored period (by July 7, 2022). The highest view count of a single OER was 3792 users, while the average one was 337 users per OER. By sector, the most users (70,205) have viewed medical educational materials; technical and agricultural materials have been viewed by 43,669 users, and economics materials by 30,039 users.

It should be noted that the actual numbers are likely to be even higher, as the production server, including all OERs, has its clone operated by one of the project partners (which is allowed by the licensing policy); however, we do not have their data available.

4.2 Quality data

Each OER allows feedback from students to be passed to its authors via the system administrator. The system also includes the “stars” rating of the OERs. We assumed that approximately one tenth of users would provide their comments, point out possible errors or recommend various improvements or additions. This assumption did not prove realistic: we only have a minimum of data from the electronic feedback channel, namely the “stars” rating. Thus, only 70 OERs were rated by users with an average rating of 3.73 stars (out of 5).

That’s why we decided to expand the feedback tool and explicitly ask the visitors to use it. We believe this will make it possible to obtain relevant data and subsequently increase the quality of the OERs.

Therefore we almost do not have electronic feedback from users; on the contrary, we have enough feedback based on direct contacts of the creative team and teachers who work with the OERs in their classes. This feedback is valuable, but since it is based on personal contacts, its extent is obviously limited.

5 SUMMARY

In the years 2017–2021, a remarkable online educational support was created, which is available on the web as an online bookstore with 662 titles. All of them are available free of charge, exclusively under open CC CC or CC BY-SA licenses.

We gradually started publishing the first teaching materials from this series in February 2020. This date coincided with the beginning of the COVID pandemic in Europe. We were therefore able to offer online teaching materials to secondary and higher education teachers, which they greatly appreciated; there was pressure to complete the materials faster and use them as soon as possible during lock-downs.

Although the project formally ended in 2021, teaching materials are still widely used and the system is still supported, which will be continued in the future. Currently, models of economic sustainability are being sought so that the e-bookstore and its titles can be developed, in addition to simple maintenance.

We also appreciate the success we achieved in the eLearning 2021 competition: the portal for electronic resources vovcr.cz was awarded the 2nd prize.

6 ACKNOWLEDGMENT

This paper has originated thanks to the support obtained from the Czech Ministry of Education, Youth and Sports (projects No. CZ.02.3.68/0.0/0.0/16_041/0008049, CZ.02.3.68/0.0/0.0/16_041/0008050, CZ.02.3.68/0.0/0.0/16_041/0008047 and CZ.02.3.68/0.0/0.0/16_041/0008052).

MONDRAGON ZTIM HUB: tematic challenges to promote STEM vocations among students

1. Motivation and learning outcomes

The term STEM (Science, Technology, Engineering and Mathematics) is one of the most commonly heard concepts in both education and business when talking about the needs of the future (Li et al., 2020). However, one of the challenges facing our society is the lack of motivation and interest in STEM disciplines of secondary-school students, especially girls (McKinsey Global Institute analysis, 2020). At the same time, the implementation of STEM initiatives in education is not easy due to the need for change that is required in the classroom.

For this reason, it is necessary to generate initiatives to help schools implement STEM activities. In this sense, the MONDRAGON ZTIM HUB project has been set up. The main aim is to promote STEM vocations among young people as a tool for providing scientific-technological solutions to the different challenges facing our society. It is a network of interconnected socio-economic agents that work at a local level to develop STEM activities in both curricular and extracurricular areas.

In summary, those attending will be able to:

- Get to know the MONDRAGON ZTIM HUB initiative.
- Learn about the methodology followed for the development of thematic challenges (Challenged based learning (CBL) methodology (Nichols et al., 2016) and specifically the ETHAZI model (TEKNIKA, 2020)) that help to raise awareness and promote STEM activities in the classroom.
- Sharing of similar problems and collection of proposals for improvement of STEM proposals.

2. Background and rationale.

Nowadays, the labor market needs STEM workers: On the one hand, because the demand for jobs related to this disciplines and careers is not currently covered; on the other hand, because, although many of the future jobs have not yet been created, they will be directly related to the scientifical, technological and digital development. In this context, in all levels of education, female students continue to be underrepresented. Furthermore, the number of women pursuing STEM studies and careers is far lower than that of men (EUSTAT, 2019). Therefore, it is essential to awaken professional vocations in STEM areas among students, ensuring gender equality and starting at the lowest levels (Eusko Jaurlaritza, 2018).

Moreover, it is known that secondary-school students' interest in and motivation for STEM disciplines, studies and careers is low. It seems that their choice of pathways changes as they grow older (Valero-Matas & Coca-Jiménez, 2021); their interest progressively decreases as they progress to higher levels (Hernández-Serrano & Muñoz-Rodríguez, 2020).

Several studies claim that there are many factors creating loss of interest in STEM, such as the traditional approach and the use of expository strategies (Hernández-Serrano & Muñoz-Rodríguez, 2020). In order to achieve greater interest in these disciplines, it is necessary to employ a practical approach to learn through interdisciplinarity, the development of practice contexts, and new and adapted teaching materials (Valero-Matas & Coca-Jiménez, 2021). This is why it is necessary for schools to implement thematic challenges in the classroom in a curricular way to make science vocations visible.

3. Workshop design.

The workshop is divided into 4 main parts as follows:

- **Contextualization: Context and introduction of the MONDRAGON ZTIM HUB initiative. (25 min)**

  The MONDRAGON ZTIM HUB initiative and its context will be introduced to the attendees. Special emphasis will be placed on the importance of collaboration between actors. Our collaborative model developed for the promotion of STEM vocations will be presented.

  Afterwards, we will proceed to create a small debate with the attendees to see which is the STEM situation in their origin region, if the objectives are aligned and gather for similar needs. Then, we will give our vision on the concepts mentioned above. With this small interaction, we intend to align the knowledge on the general objectives covered by our initiative and try to search for partners.

- **Development: Development of the thematic STEM challenges. (20 min)**

The core of the presentation lies in the design of the thematic challenges, designed for the 4 grades of High School. The details of the methodology followed will be shown through a practical example.

The proposal to incorporate MONDRAGON ZTIM HUB network agents in the thematic challenges developed in the classroom is shown as an innovative initiative. The challenges take place both inside and outside the classroom, this is due to the collaboration in the design of the challenges between schools and external agents that aim to provide a more real context for the challenge as well as to bring the local socio-economic environment closer to high school students.

At this point, a participatory intervention will be carried out in order to visualize the strengths and weaknesses of the proposal presented as well as get to know the interest that such a proposal can arouse.

- **Results: A sample of the results obtained to date. (5 min)**
  As a result the challenge's current implementation status will be presented. Challenges have been designed with constant feedback from both school and companies. This collaboration framework will be emphasized.

  Again, an interaction with attendees will be done in order to look after other methodologies applied for this aim. It will be interesting to identify similarities or how they differ.

- **Conclusions, lessons learnt and future lines: Sample of the conclusions and future lines of the initiative. (10 min)**
  To conclude the presentation, the lessons learnt and conclusions obtained will be presented, as well as future lines of action. A decalogue of outputs will be presented to serve as aspects to be taken into account for future developments. The session will end by collecting information on similar projects from the participants, so that similar experiences can be shared and learnt from.

4. Significance for Engineering Education and attractiveness of the topic.

The importance and need of a STEM educational model is becoming increasingly evident both locally and globally. In Europe, for instance, a 70% job growth in sectors such as ICT and health is expected. Accordingly, the data published in 2020 by the Basque Business Confederation indicate that the most in-demand professional profiles correspond to STEM-related higher degree studies. Nevertheless, the interest of students in STEM careers is low and industry has difficulties in finding such profiles.

If one of the principal reasons for this lack of talent is the unawareness and prejudices associated with STEM professions among young people in relation with engineering education, it is vital to break stereotypes to change the *status quo*, which are the objectives of MONDRAGON ZTIM HUB. The thematic challenges specially seeks to use STEM skills to face real-world problems and consequently to show the importance and usefulness of STEM topics. The participation of external agents provides the students a better understanding of the reality surrounding them and makes more visible and understandable engineering careers as well as reduce the fears of studying them. At the same time it encourages innovation and creativity too.

Therefore, the main value contribution of the challenges is the participation of external agents through pills or parallel actions to the challenge that allow students to acquire the knowledge or inspiration necessary to face the challenge. These will provide context and tools for their development.In short, the purpose is to bring the reality of the professions to generate solutions to a challenge in a collaborative way. This will facilitate the transition and approach to the world of the STEM professions, improving their professional development through the acquisition of technical and specifically engineering skills and improving their future employability.

The thematic challenges provide an insight into different fields of engineering, bringing students closer to the profession and showing examples of real applications. And most importantly, it reaches more girls through examples of applications with a social vocation, because that is what engineering does from our point of view.

Key words: STEM education, Challenge based learning, STEM projects, Secondary Education.

Secondary STEM education and engineering higher education: a match made in heaven?

Highly educated STEM professionals, and engineers in particular, increasingly top the lists of most wanted profiles on the European labour market (European Commission, 2020). For higher STEM education to be able to deliver the required number of STEM graduates, a sufficiently high number of students should be enrolled at the start. However, by the end of secondary education (SE), a large share of pupils who were initially enrolled in a STEM programme, opt out of STEM when enrolling in higher education (HE) (De Meester et al., 2020; Kersanszki & Simonics, 2022). From the pupils who do enroll in a HE STEM programme, an alarmingly high proportion lacks the attitude and skills necessary to successfully complete their first year (Broos et al., 2021). Moreover, pre- and in-service teachers lack sofisticated Nature of Engineering (NoE) views (Kaya, 2020), inhibiting transfer of the NoE to their pupils. This insufficient preparedness and lack of understanding of the NoE urges a new, integrated approach to STEM SE (European Committee of the Regions, 2019), that can be inspired by practices in the first years of HE engineering programmes (Engberg & Wolniak, 2013). In turn, SE practices in integrated STEM (iSTEM) can also inform HE engineering programmes. In summary: HE engineering programmes and iSTEM SE share two common goals: (1) motivating students for STEM studies/careers, and (2) preparing students for these studies and careers. This workshop aims to enhance cross-fertilization between iSTEM SE and engineering HE, in the pursuit of these goals.

A guideline for designing qualitative integrated STEM projects in six key principles

doi:10.5821/conference-9788412322262.1172

Six key principles form the basis of iSTEM education that helps pupils develop competences required in engineering and science programmes as well as in future STEM careers (Thibaut et al., 2018; Flemish Government, 2015). These principles are: (1) problem-centered learning and problem solving, (2) integration of learning contents from different STEM subjects, (3) modeling, (4) inquiry-based learning, (5) design-based learning, and (6) cooperative learning. In an ERASMUS+ partnership project launched in 2021, five European HE institutions joined forces with the primary goal to embed these principles in (i)STEM teacher education programmes in a sustainable and effective manner (CiSTEM², 2021). Through an online training that immerses student teachers in each of the six key principles, the partner institutions aim to prepare these future (i)STEM teachers to incorporate the principles in their own classroom practices.

Finding common ground through interactive group discussions

In this workshop we want to exchange good practices and stumbling blocks with respect to each of the six key principles of high-quality iSTEM education. Two central questions will be addressed: (1) How are the six iSTEM key principles embedded in HE engineering programmes (e.g., projects in the bachelor programme, theoretical courses, interdisciplinary courses…)? (2) What can (i)STEM teacher education and engineering HE learn from each other regarding these key principles to achieve their two common goals?

Small group discussions and interactive media (PollEverywhere, padlet, lucidchart, …) will be used to gather input from the public and summarize participant take-away. Via the interactive workshop activities outlined below, we want to enable participants in identifying actions and good practices for their education practice (specifically in assessing project quality, implementation and student competence training and evaluation) based on the iSTEM key principles.

(1) We open the workshop by presenting the six key principles and their implementation in STEM SE and (i)STEM teacher education.
(2) Together with the participants, we derive indicators of successful classroom implementation of each of these principles. The participants are invited to share specific examples from their practice in engineering HE to enrich the meaning of these indicators.
(3) We reflect upon the implementation in current SE and HE STEM programmes: which principles are strongly integrated, and which deserve more attention? Do SE and HE STEM implementations encounter the same struggles and opportunities? Can we get to a common understanding of practices underpinning qualitative STEM education?
(4) Additionally, we will focus on how to evaluate students' competences related to the iSTEM key principles.
(5) Finally, we want to introduce a tool to train STEM teachers and secondary school pupils in some of the iSTEM key principles. With the participants, we reflect on the usefulness of this tool for iSTEM SE and for their own HE STEM practices.
(6) We ask the participants to identify two action points for their HE engineering programme as well as for STEM teacher education with respect to the iSTEM key principles and with the aim of creating truly inspiring, competence-oriented integrated STEM education.

Outcomes of the group discussion

During the workshop the relative importance of the six iSTEM key principles in secondary and higher education and out-of-school-initiatives was discussed, along with concrete examples of practices associated with each principle. The participants agreed on the importance of problem-centered and cooperative work, along with integration between the STEM-disciplines. This further triggered the discussion about the semantics of STEM versus STEAM education, where the importance of creative thinking (be it imbedded in the A-discipline or inherently underlying the S, T, E and M-disciplines) was elaborated on. The CiSTEM^2-results, measuring the activation of the six iSTEM key principles during the iSTEM design process of multidisciplinary teams, were shared. Participants acknowledged the importance, but also the challenging nature of meaningful, deep, integrating links between the STEM-disciplines.

Reviewing Manuscripts in Engineering Education Research Journals: fairly, constructively, effectively

This session focuses on the peer review of journal manuscripts in the field of engineering education research. To the workshop we invite both experienced and new reviewers, and especially doctoral students in engineering education research.

The function of the peer review process is first to support *fair* decisions by helping journal editors identify which manuscripts most deserve to be published. The task is further to *constructively* support the authors in improving their manuscript before publication. It is through this process of selection and enhancement that the quality of the journal papers is safeguarded. By extension, this is how the whole research field cab establish and maintain respect. Therefore, reviewers play a vital role – without peer review there can be no respected field.

It is a rewarding task to review manuscripts, as a lot can be learned from it. Not least when taking one's own manuscript from submission to successful publication, it is helpful to have experience of the editorial process also from the inside. However, reviewing can also be time consuming, making it a wise investment to improve one's skills to do it *effectively*.

After the workshop, participants will be able to:

- Explain different quality criteria for scholarship in engineering education, and how to apply them
- Highlight particular aspects of a manuscript that a reviewer should consider
- Discuss how to support editors in making fair decisions and authors in improving their manuscripts
- Consider how reviewers can spend their own time wisely

The workshop is facilitated by a team of editors of the leading journals:

- European Journal of Engineering Education (SEFI)
- IEEE Transactions on Education (IEEE)
- Australasian Journal of Engineering Education (AAEE)

Workshop outline

Introductions

- Brief introductions: participants and session leaders. [5 minutes]

doi:10.5821/conference-9788412322262.1475

- The journals: aims and scope, review criteria and review process. [15 minutes]

Group activity
- Make a poster in groups of four: “Advice for reviewers”. [30 minutes]
- Vernissage (hanging the posters).

Synthesis
- Plenary discussion of results. Editors’ picks. Collected wisdom and conclusions. [30 minutes]

Participants can sign up to receive documentation from the session, and to volunteer as reviewers for the journals.

Game-based Learning in Computer Engineering: A Workshop

Abstract

Gamification has gained popularity in the last years, it is used in primary and secondary schools, as well as in companies and universities (Call, 2021). Along with this growth in popularity the number of available computer tools that facilitate the implementation of quizzes, competitions, simulations, WebQuests etc. has also grown.

Play engages students and enhances learning, however not all sorts of games are equally fruitful. As in (Dave Eng, 2019), we make a distinction between gamification and game-based learning (GBL). An example of gamification is a contest where students get points for solving the usual exercises of the subject matter. An example of game-based learning is an escape room where students get involved in studying and solving subject matter problems to get the required hints to continue the game. In this sense, game-based learning is an instance of problem-based learning (PBL) [Lima, 2017]. An interesting reflection on GBL can be found in [Valero, 2018].

The main objective of GBL is to provide an active learning environment, where students need to learn and apply the subject matter in order to participate and eventually solve the game. Compared with frontal lectures, active learning has been shown to provide higher motivation and deeper learning [Call, 2021] [Lopez-Fernandez, 2021].

From a general point of view, we can say that learning takes place in five stages [Bofill, 2007]. Namely: motivation, information retrieval, understanding, application (or practice) and reflection or feed-back. GBL, then, reinforces the autonomous realization of each of these stages.

An escape room is a game where players must solve different puzzles and riddles in order to finish the game (in order to *escape* from the room). Escape rooms have been used extensively in education, since they allow for the organization of subject matter exercises in a pleasant way [Veldamp, 2020].

Learning outcomes
We present a workshop session where we expect the participants to:
(i) Notice the difference between gamification and GBL and reflect on it (see activities below).
(ii) Learn how a well designed escape room reinforces the autonomous realization of the five stages of learning defined by (Bofill, 2007)
(ii) Finish the workshop session with some ideas on how to introduce GBL into their subjects.
We hope that this workshop will inspire participants and, maybe, engage them in proposing GBL activities for their own students.

We propose the workshop to include the following **activities**:

1. A short introduction: GBL and gamification are introduced and the timelines of the workshop are presented.
2. Participants engage in a gamification activity: they will be required to solve a simple questionnaire, and we will monitor their progress using Socrative tool (socrative.com)
3. Participants will be invited to participate in a GBL activity: an escape room where they will be required to solve simple computer programming exercices to obtain the keywords to progress on the game and exit the escape room. Notice that we do not expect the participants to know computer programming so they will be allowed to use other means (like google) to provide the answers to the riddles. In a real situation, the students are required to write the programs to solve the questions.
4. A reflection in small groups to compare the strength and weaknesses of both approaches.
5. We will continue with an open debate, where we may discuss topics such as: assessment, comparing game-based learning versus gamification strategies, strategies and tools for applying such gaming techniques in the classroom and online. The debate will be aimed to formulate conclusions and get feedback and ideas to improve our game-based activities.
6. Finally to end the session participants will be invited to take home the design of a simple escape room situation involving problems for their own courses.

Inspirational questions to open debate:
-Which sort of gaming experience provided higher motivation?
-What differences can you see between gamification and GBL?

doi:10.5821/conference-9788412322262.1244

-Think of ways to introduce GBL into your subject
-Regarding the quality or level of understanding, which experience do you think provides a deeper understanding?
-Does GBL encourage creativity? critical thinking?

Requirements
Participants are expected to bring their own laptop (or tablet, or phone) to the workshop and a headset.

Results
In this section we present the reflections of the participants to the workshop.

Strengths of the gamification strategy:

- Increased student motivation
- Quick gain
- Creates competitive learning environment between groups
- Direct and quick feedback
- "Kids" nowadays are more used to games

Weaknesses of the gamification strategy:

- The activity can be stressful.
- Focusing on the quiz without actually learning
- Only one try. It should have the option of more than one answer.
- It could be a distracting activity
- The motivation is external
- Risk of losing part of the student population
- Rewards are trivial, students may not be interested.

On the other hand, the strong points expressed about the game-based learning activities were:

- Diverting
- Focused on the topic
- Immediate application of the knowledge
- Group work (twice)
- Immersive
- More motivating than gamification
- The moments of success are rewarding
- Less risk of gender issues
- Engaging by story
- Can be very engaging
- Can foster further self-directed learning
- Learned lessons:
    - for life or
    - for community
    - for the next stage

And as weak points:

- The escape room could be run presentially, rather than digitally.
- Complex usability of the escape tools.
- Not balanced knowledge among the team members
- Too much distraction
- Different computer literacies of students
- The game should include some reflection (what have you learned, how dit you do it,...)

Acknowledgement
This work has been supported by the Institut de Ciències de l'Educació (ICE) Convocatòria de projectes d'innovació docent 2021 (Acord CG/2021/02/34, de 9 d'abril de 2021) and by the Escola Tècnica Superior d'Enginyeria de Telecomunicació de Barcelona (upc telecos-UPC-Tech).
We appreciate the participation of those attending the workshop and their valuable contributions.

Keywords: *Ethics education, Game-based learning, Artificial Intelligence*

ABSTRACT

The past few decades have seen important efforts to introduce more ethics into engineering education programs around the world, while adapting to the evolution of ethical concerns, notably in relation to digital technology and artificial intelligence. Even if pedagogical approaches based on the use of case studies or code of ethics remain among the most popular, other less well known techniques such as game-based approaches have also been identified as effective. The goal of this workshop is to offer participants an opportunity to explore how games can be used as learning experiences to develop students' ethical knowledge and skills. Participants will first get to play an online game which focuses on ethical issues in the domain of artificial intelligence, before reflecting on their experience and discussing the potential of game-based approaches for engineering ethics education.

1 BACKGROUND AND RATIONALE

There is an overall agreement that, besides technical knowledge, engineering graduates should have skills that would enable them to better serve humanity in their future jobs [1] and to deal with the uncertainties of future challenges [2]. Meta-analyses indicate that significant efforts have been made to introduce science and engineering students to ethics in the last decades [3, 4]. However, staggering developments in digital technology, particularly in the field of artificial intelligence (AI), create new ethical challenges for engineers [5]. The specific nature of the ethical issues arising from digital technology (e.g. privacy, algorithmic bias or transparency issues) require engineering students to develop new knowledge and skills to be able to walk through the dilemmatic process of decision making that significantly impacts the users of digital designs.

While the most popular teaching methods in engineering ethics education rely on the use of codes of ethics, case studies or discussions / debates [6], other less well known techniques using films and videos, science fiction or games have been explored recently [7]. The use of games – notably digital games – for learning and education has generated increasing interest in the last two decades [8]. Educational games have been used in a range of disciplines, and meta-analyses have shown positive effects of educational games on cognitive, affective or motivational skills [9, 10]. In particular, some studies suggest that games could be used to foster problem-solving and critical thinking skills [11] or to develop moral sensitivity [12]. However, prior research also shows that, to achieve ethics education goals, games should implement specific strategies such as providing "ethical choices and decision-making, which have an effect on the game play," or integrating personal reflection through the use of diaries or other devices [13].

In this workshop, participants will explore how a game can be used as a learning experience to develop engineering students' ethical knowledge and skills, and investigate more generally the potential of games for engineering ethics education. In the following, we first present the game that participants will play, before describing the learning outcomes and the format of the workshop.

2 THE GAME

Based on an original idea by two Master students at our institution, Ester Simkova and Alexandre Pinazza [14], the game that participants will play in the workshop is an online interactive story. Players play the role of a data scientist who faces design dilemmas while developing machine learning models. The decisions that players make (see example on Figure 1) change the course of the story and lead to different ethical consequences. The narrative includes two applications of machine learning technology, based on real case studies of algorithmic bias: criminal recidivism prediction (inspired by the COMPAS case [15]) and automated translation (inspired by the Google Translate case [16]).

Aiming to develop students' ethical awareness in the domain of machine learning, the game is accessible *without any background in machine learning or in ethics*. It is specifically designed as an educational tool by implementing a series of well-documented ethics education strategies [13]: players are guided to analyse their decisions before committing to a choice, they get a chance to reflect after observing the consequences of their decisions, and they are led to identify their emotional reactions at specific points in the unfolding story. Particular attention has been paid to the gamification of these features in order to preserve the immersive properties of the game.

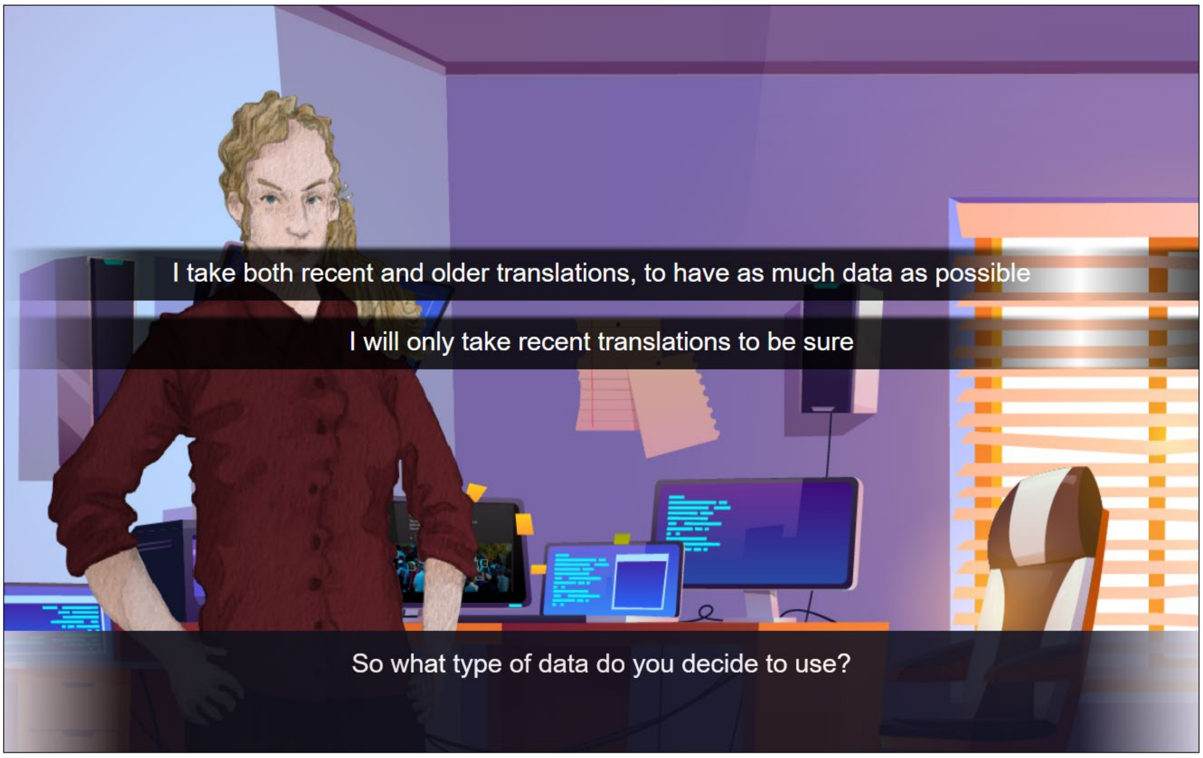

Figure 1: example of a decision that players can make in the game.

3 LEARNING OUTCOMES

Through letting participants first experience the game as users and then reflect on this experience, the workshop aims to develop participants' knowledge and skills both in the domain of ethical artificial intelligence and in the domain of game-based approaches to engineering ethics education.

At the end of this workshop, the participants should be able to:

- Explain some of the ethical issues which arise in the domain of artificial intelligence design.
- Identify features of a game that can foster students' ethical knowledge and skills.
- Evaluate how a game can be used as a formal learning activity in the context of a course to foster students' ethical sensitivity and decision-making skills.

4 WORKSHOP DESIGN

The workshop will implement an interactive and hands-on format with the following program:

- Introduction: structure of the workshop (presentation, < 5 minutes)
- Discovering the game (participants individually play the game online, 15 minutes)
- Identifying ethical questions in the game (think-pair-share, 10 minutes)
- Using a game as a teaching activity: reflection in groups and evidence from research on game-based approaches to engineering ethics education (think-pair-share and presentation, 20 minutes)
- Conclusion: take-home messages (collective summarization activity, 5 minutes)

Note: Participants will need a laptop with a web browser and internet connection to play the game. No specific prior knowledge is expected.

5 SUMMARIZATION OF THE RESULTS

More than 40 participants attended the workshop in total and played the game on the online demonstration platform hosted at EPFL (https://go.epfl.ch/MLethicsgame).

The discussions during the workshop highlighted that the game includes content related to different types of ethical issues, not only in relation to AI ethics. Participants identified questions at several levels of granularity, from individual perspectives on decision making (e.g. personal values) to more global systemic issues (e.g. inequalities), including questions of organizational culture.

Using the EPIC framework [13] as a lens for analysis, the participants identified that the features of the game support a number of the ethics education goals identified by Karen Schrier, albeit in different proportions. Overall, the game was seen as an effective way to raise awareness about ethical issues related to AI, thanks to its narrative based on realistic case studies. A number of participants indicated that the game also enables students to practice ethical reasoning and ethical reflection to some extent. Although some participants noted that the use of emojis to report emotions could lead to variations in interpretations, the “mood meter” feature of the game was thought to be useful for practicing emotion identification.

In terms of the limits of the game, some participants argued that the options offered in the decisions points of the game are too limited to be realistic. Others felt that being able to actually make these decisions and see their consequences has pedagogical value since it creates a feedback cycle in a low-stakes environment that allows for mistakes. To compensate for the individual nature of the game, some participants suggested that students play the game in groups to be able to discuss the different decisions. Overall, participants concluded that the game should be used with a follow-up debriefing activity to highlight both its underlying principles and its limits in order for students to consolidate their learning.

ABSTRACT

The use of digital tools has drastically increased in engineering education, accelerated by the COVID-19 pandemic. These tools generate important ethical issues, in particular in terms of privacy and fairness. However, very few teacher training programmes address those topics, which means that teachers are often left to figure out by themselves how to address these issues when they want (or have) to use digital tools in their teaching. In this workshop, participants will be introduced to a pragmatic approach to the ethical design of learning experiences that involve digital tools using a visual thinking guide called a ‘canvas’. Applied and hands-on, this workshop will help participants to develop a practical understanding of the

doi:10.5821/conference-9788412322262.1237

specific ethical issues related to the use of digital tools in teaching and to integrate ethical reflection into design processes when digital technology is involved.

1 BACKGROUND AND RATIONALE

Digital tools are increasingly used in engineering education, and the COVID-19 pandemic has drastically accelerated their adoption. These include general purpose tools such as search engines, translation tools or content management systems, or more specialized applications like MOOC platforms, audience response systems or learning analytics. Distance/online teaching has also developed the use of video conferencing systems, online whiteboards or collaborative document edition tools. Because they generate digital traces of users [1, 2] and can potentially be algorithmically biased [3–5] – among other issues, these tools must be used with special attention to ethical questions and this is often left to the responsibility of teachers.

While the need to develop teachers' digital competence (including the use of ICT) is clearly identified [6] and an increasing proportion of teacher training curricula address it [7, 8], ethical considerations are generally remarkably absent from their descriptions [9]. This is all the more an issue that staggering developments in digital technology, in particular artificial intelligence, create new ethical challenges which require both engineers and engineering educators to acquire new specific knowledge [10]. In the conclusions of their review of published research on teaching and learning technological practices during the pandemic, Boghian, Popescu and Ardeleanu highlight the urgent need to "instruct both teachers and students on the ethical use of information technology regularly" [11].

This workshop seeks to fill this gap by proposing a pragmatic approach to the ethical design of learning experiences that involve digital tools in the form of a 'canvas' – a thinking tool that guides analysis and design based on three main ethical principles. In the following, we first present our 'canvas', before introducing the learning outcomes and the design of the workshop.

2 THE 'CANVAS'

Frequently used in business and technology education, a canvas is a tool that implements a conceptual framework in a visual way to guide a thinking process [12]. A canvas generally takes the form of a one-page grid or diagram, which serves as a support for individual or collaborative tasks.

First developed for the humanitarian context [13], the canvas we propose implements a "principled approach" to analysis and design: central to the canvas is a set of *ethical principles* that are used as a lens to look at a specific *digital tool* when used in or designed for a specific *teaching or learning context*. The visual organisation of the canvas reflects this approach, with the principles at the centre, forming a bridge between a zone dedicated to the tool and a zone dedicated to the context, as illustrated on Figure 1.

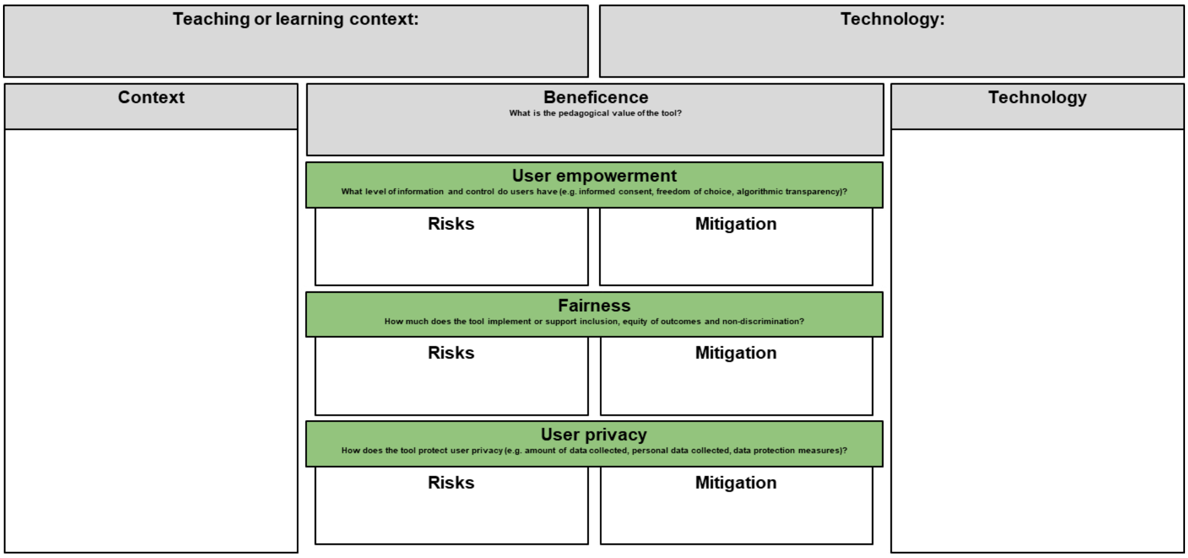

Fig. 1. The canvas with its three ethical principles at the centre.

Following a review of existing codes of digital ethics, we identified three overarching ethical principles that should we considered when using or designing digital tools:

- User empowerment: what level of information and control do users have over the tool (e.g. informed consent, freedom of choice, algorithmic transparency)?
- Fairness: how much does the tool implement or support inclusion, equity of outcomes and non-discrimination?
- User privacy: how does the tool protect user privacy (e.g. amount of data collected, type of personal or sensitive data collected and data protection measures)?

For each principle, the canvas guides participants to think about the risks associated with the use of the tool in the given context, but also to envisage mitigation options. The use of the canvas should help participants not only to develop a practical understanding of these ethical principles, but also to acquire a general methodology to integrate ethical reflection into analysis and design processes.

3 LEARNING OUTCOMES

After an introduction of the specific ethical issues related to the use of digital tools in education (as well as in general) and a presentation of the three ethical principles implemented in the canvas, participants will be given the opportunity to practice using the canvas by analysing collaboratively a real learning scenario with well-established existing technologies (e.g. Miro, Mentimeter, Google docs). Then we will step back and reflect on this experience to discuss with participants how this canvas could be used as a teaching tool, for instance as a framework for the socially responsible design of digital tools.

At the end of this workshop, participants should be able to:

- Describe examples of ethical issues related to the use of digital tools in education

- List and define ethical principles that apply to the design and use of digital tools
- Use the canvas to design and assess pedagogical activities that involve the use of digital tools
- Evaluate how the canvas can be used as a teaching tool, for instance as a framework for the socially responsible design of digital tools

4 WORKSHOP DESIGN

The workshop will implement an interactive and hands-on format with the following programme:

- Introduction: ethical issues with digital tools in teaching and learning activities and digital-specific ethical principles (interactive presentation with mini-activities, 20 minutes)
- Designing learning experiences with digital tools using the canvas (collaborative activity in groups of 4/5 people, 25 minutes)
- Reflecting on the use of the canvas and the ethical principles it implements, evaluating how it could be used as a teaching tool (collaborative activity in groups, 10 minutes)
- Conclusion: take home messages (collective summarization activity, 5 minutes)

5 SUMMARIZATION OF THE RESULTS

A total of 15 participants attended the workshop. They identified around 10 different types of software technologies that are frequently used in their educational contexts, including Learning Management Systems, forum tools, interactive whiteboards, polling systems or programming-related technologies (e.g. online programming environments or auto-grading tools).

When working in groups to design a learning experience with a specific digital tool, participants engaged with all three principles embedded into the canvas, not only the privacy aspects, as is often the focus because of laws and regulations. Mitigation options described by participants included both technical aspects, such as the types of accounts best suited to access the service, and non-technical approaches such as fairness charters for online collaboration. Some participants reported that despite some prior awareness about the potential ethical issues with the considered tool, they were sometimes surprised by either the range of data collected, the location of the data storage or the extent to which this data was shared with third parties (participants were provided with a summary of the privacy policies and terms and conditions for the considered tool).

The participants identified three different use cases for the canvas as a teaching tool:

a. As a tool to co-develop learning experiences with students, defining which tool to use and how to use it;

b. As a support for discussion with students about digital ethics and to raise student’s awareness about the ethical issues with digital technologies;
c. As a device to use in design activities, for instance in empathy exercises or as a more focused alternative to general analysis frameworks such as SWOT (Strength, Weaknesses, Opportunities, Threats) and PESTLE (Political, Economic, Social, Technological, Legal, Environmental) [14].

Finally, the participants also raised questions about how to engage educators more broadly with these issues, and how students, faculty and IT services could better collaborate and work together on this topic.

Update (Sept 26th 2022) visible at the end of document

Motivation

A world without reflection is incomprehensible. Yet why is it that educating reflective engineers is so complicated? In this workshop, participants will experience an approach that aims to embed reflection as an integrated practice of engineering education.

Relevance for Engineering and Engineering education
Today's, and tomorrow's networked society requires engineers that are able to deal with many uncertainties and complex problems, work with any other discipline, understand stakeholders of all walks of life and be open and critical towards new and different insights. At our university we want to educate those engineers of the future, for whom we believe reflection is an essential professional attribute.

The challenge
In our institution we observe that it is difficult to adopt this seemingly universal and critical attribute in engineering education. Why is that? First of all, literature on reflection has a multitude of definitions of the word 'reflection'.[1] Next to that, based on a qualitative exploration in our university, we learned that reflection is deeply context dependent. Not only is the domain of application of reflection great in its variety (e.g. reflection on yourself, on collaboration, on the design or work process or on its outcomes), there is also a cultural factor in reflection. The role and habit of reflection can be different between departments within the same institute, between institutes, let alone between countries. So, it might be completely normal to share your mistakes in one department and be frowned upon in the next. In short, next to having a plural definition, we spot a *couleur locale* in the relevance and habit of reflection.

Learning outcomes
After the workshop participants are able to:
1. Recognize the wide scope and definition of reflection. (20%)
2. Recognize, identify, describe, explain, and discuss the limited *integration* of reflection in engineering education and the limiting and supporting factors for *implementing* reflection in (engineering) education. (30%)
3. Recognize, identify, and classify how the eco-normalization model[2] helps successful embedding of reflection in (engineering) education. (20%)
4. Interpret, distinguish, and examine what are the limiting and supporting factors for implementing reflection in (each of) the participant's own context specific education. (20%)
5. Formulate first steps to improve implementation of reflection in (each of) the participant's own context specific education. (10%)

Rationale of the session
Brilliant ideas from literature and best practices of others don't survive the battlefield of teaching practice, and the application of seemingly clear-cut concepts mismatch with the messy reality of a new context. Longevity and fidelity of educational innovation [2] is quickly undermined. [3, 4] Yet embedding reflection as a core competence is a big educational innovation. So, if we want to *secure* reflection in our current and future education, how should we deal with the identified generic and context-specific varieties?
We believe this requires a particular attention to implementation. With our university-wide program called the Reflective Engineer, we grow, foster, and embed reflection as a core practice in our disciplinary education and organization. Our guide in this innovation process is the model by Hamza

& Regehr on eco-normalization, that describes the interaction between the innovation, the system where it is embedded, and the people doing the work. Moreover, to align this interaction and to embed *couleur locale,* we use co-creation as one of our main tools.
Our workshop is a representation of all beforementioned aspects: the (context dependent) plurality of reflection, eco-normalization as implementation strategy and co-creation to effectively include couleur locale.

Workshop setup
In the workshop together we (I) deconstruct the *couleur locale* of participants' contexts and we (II) analyze the stimulating and limiting interactions between system, innovation and people doing the work. (III) We ground this in theory and share an example to illustrate how we manage that in our own messy reality. This allows participants to apply these insights to their own contexts. This workshop will ask an active role of participants and will stimulate interaction.

Step	**min.**	**Activity & Facilitator role**	**Relevance & (l.o)**
Preparation		• Facilitators: prepare framework (see fig 1) on the floor of the room, using tape & paper.	Set blueprint for interaction.
Entrance	3	• Participants each receive two big paper 'dots' of approx. 15cm in two different colors. • Participants write their name on their 'dots'.	Activate participants.
General introduction	7	• All: very short round of introductions. • Facilitators introduce program.	Get familiar, set expectations.
Gather collective data	20	Participants (see fig 2): • Place first 'dot' (color 1) in the framework: role of reflection in their education. • Place second 'dot' (color 2) in the framework: role of reflection in their own practice and development. Facilitators stimulate: • Participants reflect and discuss out loud on where they place 'dots' and repositioning dots accordingly.	Benchmark of what we mean with reflection, application domains of reflection and the amount of reflection (1).
Collective data analysis	10	Facilitators enquire: • Factors in (un)successful implementation of reflection in the participants' education.	Understand (why) not all parts of reflection are in education (2).
Reinterpret implementation according to eco-normalization	15	Facilitators: • Introduce eco-normalization (fig3, Hamza and Regehr). • Plot of step 4 factors to eco-normalization. Facilitators and participants:	Familiarize with eco-normalization and based on that interpret and improve local

		• Enquire context-specificity of factors. • Explore first steps towards better local implementation.	implementation of reflection (3, 4, 5).
Case-study	5	Teaser about our inter-faculty approach to bring more reflection into disciplinary education using previously explained and experienced knowledge.	(3, 4, 5)

Follow up (sept 26th 2022)

For many participants our workshop was a hands-on experience with the ambiguity of reflection as a concept as well as its implementation in our engineering education.

Visit our website (https://www.tudelft.nl/teachingacademy/themes/reflective-engineer) to continue exploring how we develop usable, viable, long lasting interventions, or to get in touch with us on that topic (also directly through reflectiveengineer@tudelft.nl). In two weeks we will publish the results of the workshop and our reflections through our website.

Thank you all for an exhilarating session!

TEACHING ANALYTICS SKILLS IN ENGINEERING: A HANDS-ON INTRODUCTION USING JMP

V. Kraft [1]
JMP Statistical Discovery
Heidelberg, Germany

Conference Key Areas: *engineering skills; student engagement*
Keywords: *problem solving, data skills, employability*

ABSTRACT

Engineering curricula often require students to learn a range of analytics skills, which are critical for all practitioners who want to learn from data. With the right software, learning these skills can be hands-on and engaging, allowing students to explore and analyze realistic data without struggling with a clunky or tedious statistics tool. JMP is interactive and powerful point-and-click software for solving real-world engineering problems. It is ideal for engaging, hands-on teaching of relevant data skills in engineering and is also used by scientists and engineers at leading companies across the globe.

While the fundamental skills addressed in this session include understanding variation and uncertainty, we will also look at applications like data modeling, designing experiments and quality management – all from a student's perspective.

This interactive session will demonstrate how JMP can help to engage students' curiosity and teach engineering data skills which are most in-demand in industry today. We'll guide you through a series of brief demonstrations, so that you can directly experience the difference JMP can make for your course. Participants will receive a free trial license before the workshop, and the presenters will provide sample data and lead you through several hands-on examples in JMP. We will also discuss best practices and share resources to support integration into engineering courses.

1 TEACHING WITH REAL CASES

This short paper summarizes the key ideas from the practical workshop by JMP and provides the links to all free resources shared with the audience.

1.1 Why teaching with real cases?

Why should you consider using real problems – typically shared as case studies – in teaching data analytics? There are many good arguments, which include

1. Real cases help to teach the analytical skills which will be relevant for students in a future workforce (refer to customer stories [1] for examples who shared or inspired the cases discussed here)
2. Storytelling by real cases can boost the engagement of students (see [2] for a demo of visual storytelling)
3. Instead of applying a single method, students take a journey of statistical discoveries (the JMP analytical workflow [3] shows a “landscape to travel from data to insights”).

We will also discuss that real cases perfectly support the GAISE standard in statistics education [4], especially the first recommendation on teaching statistical thinking. Each case is an example for a "problem-solving and decision-making process" and requires multivariable thinking:

a. **Teach statistics as an investigative process of problem-solving and decision-making.** Students should not leave their introductory statistics course with the mistaken impression that statistics consists of an unrelated collection of formulas and methods. Rather, students should understand that statistics is a problem-solving and decision-making *process* that is fundamental to scientific inquiry and essential for making sound decisions.

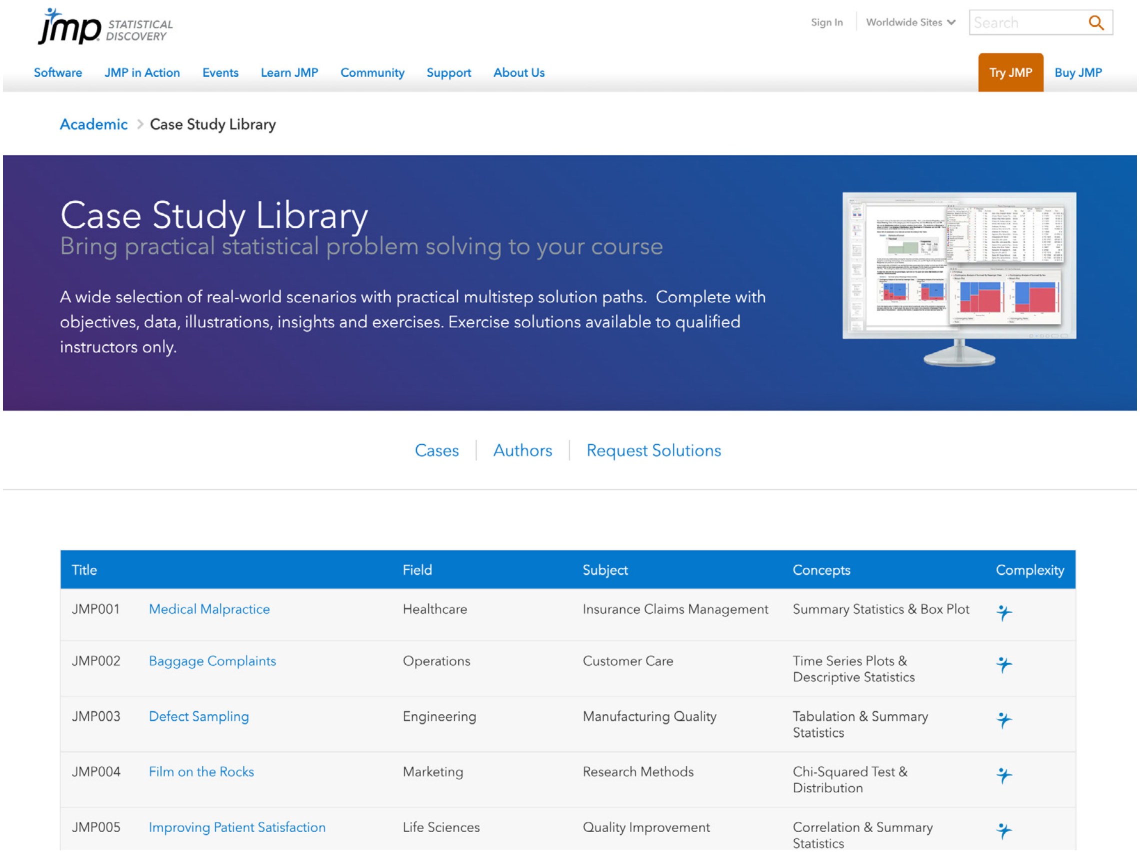
b. **Give students experience with multivariable thinking.** We live in a complex world in which the answer to a question often depends on many factors. Students will encounter such situations within their own fields of study and everyday lives. We must prepare our students to answer challenging questions that require them to investigate and explore relationships among many variables. Doing so will help them to appreciate the value of statistical thinking and methods.

Fig. 1. GAISE I recommendation about teaching statistical thinking [4]

In addition to this guideline, other revised recommendations like “3. Integrate real data with a context and purpose” and “4. Foster active learning” support the key message of this workshop.

1.2 Access to real cases

The workshop will suggest the JMP Case Study Library [5] as an open source providing free access to more than 50 case studies. Each case comes with a background story, a problem- and task description and one or more datasets, a step-by-step solution with illustrations using JMP tools and summaries about lessons learned from a business, statistician’s and JMP user’s perspective. Solutions to optional exercises are shared with authorized instructors.



Title		Field	Subject	Concepts	Complexity
JMP001	Medical Malpractice	Healthcare	Insurance Claims Management	Summary Statistics & Box Plot	
JMP002	Baggage Complaints	Operations	Customer Care	Time Series Plots & Descriptive Statistics	
JMP003	Defect Sampling	Engineering	Manufacturing Quality	Tabulation & Summary Statistics	
JMP004	Film on the Rocks	Marketing	Research Methods	Chi-Squared Test & Distribution	
JMP005	Improving Patient Satisfaction	Life Sciences	Quality Improvement	Correlation & Summary Statistics	

Fig. 2. Examples from the JMP Case Study Library published at jmp.com/cases

Most cases have been developed by practitioners in industry. They can be chosen from a list based on field and subject, covered key concepts and level of complexity.

2 LIVE DEMO

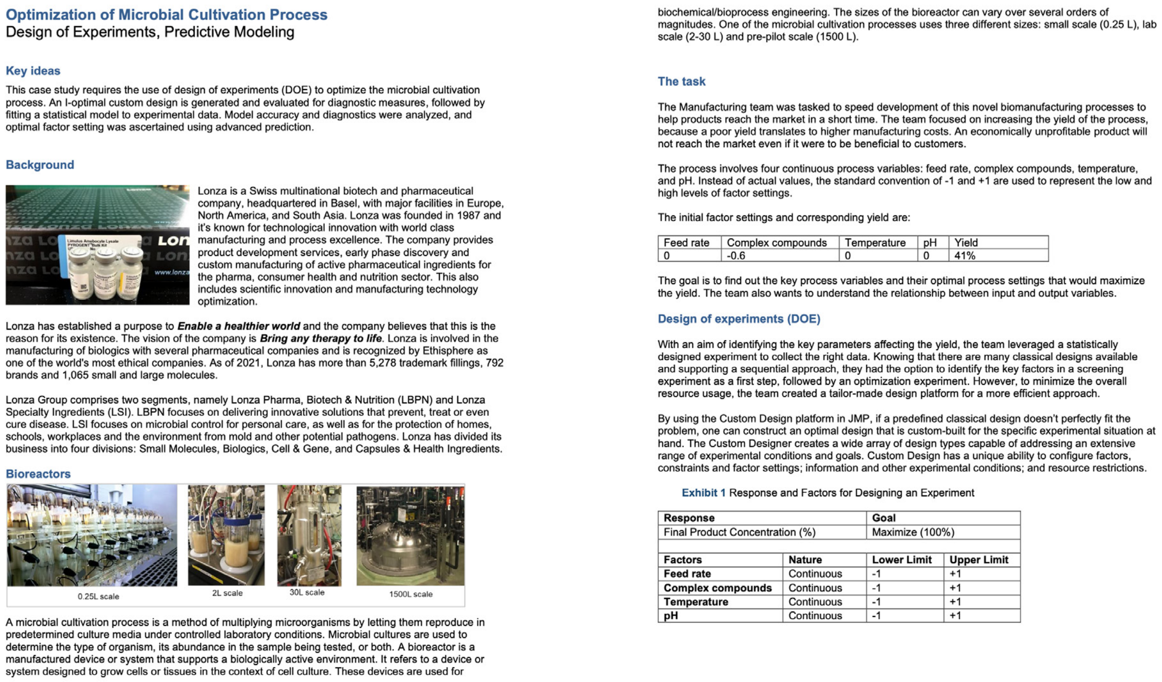
A live demo will present the solution of case #52 on process optimization in biotech from LONZA [5] (Fig. 3), showing sample content and style of a JMP case study. The demo will also provide a practical example about applying statistical thinking, combining JMP capabilities for statistical discoveries to solve a real-world problem. Alternatively, readers of this paper can watch a recorded demo [6] presented by Andreas Trautmann from LONZA, who is also a co-author of the case study.

3 CASES IN THE CLASSROOM

There are several options to use our cases studies in teaching: While educators can use case studies for in-class demonstrations, the most effective use are assignments to students as homework or group projects. The cases can stimulate discussions about which steps to take or comparisons of alternative solutions. Students can also be asked to present the learning outcome to “other decision makers”, or to explain why and how certain methods have been applied.

4 MORE TEACHING RESOURCES AND GETTING STARTED

Case studies are just one kind of teaching resources provided by JMP’s Global Academic Program. During the workshop, additional resources will be shared and



Optimization of Microbial Cultivation Process
Design of Experiments, Predictive Modeling

Key ideas

This case study requires the use of design of experiments (DOE) to optimize the microbial cultivation process. An I-optimal custom design is generated and evaluated for diagnostic measures, followed by fitting a statistical model to experimental data. Model accuracy and diagnostics were analyzed, and optimal factor setting was ascertained using advanced prediction.

Background

Lonza is a Swiss multinational biotech and pharmaceutical company, headquartered in Basel, with major facilities in Europe, North America, and South Asia. Lonza was founded in 1987 and it's known for technological innovation with world class manufacturing and process excellence. The company provides product development services, early phase discovery and custom manufacturing of active pharmaceutical ingredients for the pharma, consumer health and nutrition sector. This also includes scientific innovation and manufacturing technology optimization.

Lonza has established a purpose to ***Enable a healthier world*** and the company believes that this is the reason for its existence. The vision of the company is ***Bring any therapy to life***. Lonza is involved in the manufacturing of biologics with several pharmaceutical companies and is recognized by Ethisphere as one of the world's most ethical companies. As of 2021, Lonza has more than 5,278 trademark fillings, 792 brands and 1,065 small and large molecules.

Lonza Group comprises two segments, namely Lonza Pharma, Biotech & Nutrition (LBPN) and Lonza Specialty Ingredients (LSI). LBPN focuses on delivering innovative solutions that prevent, treat or even cure disease. LSI focuses on microbial control for personal care, as well as for the protection of homes, schools, workplaces and the environment from mold and other potential pathogens. Lonza has divided its business into four divisions: Small Molecules, Biologics, Cell & Gene, and Capsules & Health Ingredients.

Bioreactors

0.25L scale 2L scale 30L scale 1500L scale

A microbial cultivation process is a method of multiplying microorganisms by letting them reproduce in predetermined culture media under controlled laboratory conditions. Microbial cultures are used to determine the type of organism, its abundance in the sample being tested, or both. A bioreactor is a manufactured device or system that supports a biologically active environment. It refers to a device or system designed to grow cells or tissues in the context of cell culture. These devices are used for biochemical/bioprocess engineering. The sizes of the bioreactor can vary over several orders of magnitudes. One of the microbial cultivation processes uses three different sizes: small scale (0.25 L), lab scale (2-30 L) and pre-pilot scale (1500 L).

The task

The Manufacturing team was tasked to speed development of this novel biomanufacturing processes to help products reach the market in a short time. The team focused on increasing the yield of the process, because a poor yield translates to higher manufacturing costs. An economically unprofitable product will not reach the market even if it were to be beneficial to customers.

The process involves four continuous process variables: feed rate, complex compounds, temperature, and pH. Instead of actual values, the standard convention of -1 and +1 are used to represent the low and high levels of factor settings.

The initial factor settings and corresponding yield are:

Feed rate	Complex compounds	Temperature	pH	Yield
0	-0.6	0	0	41%

The goal is to find out the key process variables and their optimal process settings that would maximize the yield. The team also wants to understand the relationship between input and output variables.

Design of experiments (DOE)

With an aim of identifying the key parameters affecting the yield, the team leveraged a statistically designed experiment to collect the right data. Knowing that there are many classical designs available and supporting a sequential approach, they had the option to identify the key factors in a screening experiment as a first step, followed by an optimization experiment. However, to minimize the overall resource usage, the team created a tailor-made design platform for a more efficient approach.

By using the Custom Design platform in JMP, if a predefined classical design doesn't perfectly fit the problem, one can construct an optimal design that is custom-built for the specific experimental situation at hand. The Custom Designer creates a wide array of design types capable of addressing an extensive range of experimental conditions and goals. Custom Design has a unique ability to configure factors, constraints and factor settings; information and other experimental conditions; and resource restrictions.

Exhibit 1 Response and Factors for Designing an Experiment

Response	**Goal**
Final Product Concentration (%)	Maximize (100%)

Factors	**Nature**	**Lower Limit**	**Upper Limit**
Feed rate	Continuous	-1	+1
Complex compounds	Continuous	-1	+1
Temperature	Continuous	-1	+1
pH	Continuous	-1	+1

Fig. 3. Extract from case study #52 shared by LONZA

discussed, including the JMP Leaning Library and the Statistical Thinking online course (see [7] for “Introductory Engineering Statistics” course material).

Workshop participants and readers are welcome to contact the author for a personal discussion of JMP academic resources and capabilities.

The role of lecturers in engineering students' personal development process and the promotion of lifelong learning competencies

Naukkarinen, Johanna
LUT University, Finland

Van Den Broeck, Lynn
KU Leuven, Belgium

Craps, Sofie
KU Leuven, Belgium

Beagon, Una
TU Dublin, Ireland

Conference Key Areas: *Lifelong Learning*
Keywords: *personal development process, lifelong learning, role of faculty*

doi:10.5821/conference-9788412322262.1410

Professional engineers need to continuously update and up-skill their competencies, to keep pace with the changing technology and shifting requirements of the labour market (European Commission 2019). Educating resilient students requires a university setting that makes them aware of their professional identity and trains them in continuously re-inventing themselves (Knapper and Cropley 2000). Hence, the educational challenge is not only to prepare students for a specific career but also to build foundations for a lifetime of learning (Kamp 2016). Although teaching staff often acknowledge the importance of Life Long Learning (LLL) competencies they do not necessarily feel adequately prepared to support students' personal development and lifelong learning skills. However, to support students and prepare them for a life of LLL, lecturers need to be more systematically and explicitly engaged in the students' personal development process.

Lecturers' ability to support students' career development is related to academics' attitudes and beliefs, teaching and learning approaches, as well as the challenges met by the staff (Amiet et al. 2021). In the contemporary rapidly changing world, engineering graduates emphasize the need for generalist competence, interpersonal skills, and constant learning over formal credentials and specific technical competencies in securing employment (Nilsson 2010). Academics also perceive that enhancing students' general skills supports their career development more than focusing on specific careers (Amiet et al. 2011).

Research has shown that different pedagogical approaches influence engineering students' development of self-regulated learning and, by extension, lifelong learning skills differently. Problem- and project-based learning tend to promote metacognitive self-regulation, critical thinking, and help-seeking, whereas lectures with active learning activities promote more effective use of time and study environment. (Lord et al. 2012.) Some assessment and grading approaches even seem to undermine the types of goals associated with self-directed learning (Stolk et al. 2014) and may thus even inhibit the development of LLL competencies.

Although many academics recognize that they have a role in students' career development, they also call for the responsibility to be shared among students, lecturers, and professional staff. Lecturers with limited work experience outside university especially felt that they lacked confidence in supporting students' career development. Many academics also felt guilty for not being able to meet the students' expectations for support. They suggested that the responsibility for supporting students' career development should be better acknowledged in academic job descriptions and promotional guidelines, as well as being supported with faculty and university-level resources. (Amiet et al. 2011.)

This workshop launched the Erasmus+ TRAINeng -PDP project which focuses on how we can help students develop LLL competencies and support lecturers by designing and creating appropriate training materials. To begin, we needed a collection of perceptions regarding the role, responsibilities, resources, opportunities, and challenges of engineering lecturers to support the students' personal development process and a lifelong learning attitude. Hence, we called the SEFI community for assistance. The results of the workshop will inform the pilot projects, attitudinal survey, and training materials which will form the outcome of this project.

The workshop consisted of a short introduction to the topic followed by collaborative work and discussion in groups in the form of a learning café. The discussions addressed questions: "*What **could we do** to support the development of students' LLL competencies?" and "What **should we do** to support the development of students' LLL competencies?"* Both questions were addressed separately from three different realms of lecturers' tasks, namely instruction, guidance, and assessment.

The workshop resulted in over two hundred ideas for and insights on supporting the development of students' LLL competencies in teaching. Discussions were conducted in six groups rotating the three aspects (instruction, guidance, and assessment). In the first round of analysis, ideas were grouped into 33 categories and then further into six themes. As the work still continues, the categories and themes may undergo some changes in the future. Current six themes 1) Planning for active learning 2) Training and supporting reflection, communication, and teamwork skills 3) monitoring and explicating learning 4) providing different forms of feedback 5) creating an inclusive, safe, and curious environment 6) Training lecturers, combine ideas related to all three aspects.

Planning for active learning entails suggestions for using active instruction methods, encouraging problem-solving, being innovative with assessment methods, choosing and searching for supportive materials, promoting cooperation among students, demonstrating professional skills to students, and involving students in planning the assessment. However, it also contains reminders of remembering the different dimensions of assessment as well as the need for balancing the course requirements and not just adding LLL objectives on top of everything else.

Training and supporting reflection, communication, and teamwork skills includes many different means for encouraging and helping students to reflect on their knowledge (or lack of it), learning process, perspectives, etc. Training for reflection, teamwork, and communication skills for learning but also for assessment is emphasized. Scaffolding for the development of different metacognitive skills is perceived to be part of the guidance.

Monitoring and explicating learning refers to the ways the lecturers can help students to understand learning as a process on a general and personal level. Communicating assessment effectively is considered important and providing role models and stories is thought to enhance especially students' attitudes towards LLL. Getting the right kind of information through assessment activities is also crucial for monitoring the students' learning processes.

Providing different forms of feedback in instruction, guidance, and formative and summative assessment is often brought up in the ideas. Valuable feedback can be received from the teacher, peer students, and through self-assessment or even from experts from outside academia. Enabling students to act on the feedback is often emphasized and especially peer feedback is seen as an important way to enhance students' evaluation skills.

Creating an inclusive, safe and curious environment is seen as a prerequisite for learning from mistakes, which is considered to be a powerful way to learn through reflection. An inclusive environment calls for the lecturers to see and value students as individuals, to value diversity, and demonstrate variety in their knowledge and opinions. Especially guidance by asking questions is seen as a powerful way to support students in developing their LLL competencies and especially questions and situations which stimulate students' curiosity are valued.

Finally, it is brought up that in addition to the students, also lecturers may need training and help in understanding and mastering the same skills, whose development they are supposed to scaffold for students. Especially help for conducting a meaningful assessment, discussing assessment with students, and training for reflecting on teamwork processes is suggested as resources for supporting students' LLL.

Asking about 'coulds' and 'shoulds' did not reveal any stark lines of division and it seems that many lecturers are willing to conduct the actions they deem necessary for supporting students. Lecturers seem to be ready to act as role models and also share their imperfections and learning needs with the students to show that also they need to engage in lifelong learning. This appears to be an excellent starting point for our project aiming to help both students and lecturers in enhancing students' LLL competencies.

Overview

The workshop will give an overview of recent developments in education-focused academic career pathways, with specific reference to engineering disciplines. Workshop participants will discuss strategies for developing their academic careers through teaching excellence, Engineering Education Research (EER) and SOTL (Scholarship of Teaching and Learning), and leadership in Engineering Education. The workshop will also discuss how engineering schools can improve the support they offer to their education-focused academics.

Background and rationale

The number of academics in the UK (United Kingdom) employed on education/teaching-only contracts (as opposed to joint research and teaching contracts) has increased steadily since the turn of the century. In 2020/21, 32 percent of all UK academics were on teaching-only contracts [1]. The growth in the number of academics on teaching-only contracts appears to be part of an international trend within Europe, Northern America, and Australia driven by changes in the higher education environment such as the massification of higher education, cuts to higher education funding, research funding selectivity, and marketisation of higher education. These changes have led to institutions restructuring and adopting new strategies to ensure survival, including the increased casualisation of academic staff, and the introduction of separate academic contracts for research, education, and research and education [2].

The introduction of teaching-only academic contracts has led to the development of education-focused career pathways with opportunities for promotion to senior academic roles based on teaching excellence, scholarship, professional practice, and education leadership. However, the newness of such pathways means that there is a shortage of education-focused senior academics to provide role models and mentoring for junior academics seeking promotion to senior grades. This is further compounded by uncertainty and lack of consensus on what counts as evidence of good education practice, particularly when considering promotion to senior grades [3, 4].

The SEFI conference brings together academics of all levels and contracts with an interest in Engineering Education, including academics on education-focused career pathways. The workshop seeks to take advantage of this by bringing together these individuals, with those among us who hold senior leadership roles, to discuss and share ideas, experiences, and insights into developing successful education-focused academic careers. It is hoped that this workshop will help participants to establish supportive networks that will continue to exist beyond the conference.

Audience

Engineering academics on education-focused career pathways, and senior academics with line management for such academics and/or educational leadership and career promotion responsibilities within higher education institutions.

Timeline

Education-focused Academic Career Pathways – 10 minutes

Content outline:

- Discuss the unbundling of the academic role into specialised functions focussing on research, education (teaching and learning) and service (to include a brief overview of the underlying factors driving this change).

- Identify the emergence of education-focused distinct academic career pathways in individual universities
- Highlight the challenges and opportunities for establishing an equitable career progression for education-focused academics in different universities and countries.
- Discuss similarities and difference of the academic profession in various countries.

Career Progression through Excellence in Education Practice - 10 minutes

Content outline:

- Discuss the contested concept of teaching/education excellence in higher education
- Discuss national frameworks for recognising teaching/education excellence, e.g., the UK Professional Standards Framework (UKPSF).
- Discuss the use of teaching/education excellence frameworks in developing institutional teaching-based promotion criteria for academic staff

Establishing an EER and Scholarship Career – Strategies, Challenges & Opportunities - 10 minutes

Content outline:

- Discuss how EER (and SOTL) is defined and supported within individual higher education institutions and national higher education systems
- Identify and discuss challenges in developing and supporting EER (and SOTL) for promotion and recognition
- Discuss and propose strategies for evidencing EER attainments in institutional promotional criteria

Establishing an Education Leadership Career- Strategies, Challenges & Opportunities - 10 minutes

- Discuss the extent to which education (teaching and learning) leadership is recognised as a valid form of academic leadership within higher education institutions, and within engineering disciplines
- Discuss current institutional promotion policies and criteria with respect to promoting and rewarding those who teach and lead on education
- Discuss emerging “good practices” in relation to promoting and rewarding education leaders within higher education institutions, and, specifically, within engineering disciplines

How Engineering Schools can support education-focused academics – 10 minutes

Discuss institutional and departmental policies and practices that support career development, promotion, and recognition for education-focused academics, including:

- Fostering an inclusive academic culture that supports and encourages academics to play to their own strengths
- Continuing professional development opportunities for education-focused academics
- Promoting parity of esteem at all levels of the career ladder between education-focused academics and mainstream (research and teaching track) academics.

Wrap-up and closing comments – 10 minutes

Acknowledge emerging good practice in promoting and rewarding education–focused academics and identifying areas for collaborative research in this area.

Workshop organisation

The workshop will be organised as an interactive session in which participants are invited to actively contribute their experiences and insights in all the workshop segments. The workshop is intended to stimulate discussion amongst the workshop participants, with the hope of initiating collaborative research on academic careers and practices within engineering education.

courses. At the end of the workshop, participants will be able to make an informed decision on a suitable form of Peer Assessment for their courses.

Over the past few years, many of us have faced operating in a frequently changing teaching environment which has made evaluating and assessing students' learning outcomes and more importantly giving students feedback on their learning much more complicated.

One pedagogical tool that has been increasingly used is that of peer assessments where students give each other feedback and assess each other's work.

In this workshop, participants will be introduced to many different types of peer assessment that can be used in engineering education, such as peer reviewing (each other's work), peer grading(continuous feedback on mastery), and peer evaluation (group work) whether face-to-face, hybrid or in a fully online environment and how to do so in an inclusive way thus maintaining the important safe place that education should be.

Participants will then in small groups discuss what types of peer evaluations they use or want to use in their courses and brainstorm on ideas for implementation in their own specific case or for one of the general cases that the facilitators will have available.

At the end of the workshop participants will present their main findings back to the whole group so that they may also learn from each other. We aim for participants to leave feeling inspired at the end of the workshop to implement or improve peer assessment in their own courses.

The aggregated main findings and ideas contrived in the workshop on how to implement peer assessment will also be shared with a wider audience through the conference proceedings and the RAPIDE project website.

1 INTRODUCTION

This workshop is part of the ERASMUS+ project: RAPIDE: on Relevant Assessment and pedagogies for Inclusive Digital Education (https://rapide-project.eu) and is open to anyone who is interested in implementing or improving (digital) Peer Assessment (PA) in their courses.

2 WHY THIS WORKSHOP?

With increasing student numbers entering Higher Education across the globe and with an increasing need for flexibility in how education is delivered, lecturers are in need of more digital tools to help them in their teaching. As the recent COVID-19 pandemic has shown us, lecturers must be able to almost seemingly switch between online, blended, flipped classroom (FC), or face-to-face education in the case of on-campus education. At the same time, similar tools are needed to support Work-Based Learning (WBL) and fully online or remote learning.

One area where lecturers can struggle to deal with both the required flexibility and the increasing student numbers is in the area of assessment. At our own institution, for instance, student numbers have increased by over 15% in the last four years. Next to the debatable, all-important grade, it is also important that students are provided with timely feedback on their performance and their deliverables if we want our students to truly learn and mature. However, this can have serious implications for the workload of the lecturers involved.

3 PEER ASSESSMENT AS A SOLUTION

One pedagogical tool that has been increasingly used is peer assessment, where students give each other feedback and assess each other's work. Being able to reflect and give and receive feedback are important transversal skills for engineering students to learn to enhance their employability [1]. Already in 1998, Keith Topping published a literature review on the use of Peer Assessment in Higher Education [2]. He defined PA as:

> *"an arrangement in which individuals consider the amount, level, value, worth, quality, or success of the products or outcomes of learning of peers of similar status."*
> (Topping, 1998, p.250 [2]).

Whereas PA in the 20th Century was very much a paper-based or verbal exercise, these days optimal use can be made of Virtual Learning Environments such as BlackBoard, Brightspace, Canvas or Moodle and the digital software tools available to educators when it comes to using PA.

4 WHAT WILL PARTICIPANTS LEARN & DO IN THE WORKSHOP?

In this workshop, participants will be introduced to different types of peer assessment that can be used in engineering education, whether face-to-face, hybrid or in a fully online environment and how to do so in an inclusive way thus maintaining the important safe space that education should be.

The main learning outcome at the end of the workshop will be that participants are able to make an informed decision on how to design or select an appropriate form of Peer Assessment for their course.

Participants will be introduced to the pros and cons of the different methods and which type of PA type is suitable for what educational activity, using some of the case studies developed in the RAPIDE project as an example.

Case studies to be covered are Peer Assessment in terms of reviewing students' products, peer grading where students grade each other's work and peer evaluation where students review each other's performance in group work

Participants will also learn about the requirements digital peer evaluation systems must meet to provide a safe and inclusive learning space as well as meet the various data protection requirements.

Participants will then in small groups discuss what types of peer evaluations they use or want to use in their courses and brainstorm on ideas for implementation in their own specific case or for one of the general cases that the facilitators will have available.

At the end of the workshop, participants will present their main findings back to the whole group so that each group may also learn from the other.

5 MAIN TAKEAWAYS

We aim for participants to leave feeling inspired at the end of the workshop to implement or improve peer evaluations and peer assessment in their own courses. Participants will also be provided with some of the resources developed within the RAPIDE project for them to take home with them and use when looking at implementing PA using digital systems in their own courses.

The aggregated main findings and ideas contrived in the workshop on how to implement peer assessment in courses will also be shared with a wider audience through the conference proceedings and the RAPIDE project website.

Context

The growth of Engineering Education Research (EER) has led to claims about it becoming a globally connected field of inquiry. Following from this, recent studies have employed scientometric data drawn from SCOPUS to provide insights into the research careers of EER practitioners in parts of Europe: Portugal, Spain and the Nordic countries. Within the SEFI EER SIG, ongoing work by the workshop organisers is studying how national contexts influence the EER output in the various European countries.

Workshop Aims

1. To share with participants scientometric data on EER publication output and research careers across the countries of Europe;
2. To guide participants to situate this scientometric data in the light of their knowledge of their own institutional and national context and to compare international contexts;
3. To learn new insights from participants that broaden the base of relevant EER data from across Europe. This could lead to future work in which the findings are explored in relation to the contextual factors associated with each of the geographical regions, thus providing insight into ways to support development of EER in the future.
   It is also hoped that its findings could also involve other stakeholders who could lobby for a parity of esteem between EER and engineering research (for career progression or promotion) both at national and European levels, and for more funding for EER by European research bodies.

Workshop structure

- Participant introduction activity
- Plenary session: presentation of scientometric data on EER publications and careers in European countries
- Group activity: participants work in international breakout groups to compare and contrast the EER landscapes in their respective countries
- Plenary session: reports back from group activity
- Wrap-up, including discussion on any follow-up to workshop

WHORKSHOP SIG

How can *you* contribute to the social responsibility of your university's education?

Gunter Bombaerts, Helena Kovacs, Diana Martin, Roland Tormey
Keywords: responsibility, ethics, teacher, university, eco-system

In this SEFI ethics SIG-workshop, we actively engage with the question: "How can *you* contribute to the social responsibility of your university's education?"

This is an important question for university staff.
First, universities become (and see themselves) as increasingly important players to contribute to the sustainable development goals. Their missions [1]–[3] and strategies [4] broaden to more research, entrepreneurship and social responsibility. From the perspective of being recognized as important actors in the quintuple helix of innovation [5], (technical) university eco-system collaborations become increasingly co-creative, including complex interactions between political, economic, and education systems, natural environment and knowledge creation [6]. The technical universities' education also becomes increasingly intertwined with the eco-system partners, resulting in adapting curricula [7] and new and flexible [8] formats for ethics courses [9] such as research-based, community-based or challenge-based learning.
Second, in this transition, teachers change inevitably from purely internal staff to societal actors [10]. Willingly or unwillingly, you as an individual teacher get a more pronounced societal role, as an agent of social change (e.g. [11]). This means a growing realization that, in the language of Paulo Freire, "Education is politics…when a teacher realizes that he or she is a politician too, the teacher has to ask, What kind of politics am I doing in the classroom? That is, in favor of whom am I being a teacher?" [3:46].

If we approach this from the responsibility angle, Whitbeck's definition "exercise of judgment and care to achieve or maintain a desirable state of affairs" [4:159] can be a starting point here. As Fore and Hess note while introducing their five-sided framework of ethical becoming, "rules and codes found in discipline-specific standards are undoubtedly important, [but] insufficient by themselves for moral inquiry and ethical judgement" [5:1355]. The reflection of the impact of education to the university's responsibility then requires a focus on the actual context and social practices [15] and a broader perspective on all involved (students, teachers, university, eco-system) [16].

For the session, we propose the following **agenda:**

1. Short introduction of the context of the workshop
2. Break-out groups
   - What is your role in the university? (Ethics) teacher? (Educational) manager? What do you care about"? What do you want to change or influence? Do you focus on the classroom activities? Or do you reflect on how your activities (teaching, research, …) have a broader impact?

doi:10.5821/conference-9788412322262.1466

How do you judge things as a desirable state of affairs? How does ethics come into play?
What can you "exercise"? What can you do? What is your agency or influence? How is it limited (university, other contexts)? Do you want more influence?

- Who can or should you involve in co-constructing the educational agenda and reaching educational goals?
- How do you evaluate your influence? Student satisfaction or student learning? Do you also use input from other partners?

3. Plenum discussion, in which we bring together the different inputs and have an overall discussion.

Emerging professional skills: Insights and methods

SEFI 2022 Engineering Skills SIG Workshop Report

Neil Cooke[1], **Natalie Wint, Thies Johannsen, Raffealla Manzini, Emanuela Tilley, Yolande Berbers, Ann-Kristin Winkens, Jennifer Griffiths, Gareth Thomson, Roger Hadgraft, Kamel Hawwash,**
Engineering Skills SIG

Conference Key Areas: *Engineering Skills,*
Keywords: *project management, innovation and entrepreneurial mindset, communications, transdisciplinarity, complex systems, leadership, teamwork, skills*

ABSTRACT

In this workshop run by the Engineering skills SIG, attendees were given the opportunity to learn about emerging professional competencies, and strategies to overcome teaching barriers.The workshop format was “world cafe” with several tables for small groups to informally discuss these strategies within a time limit. Each table focussed on an emerging skill and/or scenario and participants each visited several tables. The session was informed by the engineering skills survey taken by SEFI 2021 conference attendees. It gave us views on new competencies, barriers to teaching them, and illustrations of good practice. Obstacles to teaching them include motivation, legitimacy, overloaded curriculums, student resistance, resource constraints, and pedagogical understandings.Ideally skills should be learned by students in contexts where they’re used. While many technical competencies are primarily developed in engineering practice, professional/soft abilities are often not. As a result, there ought to be some opportunity for the student to transfer, adapt and (re)learn them in an engineering degree. This report summarises the conference workshop outputs with sections for each table. Each section acknowledges the hosts/authors, a summary of the discussion, and any materials presented. Readers may find this paper useful when facilitating related discussions.

1 INNOVATION AND ENTREPRENEURIAL MINDSET (RAFAELLA MANZINI, UNIVERSITA' CARLO CATTANEO - LIUC)

rmanzini@liuc.it

1.1 What is innovation?

- Good definition: Oslo Manual (ch. 3.2, 3.3, 3.4, https://www.oecd.org/science/oslo-manual-2018-9789264304604-en.htm) and the Frascati Manual (ch 2.2-2.5, https://www.oecd.org/sti/inno/frascati-manual.htm).
- Innovation is creating value from ideas. What value? Both economic and social value.

1.2 What do we mean with “innovation skills” and “entreprenerial mindset”?

- Innovation skills: ability to contribute to transform ideas into value, with an
- entrepreneurial mindset: taking care of the idea, until it deploys its economic and/or social value.

1.3 Do we really need to teach these skills to engineering students? Aren’t they already skilled, in their specific technical area? Some provocative statements

- Engineers are highly creative, in their technical field of expertise
- Engineers are problem solvers, so they are naturally ready for innovation
- Engineers do not need to have innovation and entrepreneurship skills:

1.4 What do we really need to teach to engineering students?

- Innovation is a process, it is not only a matter of creativity and technical competences.
- The focus should be on value generation, something which is not always “natural” among engineers:

1.5 How to help students developing innovation skills and an entrepreneurial mindset

- Project – based and challenge based approaches are the most suitable;
- Case-based learning can be helpful, but it isn’t enough;
- Internships can greatly help;
- Leverage on the specialized technical knowledge and expertise of students
- Make engineering students aware of their limitations
- Create groups with mixed competences and background

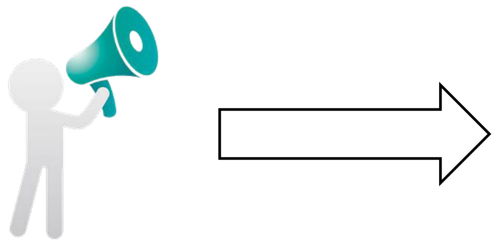
2 COMMUNICATIONS (NATALIE WINT, SWANSEA, AND JENNIFER GRIFFITHS, UCL)

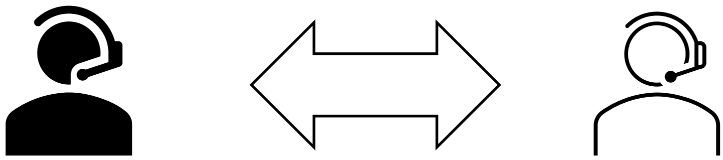
n.wint@swansea.ac.uk j.griffiths@ucl.ac.uk

2.1 Models of Communication

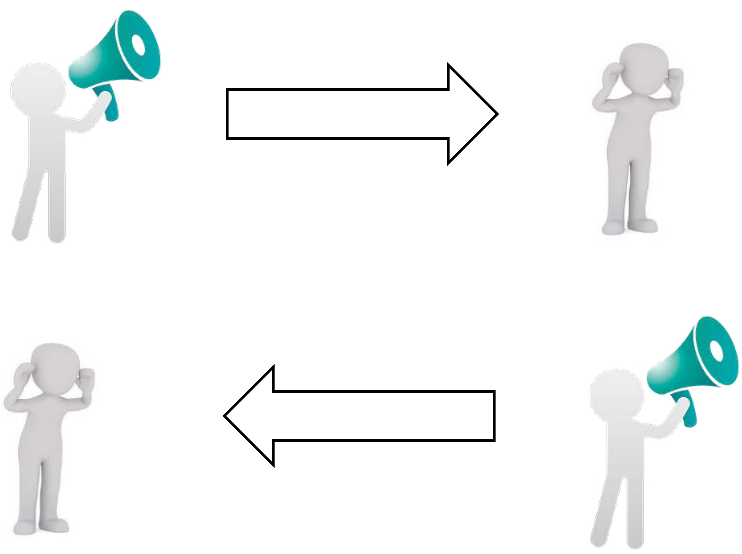
- **Linear models (e.g., Aristotle's, Lasswell's, Shannon-Weaver, Berlo's SMCR)–** only looks at one-way communication.



- **Interactive models (e.g., Osgood Schramm, Westley and Maclean) –** looks at two-way communication.



- **Transactional models (e.g., Eugene White's, Barnlund's, Dance's Helical) –** looks at two-way communication where the message gets more complex as the communication event (e.g., conversation) progresses.



2.2 Communication across disciplines

Students must communicate with people from different disciplines or cultures. They will face challenges in doing so and should therefore be aware of how to address them.

- People from different backgrounds often attach different meanings to the same word.
- People bring different perspectives to bear on what they hear and infer a different meaning than was intended. Students are therefore more likely to transcend their disciplinary perspective if they are self-aware of the set of largely subconscious assumptions.

3 INTER- AND TRANSDISCIPLINARITY (HOSTS: THIES JOHANNSEN, TU-BERLIN, ANN-KRISTIN WINKENS, RWTH AACHEN)

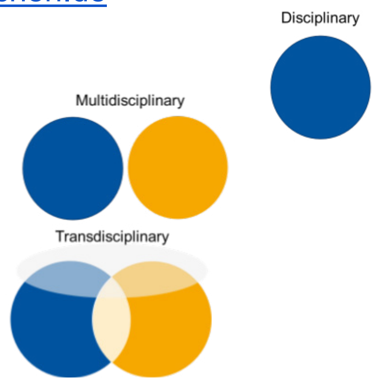
johannsen@tu-berlin.de, ann-kristin.winkens@gdi.rwth-aachen.de

3.1 What is inter- and transdisciplinarity?

Multidisciplinarity is a sum of disciplinary perspectives.

Interdisciplinarity is a transformative process of mutual cooperation among disciplines.

Transdisciplinarity is a transformative process of mutual cooperation among stakeholders from different fields – including non-academics.



(cf. "What is transdisciplinarity" SEFI@work SIG Skills, 10 December 2021)

3.2 How can inter- and transdisciplinarity be implemented in HE teaching?

Problem- and project-based Learning

Problem-based learning begins with identifying and structuring a problem and exploring its limits (Brassler/Dettmers 2017: 5). This includes dealing with relevant terms and concepts as well as critical source work. It is a student centered learning concept that addresses complex learning (Hadgraft/Kolmos 2020: 5).

- Brassler, Mirjam/Dettmers, Jan (2017): How to Enhance Interdisciplinary Competence—Interdisciplinary Problem-Based Learning versus Interdisciplinary Project-Based Learning. In: *Interdisciplinary Journal of Problem-Based Learning* 11 (2). DOI: 10.7771/1541-5015.1686.
- Hadgraft, R. G., and Kolmos, A. (2020). Emerging learning environments in engineering education. Australasian Journal of Engineering Education, 25(1), 3–16. doi:10.1080/22054952.2020.1713522

3.3 Case-based Learning

Case learning aims to develop professional intellectual and behavioral skills through a topic-specific and problem-oriented interpretation of real-life experiences (Lynn 1999: 3). Case teaching is an inductive method that builds a bridge between theoretical-declarative and practical-functional knowledge (Biggs/Tang 2011: 163). Students gain application-oriented knowledge and develop practice-relevant competencies in the theory-based and guided examination of a case.

- Biggs, John Burville/Tang, Catherine So-kum (2011): Teaching for quality learning at university. What the student does. 4th ed. Maidenhead: McGraw-Hill/Society for Research into Higher Education/Open University Press.
- Lynn, Laurence E. (1999): Teaching and Learning with Cases. A Guidebook. New York: Chatham House Publishers.

3.4 Best practices

Blue Engineering

Blue Engineering is an international and innovative workshop-style course provided by Technische Universität Berlin. It focuses on ecological and social responsibility. The course facilitates creative, interdisciplinary and sometimes heated debates on the issues posed by technology in society and in nature.

- Baier, André (2019): Education for sustainable development within the engineering sciences - design of learning outcomes and a subsequent course evaluation. TU Berlin, Berlin. http://dx.doi.org/10.14279/depositonce-8844.

Engineering for Impact

Engineering for Impact – Responsible Innovations is an interdisciplinary project- and problem-based course that introduces students to methods and tools of how science can make an impact. Students work in groups to develop a technology-based application concept for a self-selected societal challenge.

- Johannsen, Thies (2021): Integrated Classroom Learning. How to Create an Activating and Safe Environment for Online Learning in Knowledge Exchange and Innovation Education for Engineering Students. In: Jan von der Veen, Natascha van Hattum-Janssen, Hannu-Matti Järvinen, Tinne de Laet und Ineke ten Dam (Hg.): Blended Learning in Engineering Education: challenging, enlightening – and lasting? SEFI 49th Annual Conference. Berlin, 13.-16.09.2021, S. 936–950.

Project "Leonardo"

Project "Leonardo" aims to enhance and promote interdisciplinary discourses within RWTH Aachen University. In doing so, various courses are offered from usually two lecturers from different scientific disciplines that focus on social challenges. The aim is to discuss a central topic in an interdisciplinary manner under academic supervision and to bring together both students and lecturers from different disciplines.

- Winkens, A., Böschen, S., and Leicht-Scholten, C. (2021). Interdisciplinary Teaching at RWTH Aachen University: Project "Leonardo". Paper presented at the The European Conference on Education 2021, London, United Kingdom (online).

3.5 Workshop discussion

- It is important to define terms.
- There are overlaps with other relevant skills.
- Different knowledge and different understandings may be a challenge (cf. silos); results in barriers to collaborate with teachers/educators from different disciplines.
- There is generally a lack of recognition for the process, and a focus on results.
- To enhance collaboration skills interdisciplinary thesis in groups may be an effective approach; also, it raises awareness among students.
- There is usually a conflict between depth and breadth: either deep dives or broad, inter- or transdisciplinary understanding of a problem.
- How to approach inter- and transdisciplinarity? It is useful to make experiences first and then reflect them methodologically: have students make experiences rather than explaining methods theoretically.

- Usually there are deficits in institutions in regard to inter- and transdisciplinarity whereas individuals are very competent. Raises the question of institutional support.
- It may help to have testimonials from professionals that inter- and transdisciplinarity are meaningful in professional careers.
- Collaborating with industry may result in conflict of interest regarding research and commercialisation.
- A very relevant barrier is motivation of stakeholders, be it academics, students or external partners.

4 SYSTEM COMPLEXITY (YOLANDE BERBERS, KU LEUVEN)

Yolande.Berbers@kuleuven.be

4.1 What do you think System Complexity is, how would you define it, what does it include? Why is this skill important for engineers?

- Most attendees agreed that system complexity is to see non-obvious connections between things, while understanding why they behave a certain way, which gives insight into “a system is more than the parts”.

4.2 How is it taught at your institution?

- Many attendees didn’t identify a standalone teaching of this. However, in aerospace curriculum (TU-Delft) system engineering is part of the curriculum, there is a specific course on this
- Most agreed that system complexity is learned when students work on different parts of a system, and have them then integrate all these parts. Typically these are done in challenge based learning projects e.g. a Solar Car. These problems are typically “wicked”. Students should learn to model first before building, and make their reasoning explicit: ““build down the complexity to build it up” (Twente).

4.3 How is it assessed?

- A lot of visualization is necessary to understand the complexity of the system.

Report on the SEFI Working Group Workshop (19-1):

Teaching Soft Skills for Engineers of the Future by Using Projects

Organised and presented by: Nargiza Mikhridinova [1,3], Bertha Joseph Ngereja [2], Carsten Wolff [3], Wim Van Petegem [1], Mariano Alvarez Blanco [4]

[1] KU Leuven, Belgium; [2] The Norwegian University of Science and Technology, Trondheim, Norway; [3] Dortmund University of Applied Sciences and Arts, Germany; [4] Siemens Digital Industries Software, Leuven, Belgium

1. The Concept:

Workshop rational: Engineers work in projects and need certain soft skills to succeed in this work environment. Teaching soft skills to engineering students can be supported by creating project situations which generate a relevant learning experience. The workshop is intended for participants who want to look deeper into how to create such project situations in student projects.

Learning outcomes: During the one-hour workshop "Teaching soft skills for engineers of the future by using projects" participants will learn:

- How to plan, prepare and conduct agile cross-border projects with industry involvement for educational purposes
- How to select a relevant project case
- How to build the teams for project assignment
- Participants will be provided with:
    - Template and example of the course concept with learning activities' plan
    - Template and example of the case study description
    - Working template for the self-evaluation for roles identification

Concept and engagement scenarios: The workshop will have 3 parts:

- Part 1: project-based learning and agile cross-border projects,
- Part 2: roles and soft skills model, team formation and relevant exercises,
- Part 3: discussion and feedback from industry partners.

Part 1 description:

An introduction to the concept of agile cross-border projects [1] will be provided, including results of the ongoing research from students' and trainers'/lecturers' perspectives. During the session, participants get familiar with the course concept including the intended learning outcomes and the learning activity plan.

Part 2 description:

Introduction to the project case development [2] and know-how to refine and tailor a project case with companies for training soft skills [3, 4], as well as roles definition and team formation models and processes. Participants of the workshop will perform a role identification exercise based on Belbin's team roles [5]. After exercise the discussion will follow about matching their results with the Scrum roles.

doi:10.5821/conference-9788412322262.1471

Part 3 description:

a) Discussion between industry partners and the workshop participants on impact of soft skills in ongoing projects, training strategies to develop soft skills of employees, as well as perspective of the industry on skills of “fresh” engineering graduates.
b) Feedback and discussion about soft skills and personality traits [6] in order to train a desired set of soft skills.

Participants will be asked to assess and evaluate the concept; the workshop materials will be made available to all participants after the workshop (via cloud storage).

2. Results and Discussion

The workshop was attended by appr. 50 people (Fig. 1). After Part 1 on project-based learning and agile cross-border projects was concluded, the participants applied the Belbin’s test by their own with assistance of organisers (Part 2), and then in Part 3 we had a discussion and feedback from Siemens Digital Industries Software (Leuven, Belgium).

Fig. 1. Organisers and attendees of the workshop

From our point of view, the workshop was very relevant and interesting to participants. Particularly Part 1 arose a high interest of participants, and they were actively engaged in the discussion on conducting agile cross-border projects, and how they can replicate the same methodology in their courses.

Important to mention, Part 2 arose an interesting discussion about ending the use of the term "soft" as it sends the wrong message to students and lecturers, and other people in organizations. That because they are soft, it doesn’t mean they are less important. (You may be interested in reading a paper on a similar matter: *A hard stop to the term “soft skills”,* https://doi.org/10.1002/jee.20442).

The discussion from Part 3 also emphasized the need for higher education institutions to really focus on soft skills for engineering students. Companies are investing a lot to ensure that their employees possess both technical and soft skills. But there is still a need for higher education institutions to bridge the soft skills gap early enough in learning trajectories.

The participants were given the link to download the workshop materials, which can be accessed via https://fh-dortmund.sciebo.de/s/jxS7pIx5Do0WIra.

At the end, the participants evaluated the workshop. Although, the response rate was very low (16%), below you may find some interesting results, and insights (Table 1).

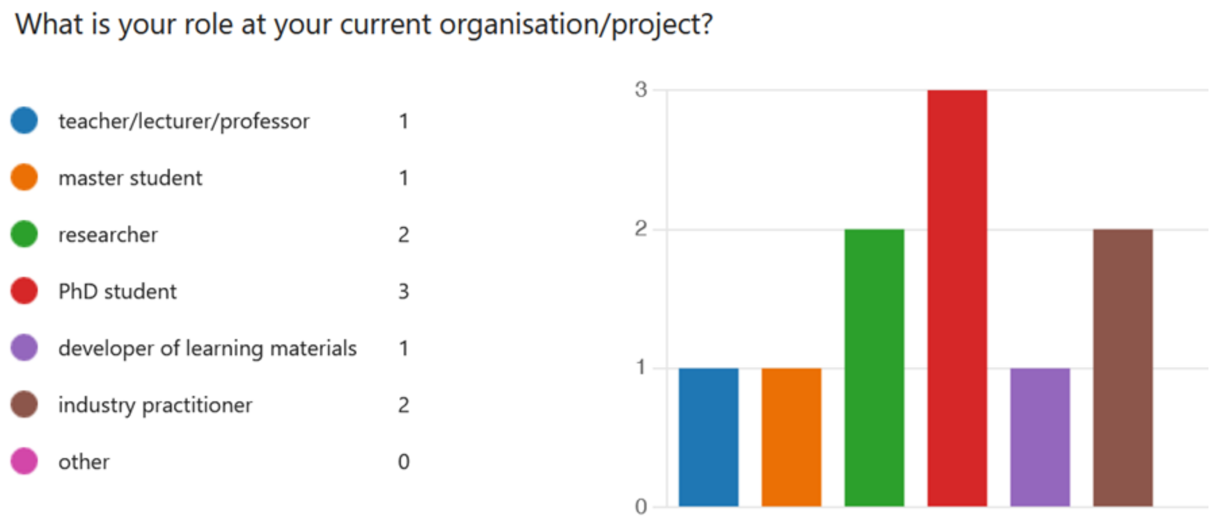


Fig. 2. Profile of respondents

Only 38% of respondents experienced special tools for assigning specific team roles to people in the project settings.

Table 1. Insights into means of soft skills' development

What were the means or approaches applied to train these particular deficit skills?	What would be your suggestions to improve soft skills development?
• Creative challenges, daily social conflicts between technical opinions encountered • Project-based learning on real-world problems • Meeting and collaborating with disciplines outside of mine • Through having sufficient knowledge about the topic • Practice	• The implementation of more workshops and to invest on team working innovation on the industrial businesses • Learning by doing • Exposure to different disciplines early on in education • Make a lot of real situation practical experiences, even better do them in industry • A holistic understanding of how the whole enterprise functions • Project-based tasks within all subjects of the curriculum

3. Limitations

While organising the workshop, we were informed on appr. number of participants for the workshop as 20. Since we had about 50 participants, we did not have enough materials and capacity to help all participants with Part 2. At the same time, we were positively surprised with this attendance rate, and believe that this shows a high demand and importance of our research and education focus.

Since the evaluation took place before Part 3, and due to the remark above, this limited the response rate of our evaluation.

4. Conclusion

If you want to help our research, and managed to check the materials via the link mentioned above, please fill in the evaluation/feedback form: https://forms.office.com/r/JfGg92HRAA

Several discussions proceeded after the workshop, and defined future research collaborations. To conclude this report, we want to use one of the statements a participant shared: "*The development of soft skills is required to complement the development of technical skills*."

5. Acknowledgement

The workshop was organised in frames of Erasmus+ KA2 Knowledge Alliance project 621745-EPP-1-2020-1-DE-EPPKA2-KA "ProDiT- Projects for the Digital Transformation".

Promoting Active Learning in STEM Subjects

Rinneheimo, Kirsi-Maria

Conference Key Areas: *Student Engagement, Teaching methods, Assessment*
Keywords: *active learning, assessment, digital tools, learning and pedagogical technologies*

doi:10.5821/conference-9788412322262.1472

Literature does not provide a universal definition of active learning. Bonwell & Eison (1991) defined active learning as "instructional activities that involve students in doing things and thinking about the things they are doing". Active learning can be considered as anything but passive listening to a lecture. Most typically the concept of active learning encapsulates methods that activate students during in-class sessions (Prince, 2004).

Several research studies have advocated active learning methods in teaching and learning STEM subjects (see e.g. Freeman et al. (2014), Theobald et al. (2020) and Prince (2004)). Many benefits of active learning have also been highlighted. Meta-analysis of Freeman et al. (2014) revealed increased course scores and passing rates in STEM courses under active learning. The effects seemed to be greatest with small group sizes (under 50) even though active learning methods appeared to work across all group sizes (Freeman et al., 2014)

The drop-out rates are high in the field of engineering throughout Europe. In Finnish universities of applied sciences the percentage of graduates in ICT engineering after 5 years of studying is 40 % and in engineering 48 % (Vipunen). These figures are quite low. Engaging students in their learning process seems to promote retention rates. One way to engage students in their studies seems to be using active learning methods.

The objective of this proposed workshop is to enhance educators' competence of such instructional design that improves students' active learning. The workshop aims to promote digital and pedagogical competence of engineering educators by introducing methods and tools for promoting active learning. By increasing such competences of educators, it gives them tools and knowledge to redesign their teaching and implement digital resources and activities (e.g. TPACK, active learning, self-regulated learning, digital languaging and assessment) for different personalized learning scenarios.

The content of the proposed workshop will be twofold. On one hand, it presents DigiSTEM project results, and on the other one, participants will share their experiences and expertise related to using digital tools and pedagogy in STEM education. The session itself utilizes active learning methods. Participants will keep small pitches of their best pedagogical practices in teaching/learning of STEM subjects and participate in group working. Hence, participants will actively construct content for the workshop. Working activities in the groups will be focused on the following issues:

- Many forms of assessment - In what ways is it possible to reduce the amount of teacher's assessment work?
- What kind of learning technology / digital tools do you use in teaching? Share your best experiences.
- What kind of active learning methods are you using?

The authors will collect a list of participants. As a result of the workshop, a collection of best practices, examples of using digital tools, pedagogical solutions and summary of workshop ideas will be created and sent to the session participants. Aim is to create a collection that includes elements among others e.g. innovative pedagogies, utilizing digital assessment, promoting self-regulated learning and using online resources for STEM subjects' learning purposes. This collection seeks to support pedagogical and digital learning methods that activate students and promote self-regulated learning.

The workshop focuses on the pedagogical issues and also on concrete actions and examples of usability of technology. At the end of the workshop participants are expected to experience for example the following outcomes:

- Reflect on how their courses support pedagogical and digital learning methods that activate students and promote self-regulated learning.
- Share concrete actions and examples of usability of technology and pedagogical solutions in STEM education.
- Discuss how using digital tools and pedagogy in STEM education could be designed to optimize learning outcomes in engineering studies.

- Obtain relevant information about various possibilities of online tests used for assessment of acquired knowledge and competencies by means of both - formative and summative testing
- Learn about available software options and solutions for digital (online) testing and receive practical advice on good experience with the development and use of online tests (suitable topics, design of questions, choice of answers, ways to insert answers, automatic evaluation, etc.)
- Analyze the impact of digital learning scenarios (on-line, distance, blended, hybrid, …) on the quality and sustainability of acquired knowledge and competencies

Responsible Innovation as a vehicle for teaching ethical and social dimensions of technology

Roach, Kate
University College London, United Kingdom

Tilley, Emanuela
University College London, United Kingdom

Nyamapfene, Abel
University College London, United Kingdom

Seren Smith, Matthew
University College London, United Kingdom

Hughes, Stephen
University College London, United Kingdom

Conference Key Areas: *Ethics in Engineering Education, Social and Service Learning, Curriculum Development*
Keywords: *Responsible Innovation. Ethics. Social Responsibility.*

doi:10.5821/conference-9788412322262.1468

This session is designed for anyone with an interest in teaching ethics, Responsible Innovation (RI) or both. We aim for a lively session in which participants leave with new ideas on how they might embed RI in their modules or curricula. The session will be of interest both to those who involved in teaching modules and to those who are responsible for higher level curriculum design.

Workshop leads are also interested in understanding more about how members of the engineering education community are using RI in their programmes and we hope that this will be a forum for the exchange of ideas all round. Is RI (or elements of it) part of an already existing curriculum or module that you run? From our experience, RI is used most often in areas of the curriculum where sustainability is considered and the two endeavours do have synergies, which will be discussed in the workshop.

Background and relevance?

Over the past two decades there has been a growing emphasis on incorporating social and ethical perspectives in engineering education, and at the same time the concept of Responsible Innovation (RI) has emerged in the UK and Europe as a way of ensuring new technologies align with societal needs. The outcome is that RI frameworks are growing in popularity as a vehicle for teaching ethical and societal dimensions of technical innovation.

At its most fundamental, RI holds that moral values are embedded in technologies and that normative deliberation should be part of all stages of technological innovation [1]. RI is an ethical construct. Indeed, many educators treat it as a special case of ethics [2] but here we present our own on-going experience of using RI and its practice as a tool for teaching and addressing curriculum development. Using a framework (AREA) that is widely employed in the UK we will demonstrate how we can map curricula and modules in search of opportunities to embed RI within our engineering modules and student projects.

One advantage of using RI frameworks over teaching classical ethics is that RI is explicitly future oriented. Where ethics classes often focus on retrospective case studies, RI can be used in real-time in design projects. The AREA framework prompts practitioners to ask questions that will help to anticipate the impacts of research and innovation before they occur [3]. It encourages the engineer to understand how it is possible to innovate *with* and *for* society and it creates opportunities both for two-way dialogue and for co-creation. RI is especially helpful in the upstream phases of project development but in iteration it can also aid in assessing and responding to downstream technological impacts. In the broadest sense RI is a set of tools and techniques that enable engineers to probe the social world.

What is RI? And what is RI for you?

RI is often criticised for its vagueness, but this mistakes its purpose. RI is not a theory or a discipline and as such it does not have long held or rigid epistemic boundaries. RI is a process designed for use in knowledge production and technical innovation that can aid producers and innovators to embrace ethical, contextual and sustainability issues upstream and downstream of innovation. Key to this process is the opportunity it affords for making changes in designs in response to engagement with stakeholders.

Participants who join this workshop will take away -

- An understanding of the RI AREA framework and how to use it as a means of identifying normative material in the curriculum
- Ideas on how they might embed RI into modules and programmes.
- Ideas on the competencies that educators may need to teach RI effectively
- Going forward, an opportunity to build a network of educators who are interested in developing RI in engineering curricula

Workshop Format

Presentation on using RI and the AREA framework.

The aim is for participants to learn about the four steps of the RI framework – anticipation, reflection, engagement, action – and the ways they can be used for teaching.

(15 mins)

Activity 1: Mapping your module or your programme using AREA.

The aim for this group activity is for participants to identify where ethics, social context, value and impact are taught in their own modules and curricula – is your provision mostly about, through or for RI?

Sum up and introduction –

(30 mins)

Activity 2: Ways to teach RI using AREA

Using the output of the previous activity participants will explore opportunities to embed and extend ethics provision perhaps by including elements of RI in active-learning or PBL activities.

Sum up and introduction –

(45 mins)

Activity 3: Brainstorming the competencies that educators need to have within themselves to include this material in curricula

This is a chance to think through how we as teachers need to develop in order to teach this kind of material and a chance for discussion and reflection on the learning and how we would like to take it forward.

Sum up.

(60 mins).

The results of this workshop will be outlined in the final workshop report.

REPORTS

SEFI 2022 AWARDS

Every year, SEFI uses the unique opportunity of its Annual Conference to SEFI acknowledges the commitment and hard work of many professionals through awards.

Leonardo Da Vinci Medal:

The Leonardo da Vinci Medal is the highest distinction SEFI can bestow. The SEFI Board of Directors awards the Medal to living persons who have made an outstanding contribution to engineering education and have been of international significance.

This year, SEFI awarded the SEFI Leonardo Da Vinci Medal to **Dr Faraón Llorens Largo,** a full professor of Computer Science and Artificial Intelligence at the University of Alicante (UA) as well as the Santander-UA Chair of Digital Transformation, for his outstanding and innovative approach to engineering education, pioneering efforts in digital transformation and his international impact in Spanish-speaking countries.

Fellowship Awards:

The SEFI Fellowship Award acknowledges meritorious service to engineering education in Europe. The awardees may use the expression "Fellow of SEFI" (F. SEFI) as a postscript to their name. Additionally, the nominees are individual members of SEFI who have worked in the field of engineering education for at least five years.

Therefore, during the annual conference, SEFI granted the Fellowship Award to three outstanding academics:

- **Prof. Jonte Bernhard**, Linköping University, a leading figure for many years in the creation of the SEFI Special Interest Group for Engineering Education Research, as well as the Nordic Engineering Education Research Network. In addition, another essential defining quality is that he elevates younger talents and encourages renewal.

- **Prof. Mike Murphy**, Dublin Technological University, is the second awarded with the SEFI Fellowship for his diligent work as SEFI President and Vicepresident, Chair of the SEFI Dean’s Council as well as after his mandate ended. His dedication ensured the much-needed continuity within our organisation and major development in several areas, notably the SEFI Special Interest Groups.

- **Prof. Şirin Tekinay**, George Mason University, was also honoured with the SEFI Fellowship 2022 due to her meritorious service to engineering education. Besides her core area of research and teaching, she has focused on different aspects of Higher Education and Engineering Education, such as diversity with particular emphasis on women in engineering, professional identity, multi-disciplinarity in teaching and research, design thinking and convergence research, technology-based learning platforms, sustainability, and engineering for peace. Moreover, Professor Tekinay initiated and contributed to many SEFI activities, including the Susan Ihsen Best Paper Award Programme, the Maffioli Award and relations with the Global Council of Engineering Deans.

SEFI Francesco Maffioli Award:

The SEFI Francesco Maffioli Award is granted to individual teachers, or a team of teachers, from SEFI member institutions of higher engineering education. This award aims to recognise the open development of open curricula, learning environments or tools, novel didactics, methods, or systems in engineering studies.

As a recognition of the extraordinary social impact of this project, this year's SEFI Francesco Maffioli Award for Excellence in the Development of Learning and Teaching in Engineering Education has been awarded to **Dr Joost Vennekens** of KU Leuven, in recognition of the extraordinary social impact of his project. Dr Vennekens' work involves Service Learning as a pedagogical means to enhance the creativity and empathy of students in the Bachelor of Engineering Technology: Electronics-ICT. The project was featured as an example in an EU report on Service Learning and on several Service-Learning platforms across Europe.

FACE TO FACE AGAIN – REPORT FROM THE DOCTORAL SYMPOSIUM IN ENGINEERING EDUCATION RESEARCH AT SEFI 2022

ABSTRACT

The 6th Doctoral Symposium at SEFI 2022 attracted 20 doctoral students and 17 senior researchers. After two years as an online event during the pandemic, it was organised as a fully in-person event. In preparation, the doctoral students wrote extended abstracts to introduce themselves and their PhD projects, while the seniorsprovided reading recommendations and advice. The intense, full-day program was based on group discussions and interactive plenary sessions. The Doctoral Symposium was concluded by a session in which each participant presented their take-home message. This paper outlines how the Doctoral Symposium was organised and summarizes some of the documentation.

1 INTRODUCTION

1.1 The SEFI Doctoral Symposium

With the exception of a few larger research centres, doctoral education in engineering education research (EER) is often organised in relatively small scale at each institution – this is not least true in Europe. Therefore, it is important for PhD students to network outside their own research environment, in order to enhance the doctoral student experience, support their development as researchers, and increasetheir understanding of the EER field as a whole. Creating and maintaining connections between researchers, and regional and international networks, are then strategies for strengthening the research field (Borrego & Bernhard, 2011; Edström etal., 2018).
The European Society for Engineering Education (SEFI) recognises the EER field and its importance for furthering engineering education. Through the Doctoral Symposium in Engineering Education Research, SEFI offers PhD students opportunities to share their work with peers and with senior researchers, to build theirpersonal network and exchange feedback. The aim is that participants will:

- meet other students and supervisors to extend their network and view of theEER field,
- present and discuss their own work and the work of others,
- get perspectives from scholars outside their own institution,
- contribute to the conference and the SEFI EER community, and
- promote collaborative research and elaborate future research directions.

In five previous SEFI conferences, a Doctoral Symposium in Engineering Education Research (DS) has been held as a full-day pre-conference event: before the SEFI Annual Conference 2016 in Tampere, 2018 in Copenhagen, 2019 in Budapest, 2020in Twente (online), and 2021 in Berlin (online).

The purpose of this paper is to document and share some insights into the process and products of the DS 2022. In the following, we discuss recruitment of participants – both the doctoral students and experienced researchers, and explain the activitydesign. We present parts of the rich material that was created, in particular the advice from seniors and the individual reflections from all participants.

1.2 Back to a face-to-face Symposium

Due to the Covid-19 pandemic the DS had to be arranged online in 2020 and 2021.This year, the SEFI annual conference as well as the DS were back to in-person meetings. As organizers, we had very much been looking forward to arranging the DS as a face-to-face event again. There was however still a risk for new outbreaks which could force us to transfer the DS, and indeed the whole conference, to an online event again. Another risk which could cause low attendance was if the intended participants would be afraid to start travel internationally again, or not allowed to by their universities. Luckily, both these fears were unfounded and the participation at the DS was back to similar numbers as before the outbreak of the pandemic. The only disturbance due to the aftermath of the pandemic was that airlines and airports could not handle the return of traffic post-pandemic. This had, unfortunately, as consequence that a few accepted doctoral student and senior participants could not arrive in Barcelona in time for the DS.

1.3 Doctoral Student Participants

The doctoral students interested in participating were invited to send an extendedabstract, containing:

- *A general introduction* (background and interest in EER),

- *An outline of their research* (elevator pitch, research interest, thesis title,supervisors, current work),
- *Reflections* (questions, challenges, dilemmas, wishes and ambitions),
- *Preferences for networking* (at SEFI2022, and for keeping in touch).

The extended abstracts that were submitted showed that the doctoral students werein various stages in their PhD projects, representing various topics from policy level to fine-grained classroom studies. Twenty-four doctoral students were accepted, butfour of them had to cancel due to illness or flight problems. Finally, 20 students attended representing 10 countries: Belgium, Denmark, Germany, India, Ireland, theNetherlands, Norway, Sweden, the UK, and the US.

1.4 Senior Participants

A number of experienced researchers in the field – here called senior participants – were invited to provide the PhD students with feedback, coaching and guidance. It isimportant for the quality of these discussion that there is a high number of seniors.
Just like in the previous symposia, the organisers wanted to keep the ratio of seniorsto students very high, aiming at approximately 2 seniors per 3 doctoral students. Theinvitations were apparently very attractive, as almost every person agreed to extend their travel to volunteer their time, on a Sunday. This year there were in total 17 seniors, including the organising team (the authors of this paper). They came from Australia, Belgium, Denmark, Ireland, the Netherlands, Portugal, Sweden, Switzerland, South Africa, the UK, and the US. Hence, the seniors were even slightlymore geographically diverse than the doctoral students.

1.5 Groups

The core of the symposium consisted of group activities in which doctoral students and seniors worked together. Seven groups were formed, each containing 3 doctoralstudents and 2–3 senior participants. The groups were composed taking into accounta balance between diversity and similarity regarding: years of experience; research interests – both in terms of topics and methods; university and country. A compilationof all extended abstracts was sent out to all participants. The instruction was to prepare by reading the abstracts of the doctoral students, at least the ones in their own group. The groups were formed a week in advance, but some last-minute changes were made due to the late cancellations.

1.6 Event Outline

The event took place on Sunday September 18, as a pre-conference day before theSEFI 2022 Annual Conference. The program was designed to accommodate lively and deep discussions between PhD students and experienced researchers. The main parts of the program were group activities, interspersed with plenary activities:

09.30 – 10.00 Coffee & Tea
10.00 – 10.30 Introductions and instructions for the day
10.30 – 12.30 First group session
Lunch
13.30 – 14.15 Speed dating
14.15 – 15.30 Second group session
15.30 – 16.30 Plenary report: Take-home messages and final reflections

2 DOCUMENTED RESULTS

2.1 Getting to Know the Experienced Researchers

The senior participants were asked to submit some reading tips for the doctoral students. The first question was: *If a doctoral student wanted to read something byyou, what would you* *recommend and why?* In response, the seniors mentioned thefollowing selection of their own work (in alphabetical order).

Diana Bairaktarova

I would recommend my most current publication. It is a guest editorial and the article frames itself in the context of the Ukraine situation, which feels close to home for me. The editorial is one of the thingsthat I worked on, feeling the urgency to put concerns into action. The article offers an overview of key educational theories and how these can be utilize in educating more empathic engineers for their rolesas global citizens. In the editorial, I also cite the dissertational work of one of my graduate students, which makes this publication even more special for me:

- Bairaktarova, D. (2022). Caring for the future: Empathy in engineering education to empowerlearning. *Journal of Engineering Education*, *111*(3), 502-507.

Jonte Bernhard

My first choice is a paper with Caroline Baillie. We discuss issues related to quality in engineeringeducation research (EER):

- Bernhard, J., & Baillie, C. (2016). Standards for quality of research in engineering education.

International Journal of Engineering Education, 32(6), 2378-2394.

Next, this one discusses and reflects on the relationship between "pure" engineering research andengineering education research:

- Bernhard, J. (2015). Engineering education research as engineering research. In S. Hyldgaard Christensen, C. Didier, A. Jamison, M. Meganck, C. Mitcham, & B. Newberry (Eds.), *Internationalperspectives on engineering education: Engineering education and practice in context, Volume 1*(pp. 393-414). Springer.

This paper demonstrates how engineering thinking, indeed, can improve the methods of EER:

- Carstensen, A.-K., & Bernhard, J. (2019). Design science research – a powerful tool for improving methods in engineering education research. European Journal of Engineering Education, 44(1-2),85-102.

Shannon Chance

In this article we discuss differences between two major methodologies used in engineering educationresearch, and then they demonstrate how they applied each methodology to one qualitative dataset (transcribed interviews). Results of each analytical process aligned in this study, yet each method uncovered slightly different findings; a primary lesson is that the lens we view the world (data) throughinfluence what and how we see.

- Chance, S., Duffy, G., & Bowe, B. (2019). Comparing grounded theory and phenomenology as methods to understand lived experience of engineering educators implementing Problem-BasedLearning. *European Journal of Engineering Education, 45*(3), 405-442.

Inês Direito

Launching into any new topic in your PhD, you may feel overwhelmed. The available information may seem too vast and complex to synthesize and summarize. This is made more complex by EngineeringEducation Research being an emergent new field – one that draws from, and combines, expertise in multiple disciplines – which adds to the complexity of selecting and analysing literature. Using a structured approach to identify, select, and analyse the existing body of literature can help you build confidence by helping ensure consistency, quality, and reliability of your review. This paper presents asystematic literature review in a relatively unexplored area in Engineering Education (grit's influence on students' performance).

- Direito, I., Chance, S., & Malik, M. (2021) The study of grit in engineering education research: asystematic literature review. *European Journal of Engineering Education,*

46(2), 161-185.

Xiangyun Du

This work was led by one of my PhD students and exemplifies how a systematic review study servesas a start of a PhD project. It is a good example supporting how to get a PhD journey started.

- Chen, J.B., Kolmos, A. & Du, X.Y. (2020). PBL in Engineering Education – Forms of Implementation and Challenges: A Review of Literature. *European Journal of EngineeringEducation, 46*(1), 90-115.

Kristina Edström

In this paper I reflect on engineering education research, especially in relationship to engineering education development. I think we all need to consider our role as researchers along these dimensions. What is the purpose of our work: who do we want to be, and what do we want to achieve?

- Edström, K. (2020). The role of CDIO in engineering education research: Combining usefulnessand scholarliness. *European Journal of Engineering Education, 45*(1), 113-127.

Anette Kolmos

- Kolmos, A. (2021). Engineering Education for the Future. In *Engineering for Sustainable Development: Delivering on the Sustainable Development Goals* (p. 121-128). UNESCO.
- Kolmos, A., Holgaard, J. E., & Clausen, N. R. (2021). Progression of student self-assessed learning outcomes in systemic PBL. *European Journal of Engineering Education, 46*(1), 67-89.

Greet Langie

- Craps, S., Pinxten, M., Knipprath, H., Langie, G. (2021). Different roles, different demands. A competency-based professional roles model for early career engineers, validated in industry andhigher education. *European Journal of Engineering Education, 47*(1), 144-163.

Melissa Marinelli

This paper uses an interesting theoretical framework to understand how industry -university relationships are started and to provide recommendations for improved industry engagement. I thinkthe study is useful as it uses theory and empirical analysis to address a pertinent issue. It links to myresearch interests of bridging education and practice, student employability, and professional awareness and identity.

- Valentine, A., Marinelli, M., & Male, S. (2022). Successfully facilitating initiation of industry engagement in activities which involve students in engineering education, through social capital.*European Journal of Engineering Education, 47*(3), 413-428.

John Mitchell

An accessible study that looks to understand the development of in the context of an education change.

- Mitchell, J. E. & Rogers, L. (2020). Staff perceptions of implementing project-based learning inengineering education, *European Journal of Engineering Education, 45*(3), 349-362.

Mike Murphy

- Murphy, M., Chance, S. & Conlon, E. (2015). Designing the Identities of Engineers. In *EngineeringEducation and Practice in Context, Vol.2* . Springer.

Kate Roach

I chose this paper, because it came about through an unexpected opportunity. I collected student evaluations from a large scale module which I ran at the time and while preparing it for university processes, I noticed that there were some interesting trends and comments on authenticity and that was how the paper came about. The original data was simplicity itself in its conception and execution.The analysis was also straight forward. Even so the data reaches into some of the deeper debates and issues relating to authenticity in engineering education.

- Roach, K., Tilley, E., & Mitchell, J. E. (2018). How authentic does authentic learning have to be?,

Higher Education Pedagogies, 3(1), 495-509.

Corrinne Shaw

The reason for this selection is that this is my most recent publication with my research team exploringthe students' transition into undergraduate engineering. Our team has a long collaboration of reflexive practice and this article reflects a particular point in our journey of understanding and leveraging the resources that diverse students bring with them.

- le Roux, k., Ngoepe, M., Shaw, C., & Collier-Reed, B. I. (2022). Language and disciplinary literacies for accessing, learning and communicating meaning: students' experiences of the transition from school to first-year undergraduate engineering, *European Journal of EngineeringEducation*.

Roland Tormey

I'd recommend the following paper because it shows how conceptual and empirical work can come together to do something worthwhile. It is also a project of a scale that is similar to a doctoral project:

- Tormey, R. Rethinking student-teacher relationships in higher education: a multidimensionalapproach. *High Educ 82*, 993–1011 (2021).

Esther Ventura-Medina

This is a qualitative research based on naturalistic data analyzed with Conversational Analysis to capture the interactions that take place between members of a team to elucidate how they managetheir work:

- McQuade, R., Ventura-Medina, E., Wiggins, S., & Anderson, T. (2020). Examining self-managedproblem-based learning interactions in engineering education. *European Journal of Engineering Education, 45*(2), 232-248.

Pieter de Vries

I would recommend something that is about to be published, so cannot give you the reference yet. The title is: 'The Ethical Dimension of Emerging Technologies in Engineering Education' and it is aboutthe values and risks of using these technologies in Engineering Education. Emerging Technologies are part of the constituting datafication and digitalisation process that poses major challenges to the current educational infrastructure. Universities are challenged to respond to the demands that seem todevelop faster and become more complex. The complexity though is not just technical, it is the combination of technology, and specifically big data use, the link with job requirements, educational practices, ethical responsibilities, and socio-cultural aspects of education. The purpose of this paper is to analyze and discuss elements of those issues in trying to clarify the complexity and lower the threshold for those who are involved and looking for a better understanding of the opportunities and challenges.

Patric Wallin

I would recommend an article that I wrote together with three students on reclaiming higher educationas a space for play. I think it provides an interesting contrast to many other articles and challenges traditions on several levels. Furthermore, I think it illustrates how to write a piece where the research process, content and presentation all line up to create a whole.

- Wallin, P., Mariussen, K. L., Mogstad, H., & Sønderaal, M. (2021). A dialog on reclaiming highereducation as a space for play. *The Journal of Play in Adulthood, 3*(2).

Bill Williams

- Trevelyan, J., & Williams, B. (2019). Value creation in the engineering enterprise: an educationalperspective. *European Journal of Engineering Education, 44*(4), 461-483.

2.2 Reading Recommendations from the Experienced Researchers

Next, the senior researchers were asked to give input following the prompt: *Recommend one paper, not your own, for a starting PhD student?* This resulted in acomprehensive collection of publications.

Diana Bairaktarova

- Johri, A. & Olds, B. (2011). Situated Engineering Learning: Bridging Engineering EducationResearch and the Learning Sciences. *Journal of Engineering Education, 100*(1):151-185

Jonte Bernhard

- Case, J. M. (2019). A third approach beyond the false dichotomy between teacher- and student-centred approaches in the engineering classroom. *European Journal of Engineering Education, 44*(5), 644-649.

Shannon Chance

My primary recommendation is a textbook rather than a journal article:

- Major, C. H., & Savin-Baden, M. (2012). *An introduction to qualitative research synthesis: Managing the information explosion in social science research*. Routledge.

As for journal publications, I would recommend an excellent example of a systematic literature review:

- Campbell, A. L., Direito, I., & Mokhithi, M. (2021). Developing growth mindsets in engineeringstudents: a systematic literature review of interventions. *European Journal of Engineering Education, 46*(4), 503-527.

Tinne De Laet

- Fleur, D.S., Bredeweg, B. & van den Bos, W. (2021). Metacognition: ideas and insights fromneuro- and educational sciences. *npj Sci. Learn. 6*(1), 1-11.

Inês Direito

- Siddaway, A. P., Wood, A. M., & Hedges, L. V. (2019). How to Do a Systematic Review: A BestPractice Guide for Conducting and Reporting Narrative Reviews, Meta-Analyses, and Meta- Syntheses. *Annual review of psychology, 70*, 747–770.

Xiangyun Du

- Borrego, M., Douglas, E. P., & Amelink, C. T. (2009). Quantitative, qualitative, and mixed researchmethods in engineering education. *Journal of Engineering Education, 98*(1), 53-66.

Kristina Edström

A special issue in EJEE should be a state-of-the-art collection of papers on a specific theme. Recentlywe published special issue on the theme "*Early Career Engineers and the Development of Engineering Expertise*". The editorial introduces the topic and the ten amazing papers:

- Buckley, J., Trevelyan, J., & Winberg, C. (2022). Perspectives on engineering education from theworld of practice, European Journal of Engineering Education, 47(1), 1-7.

Anette Kolmos

- Repko, A.F., Szostak, R., & Buchberger, M.P. (2013). *Introduction to interdisciplinary studies.*Sage, London.

Greet Langie

- Naukkarinen, J. & Bairoh, S. (2022) Gender differences in professional identities and developmentof engineering skills among early career engineers in Finland. *European*

Journal of Engineering Education, 47(1), 85-101.

Melissa Marinelli

Again, this is a paper that bridges engineering education and practice. It presents a way of thinkingabout early engineering careers that is new and different.

- Craps, S., Pinxten, M., Knipprath, H., & Langie, G. (2022) Different roles, different demands. A competency-based professional roles model for early career engineers, validated in industry andhigher education. *European Journal of Engineering Education, 47*(1), 144-163.

John Mitchell

- Case, J. M., & Light, G. (2011). Emerging research methodologies in engineering educationresearch. *Journal of Engineering Education, 100*(1), 186-210.

Mike Murphy

- Mitcham, C. (2014). The True Grand Challenge for Engineering: Self-Knowledge. *Issues in Science & Technology, 31*(1).

Kate Roach

This is an editorial rather than a research paper, but it is timely and important. It takes as its starting point the complexity of current global crises and raises theoretical lenses that may help us to think about how to deliver support for complex problem solving. This piece is very timely and speaks to theneed to help students develop the knowledge, skills and attributes they will need to live and work in a rapidly changing world.

- Chance, S. et al (2019). Guest editorial special issue on using enquiry-and-design-based learningto spur epistemological and identity development of engineering students. *IEEE Transactions on Engineering, 63*(3), 157-164.

Corrinne Shaw

- Kvale, S. (1983). The qualitative research interview. *Journal of phenomenological psychology,14*(1-2), 171-196.

Roland Tormey

A systematic literature review is a great starting place to develop a doctoral picece of work. This onewas done as part of a PhD project:

- Zhang, F., Markopoulos, P. & Bekker, T. (2020). Children's Emotions in Design-Based Learning: aSystematic Review. *J Sci Educ Technol 29*, 459-481.

Esther Ventura-Medina

This paper summarizes quite well different approaches to research in engineering education. Althoughthere are other perhaps more recent papers I always refer back to this one.

- Borrego, M., Douglas, E. P., & Amelink, C. T. (2009). Quantitative, qualitative, and mixed researchmethods in engineering education. *Journal of Engineering education, 98*(1), 53-66.

Pieter de Vries

A comprehensive analysis of Edtech development and policy under Covid:

- Williamson, B., & Hogan, A. *Pandemic Privatisation in Higher Education: Edtech & UniversityReform* (p. 80). 2021.

Patric Wallin

Time is an important concept in all types of research and this paper challenges the reader to thinkdeeper about it. While it is not situated within Engineering Education Research, I think it is highly relevant.

- Bennett, A., & Burke, P. J. (2018). Re/conceptualising time and temporality: an exploration of timein higher education. *Discourse: Studies in the Cultural Politics of Education, 39*(6), 913–925.

Bill Williams

- Passow, H. J., & Passow, C. H. (2017). What competencies should undergraduate engineering programs emphasize? A systematic review. *Journal of Engineering Education, 106*(3), 475-526.

2.2 Advice from Experienced Researchers

In their advance input, seniors were also asked to give one general tip for a startingPhD student.

Diana Bairaktarova

Expand on your professional network while in grad school to engage with scholars from other fields.

Jonte Bernhard

Think through your research question(s), i.e. find interesting problems you want to investigate. In myopinion the quality of the insights generated is more important than mechanically following a method.

Shannon Chance

Cultivate mentors. Find a range of people with varying expertise and perspectives who are willing to chat with you from time to time and provide you ideas to help you dream big. Make sure you let themknow when they've made a difference in your life.

Tinne De Laet

Talk to your colleagues, also the ones of other domains. They well help enrich your work and broadenyour horizons.

Inês Direito

Invest time in literature reviews - both before and after data collection. These help you to develop yourresearch aims and conclusions.

Xiangyun Du

The well-being of a PhD study is highly related to your passion, purposefulness, making milestones toobtain feelings of achievements, and being agentic in one's choices and actions.

Kristina Edström

The senior researchers are absolutely delighted that you have come to this field. They will offer support in so many different ways – here in the Doctoral Symposium, attending your conference talk,as reviewers of your manuscripts, in your doctoral defense, or just chatting with you during the conference dinner. Soon, much sooner than you think, it will be your turn to support others who comeafter you.

Anette Kolmos

Keep working on your research question and the purpose of the study.Be careful with review, methodology.

Work on your confidence - you are the one who knows most about the subject.

Greet Langie

Focus

Melissa Marinelli

Remember your 'why' - why did you choose to start your doctoral studies? Why is your work importantto you? In tough times, these motivations will get you through!

John Mitchell

Refine and be clear on your research question so that you can try to avoid being distracted from theinevitable interesting rabbit-holes that will appear - but always write them down for later.

Mike Murphy

It's a marathon, not a sprint; therefore be measured and not impatient.

Kate Roach

Keep research questions and data collection as simple as you can - complex data does not equalcomplex thinking!

Corrinne Shaw

Becoming part of a community of practice and write, write, write some more.

Roland Tormey

Write something every week. Writing is a skill that cannot be done judiciously unless it is done withpractice.

Esther Ventura-Medina

Take ownership of your project and make sure you have a clear research question.

Pieter de Vries

Go for the nuts that are self-explanatory!

Patric Wallin

Look beyond the Engineering Education Research literature and engage with literature from otherdisciplinary contexts, also look into education philosophy, critical pedagogy and theory of higher education.

Bill Williams

Identify one or two scholars whose work really speaks to you. Speak to them.

2.3 Group Notes

The six groups wrote collaborative notes during their time together, in total 3 hours. AGoogle Document was prepared with space for each group. The downloaded versionof the notes is 15 pages long in total, and it is outside the scope of this report to analyse this comprehensive material. However, the groups seem to have followed the suggestions in the instructions, as the notes contain generous amounts of:

- Interesting things that resonate with us
- Ideas and strengths that we have identified
- Problems, questions or issues we have identified
- Tips, things to do, read or think about

2.3 Take-home Messages

Each participant was asked to formulate a short nugget of wisdom during the day, asa take-home message from the DS. In the final plenary session, each participant hadone minute to present their take-home message. Below the messages of doctoral students and seniors are mixed and appear in no particular order.

Kate Bellingham: The dichotomy I am dealing with - to help universities improve their recruitment ofwomen while using a novel theoretical approach of a dating model - might be solved if I'm less ambitious: Keeping it smaller scale allows me to hear some individual stories, see if the model is useful, then hand that on for further research projects. I shouldn't aim to solve it all myself!

Mariana Velho: Do my research in collaboration with secondary schools in Portugal in order to get abetter and more diverse sample.

Nargiza Mikhridinova: I will check other methodologies and reduce my PhD project ambitions inorder to keep it feasible. Critical incident technique recommended sounds very promising to be applied.

Greet Langie: The EER-community is getting better interconnected, and this despite the fantastic factthat we are also getting bigger.

Bill Williams: I’m reminded once again of the value of finding connections between ideas, people indifferent contexts.

Melissa Marinelli: The power of diverse perspectives and backgrounds in discussing issues. The common threads that run through diverse projects. An observation - the many different backgrounds ofengineering education PhD students - psychology, philosophy, education science, engineering, computer science, industry experience… very different to my local context in Australia.

Marten Westerhof: be explicit

Vivian van der Werf: In an interview, each word of a sentence can be a data point, whereas in a questionnaire, only each question is a data point (mentioned by Patric). For my own research I will consider using additional individual interviews besides focus groups for interviewing teachers on developed curricula materials (tip by Esther). Reason: focus groups might not always provide additional information as people tend to agree on everything. Individual interviews may show people'sactual opinions better than in a group.

Max Vincent Uzulis: It is always good to discuss one's research with others to reflect upon our own methods and approaches. I learned a great lot about my own research and the interesting projects ofthe other group members.

Esther Ventura Medina: Nice to see Qualitative approaches becoming more prominent - excitingtimes ahead! Having said this, be mindful that your methodology should help in answering your research question(s).

Patric Wallin: It is important to find a balance between researching stuff within the education system and critically questioning that very system. This balance might be different depending on your positionand context, but reflecting on it and being aware of it is important. Never forget that systems can be changed and if you want work towards changing them.

Gitte van Helden: Even (or maybe especially) when your ideas are not yet fully clear and well-articulated, talking about it with others can be very helpful.

Elizabeth Rees Chin: Great to have advice, insights and perspectives on my project - adding in observations to interviews will also be helpful. Lovely to hear those with diverse/non-traditional backgrounds. Also super interesting to hear about everyone else’s projects and to share our experiences. A great event.

Diana Bairaktarova: I love the level of engagement in a small group gathering and I am fascinatedwith the quality of work of the doctoral students and their investment in engineering education research. Kudos to the organizers and to all Doctoral students from whom I learned so much todayand I am sure I will continue learning about the future of engineering education.

Mike Murphy: I am astonished with the variety of EER topics presented today. In addition to the variety, the practical nature of them is very encouraging.

Urša Benedičič: Make it simple and be critical. Be clear on what you will and what you will NOT do.

Mieke Cannaerts: Make sure you know why you make certain choices and if they contribute to answering your question, but also don't lose sight of what you are passionate about.

Panagiotis Pantzos: Critique of method (SDT)

Kate Roach: So lovely to hear the enthusiasm and to see the talent in the room. My main message iskeep it simple and stick with what you love.

Roland Tormey: Stop and think about what you are doing - don’t do something unless you can defend it. And make sure you can defend what you have done.

Melanie Herzig: Different sessions, experiences, perspectives, and methods shape my research

Sam Snyder: Practicing the discussion of my dissertation has helped me reaffirm my and critique mywork, and getting detailed feedback from other engineering educators has been indispensable

Wei Siqing: Limit or narrow down my research scope further to be easier to be answered and understood for others simply.

Anette Kolmos: Open education opens door for new era of education.

Styliani Malkogeorgou: Discussing my work with other PhD students and experienced researchersgave me a new perspective, made me think and reevaluate my research and approach.

Inês Direito: It has been wonderful to meet old and new colleagues who are so passionate about engineering education and research. We can learn so much from each other, listen to different perspectives - especially in informal contexts. To the PhD students: network as much as you can (andhave fun!)

Gouri Vinod: I learned about the importance of being clear about the definitions I hope to use in my thesis- an issue I mentioned I wanted to tackle during SEFI. I also learned that it is better for my PhD- level research to be more focused than it is for it to be broad, so I have thought about how I can narrow down my proposed research plans so it is more realistic to complete during the next few years.Being able to network with those I hope to work with during the data collection stage of my project hasalso been extremely helpful- in addition to hearing about everyone’s research interests :)

Luke Dokter: Fantastic diversity of very interesting people here that I am looking forward to getting to know better. It is good to be ambitious, but don’t be too ambitious! Focus on completing the doctorate rather than trying to investigate and solve all of the problems that I have identified in my work.

Acceptance of my doctorate within a more traditional engineering context could be a challenge, but being aware of my audience is important. Tailor the message in order to reach your audience. I have aunique opportunity to develop something of importance for the Norwegian Armed Forces and am lucky to have a position that allows me access to employers and former students, something that is almostimpossible at other Universities.

Ann-Kristin Winkens: Bill advised this morning, “Identify one or two scholars whose work really speaks to you. Speak to them.“ This is the most important message for me today, don’t be shy, talk topeople, ask questions – you are not alone. Everyone is faced with some kind of challenges.

Xiangyun Du: It is exciting to learn about the growing scope of EER, with so many new topics and stronger passion than ever before :-). This gives space for discussions on what a EER PhD project may mean. In particular, how to get a PhD project started? What questions to ask and what scope andambition can be feasible? This can be quite different if it is a monograph targeted or article-binded theses. It is also quite interesting to discuss with PhD candidates about their ambitions, goals and plans, how much insights they can go into research and how much change they can make in the real world.

Pieter de Vries: Very pleased to see so many EE enthusiasts. Even when most want to change theworld, it is promising. The diversity is challenging though and the tendency to caress the niche approach certainly has no future. More motivated students is part of the solution.

Shannon Chance: Use this face-to-face conference to build and strengthen your networks so you'll be able to collaborate more effectively online when you're back home. Find people who have interestssimilar to you or who you think can shed light on specific questions you have, and try to stay connected with them. We're a very warm and welcoming community. Don't be afraid to approach people at SEFI and in the EER community to ask questions and suggest topics to discuss.

Xiaoling Zhang: Limit the research scope, do more concrete work. Read more methodologies and theories. Start small and don't aim to save the "world" within a PhD project. There is a whole life formore work to be done.

Dimitri Eckert: 1. Read more about Methodology, Theories and Methods to get a more rigorous planfor my research. 2. See what tools already exist that I can use.

Abhijith Venugopal: 1. Importance of 'scope' 2. addressed the dilemma in methods 3. Narrow down the concepts to focus, and to complete the degree, 4. Need to have a look into the framework (evolving one), 5. Insights on recommended readings and projects, General: PhD is not the ultimate aim in life, students should narrow down and stick to the specific topics. These interactions are very helpful to ensure that the researcher moving in the right direction. First time seeing these many peopleworking in EE research!

Corrinne Shaw: I was struck by the nature of the research problems that PhD students have set themselves to solve, often as a consequence of their own experience in education or their observations of how others learn and experience education. Finding out how the problem came aboutand what contributes to its continuation can be enough for a research study. These are complex problems and the role of the PhD is to solve the research problem and perhaps not the practical problems that were initially observed.

John Mitchell: The range of topics being covered by the PhD students represented is inspiring. The questioning of the level of progress and the need for direction on methodologies and theoretical lens reminds me of the troubled times of my own PhD and just underlines how necessary sessions such asthis are and how much more we could be doing as a community to support our early career researchers.

Kristina Edström: The goal of a PhD education is to become an independent researcher. During yourPhD, take the opportunity to develop into a whole scholar. In addition to your thesis, learn to teach, give seminars and workshops, organise stuff, develop your networks, lead projects, apply for funding. And learn how to review manuscripts – see me after class!

Jonte Bernhard: I am glad that so many could participate in the symposium today and I am very happy we are back to face-to-face meetings again. I hope the meeting has inspired you and you have learned something. You can always learn something by extending your network and you get new perspectives from visiting other institutes and communicating with people outside your own close circle. Never stop to keep your mind open!

3 REFLECTIONS AND WAY AHEAD

The SEFI 2022 Doctoral Symposium was successfully carried out in a face-to-faceformat again. 20 doctoral students and 17 seniors worked together in shaping the future of the engineering education research community. Our impression is that participants were very pleased with meeting face-to-face again and making use of the advantages and affordances of such a meeting format.

On the other hand, we have successfully arranged online DS meetings in 2020 and 2021, and these experiences certainly showed that a remote format was feasible.
However, there are some trade-offs. One great advantage with the online format was that participants who, for various reasons, would not be able to travel to a conference could still attend. The downside is that quite many participants found a full day online quite wearying, and very much so for those located outside European time zones.
For those who are anyway travelling to the conference, a day of face-to-face meeting is less tiring, even energizing, and may also be more rewarding.

We believe that face-to-face and online meetings could complement each other in afavourable way. One way forward could be to use the online format to arrange meetings and webinars *between* an annual, face-to-face, SEFI conference and DS. As mentioned in the introduction, many doctoral students and senior researchers in engineering education in Europe work in small groups. The online format could enable shorter, more frequent meetings, in between face-to-face conferences and seminars, that could further strengthen the research community in engineering education research. Such initiatives are also underway in co-operation with SEFI special interest group for Engineering Education Research and different engineeringeducation research centres.

4 ACKNOWLEDGEMENTS

The authors wish to thank every single participant in the Doctoral Symposium over the years, doctoral students as well as seniors. The success of the activity is a directresult of your engagement and enthusiasm. We thank the organisers of the SEFI Annual Conferences for great hospitality during the pre-conference day. We thank SEFI for being entrusted with the stimulating task of organising this activity. Finally, we gratefully acknowledge how SEFI supports the EER field in many ways, among them the Doctoral Symposium.

Problem Summary
Clipping is a form of distortion that can occur when the amplitude of a sinusoidal signal exceeds a threshold or saturation value of an electronic component. A common example occurs when the power of a sound signal exceeds the power of the amplifier it is passing through. The figure below shows an example of clipping of a simple sine wave. Note how the signal is "clipped" where the magnitude of the signal exceeds the saturation voltage of plus or minus 5 volts.
Clipped Sine Wave
signal (volts)
time (seconds)
Write a script to generate the signal values for the figure above corresponding to 200 equally-spaced time values ranging from 0 to 6π. Assign these time values to the variable Time. Assign the resulting voltage values to the variable signalVoltage.

Definite Integrals in Maxima and Minima
To maximize F(a) = ∫ sin(ax) sin(x/a) dx for a ≥ 0, first, define the symbolic variables and assume that a ≥ 0:
syms a x
assume(a >= 0);
Then, define the function to maximize:
F = int(sin(a*x)*sin(x/a),x,-a,a)
Note the special case here for a = 1. To make computations easier, use assumeAlso to ignore this possibility (and later check that a = 1 is not the maximum):
assumeAlso(a ~= 1);
F = int(sin(a*x)*sin(x/a),x,-a,a)
Create a plot of F to check its shape:
fplot(F,[0 10])
Fa =

Solve a mass-spring damper system (DRAFT)
Copy Delete
‹ Back to Instructor View
This example shows the recommended way to assess the output of a variable-step solver such as ode45 for first-order odes. Supplying a time vector instead of a time span to the solver ensures the returned reference and student solutions are evaluated at the same time points without forcing a specifc approach.
The mass-spring-damper system is commonly used in dynamics to represent a wide variety of mechanical systems in which energy can be both stored and dissipated. Consider the suspension system for a tire on a car -- modeled as an ideal mass-spring-damper system -- that encounters a bump in the road, causing a displacement in x. As the system recovers, the position will oscillate about 0 until the energy is dissipated (shown in the graph below).
Displacement vs Time
Displacement (m)
Time (s)
The system response is described by the following equation:
$m\ddot{x}(t) + c\dot{x}(t) + kx(t) = 0$
Using the following parameters:
mass $m = 1100$ kg
spring constant $k = 570$ N/m
damping coefficient $c = 430$ N-s/m

SIEMENS SKILLS FOR SUSTAINABILITY

AUTHORS:

Kirsten Williamson
kirsten@petruscommunications.com

Dominic Sproston
dominic@petruscommunications.com

ABSTRACT:

Since the start of the industrial revolution, more than two centuries ago, the life of mass-produced goods our society has come to rely can be traced as a straight line from raw material, through manufacturing and usage, to end in a landfill. However, considering the climate crisis we face today, that is no longer a viable business model.

Rather than the line from raw material to landfill that exists now, when a product in a circular economy reaches end of life it is broken down, reused, retooled, and recycled as completely as possible. To truly realize the potential of a circular economy, the principles of sustainability must be ingrained in a design from the very conception of a product. While a circular economy does offer benefits in the areas of cost and sustainability, it does present new challenges when transitioning from our current economic model.

As part of an ongoing series of industry-faculty dialogues, we're excited to be holding this roundtable during SEFI 2022 to discuss: **'What mindset, skills and tools do students need to learn, and how, to bring and keep the circular economy in the workplace?'**. Through industry insights and peer exchange, we aim to facilitate the exchange of knowledge and ideas to help embed this topic within engineering curriculums.

Siemens skills for sustainability network

Formed in 2022, the Siemens Skills for Sustainability Network has the ambition to support educators in our common goal of enabling the global workforce of the future to develop innovative sustainable solutions that drive the circular economy – a pivotal discipline to deliver the SDG commitments.

This October, in two online roundtable discussions and one in-person session held at SEFI, we asked industry and faculty from around the world to discuss the mindset, skills, and tools that students need to drive circularity in industry. Together we explored the role of the faculty, students, and industry in creating a more sustainable and circular mindset.

The full report from this roundtable series is available here: https://blogs.sw.siemens.com/academic/skills-for-sustainability-network-october-roundtables/

What mindset, what skills, and what tools do students need to learn, and how, about the circular economy?

Participants came up with many ways that students can learn and practice circularity in their engineering programs. Several spoke about the mindset shift that needs to happen not only for students but also for university faculty and industry, as well. A major point was the importance of systems thinking – students need to be taught to look at the entire supply chain when making decisions about sustainability and circularity. Building solutions that use locally available resources and suppliers was another key theme, and multiple participants suggested project-based learning as a key to consolidating theoretical knowledge into actionable skill.

As well as these themes for addressing circularity in the classroom, participants returned several times to the importance of getting students involved in both existing industry and entrepreneurial activities. The consensus was clear that there’s no single road to sustainability and imbuing students with the skills, knowledge and mindset to change the way businesses operate is an all-hands effort.

Values and Mindset Changes

Participants discussed multiple ways of adjusting student mindsets. One major point was that sustainability mustn’t be ‘tacked on’ to all that we currently teach, rather, there needs to be a radical shift in how we teach problem solving. Students need not only to be taught a new approach to solving problems but also encouraged to help reshape the very values fundamental to the practice of engineering, so that they can champion sustainability in their careers.

“So, for manufacturers who've always received revenue and received value when they've changed ownership of a good, that model is not a sustainability-driven model. It's a take, make, dispose driven model. And if that's what you're optimized on, that's what it's going to drive you to.”

Eryn Devola, VP of Sustainability, Siemens DISW

Participants also felt very strongly that industry must change how they assign and derive value vis-à-vis sustainability and circularity. Companies often say they value sustainability in their messaging but ultimately select their materials and manufacturing practices without regard for the true cost to society or any negative, albeit unintended, externalities. Companies and markets need new ways to measure cost and value in order to get serious about sustainability.

Systems Thinking

Participants noted often that engineering has traditionally been a highly siloed practice and students often don’t understand the many steps that a product might go through before reaching a consumer, and the many factors that contribute to the sustainability or circularity of the final product. Students must be trained to think about all the resources and inputs required to design a product as well as the possibilities for the end of the product lifecycle. Environmental impacts in sourcing, testing, manufacturing, de- and re-purposing, as well as the social impacts like working conditions and living wages must be fundamental to product, process and system design. Students need to understand how to look at the ‘big picture’ and consider every step before and after a product is designed and manufactured.

"The knowledge of the materials from which products are made as well as the manufacturing processes they undergo before becoming products will greatly assist the students in understanding circularity and sustainability. It is necessary to change their mindset against the dangers of buy, use and dispose."

Mohammed Dauda, Professor of Mechanical Engineering, University of Maiduguri, Nigeria

Sustainability and Systems-Based Projects

Systems-based thinking should be introduced to students through real-world projects. Ideally, participants agreed that students should see these concepts as early as possible. First-year students should be immersed in projects that directly address circularity and sustainability, while project work done throughout the curriculum must incorporate systems thinking and sustainability as fundamentally as physics and mathematics. If students are to really integrate the importance of sustainability, it should be taught early and continually.

"With first-year engineering students, we try and present engineering as an endeavor that occurs within social contexts. Our approach is to introduce them to the concepts of production, of sustainable production, of their relationship with the environment."
Corrinne Shaw, Senior Lecturer, University of Cape Town, South Africa

Students as Drivers of Change

Students also need to gain the mindset needed to become advocates for sustainability. This can be through small projects using local materials, or through creating entirely new businesses. Either way, students are the future drivers of change. Part of the mindset students need to create a sustainable and circular economy is the knowledge that they can lead change themselves.

"So, what is the economic answer? Entrepreneurship. We need new businesses; we need new companies. And this is what we could teach our students, to say, 'Okay, I've got a new idea which is sustainable.' Well then, be a founder and make your own business out of it."

Jan Robert Ziebart, Professor of Applied Sciences, FH Bielefeld, Germany

Students will become business leaders and start-up founders and can take what they learn about sustainability into those companies. Sustainable companies will drive the future and current students will be the ones leading the way in creating them.
